Mr. Geo. Cragg, gardener to Walter C. Walker, Esq., Percy Lodge, Winchmore Hill, was first for a group of exotic Orchids, the plants being well flowered, and consisting of pleasing varieties of Cattleyas, *Lælia*s, *Odontoglossums*, *Oncidium*s, and *Cypripedium*s. Mr. C. Turner was a good first for a group of Roses, the exhibit consisting of well-flowered plants of *Crimson Rambler*, *Charles Lawson*, *Duchess of Albany*, *Juno*, *Marchioness of Londonderry*, *La France*, and others. Messrs. William Paul & Son, Waltham Cross, came second with a group of little less merit, amongst which were fine plants of *Crimson Rambler*. Mr. C. Turner was first for a group of greenhouse Azaleas (open to nurserymen), the plants being thickly covered with bloom. Mr. W. Barrett, gardener to Mrs. Thornton, The Hoo, Sydenham Hill, was a capital first for a group of the same plants (open to amateurs) with large, well-flowered plants. The second prize in this class fell to Mr. R. Scott for plants not quite so fine.

Mr. W. Barrett was also first for a group of Azaleas, any size, the second, as in the former case, being gained by Mr. Scott.

Among the miscellaneous exhibits, Mr. W. Rumsey, Waltham Cross, sent a large group of Roses in pots and cut blooms. The former were well-grown plants, thickly covered with flowers; amongst other varieties being *Albert Page*, *The Queen*, *Magna Charta*, *Spenser*, *Mrs. J. Laing*, *La France*, *Mrs. Rumsey*, *John Stuart Mill*, *Princess Vera*, *Duchess of Albany*, and *Madame Isaac Periere*; and among the latter fine flowers of *Niphetos*, *Maréchal Niel*, *Marie Van Houtte*, and *Baroness Rothschild* were very conspicuous.

Mr. J. Perry, gardener to J. C. Tasker, Esq., Middleton Hall, Brentwood, sent a group of Cannas, amongst which were *Progression*, *Paul Bryant*, *Alphonse Bouvier*, and *Madame Crozy*. A very creditable bank of Roses in pots was also exhibited by Mr. Perry, the finest plants being *Turner's Crimson Rambler*, *Innocente Pirola*, *Cleopatra*, *Ella Gordon*, *Ernest Metz*, *The Bride*, and *La France*. Mr. R. Scott added to the beauty of the show by exhibiting an interesting group of plants arranged effectively, and composed chiefly of *Azalea mollis*, *White Marguerites*, *Cannas*, *Lilium Harrisii*, *Caladiums*, *Asparagus plumosus*, with *Palms* and *Ferns*. Mr. T. S. Ware sent a collection of Tulip flowers consisting of all the sections, the blooms being large, substantial, and varied in colour. This same firm also staged plants of *Pæonies* in bloom.

Messrs. T. Rivers & Sons, Sawbridgeworth, Herts, sent a group of Peaches and Nectarines in pots. The plants were thickly studded with fruits, which were of a delightfully rich colour, testifying to the fact that the plants had been highly cultivated. Messrs. B. S. Williams and Son, Holloway, sent a fine exhibit of mixed foliage and flowering plants, which were arranged with taste, and consisted mainly of *Dracenas* *Lord Wolseley*, *pendula*, *Madame F. Bergman* and *Lindeni*; *Crotons* *Bachi*, *Disraeli*, and others; *Caladiums* *Leopold Robert*, *Alice Van Geert*, *candidum*, and *Baron James de Rothschild*, together with *Amaryllis*, *Anthuriums*, *Palms*, and plants of *Ficus elastica*. The same firm also exhibited floral designs in the form of wreaths, bouquets, and baskets of flowers, which in the tastefulness and elegance of construction produced a pleasing effect. Messrs. John Laing & Sons, Forest Hill, exhibited a very creditable group of mixed flower and foliage plants, which were tastefully arranged on a mound. Particularly noticeable were fine well-grown plants of *Gloxinias*, amongst others being *Majestic*, *Mrs. Laing*, *John Laing*, and *Leopard*; *Begonias* *Duke of Fife*, *Duchess of Teck*, *Laing's Triumph*, and *Earl of Cranbrook*; *Caladiums* *Baron de Mamore*, *Rose Laing*, and *Pauline Guichard*,

Orchids were represented with *Dendrobium thyrsoflorum*, *Oncidium sarcodes*, and *Cymbidium Lowianum*. Several fine *Crotons* were also included—namely, *Thompsoni*, *Countess*, *Burtoni*, and *Reidi*, as also were plants of *Azalea mollis*, *Cannas*, *Nepenthes Mastersiana*, *Anthuriums*, *Dracæna Sanderiana*, and *Erica Cavendishiana*.

Messrs. Barr & Son, Covent Garden, sent a fine display of Tulip blooms and other hardy flowers. Amongst the former being *Coffee Colour*, *Crimson Beauty*, *Striped Beauty*, *flava*, *Yellow Queen*, *Goldflake*, together with many rectified and breeder blooms of distinctive form and variety. Messrs. Jas. Veitch & Sons, Chelsea, staged Tulip flowers in fine form and excellent variety, composed of *Isabella*, *Cramoise brilliant*, *perfecta*, *Constantinople*, *Coffee Colour*, *lutea major*, *Golden Eagle*, *Czar Nicholas*, *Prima Donna*, *Aster*, *Anna*, *Osman Pacha*, and many others.

Messrs. Dobbie & Co., Rothesay, staged a fine collection of cut Viola blooms, the colours being varied, and many of the sorts very distinct. Conspicuous in the collection were *Ceres*, *Miss Gibson*, *Gem*, *Neptune*, *Archibald Grant*, *Lemon Queen*, *J. B. Riding*, *Lucy Ashton*, *Cherry Park*, *Gipsy Queen*, *Ariel*, *Rob Roy*, and *White Flag*. Messrs. W. Paul and Son exhibited a very large and magnificent group of Roses in pots, the flowers and foliage being almost perfect. Amongst many others were noticed *Maréchal Niel*, *Victor Verdier*, *Spenser*, *Harrison Weir*, *Duke of Teck*, and *A. K. Williams*. Mr. George Mount sent fine stands of cut Roses, consisting chiefly of *Catherine Mermet*, *Ulrich Brunner*, *Maréchal Niel*, *Mrs John Laing*, and *Lady Fitzwilliam*. Mr. Arthur Knowles, Woking, Surrey, sent specimen flowers of *Daphne cneorum major*.

### THE VITALITY OF SEEDS.

THE duration of the vitality of seeds is perhaps the most important of the various phenomena of plant life, especially when considered in connection with the introduction into a country of the economic plants of other countries. It is a subject that has engaged attention from very early times, and the literature relating thereto is considerable. Much of this, however, is of traditional and unpractical character; but even if we confine ourselves to the demonstrable, or demonstrated, the subject is almost inexhaustible. There is such an infinity of variety in the behaviour of seeds under different conditions, that it is impossible in a short account, such as this must be, to do more than convey a general idea of the subject.

Perhaps the best way to treat the question, apart from technicalities, is to consider the vitality of seeds under ordinary and extraordinary conditions. In the development and germination of seeds there is, in a sense, usually a period of gestation and a period of incubation, as in oviparous organisms of the animal kingdom; and the duration of these periods is within definable limits, under ordinary conditions, though seeds do not exhibit the same fixity of time in regard to development and vitality as eggs. The embryo of a seed is the result of the impregnation of the female ovum in the ovary or young seed vessel, by the male element, generated in the anthers; and in the mature state this embryo may fill the whole space within the skin, or testa, of the seed, as in the Bean and acorn; or it may be a comparatively minute body, as in Wheat, Maize, and other cereals; the rest of the seed being filled with matter not incorporated in the embryo. The difference is one of degree in development. In the one case, the growing embryo has absorbed into its own system, as it were, before germination or the beginning of the growth of the embryo into a new plant, the whole of the nutrient material provided in the seed for reproduction; whereas, in the latter case, the process of absorption and utilisation of the "albumen," or nutrient matter, takes place after the seed is detached from the parent plant, and during the earliest stage of growth of the new plant; so that the plant is nourished until it has formed organs capable of assimilating the food obtainable from the atmosphere and earth.

Between these two extremes of development of the embryo, or future plant, before organic connection with the parent ceases, there is every conceivable degree and variety; and, as will presently be explained with examples, some plants are viviparous, in the sense that the embryo commences active life before being severed from the parent, so that when this occurs the plant is in a position to draw its sustenance from unassimilated or inorganic materials. Now it is a curious and unexplainable fact that certain seeds exhibiting the extremes of embryonal development, instanced in the Bean and Wheat, are equally retentive of their germinative power. The longevity, if it may be so called, of seeds is exemplified in "exalbuminous" seeds as well as in "albuminous" seeds of every degree. It should be mentioned, however, that the difference is not so much one of assimilation or development as of the earlier or later transfer of the nutrient matter of the seed to the embryo or plantlet.

Assuming the perfect maturation of a seed, certain conditions are necessary to quicken its dormant vitality; and the two principal factors are heat and moisture, varying enormously in amount for different plants, and acting much more rapidly on some seeds than on others, even when the amount required is much the same. Neither under natural nor artificial conditions will some seeds retain their vitality more than one season; and all the resources of the accumulated experience of seed importers from distant countries are insufficient in some cases to maintain their vitality. It is not altogether because the interval between the dispersal and the germination of the seed, under ordinary conditions, is necessarily longer; but rather because in the one case the conditions under which a seed will germinate are

much more restricted than in the other. Let us now examine the natural conditions under which seeds are commonly produced and dispersed, in relation to the retention of their vitality; and we shall learn how much more it depends on their nature, or natural means of protection, than on the seasons. An Oak tree sheds its acorns in the autumn, and the leaves which fall afterwards afford them some protection from frost and excessive dryness. But the leaves might be blown away from one spot, and the acorns exposed to intense frost or drought, either of which will speedily kill them. In another spot the leaves may drift into thick layers, with an excessive accumulation of moisture, causing decay of the underlying acorns; and there are many other unfavourable conditions which may destroy the vitality of the acorn. It is apparently impossible, however, to preserve an acorn's vitality by any artificial means for more than one season.

The Scarlet Runner Bean loses its germinative power on exposure to comparatively slight frost, the degree depending on the amount of moisture in it; yet it will retain its vitality for an almost indefinite period under favourable artificial conditions. In both of the examples given, germination would naturally follow as soon after maturation as the conditions allowed. The seeds of the Hawthorn behave differently. Each has normally three to five seeds, every one of which is encased in a hard, bony envelope, in addition to its proper coat or testa. Committed to the earth, and under the most favourable conditions, these seeds do not germinate till the second year, and often not so soon. In this instance prolongation of vitality is probably due in some measure to the protective nature of the shell enclosing the seed.

Returning to seeds in which the embryo or plantlet forms only a very small part of the whole body, Wheat may be taken as a familiar and easily observed illustration of a seed, the vital energy of which requires very little to stimulate it into active growth; and yet this same one, having no special protection in the way of coating, will retain its vitality as long, perhaps, as any kind of seed, if not under the influence of moisture. The primary condition to the preservation of vitality in a seed is perfect ripeness. Unripe seeds of many kinds will germinate and grow into independent plants if sown immediately after removal from the parent. The facility with which immature Wheat will germinate is most disastrously exemplified in a wet harvest, when the seeds will sprout while the corn is standing or in sheaf; thus destroying more or less completely the value of the grain for flour, as the starch or flour is consumed in the development of the embryo, or what is left is so deteriorated by chemical change that it is not good for food. There is perhaps no other seed more susceptible to moisture, and none less affected by dryness, or by heat or cold in the absence of moisture.

The kind of vivipary exhibited by the Wheat is occasionally observed in various other plants; and sometimes the seeds of pulpy fruits germinate in the fruit. There is also a class of plants in which vivipary is normal. Prominent in this class are the Mangroves (*Rhizophoræ* and others) of seashores in the tropics. In these plants there is a remarkable adaptation to conditions, which insures their reproduction. From the very inception of the embryo there is no apparent interruption of active vitality in its development and germination. In the earliest stage the cotyledons or seed-leaves are formed, and the radicle or future primary root is represented by a very small point. When the former have attained their full development, which is not great, the latter begins to grow and rapidly increase in size. Each fruit or seed vessel, it should be mentioned, contains only one seed, the rootlet of which points to the apex of the fruit. Soon this rootlet pushes its way through the apex of the fruit, and grows into a spindle-shaped body of great density and length; the cotyledons or seed leaves remaining partly inside the fruit, and acting as an organ of absorption from the parent plant to nourish the seedling. In *Rhizophora mucronata* this radicle attains a length of 2 to 3 feet, and the seedling eventually falls, and by its own weight penetrates and sticks in the mud, leaving the fruit, containing the exhausted cotyledons, attached to the tree, where it dries up. Another singular adaptation to conditions is the vital development of the seeds of aquatic plants which ripen their seeds on or under water. *Vallisneria* is a remarkable instance of this. The unisexual flowers are formed under water; the female on long coiled stalks, which at the right period uncoil, and the flower rises just above the surface of the water. Simultaneously the short-stalked male flowers are detached from the base of the leafstalks, and also rise to the surface. After impregnation has taken place, the stalk of the female flower coils up again, and draws the seed vessel down under water, where the seeds ripen.

It has been explained that heat, moisture, and air are necessary to the germination of seeds, varying immensely for different seeds. We come now to the behaviour of certain seeds under the influence of an unusual or unnatural amount of moisture, heat or cold, especially in relation to the length of the duration of exposure to any one of these factors. It has been proved beyond dispute, by actual experiment, that the vitality of certain seeds, notably various kinds of Bean and *Convolvulus*, is not impaired by immersion in sea-water—or rather floating and partially submerged—for a period of at least one year; and that after having been kept quite dry for two or three years. Plants are actually growing at Kew from seeds treated as described; and some years ago several seeds of *Eutada*, cast ashore in the Azores, whither they had been transported by the Gulf Stream, were raised at Kew.

So far as at present known, all the seeds that will bear very long immersion without injury have an intensely hard, bony, or crustaceous coat, that would withstand boiling for a minute or two without killing the embryo. Yet it is difficult to understand this power of resistance, especially after being kept dry for a long time. This imperviousness to

water explains the wide distribution of many seaside plants, the seeds of which are conveyed by oceanic currents. How long such seeds would retain their vitality in water is uncertain, because experiments have not reached the limit. Many readers will remember Darwin's experiments in this connection; but it should be borne in mind that they were chiefly with seeds of plants not at all likely to be dispersed by the sea.

It has already been stated that some seeds will bear immersion in boiling water for a short time, and gardeners occasionally practise this treatment to accelerate the germination of hard-coated seeds. But seeds of all kinds will bear for a considerably longer period a much higher dry temperature than soaking in water of the same temperature. It is recorded, by trustworthy authorities, that the seeds of many plants—Poppy, Parsley, Sunflower, and various kinds of grain, for instance—if perfectly dry, do not lose their vitality when subjected to a temperature of 212° F. for forty-eight hours; and for shorter periods to a much greater heat. The result in most cases, though not all, is a considerable retardation of germination. Dry grain is equally impervious to cold. In 1877, seedling Wheat was exhibited at the Linnean Society that had been raised at Kew from grain that had been exposed to the intense cold of the Arctic expedition of 1874 to 1876.

The next question that arises is, How long do seeds retain their vitality when stored in the ordinary ways adopted by dealers? As a rule, seedsmen and gardeners prefer new seeds, because a larger percentage germinates; and mixing old seeds with new tells its own tale in irregular germination. Nevertheless, there are many seeds that retain their vitality from five to ten years sufficiently well to be depended upon to yield a good crop. Old Balsam seeds, other things being equal, have the reputation of yielding a larger proportion of double flowers than new; and some gardeners consider that Cucumber seeds of four or five years of age give better results than those of the previous year. As already mentioned, perfectly ripened seeds will retain their vitality longer than those imperfectly ripened. In illustration of this, we note that Carrot seeds grown in France retain their germinative power, on the average, longer than English-grown seeds, owing to climatal differences.

There is one other natural condition in relation to the vitality of seeds that should be mentioned: that is, the duration of the vitality of seeds on the mother plant. Some of the Australian *Proteaceæ*, and some of the Fir trees, especially North American, bear the seed-vessels containing quick seeds of many successive seasons; and only under the influence of excessive drought or forest fires do they open and release the seeds. Rapid forest fires are often not sufficient to consume the cones, but enough to cause them to open and free the seeds for a succession of trees. The unopened cones of thirty years have been counted on some Fir trees; and it is averred that the first seed-vessels of some proteaceous trees do not open to shed their seeds, under ordinary conditions, until the death of the parent plant, so that a tree may bear the accumulated seeds of half a century or more.

Finally, a few words respecting the extreme longevity attributed to certain seeds. The reputed germination of "mummy Wheat," from two to three thousand years old, has been the theme of much writing; but the results of careful subsequent experiments with grain taken from various tombs do not support the doubtless equally conscientious, though less skilfully conducted, experiments, supposed by some persons to have established the fact of Wheat of so great an age having germinated. Indeed it is now known that the experiments mainly relied on to prove this long retention of vitality were falsified by the gardener who had charge of them. Nevertheless, there is no doubt that some seeds do retain their vitality for a very long period, as is proved by numerous well-authenticated instances.

Almost every writer on physiological botany cites a number of instances. Kidney Beans taken from the herbarium of Tournefort are said to have germinated after having been thus preserved for at least 100 years. Wheat and Rye are also credited with having retained their vitality for as long a period. Seeds of the Sensitive Plant (*Mimosa pudica*) kept in an ordinary bag at the Jardin des Plantes, Paris, germinated freely when sixty years old. A long list might be made of seeds that have germinated after being stored for twenty-five to thirty years. If seeds retain their vitality for so long a period as this under such conditions, it is quite conceivable that seeds buried deeply in the earth, beyond atmospheric influences, and where there was not excessive moisture, might retain their germinative power for an almost indefinite period; and the fact that plants previously unknown in a locality often spring up where excavations have been made, bears out this assumption. The same thing happens in arable land should the farmer plough deeper than usual; and deeper tillage, which would otherwise be beneficial, is often avoided on this account.

A careful writer like Lindley states, though without qualification, that he had Raspberry plants raised from seeds taken from the stomach of a man whose skeleton was found 30 feet below the surface of the ground. Judging from coins found at the same place, the seeds were probably 1600 or 1700 years old. One more example of seeds germinating that are supposed to have been buried some 1500 to 2000 years. About twenty years ago on the removal of a quantity of slack of the ancient silver mines of Greece, several plants sprang up in abundance previously unknown in the locality. Among these was a species of *Glaucium*, which was even described as new; and it is suggested that the seed may have lain dormant for the long period indicated. But there is not the amount of certainty about any of these assumed very old seeds to convince the sceptical or to establish a fact. It remains yet for somebody to institute and carry out careful investigations where excavations are being made.—W. BOTTING HEMSLEY (in "Nature").

## HARDY FRUIT GARDEN.

**Hoeing among Trees and Bushes.**—A little attention to hoeing down seedling weeds and any advanced in size during sunny weather, will tend to keep the fruit quarters in good trim, and reduce similar work in the future. Weeds abstract food from the soil just as much as legitimate crops. Their presence on the ground ought not, therefore, to be tolerated for this reason as well as the important one of neatness and high cultivation in the fruit garden.

**Strawberries.**—If mulchings of manure for assisting the growth of Strawberry plants, maintaining the soil moist, and the fruit clean, have not yet been applied to established fruit-bearing beds this ought to be carried out at once. In moist weather a little soot sprinkled over the roots will act most beneficially, not only in nourishing the feeding fibres now in active operation, but in preventing the depredations of slugs among the swelling and ripening fruit later on. In dry, poor soils, a dressing of nitrate of soda is of great assistance in accelerating growth, being especially serviceable to the older, though not absolutely exhausted beds. Apply it at the rate of 1 oz. per square yard. Pound it small, and keep it away from the foliage. Liquid manure should also, if possible, be given to the plants whenever they promise to bear freely and the soil is somewhat poor. Fruit for exhibition will need extra attention given to the plants. Flower trusses must be thinned, and deformed fruit cut out as soon as detected. Fine large fruit of delicious quality is the outcome of intelligent attention, good soil, and judicious feeding.

**Planting Forced Strawberries.**—Plants of good varieties that have been forced are worth retaining, if only to provide stock for obtaining a supply of runners. After duly hardening the plants in cold frames they may be planted in rich, well prepared soil made firm about them. Afford water liberally in dry weather until the plants are well rooted.

**Young Plants.**—Very young or recently planted Strawberries must, if flowering, have the blooms nipped off, so that the energies of the plants may be utilised in the production of vigorous growth. This treatment secures plump, stout crowns for the succeeding year's crop. Keep down runners as they are produced. Using the Dutch hoe between the plants encourages growths, but in hot, dry weather cover the soil with manure.

**Tying and Stopping Vine Shoots.**—The growth of Vines on outdoor walls is advancing, and the shoots require attention in securing them in position, stopping them one or two joints beyond the bunches of fruit. Fruitless shoots if reserved must be stopped at the sixth leaf. Overcrowding is prevented by timely disbudding, but where shoots are still too thickly placed have no hesitation in cutting some out, dispensing with a few at a time, which is better than clearing off a number of growths at one operation, and so preventing any possible check.

**Apricots, Peaches, and Nectarines.**—Look out for aphides on the young shoots, giving the first comers a dusting of tobacco powder, afterwards washing it off, or syringe with a diluted solution of tobacco juice, a pint of the latter to 2 gallons of soapy water. Curled leaves on Apricots may probably be found occupied with the leaf-rolling caterpillar. The best method of exterminating it is by crushing the grubs, as insecticides cannot reach them. Flowers of sulphur dusted on leaves affected with mildew will destroy the fungus, so also will sulphide of potassium, half an ounce to the gallon of water, sprayed on the foliage affected.

**Gooseberries.**—Caterpillars infesting Gooseberry bushes cause considerable damage by eating away the succulent parts of the leaves, therefore the first broods that may appear ought to be destroyed as soon as possible. At this early stage it is safe to use white hellebore powder to kill them, which it does readily. Dredge it on the infested parts, or if it can be more easily applied with the syringe mix 2 ozs. into a paste with boiling water, and add 2 gallons of water before using. Hellebore being a poison, it should be washed off the fruit before gathering. Red spider on Gooseberry foliage may be destroyed by syringing both sides of the foliage with a mixture of sulphur and softsoap, 2 ozs. of each to the gallon of water. Some of the numerous insecticides so readily obtainable are very useful remedies to have at hand when time presses and insects are rapidly increasing. Remedies applied at the first attacks save both time and trouble afterwards.

**Watering Fruit Trees.**—Wall trees and others in dry positions ought to have the soil moistened if at all deficient in that respect. Clear water applied now to dry soil will prepare it to receive liquid manure when the fruit is swelling, additional assistance then being needed by the roots. Young trees newly planted will require water during prolonged dry periods, following with light mulchings of short manure to conserve the moisture. Heavy and retentive soils need little, if any, water at present, but the surface must be kept loose. Liquid manure may be applied to old Gooseberry and Currant bushes, which will enhance the size of the fruit now swelling.

**Removing Superfluous Growths.**—Continue removing shoots or growths that crowd on those necessary to retain, or that are ill placed in any way. It is especially necessary to be particular in this respect, and in regulating the growths when training young trees, as by these means, properly directed, the foundations of symmetrical specimens are laid.

## FRUIT FORCING.

**Peaches and Nectarines.**—*Earliest Forced Trees.*—Where a house of the very early varieties, such as Alexander, Waterloo, and Early Louise Peaches, Advance and Early Rivers Nectarines, was started at the middle of December, and forwarded by fire heat since the new year, the fruit will be ripening or ripe. This is a clear gain of a month on the older and more approved forcing varieties, such as Hale's Early, Royal George, Stirling Castle, Dymond, and Grosse Mignonne Peaches, Hunt's Tawny, and Stanwick Elruge Nectarines; and the fruits being early bring good prices in the markets, these ranging from 18s. to 36s. per dozen this year, the difference in the values being due to the size, colour, and condition of the specimens. While the fruit is ripening, and until it is cleared from the trees, water must be withheld from it, but a genial condition of the atmosphere must be maintained for the benefit of the foliage, the paths and borders being damped as occasioned by their becoming dry, and water be duly supplied to the soil, so as to keep it in a healthy condition. No injury results from the moisture provided it is accompanied by judicious ventilation, a little being afforded constantly at the top of the house.

*Trees Started at the New Year.*—Where these consist of varieties last named in the preceding paragraph the fruit will be in the last stages of stoning, the second early varieties having completed that process, and must not be subjected to a higher temperature than 60° to 65° by artificial means, commencing to increase the ventilation at 65°, not allowing 75° to be exceeded without full ventilation. Tie in the shoots as they advance, removing superfluous growths, as it is important no more be trained-in than can have full exposure to light and air. If the shoots are crowded thin them as soon as the stoning is completed. Allow one fruit to every square foot of trellis covered with foliage, which will be one to every shoot of last year, although vigorous shoots may be allowed to carry two fruits. By apportioning the fruit to the vigour of the trees or degrees of this in different parts the evenness of the growth may be maintained throughout the tree. After the stoning is completed maintain adequate supplies of moisture in the house by syringing up to the fruit commencing to soften, when it must be discontinued over the trees; but the borders and paths well damped twice a day, or as occasion require. Inside borders require water about once a week when of a porous nature; firm and retentive soil need supplies less frequently. A light mulching of short, sweet material will save watering, encourage surface roots, and promote a genial condition of the atmosphere. Unless it is desired to accelerate the ripening, continue 60° to 65° as the night temperature, and 65° by day artificially in dull weather, and 75° with sun heat, closing at the latter with abundance of moisture. In a higher temperature, and correspondingly moister atmosphere, the fruits swell to a great size after stoning, being very tempting in appearance if well exposed to light, but they are not so well flavoured as those produced in less heat and moisture, with free ventilation.

*Trees Started in February.*—As the fruit is now commencing the stoning process in earnest the number, if too many, should be reduced, leaving two fruits on strong shoots, but one will be sufficient on the weaker. Reserve in all instances the best situated fruits for receiving air and light. Avoid crowding, thinning where too close, stopping laterals to one joint, and pinching off the points of successional growths at about 15 inches from their base. The temperature by artificial means may be kept at 55° to 60° at night, 60° to 65° by day artificially, ventilating from 65°, and fully between 70° and 75°, it not being possible to give too much air to Peach houses, only avoid sudden fluctuations, and secure the requisite temperature for steady progress.

*Trees Started in March.*—To secure fine fruit and full crops without distressing the trees, thinning must commence early and be followed up so that few more than will be required for the crop remain at the commencement of the stoning process. It can now be seen which fruits have taken the lead, hence they should be reduced to two or three on strong shoots, one or two on medium, and one or none on weak. Remove all superfluous growths, the remaining shoots being trained to the trellis as they advance. Afford nourishment to weakly trees, either as top-dressings of the advertised fertilisers, washed in or as liquid manure. Vigorous trees need mineral matter, such as lime, phosphate or superphosphate being most suitable, washing in with clear water only.

*Late Houses.*—As the crop is now well set, a moderate syringing on fine mornings will be of great assistance in ridding the fruit of the remains of the flowers. Commence thinning when the fruits are the size of horse beans, removing the smallest and worst placed, leaving a few more only than will be required for the crop. Disbudding and heeling-in the shoots should be carefully attended to. A temperature of 50° at night will be safe, and 55° by day artificially, ventilating freely from and above that unless it is desired to hasten the crop, when a temperature of 55° at night and 60° to 65° by day artificially may be secured with 70° to 75° by day from sun heat, ventilating from 65°. This rapid forcing is not desirable nor at all times safe.

*Unheated Houses.*—A moderate syringing on fine mornings or early in the afternoon will be of great assistance in ridding the fruit of the

remains of the blossom, tend to prevent incursions of red spider, and keep down other pests. The houses, however, must not be kept very moist, and the foliage should always be dry before night, as the weather is not yet to be depended on, and a sudden severe frost occurring whilst the house is moist is much more likely to prove disastrous to the crop than when the atmosphere is dry. Ventilate at 50°, not allowing an advance to 65° without full ventilation, and close at 50°, or before if there is a prospect of frost at night. If water is necessary, apply it sufficiently early in the day to allow of the surface becoming fairly dry before night.

**Pines.**—With the weather changeable and the fruits of early started plants in an advanced stage special attention is necessary, a moderately moist atmosphere and high temperature being essential to their well-being, which condition renders them susceptible of injury from the effects of bright sun, sudden outbursts telling disastrously on the crown, which is not infrequently scorched if the ventilation is not carefully attended to. Watering will require attending to once a week, but avoid indiscriminate periodical drenchings. Plants that have heat at the roots by means of hot-water pipes need more than those having the heat furnished by fermenting materials. In either case water should be given as often as required, on every occasion supplying some stimulant, such as guano, 1 lb. to 20 gallons of water. Admit air at the top of the house by or soon after the sun acts powerfully thereon, maintaining the temperature during the day at 80° to 90°, closing at 85°; but unless it be desirable to enlarge the crowns, do not quite close the house. Fire heat must be employed to prevent the temperature falling below 70° at night, and raise it to 75° in the day, the bottom heat being kept at 80° to 90°. Syringe the house and plants two or three times a week, according to the weather, and maintain the atmosphere in such condition as to secure the perfect development of the fruit.

**Cherry House.**—Cherries ripening rapidly must be kept dry, but the borders and paths should be sprinkled as required to maintain a genial atmosphere for the benefit of the foliage, air being admitted constantly, or condensation will seriously affect the fruit, causing it to crack. Examine the border, and if necessary afford a thorough supply of water. Tie-in the shoots as they advance, and stop those not required at about the fifth leaf. Ventilate freely on all favourable occasions, and when the external conditions are unfavourable recourse must be had to the heating apparatus to insure a circulation of warm, dry air. Black aphides must be kept in check by fumigation or vapourisation, or by dipping the shoots or leaves in tobacco water. Netting will be necessary over the ventilators, with sufficiently small mesh to exclude birds.

**Cucumbers.**—Plants in bearing all the winter will now be showing signs of exhaustion, and had better be removed and young plants placed in without delay. All the old soil must be taken out and the house thoroughly cleansed, using entirely fresh sweet material for the young plants. If there is any suspicion of eelworm, syringe the house in every part with a mixture of petroleum and water, a wineglassful to 3 gallons of water, keeping mixed by alternate squirts from the syringe into the vessel and over the woodwork. For the walls and soil parts use that amount of phenyle or creolin instead of the petroleum, and if need be disinfect the soil, using the phenyle at the rate of a wineglassful to 3 gallons of water, moistening the soil evenly through. Assist young plants showing signs of weakness by removing the staminate flowers and the first fruits, stopping at every third or fourth joint, removing all weakly and superfluous growths. Shading will be necessary for an hour or two in the middle of the day when the sun is hot, especially houses facing south, but let it be done before the plants flag, as afterwards it will only prevent further mischief, flagging being invariably injurious.

Houses with roofs facing east and west will not require shading. Little or no fire heat will be required by day, shutting off the valves at about 8 A.M., and opening them again at about 5 P.M. Syringe the plants moderately between 3 and 4 P.M., or earlier, keeping a good moisture all day by damping the floors. Aphides must be kept under by fumigation, filling the house with smoke in the evening and repeating it early in the morning, or it may be practised on two or three consecutive evenings. It is essential to have the foliage dry, but the floor well damped. Red spider may be kept under by removing the worst leaves and syringing somewhat forcibly, but not so as to damage the foliage. Ammonia in any form is disliked by these insects, hence guano or soot water at the roots benefits alike the plants. A little sulphur brushed on the hot-water pipes with a little milk to make it adhere is good against red spider, white fly, and mildew.

**Pits and Frames.**—Sow seeds for raising plants to occupy pits and frames after being cleared of bedding plants, or early Potatoes. Cucumbers do excellently in such structures, a fair bottom being secured by using the least decomposed material from Seakale, Rhubarb, or exhausted hotbeds, which, with about a fourth of fresh material, will afford all the heat required. Close the pits and frames as early in the afternoon as is safe, not allowing the temperature to exceed 90° to 95°, and employ good night coverings. Maintain a bottom heat of 80° to 90° by duly renewing the linings. Prepare for planting out ridge Cucumbers under hand-lights, the plants being hardened previously.

**Strawberries in Pots.**—There must not be any lack of moisture at the roots of Strawberries, as when the sun is powerful the fruits are apt to have the skin dried, and they do not swell properly afterwards. After the fruits commence swelling a brisk moist heat is essential, supplying liquid manure liberally until the fruit change colour, when

it must be discontinued, giving less water at the roots. Admit air freely whenever the weather is favourable, avoiding drying currents. Thin the fruits well on late plants, especially the late varieties. Water the plants twice a day, and in bright weather three times, at least examine the plants for that purpose and supply it if required. Liquid manure may be given at the afternoon watering.

## APIARIAN NOTES.

BRIGHT sunshine, easterly winds, and frosty nights have continued for about two weeks. Bees do not work as eagerly as some people think they ought, the reason being honey is scarce, owing to the drought.

Everywhere the bright weather is stimulating the bees to breed, and many hives are now well forward, but are on the verge of starvation, which liberal feeding will keep right, and if favourable weather comes during the next two months end in profit.

There are exceptionally sheltered places near woods where honey trees and flowers abound, hives in some cases being too heavy. Frame hives are easily remedied by removing sealed combs, substituting full sheeted frames. Hives having fixed combs and over-charged with honey should have supers added. When the bees have these well combed, invert the hive, and with a spatula or other instrument break the seals of some of the overloaded combs. This has been done under my instructions in several cases, and is giving every satisfaction.

Although I advise supering in such cases, I by no means recommend it generally until the hives are crowded with bees and the honey flow at hand, unless with hives specially wanted to swarm from which supering is withheld, and in some cases the hives are undersized.

The difference between bees in a hive containing 2000 cubic inches and one nearly as large again, all things being right, favours the bee-keeper from 50 to 100 per cent. more honey where the latter is used. The former may at times fill a super earlier, but it afterwards falls greatly behind.

Nuclei may now be formed as soon as the first swarm has issued. About eight days after the issue of the first swarm divide the brood combs into nuclei boxes holding from three to four frames, making sure each nucleus has a queen cell. Reject all attenuated or smooth walled cells. It is not a bad plan, if there are hives not forward enough for profit, to divide their bees and combs amongst the nuclei, reserving the queen, joining her to a newly swarmed hive, making sure all queen cells are destroyed before doing so.—  
A LANARKSHIRE BEE-KEEPER.

## SEASONABLE NOTES.

As there is now a decided change in the weather for the better, the sun shining daily from an almost cloudless sky, the barometer being high and a corresponding rise in temperature, trees and plants bursting into bloom in all directions, will enable the bees to supply the wants of the daily increasing population of their hives.

Notes should be made of the many varieties of flowers now in bloom that are most frequented by the bees. In the majority of agricultural districts these will be very plentiful. Apples trees are a mass of bloom, and there is a great promise of a heavy crop of fruit if not injured by the late frosts. As vegetation generally is later than usual the bloom will probably escape, as it is quite unusual to have so severe a frost so late in the season as was experienced on the 21st of May last. Plums, Pears, and Cherries are now in full bloom, which, thanks to the bees, will be fertilised, and the trees probably in due course be heavily laden with fruit. From the flowers of these trees a great amount of honey and pollen is obtained, notably in the South and West of England, where many acres of fruit trees are grown. In my own district only sufficient honey is obtained for supplying the present wants of the bees, as fruit trees are not grown in sufficient numbers, and as a rule stocks are not forward enough for supering so early in the year.

The wild Cherry has been a perfect sheet of blossom, and has been of great assistance to the bees. The Sycamore tree, so common in our woodlands, is now in full bloom and produces a great amount of honey and pollen, and is most serviceable to the busy workers in building up strong colonies, for the honey flow which we obtain from the field Beans and White Clover. The former promised well in the autumn, but the majority of crops that I am acquainted with have succumbed to the severe winter, and

the land in which they grew has in several instances been sown with Oats.

Clover, however, has wintered remarkably well; the plants are thickly set on the land, and should the weather be favourable, will be followed by a heavy crop of bloom from which superior samples of honey will be obtained. Wallflowers are now in full beauty; these are much frequented by bees, and are appreciated for their rich perfume. Seeds of these should now be sown for a supply of plants for another year, and ought to be planted in their permanent places in the autumn. Aubrietias, both the blue and purple varieties, form a carpet of flowers, and being a dwarf growing, spreading plant, should be planted as an edging to beds or borders and on the rockery where they may remain for several years without being disturbed. They are propagated by dividing the plants as soon as they have finished flowering, or the blue variety may be obtained from seed, which should be sown at once, and the plants will flower next spring.

Some of the plantations in this neighbourhood are now carpeted with tens of thousands of the wild Hyacinths, forming a mass of colour not easily to be forgotten. These are also very useful for the bees.—AN ENGLISH BEE-KEEPER.

#### FOUL BROOD IN BEE HIVES.

THE "North British Agriculturist" says:—"We had occasion the other week to show that in the south-western counties of Scotland milk is now so plentiful that the creameries are being flooded with it, even though the price has been reduced to 4d. per gallon. As to honey, the Baronet of Southwick tells us that any working man who has a fancy for bee-keeping can, almost at no cost to himself, produce from a ton to a ton and a half of it per annum, and 'at the moderate computation of 1s. per lb. a ton of honey must realise £120;' but 'as that honey was very often worth 2s. 6d. per lb.' 'the working man who had a fancy for bee-keeping' could very often realise £300 per annum for his honey harvest! If the genial Baronet had said that 'the working man who had a fancy for bee-keeping' could produce annually on an average something like 300 lbs. avoirdupois of honey instead of £300 sterling value in honey he would, we fear, have been much nearer the mark than he was. According to Sir Mark Stewart, foul brood in bee hives is something like tuberculosis in cattle, as the bees affected with this disease become 'piners,' and die off. The deputation to Mr. Gardner urged that power should be given to some properly constituted authority to inspect bee stocks and stamp out all affected stocks. Foul brood is undoubtedly causing a serious loss to those who have hitherto pursued the industry of bee-keeping, and it is to be hoped that effective measures will be taken for the stamping out of this disease."

#### TRADE CATALOGUES RECEIVED.

W. & J. Birkenhead, Sale, Manchester.—*Illustrated Fern Catalogue.*

F. Cooper & Sons, 30, Manners Street, Wellington.—*Plants and Bulbs.*

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Vine Growths Deformed** (*D. and W. B.*).—By an oversight, 1 oz. instead of 1 lb. of sulphate of iron was given in the reply on page 417.

**Tomato Plants Infested with "Black Stripe"** (*St. Julien Arabin*).—By treating the affected plants with Bordeaux mixture there is a probability that the copper to some extent would enter the tissue

(epidermal cells) and act on the fungus, so that the fruit would mature. The better plan is to use the lime and copper carbonate, as that does not enter the tissues, and there is no danger of poisoning anyone. By pulling up the affected plants the disease is kept from spreading, and there is an end of it providing the plants are burned. We shall shortly publish the results of a microscopical examination of the plant by Mr. G. Abbey. The plant did not arrive soon enough for this to be done this week.

**Weevils Eating Roses** (*D. B.*).—The enemy is the destructive weevil, *Otiorynchus sulcatus*. You should catch all you possibly can with the aid of a lantern at night, as not only are they most voracious, but their larvæ in the soil devour the roots of various kinds of plants. Sulphuring heated pipes in vineries will not kill thrips, and the fumes are injurious to newly set Grapes. Sponge the leaves with an insecticide before the insects increase, and you may prevent much after trouble and serious injury to the Vines.

**Snowdrops and Daffodils under Oak Trees** (*C. N.*).—The land cleared before the bulbs were planted should be kept free from the Nettles. They are best pulled up with a gloved hand, taking care not to draw the bulbs with the roots. The Nettles will injure and weaken the bulbs, smothering them, as the roots leave very little space for anything, and the tops appear in spring before the leaves of the bulbs have died down; hence they cannot thrive where Nettles grow strongly. The decay of the Nettle tops will not do the bulbs any good under the circumstances. They will, in fact, do them a great deal more harm than good if allowed to increase.

**Fungus in a Mushroom Bed** (*F. G. R.*).—We are of opinion that it is not practicable to apply anything to the bed strong enough to destroy the fungus that infests it without destroying or seriously injuring the Mushroom spawn also. The manure must have contained spores of the invader, and possibly was not sufficiently heated during fermentation before making the bed. You might try experimentally a solution of salt at the strength of 2 ozs. and upwards to the gallon of water. Twice that quantity of salt has been used, but we advise you to proceed cautiously and note the effects on a portion of the bed before giving a general application. Perhaps some of the larger clumps of the noxious fungus could be dug out, and if it "runs" close to the surface of the bed this could be removed, afterwards casing with a mixture of loam and fresh cow manure.

**Vine Leaves Warded** (*W. M. L. M.*).—The small warts on the under side of the leaves and corresponding depressions on the upper are caused by mites (*Phytoptus vitis*) now in the egg state. There are no larvæ at present discoverable in the blisters, but they will soon emerge, when they will feed on the tissue and cause it to become brown, more or less, and sometimes shrivel. The affection seldom does much harm. The leaves becoming brown or shrivelling should be destroyed by fire, and in the winter the Vines should be dressed with a solution of copperas, 1 lb. to a gallon of water, applying with a brush in the usual manner of winter dressings, collecting and burning all the leaves of the affected Vines as they fall, or preferably before. A dressing of sulphate of iron, quarter oz. per square yard, may also be given the border, but with care in destroying the affected leaves the injury will not proceed much farther.

**Vine Foliage Flagging and Shrivelling** (*W. S. W.*).—It is impossible to tell you "the cause of the foliage of Vines flagging every day and shrivelling up." We have known it arise from the grubs of the Vine and other beetles feeding on and destroying the roots as fast as produced, so that the Vines could not derive the needful nourishment. At another time we have known mites appear on the young growths and prevent their satisfactory development. At times the young shoots refuse to grow more than a few inches, then stop, some not even starting from the buds. It may arise from slime fungus, fungi proper, or nothing but from a soddened condition of the soil, or from unripe wood, or impaired growths brought about by the application of some substance in the previous seasons or winter. If the roots are quite healthy and the soil in good condition you may induce growth to start at the lower part of the stem by cutting the laterals to one joint or leaf and confining them to that, so that the dormant buds must start, if there be any, selecting the most promising of these and letting them grow according as you require canes, pinching the laterals to one leaf and sub-laterals, also to one leaf as made, you will soon get a good cane or canes of a yard or more long, when you may cut away the old rod or rods, and there will not be any bleeding, as the new growths appropriate the sap. If you cut the Vines down entirely, that is below all the leaves, it is likely they will bleed considerably, and the growth be late in starting, besides there would be a great loss of stored matter, weakening if not causing their collapse.

**Figs Diseased** (*C. J.*).—The leaves are large, quite clean, and of fair texture, but the footstalks are rather long, and the young wood is somewhat long jointed, the latter being nearly twice that in distance of the previous year. This indicates that the house has been kept close, moist, and warm. The wood of the current year is also lean as compared with last season's, which would be induced partly by the aforementioned conditions and partly by that of the soil. This is of a close soapy nature and very wet, otherwise an excellent staple for the growth of Figs. We mention these matters as possibly producing that condition of the fruit favourable for the development of the disease with which they are infested, and it would be well to bear the matter in mind for avoidance in the future. Perhaps the drainage of the border is defective. This should be attended to and rectified at the proper

time, when at least one-fifth of old mortar rubbish should be mixed with the soil, this being made quite firm. In the meanwhile keep the soil as dry as you can without distressing the foliage of the trees and the growths rather thin, admitting air freely on all favourable occasions, especially in the early part of the day. The fruits, which appear to be Brown Turkey, have safely passed the flowering stage and contain numbers of seeds quite clean and healthy, but at the upper part of the fruit some of the pericarps are discoloured and their substance destroyed. If you cut one open and examine it just within the "eye" you will see this destroyed and brown decaying matter, also that it extends inwards from the eye. Now, when this eye was open for flowering the spore of a fungus gained access, and the growths from that have produced the mischief. Later you will find that a spot appears on the apex of the fruit affected, something that develops outgrowths, and usually of a pink or salmon colour. This is the "spot" fungus (*Gæosporium læticolor*). You may dress the hot-water pipes lightly with a cream formed of flowers of sulphur and skim milk, the fumes from which are inimical to the fungus spores germinating, or put the sulphur in shallow vessels or saucers, just covering it with water and place in the house so that the sun can act directly upon them. In the winter the wall and trees may be washed with a solution of copperas (sulphate of iron), 1 lb. to a gallon of water, applying with a half-worn paint brush to the trees in a careful manner, but wetting every part, while for the wall form an ordinary whitewash consistence by the addition of quicklime. Burn all affected fruits. The smaller ones are not affected, and they will ripen if the fungus is kept at bay, ventilating freely, and providing otherwise suitable conditions for attaining the desired object.

**African Palm Oil** (*H. W. G.*).—The Palm oil of Africa is extracted from the tree called *Elais guineensis*. It is found throughout the whole of the east coast of Central Africa, whence it has been introduced to the West Indies and South America, where it is cultivated for its oil. The tree attains to the height of 30 feet. The leaves are 15 feet long, and their footstalks, for 4 feet below the leaflets, are armed with hooked spines. The flowers have a strong and peculiar smell, like aniseeds mixed with Chervil leaves. The fruit forms an immense head, consisting of a great number of bright orange-coloured drupes, having an oily pulp and a stone in the centre, and it is from these drupes that the oil is obtained. The fruit is first bruised in wooden mortars to a paste, and this paste is then boiled in water; a reddish or orange-coloured oil rises to the surface, and is removed after the whole has been allowed to cool. When fresh it has an agreeable odour of Violets, and an oily consistence; but as it is removed into cooler regions it acquires the solidity of butter. This oil is called ghea (butter) by the natives, and is universally employed by them as butter is in Europe, and with it they daily anoint their bodies. The quantity of Palm oil now imported to this country is enormous. It is employed in the manufacture of candles, toilet soaps, and common hard soaps; and very extensively in antifrictions for the wheels of railway carriages. Palm oil contains 31 of stearin, and 69 of olein. Besides this oil, which is also called Palm butter, there is another oil obtained from the nuts by expression; and by boiling these nuts the natives make an excellent Palm soup. The tree yields from its trunk an abundance of Palm wine.

**Names of Fruits.**—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state.* (*Jack*).—The Apple is Northern Greening, also called the John Apple—a very useful variety. (*F. M.*).—Gooseberry Apple, one of the latest keepers of all.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*G. P.*).—1, *Ribes aureum*; 2, *Asparagus deflexus*. (*S. P. S.*).—*Cattleya Mendeli*. (*C. J. W.*).—1, *Saxifraga oppositifolia*; 2, *Sempervivum arboreum*; 3, *Kennedyia rubicunda*; 4, *Leptospermum scoparium*. (*M. E.*).—1, *Phlebodium aureum*; 2, *Cyrtomium falcatum*; 3, *Woodwardia radicans*; 4, *Pteris longifolia*; 5, *Asplenium bifforme*; 6, *Adiantum pedatum*. (*N. O. M.*).—1, *Epimedium alpinum*; 2, *Cerasus padus* (Bird Cherry); 3, *Exochorda grandiflora*. (*M. J.*).—*Brachysema lanceolata*. (*J. H.*).—1, *Polygala Chamæbuxus*; 2, *P. Dalmaisiana*. (*P. H. J.*).—1, *Amelanchier Botryapium*; 2,

*Ranunculus amplexicaulis*; 3, *Phlox subulata*; 4, *Cardamine pratensis flore-pleno*; 5, *Corydalis nobilis*; 6, *Saxifraga (Megasea) crassifolia*. (*G. N. A.*)—A *Hænanthus*, probably *cinnabarinus*. These plants are frequently grown in this country. (*G. H. T.*).—1, Specimen withered, possibly an *Amelanchier*, send fresh; 2, *Amelanchier Botryapium* (the Snowy Mespilus); 3, totally insufficient; 4, *Ophiopogon Jaburan variegatus*.

POOR LAND.

POOR Pasture was the title which we had in mind for this article before sitting down to write it, but a little consideration under the light of recent experience induced us to adopt the more comprehensive designation of Poor Land, as calculated to meet a more general want. If pasture is now difficult to manage, what are we to say of arable land, what are we to

do with it? There are two sides to every question, two points of view from which, in common fairness, land difficulties must be regarded, and while we are asked with persistent reiteration to "Pity the poor farmers," what, we ask, is to be done for the landlords, with rents reduced and with land thrown on their hands foul with weeds, exhausted of fertility—farmed out?

"I see little or no inducement to cultivate land at the present ruinous prices; farmers and landlords are bankrupt all round us," writes the agent of an East Anglian estate, in a letter which also tells of a farm in hand of some 400 acres, only 70 acres of which is in pasture; of a farmer giving up a farm of 600 acres next Michaelmas for another of only 130 acres, and so on. Well do we know from our own experience in the management of East Anglian farms how great are the difficulties, how severe the struggle to hold on at all. It is only because rents have come down by from one-half to two-thirds that tenants have been kept going. We suggested long ago a system of temporary pasture and co-operative butter factories instead of Wheat in order to effect a considerable reduction in the area of arable land, but our words were as nought to the corn farmers.

More hopeful, more elastic, altogether on a sounder basis is the agricultural situation in those districts where land is mainly in grass, but even there difficulties occur, and there is much to be done in the way of improvement. Here are one or two examples. Of certain farms which have recently been acquired by purchase to enlarge the bounds of an estate in the Midlands, one is being kept in hand till next Lady Day in view of placing the farmhouse and homestead in thorough repair, in repairing the sadly neglected fences and gates, and, most important of all, effecting a thorough renovation of the pastures. We may mention that there are four applicants for this farm; it is quite probable there will be more before we have done with it.

The late tenant's claim for tenant right was heavy on the score of improvement of pasture, which we found consisted in carting, and spreading on it a considerable quantity of road sidings. This idea of improvement is not at all in accordance with ours. We have given the whole of the pasture, both that reserved for hay and that for grazing, a dressing of chemical manure consisting of 2 cwt. of phosphates, 1 cwt. nitrates, and half cwt. potash per acre. This will give it a good start; it will be stocked with store cattle this season, and in September all the upland pasture will be folded with sheep.

It will then come to hand next Lady Day in a sound fertile condition, and it will be our aim to secure a really good tenant for it, who will continue to cultivate the pasture on the same sound principles. This example of practice should prove a valuable object lesson for the old tenants who have absolutely no system of pasture cultivation, have never set a sheep fold, nor purchased any manure. They trust to the excreta of grazing cattle, to natural fertility of soil, and very much indeed to the weather. In thinking over this matter it occurred to submit our scheme to Mr. Thomas Brown of King's Lynn, whose standing as an agricultural chemist is of the highest, and who has so long been conducting experiments with manures. He replied, "I cannot see in what direction I can improve on your proposition. By your means the most worn pasture would be restored."

On another estate in the same district we have a farm which fell in hand at Lady Day, of which about fifty acres are in plough. Of this two fields, which were fairly clean, have been laid down to grass with a crop of Oats, and a similar dressing of chemical manure to that already mentioned. A field of Wheat has had a dressing of 1 cwt. nitrate of soda per acre, and the remainder of the land is to have a summer fallow. Of this, one field is just a bed of Thistles, and the

remainder is so foul with couch grass that steam cultivation will be applied to the whole of it. We were at first inclined to take a crop of roots from the Thistle field, but it is such a bad case that we decided to seize the lucky chance to eradicate a pest which had evidently been trifled with for many years, or it never could have become so bad.

#### WORK ON THE HOME FARM.

Corn rolling has been pushed as the weather has been so favourable, grass seed being sown first on the spring corn where the land is going down either to temporary or permanent pasture. In this work we keep to the old plan of sowing the corn first and having the plant well above the surface before sowing the Grasses and Clovers in mixture, in order that the grass may not become so rampant as to prove very troublesome at harvest time. All land in fallow, whether with or without a root crop, has been kept well stirred, and couch fires have been kept going.

In our uncertain climate the only safe plan is to never miss a chance of pushing on such work, even at the expense of something else. The weed pest is one of the hindrances to successful farming that demands much more systematic treatment on the principle of prevention than it generally receives. It must surely be obvious that to wait till perennial weeds become strongly established on the land before grappling with them is as foolish as it is costly.

Give all possible attention to root and green crops so as to have an ample provision for a possible droughty autumn as well as for next winter. Get forward with land intended for Green Maize, which is just one of those crops that must be sown neither too early nor too late. It is sensitive to frost, therefore do not sow till risk of harm to the young plant from cold is past, and then do not lose an hour. Generally, the end of May is regarded as the best time, and wherever it is found to answer—*i.e.*, localities where there are four months without frost, it should be grown for the marvellous bulk of crop, for its nutritious properties, and because cattle are so fond of it.

See that there is no negligence about calves. Let all very young ones have milk at least three times daily, that others have plenty of nourishing food and are kept going in the best way without check of any sort. On bright warm days now we always have the forward calves out in the paddock, only taking care to get them into the yard or hovel early in the evening, and to keep them in altogether on the wet, cold days which occur at this season of the year. Careful feeding, no undue exposure, kindly, gentle treatment are the chief points in this work, which must have attention.

#### OUR LETTER BOX.

**Value of Grass (W. L. H.).**—The value of your five acres of grass to let for hay (and presumably for the aftermath as well) depends not only upon the quality of the land and condition of the grass now, but also upon local circumstances. If the land is really rich in fertility, and the herbage is exceptionally good—*i.e.*, of vigorous growth, and really thick on the land, it may be worth from £2 to £3 per acre. But its value must also depend upon its surroundings. If such a crop is really in demand in your neighbourhood, and good pasture is at all scarce, then you might obtain the higher amount. In the Midlands, where so much of the land is in grass, the "keeping"—practically the same as the heavy crop and aftermath—is very cheap this season, for the simple reason that stock is dear and scarce, and there is a positive glut of keeping in the market. A lot of it was let by auction last week at from 12s. to 14s. per acre, and much of it was not let at all, not a bid being made for it.

#### REMARKS.

- 5th.—Bright early, frequently cloudy after 10 A.M.; brilliant night.  
 6th.—Almost cloudless throughout.  
 7th.—Almost cloudless throughout.  
 8th.—Believed to be absolutely cloudless.  
 9th.—Bright sunshine till 11 A.M., hazy after with detached cloud; threatening at times in afternoon, and spots of rain at 5.30 P.M. Solar halo at 6 P.M.  
 10th.—Sunny almost throughout, but occasional cloud.  
 11th.—Unbroken sunshine all day.  
 Another fine week, and warm, but not unprecedentedly so.—G. J. SYMONS.

# DICKSONS' NEW IRISH ROSES.

ALEX. DICKSON & SONS

Have pleasure in announcing for distribution in May a further series of their

**CELEBRATED PEDIGREE ROSES,**  
 HELEN KELLER (H.P.), Rosy Cerise, superb .. 10/6 each  
 MAVOURNEEN (H.P.), Silvery Flesh, first rate 10/6 ..  
 MARJORIE (H.T.), White, Pink centre, very pretty 7/6 ..

ALSO  
 The Best of the NEW FRENCH & BRITISH ROSES.  
 Descriptive Catalogue Post Free on application,

## NEW (H.T.) ROSE BELLE SIEBRECHT (Mrs. W. J. Grant).

Raised by ALEX. DICKSON & SONS, distributed by SIEBRECHT and WADLEY, New York.

The most valuable introduction of the past ten years. This superb variety has gained the highest awards wherever exhibited in Great Britain and America, chief among these being the National Rose Society's Gold Medal.

Valuable alike for exhibition, decorative, and forcing purposes. No collection, however small, complete without it.

PLANTS IN POTS IN MAY, 10/6 EACH.

Full Descriptive Particulars Post Free on application to

**ALEX. DICKSON & SONS,**  
 ROYAL NURSERIES,  
 NEWTOWNARDS, Co. DOWN,  
 SOLE AGENTS FOR EUROPE.

**C. COX,** Horticultural Engineer,  
 TUNBRIDGE WELLS.

### THE HERCULES.—Design Registered. TENANT'S FIXTURE PORTABLE SPAN-ROOF CURVILINEAR CONSERVATORY OR GREENHOUSE

No brickwork required. These houses are made of the best materials, painted four coats, and glazed with 21oz. clear sheet glass, a flat painted stage is fixed on each side and one end, and slatted path up centre.

CASH PRICE, Carriage Paid to nearest Station in England & Wales, within 100 miles of Tunbridge Wells—fixed free:—

## FLORISTS' FLOWERS AND HARDY BORDER PLANTS.

FORBES' NEW CATALOGUE for 1895 is enlarged to about 150 pages, and very materially improved, embracing everything—new and old—worth cultivating in the way of FLORISTS' FLOWERS and HARDY PLANTS, with accurate descriptions and prices. Copious notes as to their origin, how and where best to grow, a full index of the common or popular names of HARDY BORDER PLANTS, and a vast mass of other valuable information that cannot be had elsewhere, which renders this the BEST, MOST RELIABLE, and COMPLETE CATALOGUE ever issued on this popular class of plants. Free on Application.

**JOHN FORBES,** Nurseryman,  
 HAWICK, SCOTLAND.

## STRAWBERRIES.

Special low quotations for quantities for market growing. In small pots for fruiting first year. Open-air runners very cheap. All the leading varieties, new or old.

## FRUIT TREES OF ALL KINDS. SEND FOR LIST.

**JOHN WATKINS,**  
 Pomona Farm Nurseries,  
 WITHINGTON, HEREFORD.

## GATHER HONEY FROM YOUR FLOWERS. WHY NOT COMMENCE BEE-KEEPING?

Fruit trees to which Bees have access bear the most abundant crops

## CHEAP GLASS FOR GREENHOUSES, &c.

In Sizes, 14 by 10, 16 by 9, 18 by 8, &c., at 7/9 PER 100 SQUARES. Glass Cuttings, 7 in., 8 in., and 9 in. wide, including Laps, at 6/3 PER 100 RUN FEET.  
**LAMBERT & SONS, MIDDLESBROUGH.**

## DICKSONS EVERGREEN Lawn Grasses

Delivered Free by Rail or Parcel Post.  
 The Selections we offer are composed exclusively of the dwarfest growing and finest leaved grasses, and form in a very short space of time a beautiful velvety turf of the finest texture and colour.

"The Bowling Green here which was prepared last October and sown with your *Lawn Seed* last April, was opened on Saturday, July 7th, and it gives me much pleasure to inform you that the turf and growth of seed far exceeded the expectations of the members of the Bowling Club. I have no hesitation in stating that sowing seed is far preferable to turfing new ground."—P. WILSON JONES, Esq., Newtown.

"I never saw any *Lawn Grass Seeds* do so well as the mixture I had from you without *Rye-Grass*. The result from this was most satisfactory."—Mr. GEORGE DEAN, Ildecks.

Extra Select Mixed Dwarf Evergreen Lawn Grass, entirely omitting *Rye-Grass*.  
 Per lb., 1s. 6d. Per cwt., 160s.

Extra Select Mixed Dwarf Evergreen Lawn Grass, including a small proportion of Dwarf *Perennial Rye-Grass*.  
 Per lb., 1s. 3d. Per cwt., 135s.

**DICKSONS** Seed Growers, Nurserymen, &c. **CHESTER**

## Journal of Horticulture.

THURSDAY, MAY 23, 1895.

### THE CHECK IN MAY.

WHEN the "Promise of May" was being written last week the sun was shining its hottest for the season, and pedestrians were seeking the grateful shade of trees and buildings. Many were the rejoicings and mutual congratulations that summer had come, and not a few of the comparatively young and sanguine were confident it had come to stay. Older heads were shaken in remembrance of more than one rude check having been given to their plants and trees by the sudden rising of the wave of cold which wrought disaster, and they felt, but scarcely liked to say so, that it would be sure to come before the month was out this year. Wise were those who were not tempted to remove their tender plants from where they could be protected, but the gentle note of warning sounded was not quite in time for all to consider whether they should halt or not. Here is a case in point which arrived with the above heading from the "The Missus."

"When I took up your Journal yesterday morning to enjoy with my breakfast coffee, I was forcibly reminded of 'Punch' some years ago—a little punning effort when 'F. May's' signature made Bank of England notes of value. Alas! that signature is of no such promise now, and alas! too, what of 1895 and this promise of May?"

"Wednesday, just as we finished planting four crescent beds with *Tropæolums*, a cold dull change in the atmosphere made us shiver after the days of 'cloudless beauty' and summer glow; the air felt decidedly nipping. By late evening the north wind rose. Thursday broke with dull skies and the wind still higher. All day it increased, and at times was accompanied with sharp, sleety showers! Oh, how bitter! How pinching the gale felt, and what fearful wreckage of our handsome *Beech* trees just in their early summer dress! The garden that had looked so trim and neat was strewn from end to end with leaves and small branches. The fine old *Sycamore* in the village street on the north side looked like some of the flags that adorn St. George's Chapel, Windsor; looked as though it had braved the battle as well as the breeze.

"Thursday night was still rough. Friday morning no better, and at noon a heavy steady rain set in, which from the state of the roads must have continued through the greater part of the night. This morning (Saturday) dawned dull and cold. The wind lulled, the rain uncertain whether to come or go. What the effect on the Apple trees will be no one can tell yet. It is possible the damage may not be so great as one expects, but at present everything is too wet for an investigation.

"Roses had made wonderful progress, but alas! the devastation is great; a cherished archway of climbing Roses is gone, but like the phoenix of old will arise from its own ashes—in other words, will grow from the bottom again. The weeping Rose is like a shorn lamb; but this subject is too wide, and I must leave it to 'D., Deal,' and clerical 'Raillem' to give us in their own good time words of hope and consolation."

The above letter embodies, we have no doubt, the experience of hundreds of persons; yet though the temperature fell in some cases nearly or quite 70° in thirty-six hours last week—namely, from over 120° in the sun to 32°, we are glad to think that nothing like the loss will be experienced that followed on the disastrous loss of last year, and "check" changes to "promise" once again—a promise of flowers in infinite variety and countless numbers.

We are on the eve of a great show. Huge marquees are erected within five minutes walk from Fleet Street. It is something to have a fine space of some 4 or 5 acres practically in the heart of the City, approached by the "finest promenade in Europe," parallel with the ancient and broad-breasted Thames. It is fortunate, too, that the Benchers of the Inner Temple Gardens permit their use by the Royal Horticultural Society once a year, in order that all which is newest and best in flowers and other garden produce may be displayed for the enjoyment of the thousands who will assemble to enjoy the feast. Fortunate also is it that a Royal lady has consented to open the exhibition—one who never fails to attract by her presence, and who wins more and more homage and affection as the years roll round—the Princess of Wales. Only a softening of the wind and clear skies, are needed to make the show now in preparation a brilliant success.

## THE TEMPLE SHOW.

MAY 21ST, 22ND, AND 23RD.

ON Tuesday the wind softened, but the sky was not clear, nor was the popular Princess able to attend (unfortunately through indisposition), crowds of persons who assembled on the embankment being accordingly disappointed; but there could be no disappointment with the show, which from a floral point of view, is the richest and most extensive in the British Isles. It was thought that the weather, which of late has been so unfavourable, would have marred to a certain extent the beauty and completeness of the exhibition, but happily such was not the case. Readers well know the extent to which the exhibition has grown during the time that it has been in progress, and this year it was perhaps more beautiful than ever. We noticed an innovation, emanating from a suggestion of Mr. Newton (the able gardener at the Inner Temple) in the form of covering the long walk at the bottom of the gardens, and running parallel with the river. This idea was an excellent one in every way, and especially in the saving of the cherished lawn and the expense of several tons of boards for flooring.

It may be of interest to know how so much space was taken up, so we give the dimensions of the five principal marquees. The largest was 150 feet long by 60 feet broad; the next 120 feet by 40; No. 3, 170 by 28; No. 4, 150 by 28; and No. 5, 110 by 28, the figures being in each case approximate, and rather under than over the average. Despite this enormous provision it was found necessary to curtail the space allotted to almost every exhibitor, a proceeding that has nothing to commend it, and which should if possible be obviated on future occasions by a pre-arrangement of space. Unfortunately an exhibitor of some forty years' standing felt himself shut out by a misinterpretation of the conditions affecting duplicates, which it seems did not apply to varieties of plants but only to flowers in a cut state. This was a pity, because Mr. John Laing always exhibits well, and is said never to have been better prepared than on the present occasion.

Though essentially a flower show, fruits and vegetables were represented in fair numbers and high quality, but the other compartments comprising Orchids, greenhouse and stove plants, and hardy flowers took up by far the greatest amount of space.

As is usual on this occasion Orchids formed a most superb feature, being shown in little short of perfect condition: Arranged in the same tent as the Orchids were the Roses, than which nothing makes a brighter display, while passing on into other marquees we found glowing Begonias, charming foliage plants, elegant Ferns, softly hued Gloxinias, and in endless variety hardy plants and flowers, from modest alpine to the imposing Pæonies. Before turning to the general report, it may be worth while to point out that the exhibits were noted practically as staged, and not in order of merit, as the show was not competitive.

### ORCHIDS.

As has been suggested, Orchids made an exceedingly beautiful display, being splendidly diversified; in fact, all the best now in flower were represented in one collection or another. Conspicuous on entering the large marquee was the superb arrangement of Messrs. F. Sander and Co., St. Albans, in which the blending of colours was tastefully carried out. It was impossible for us to name all the kinds staged, but a few of the best were *Cattleya nobilior*, Sander's variety; *C. Mossiæ* Prince of Wales, an exceedingly beautiful form; *C. Mossiæ*, *C. dolosa*; *Lælia purpurata* Princess of Wales, a variety worthy of its illustrious name; *Lælia purpurata*, in fine variety; *L. p. alba*; *Lælio-Cattleya Phœbe*, a charming bigeneric hybrid of beautiful colour; *Cypripedium Chamberlainianum*; *C. Lawrenceanum*, a grand example in a pan; *C. selligerum*; *Odontoglossum vexillarium* in great variety, and of which a spotted form named Princess of Wales was quite out of the common; *O. sceptrum*; *crispum*, in large numbers and of various forms, of which Florrie was amongst the best; *crispum xanthotes* (see woodcut, fig. 74), and Duchess of York. In addition to these were Phaius, Dendrobiums, Oncidiums, Masdevallias, Sobralias, and others of more particular botanical interest.

Mathew Wells, Esq., Broomfield, Sale, Manchester, staged a few Orchids of high quality, in which most noticeable was a plant of *Cattleya Mossiæ*, carrying handsome charmingly coloured flowers.

The group of Orchids shown by Mr. W. H. Young, gardener to Sir F. Wigan, Clare Lawn, East Sheen, was not extensive, but of great interest, and comprised some grand flowers. Very beautiful was a form of *Cattleya Mossiæ* named Lady Wigan, *C. Warneri*, *C. Schilleriana*, several *Mossiæ* and *Mendeli* varieties of merit, a big specimen of *Oncidium sphacelatum*, *Cypripedium Rothschildianum*, *C. Chamberlainianum*, *C. cymatodes*, *Odontoglossum polyxanthum* var. *grandiflora*, *O. vexillarium*, and *O. crispum* in variety. Charmingly staged was the exhibit of Mr. Davis, gardener to J. Gurney Fowler, Esq., Glebelands, South Woodford, and in which excellent culture was very conspicuous. Perhaps of the whole the *Cattleya Mossiæ* in variety were most noticeable, but the *Odontoglossum crispum* were equally good. Of the *Cypripediums* note was taken of *Lawrenceanum Hyeanium* (in splendid condition), *grande*, *Lawrenceanum*, *bellatulum*, *ciliolare*, *bellatulum excellens*, *volonteanum*, and *Chamberlainianum*. *Epidendrum Wallisi* was singularly beautiful, as also was *Phalænopsis amabilis*. Also highly creditable were *Lælia purpurata*, *Cattleya Mendeli*, *Masdevallias*, and others.

Messrs. B. S. Williams & Son, Upper Holloway, as might have been expected, showed in their very best form, and put up a group that attracted attention, as well for excellent arrangement as for high quality. An admirable centrepiece was formed with a plant of *Cymbidium Lowianum*, ranged on each side of which were large numbers of Orchids in variety. Special attention may be called to *Odontoglossums Alexandræ*, *Warneri*, *Lælia purpurata rupelliana*, *Cypripedium grande*, *Odontoglossum facetum*, *O. vexillarium* in variety, *O. polyxanthum*, *Dendrobium densiflorum*, *Vanda teres Andersoni*, *Cattleyas Mossiæ* in variety, *C. Mendeli* in variety, *Odontoglossum Alexandræ giganteum*, *Vanda suavis*, *Tricopilia crispa*, *Cypripedium Chamberlainianum*, *C. grande*, *Ada aurantiaca*, the colours of which formed a pleasing diversion, and numerous others of equal merit, but for which space cannot be found for individual mention.

From Baron Schiöler, The Dell, Egham, came an almost perfect exhibit—in fact, just such an one as was anticipated from this source. The arrangement was as good as the flowers, and the use of small Ferns aided much in the improvement of the display. The *Odontoglossums* were superb, especially of the *crispum* section, in which were noticed *Bonnyanum*, *apiatum*, *xanthotes* (fig. 74), *Wilckeanum*, and *giganteum*, while other *Odontoglossums* included *excellens*, *vexillarium Pescatorei*, *cuspidatum xanthodon*, *luteo-purpureum*, *polyxanthum*, and others. A plant of *Masdevallia nycteryna* carrying extraordinary numbers of flowers was conspicuous. The *Vanda teres* staged here were superb, as also were the *Cattleyas*, of which *Mossiæ* and *Mendeli* were very showy. A plant of *Skinneri* and another of *Skinneri alba* attracted attention, as also did the many *Cypripediums*, *Masdevallias*, *Vanda suavis*, *Epidendrum*, and *Lælia purpurata* in variety.

The arrangement of Mr. W. White, grower to Sir Trevor Lawrence, Burford Lodge, Dorking, was particularly noteworthy for high quality, in which respect nothing was lacking. Delicately beautiful was *Lælia majalis*, while *Cypripedium Stonei platyænum* was conspicuous for magnificent blooms and excellent culture. Shown with this were blooms of the type, the difference being very marked. Other plants were *Masdevallia Shuttryana*, *M. Veitchi*, *M. Harryana lateritia*, *Cypripedium Elliottianum*, *Cymbidium Lowianum viride*, *Cattleya citrina*, *Vanda Dennisoniana*, *Odontoglossum citrosimum*,

*Cattleya Mossiæ* Wager's var., *Odontoglossum vexillarium*, *Epidendrum Stamfordianum*, *Dendrobium Bensoniæ*, *Aërides Fieldingi*, *Lælia purpurata* in variety, and very many others.

*Odontoglossums* were the feature in the arrangement of Mr. D. Masterton, gardener to Welbore S. Ellis, Esq., Hazelbourne, Dorking, high quality being combined here with good numbers. *Crispums* and *Alexandræ* were extremely diversified, as also were the *vexillariums*. Others seen were *Coradenei*, *cordatum*, *Pescatorei*, and *citrosimum* (small). Added to these were *Cattleya Mossiæ*, *C. gigas*, *C. Mendeli*, *Cypripedium bellatulum*, *C. Chamberlainianum*, and a few other kinds.

Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, sent Orchids which, intermingled with Ferns and Palms, produced a very charming effect. Amongst these Orchids were *Cypripedium barbatum*, *Cattleya Mossiæ* in variety, *C. Skinneri*, *Cymbidium Lowianum*, *Lælia purpurata*, *Odontoglossum cordatum*, *O. Alexandræ*, and numerous others.

Mr. Jules Hye, Leysen, sent a plant of a superb *Cattleya Lawrenceana* named *atro-rubens*, which was deservedly accorded an award of merit. From the same source came *Miltonia Bleuiana virginalis*, first-class certificate; *Cypripedium Lawrenceanum Hyeanum superbum*, *Lælio-Cattleya Hippolyta*, and *Miltonia vexillaria gigantea*.

Mr. Ch. Vuylsteke, Belgium, was represented by a plant of *Odontoglossum Pescatorei* La Perfection, which received an award of merit, a few others also being shown by this exhibitor. Mr. J. Cliffe, gardener to H. Shaw, Esq., Ashton-under-Lyne, sent *Odontoglossum Shawianum*, *Cypripedium Victoria Maria*, and a fine plant of *Dendrobium Dalhousianum*. Mr. J. Prewett, Hammersmith, staged a hybrid *Cypripedium* that was, however, passed by the Committee, and Thos. Statter, Esq., Stand Hall, Manchester, exhibited an example of *Odontoglossum Johnsoni* carrying a magnificent spike.

Small but interesting was the exhibit of Mr. W. Buckwell, gardener to M. S. Cooke, Esq., Kingston Hill, S.W. It was composed of *Odontoglossums*, *Masdevallias*, *Cattleyas*, *Epidendrums*, and others, all in variety and good condition.

In the smaller Orchid tent Messrs. W. L. Lewis & Co., Southgate, were in strong force with a very handsome arrangement of superb Orchids. In this *Cattleyas* of the *Mossiæ* section were excellent and extremely varied, comprising many of the best forms in commerce. *C. Mendelis* were also seen, and in almost equal numbers, such again being the case with *Lælia purpurata*. *Odontoglossums* were very beautiful, and included *crispum*, *vexillarium*, and numerous others. *Cypripediums* in grand condition were particularly noticeable, as also were splendidly grown *Oncidium*s. For *Lælia purpurata Bella* this firm received an award of merit.

Mr. J. Cypher's arrangement was very imposing, and in every way highly creditable to this Cheltenham house. The plants plainly denoted splendid culture, and were carrying flowers of perfect colour, form, and substance. *Lælia purpurata* in variety somewhat preponderated, but *Cattleyas Mossiæ* and *Mendeli* were also superbly shown. *Odontoglossums*, *Dendrobium*s, *Cypripedium*s, *Masdevallias*, and *Ada aurantiaca* contributed much to the general effect.

One of the most showy of the exhibits in the Orchid section was arranged by Messrs. H. Low & Co., Clapton, and occupied a large amount of tabling. *Cattleya Mossiæ* were exceptionally fine and extremely varied, as also were those of the *Mendeli* type. Of the latter section was a variety named *grandis*, and for which an award of merit was accorded. A like honour was adjudged to an *Odontoglossum* from which the name had been removed. *Cypripediums* were also to be seen in good condition, besides which were *Odontoglossums*, *Dendrobium*s, and many other kinds.

Messrs. Charlesworth & Co., Orchid growers, Heaton, Bradford, contributed an extremely chaste and diversified collection, in which *Lælia purpurata* in variety were particularly bright. *Cypripedium Elliottianum*, *C. bellatulum*, *C. caudatum*, *Odontoglossums*, *Cattleyas*, and *Dendrobium*s were also very conspicuous.

#### ROSES.

A magnificent group of Roses in pots was exhibited by Messrs. Wm. Paul & Son, Waltham Cross, who also showed fine stands of cut blooms. The healthy condition and excellent flowers of the former gave ample evidence of high culture, as with no exception they were crowned with blooms. Amongst many splendid varieties were noted *Clare Jacquier*, *Madame C. Guinnoiseau*, *Caroline Testout*, *Danemark*, *White Lady*, *Corinna*, *Perle des Jardins*, *Clio*, *Madame de Watteville*, *Duchess of Albany*, *Duke of York*, *William Allan Richardson*, *Crimson Queen*, *Madame Montet*, *Crown Prince*, and several plants of the fine *Tea Rose Enchantress*. Amongst the cut blooms which added much to the beauty of the display were *Jeannie Dickson*, *Perle des Jardins*, *Spenser*,

*Niphetos*, *Duke of Teck*, *Dr. Andry*, *Grace Darling*, *Crimson Queen*, *Victor Verdier*, *Mrs. John Laing*, *Corinna*, *White Lady*, *Lady Henry Grosvenor*, *La France*, *Margaret Dickson*, *Marie Van Houtte*, and *L'Idéal*.

An excellent collection of Roses was exhibited by Mr. C. Turner, Slough, amongst which fine plants of the bright and well-known *Crimson Rambler* played a conspicuous part, the extreme beauty of this variety being shown in well-flowered examples of bushes and standards. It must not be thought, however, that this was the only one worthy of note, as all others were of an equally high order of merit, and consisted of well-flowered plants of *Margaret Dickson*, *La France*, *Juno*, *Mrs. J. Laing*, *Maréchal Niel*, *Edward Morren*, *Céline Forestier*, *Ulrich Brunner*, *Edith Gifford*, *Madame Lacharme*, *William Allan Richardson*, *Camille Bernardin*, *Dr. Andre*, *Mrs. Paul*, *Madame Victor Verdier*, *Madame Lacharme*, together with several others of quality by no means inferior.

Messrs. Paul & Son, Cheshunt, were also represented with a fine group of plants, all well grown, and crowned with large and well-formed blooms in great variety. Chiefly conspicuous in the exhibit were *Maréchal Niel*, *Mrs. Paul*, *Catherine Soupert*, *Captain Hayward*, *Paul's Early Blush*, *Merveille de Lyon*, *William Warden*, *Turner's Crimson Rambler*, *Paul's Carmine Pillar*, *La France*, *Margaret Dickson*, *François Levet*,

FIG. 74.—ODONTOGLOSSUM CRISPUM XANTHOTES.

*Captain Hayward*, *Edouard Morren*, *Ulrich Brunner*, *Violette Bouyer*, *Elise Finger*, *Etoile de Lyon*, together with many others. The whole was staged in one corner of the large tent, and it is needless to add formed a very conspicuous object.

A somewhat smaller but equally superb group of Roses was exhibited by Messrs. Geo. Jackman & Son, Woking, Surrey. The plants were trained as dwarf specimens, and comprised amongst other varieties well grown plants of *Céline Forestier*, *Duchesse de Morny*, *Turner's Crimson Rambler*, *Madame Lacharme*, *Anna Alexieff*, *Comtesse de Serenye*, *John Hopper*, *Alfred Colomb*, *Magna Charta*, and *Merveille de Lyon*, many of which were carrying an exceedingly large number of fine blooms.

A pleasing spectacle at the entrance of one of the tents was a small but exceedingly pretty group of Roses in pots, exhibited by Mr. Frank Cant, Colchester. The flowers were good and in kinds varied, chief amongst them being *La France*, *Margaret Dickson*, *Caroline Testout*, *Ulrich Brunner*, *Jeannie Dickson*, *Marchioness of Londonderry*, *Dr. Andry*, *Duke of Teck*, *Mrs. Paul*, *John Bright*, *Duke of Edinburgh*, *Merveille de Lyon*, *Mrs. John Laing*, *Star of Waltham*, *Madame George Paul*, *Duke of Connaught*, *Fisher Holmes*, *Duchesse de Morny*, and *Captain Christy*.

Mr. W. Rumsey, Waltham Cross, exhibited a fine collection of Roses, both in pots and as cut blooms. Amongst the former were well flowered plants of *The Queen*, *Miss Hassard*, *Magna Charta*, *Crimson Rambler* and *Niphetos*, and of the latter *Maréchal Niel* and *Niphetos* were exceedingly fine.

Mr. George Mount, Canterbury, staged a superb collection of cut Roses, comprised of varieties *Baroness Rothschild*, *Catherine Mermet*, *Mrs. John Laing*, *The Bride*, *La France*, *Lady Mary Fitzwilliam*, and others, all of which were very creditable.

## PLANTS AND FLOWERS.

At the entrance of the large tent was a fine display of flowering and foliage plants, exhibited by Messrs. W. Cutbush & Sons, Highgate. Several large Palms formed a background to the group, which was made up of large plants of *Azalea mollis*, *Hydrangea Thomas Hogg*, *Leschenaultia biloba major*, together with healthy plants of *Souvenir de la Malmaison* Carnation, crowned with magnificent blooms. No less fine were a number of plants of the border Carnation Countess, with its graceful habit and large pure white flowers, whilst the ever popular *Uriah Pike* was very conspicuous in the exhibit.

For taste and gracefulness in arrangement and general excellent quality of the plants a high word of praise is due to Messrs. Wills and Segar, South Kensington, for the artistic group of foliage plants exhibited by this firm. The orthodox sameness which generally characterises such displays was done away with, and the whole arranged so as to make a pleasing effect. Amongst others, were noticed the following plants:—*Anthurium crystallinum*, *Kentia Belmoreana variegata*, *Dracaena Bergmanni*, *D. Lindenii*, *D. Goldieana*, *Zingiber variegata*, *Alocasia intermedia* and *Phrynium Thibautianum variegatum*, *Asparagus tenuissimus* and *plumosus nanus*, together with *Seaforthia elegans*, *Phoenix rupicola*, *Cocos Weddelliana*, *Leucostegia immersa*, and *Thrinax elegans*. Messrs. J. Waterer & Sons, Bagshot, were in evidence with *Rhododendrons*, the plants being in pots and forming a bright and effective display with their large flowers of many colours. Amongst others were noticed *Princess of Wales*, *John Waterer*, *album elegans*, *Mrs. John Clutton*, *Duchess of Edinburgh*, *Minnie*, *Lady Howe*, *Mrs. Tritton*, *Charlie Waterer*, *Duchess of Bedford*, *Chionoides*, *Sir Henry Mildmay*, *Francis B. Hayes*, *Kate Waterer*, *H. W. Sargent*, and *Marchioness of Lansdowne*. The same firm also exhibited a fine group of *Acers* in pots, their bright and varied forms of foliage being very pleasing. Conspicuous in the group were *Acer palmatum roseum marginatum*, *A. palmatum dissectum ornatum*, and *A. palmatum tricolor*.

A bright and diffusive display of trained *Azaleas* came from Mr. Charles Turner, Slough, the plants in their somewhat stiffly trained forms being covered with bloom, and composed of such varieties as *Princess S. Clotilde*, *Lively*, *Duchesse A. de Nassau*, *Madeline*, *Grandis*, *Charmer*, and *Madame Van Houtte*. Messrs. John Peed & Sons, Norwood Road, London, exhibited a magnificent group of *Caladiums*, the plants being exceedingly fine and varied in colour. The whole were tastefully arranged with a groundwork of *Maidenhair Fern*, and amongst other varieties were noticed splendid specimens of *Princess of Teck*, *Ibis Rose*, *Lillie Burke*, *Rose Laing*, *La Lorraine*, *Raymond Lemoinier*, *Comtesse de Brosse*, *B. S. Williams*, *Madame Alfred Magre*, *Gaston Chandon*, *Excellent*, *Princess Royal*, *Clio*, *candidum*, *Marie Freeman*, *Charlemagne*, *John Peed*, and *John Laing*.

Large trained plants of *Clematises* were exhibited by Messrs. Richard Smith & Co., Worcester, the size of blooms and healthy appearance of which gave ample evidence that the examples were rapidly nearing perfection. Amongst the varieties *Madame Van Houtte* was very effective, with its large white flowers; *Lucy Lemoine*, a pretty double of the same colour, and no less merit; while *Belle of Woking*, *Excelsior*, *Venus Victrix*, *Fairy Queen*, *Beauty of Worcester*, *Lord Derby*, *Sensation*, and *Princess of Wales* were also worthy of honourable mention. One corner of the large tent was filled with a fine group of foliage and flowering plants, exhibited by Mr. W. Iceton, Putney. The Palms and *Dracaenas* were large, and presented a healthy appearance, whilst amongst the blooming section were noticed *Lilium Harrisii*, *Tuberoses* in fine form, together with *Ericas* and *Saxifragas*, tastefully bordered with the variegated foliage of diminutive *Caladiums*.

A magnificent group of *Malmaison Carnations* was shown by Mr. Jennings, gardener to L. de Rothschild, Esq., Ascott, many of the flowers being of enormous size, whilst the foliage was vigorous and gave every indication of perfection in health. This exhibit of its kind was one of the features of the show.

An attractive group of *Cannas* was exhibited by Messrs. Paul and Sons, Cheshunt, amongst other bright flowers being noticed *Phalenos*, *Cheshunt Yellow*, *Cousin Jacob*, *President Chandre*, *Comet*, and *Antoine Barton*.

*Caladiums* in splendid form and variety were exhibited by Messrs. J. Veitch & Sons, Chelsea, the plants being remarkably fine and displaying several different shades of colour. Amongst many others, all of which were striking, were noticed *Raymond Lemoinier*, *Excellent*, *Ibis Rose*, *Madame Alfred Magre*, *Ladas*, *F. W. Moore*, *Madame Leon Say*, *Duke of York*, *Henry Irving*, *Tennyson*, *Lord Derby*, *Chelsea Gem*, *Lord Rosebery*, and *Duchess of York*. Of no less order of excellence in their particular section was a fine group of hardy flowering plants exhibited by the same firm, and composed chiefly of *Azalea rosæflora*, *Azalea mollis* *Anthony Koster*, *Hydrangea paniculata grandiflora*, *Lilium Harrisii*, *Clethra alnifolia*, *Pæonias* *Moutan* and *Elizabeth*, *Genista tinctoria*, *Azalea rustica virgile*, *Cytisus scoparius grandiflorus* and *C. purpureum*, *Olearia Gunni*, and *Spiræa astilboides*, together with *Acers* in variety and other foliage plants.

A striking feature in the show was the group of plants exhibited by Messrs. W. Balchin & Sons, Brighton, amongst which a large number of plants of *Leschenaultia biloba major* stood out in pleasing conspicuousness, the clear blue flowers of which were exceedingly effective. Other plants in the exhibit were *Erica perspicua nana*, *E. coccinea minor*, together with well-flowered plants of *Boronia serrulata* and *heterophylla*, and the pretty variegated *Coprosma Baueriana variegata*.

Messrs. W. Fromow & Sons, Chiswick, exhibited an effective group

of *Acers* in pots interspersed with plants of *Lilium Harrisii*. Amongst the former were good plants of *A. palmatum roseum marginatum*, *A. palmatum dissectum ornatum*, *A. japonicum laciniatum*, *A. palmatum variegatum*, and many others of these pretty ornamental plants.

Worthy of high praise was the group of *Pelargoniums* exhibited by Mr. Chas. Turner, the plants being of extraordinary size, and thickly covered with flowers. Very bright, and of great variety in colour, were the following varieties—*Prince Leopold*, *Lady Carrington*, *East Lynn*, *Spotted Beauty*, *Joe*, *Ambassador*, *Blue Beard*, *Iona*, *Gold Mine*, *Statesman*, *Edward Perkins*, *Princess of Teck*, *The Shah*, *Duke of Norfolk*, *delicatum*, *Duchess of York*, and *Maggie*.

Another magnificent display of *Pelargoniums* was that of Mr. H. J. Jones, Lewisham, his plants giving abundant evidence that they had been thoroughly well grown, as in addition to these being large the flowers were of excellent substance, also bright and varied in colour. Amongst others the following kinds were particularly effective:—*Princess May*, *Mrs. W. Wright*, *Dark Chinese*, *Edward Perkins*, *James Douglas*, *Pearl*, *Lady Isabel*, *Duke of Portland*, *Mrs. H. M. Stanley*, *Maggie*, *Rose Queen*, *Rosebud*, *May Queen*, *Mrs. H. J. Jones*, and *Eucharis*. *Begonias* were also well and pleasingly shown by the same firm, the plants with their bright and distinct flowers being artistically interspersed with *Ferns* and small *Palms*. Conspicuous amongst many other varieties were excellent blooms of *Redcap*, *Magnet*, *Golden Queen*, *Mrs. R. Hoffman*, *Florence Pearce*, *Mrs. E. Beckett*, *nigra*, *Jealousy*, *Exquisite*, *delicatum*, *Starlight*, and *Dr. Shaw*. *Ivy-leaved Pelargoniums* were shown in excellent form by the same firm, the plants of many different varieties being thickly clothed with bloom. Amongst many others were noticed *Distinction*, *La France*, *Ryecroft Surprise*, *Isadore Feral*, *Surcouf*, *Liberty*, *Cuvier*, *Jersey Beauty*, *Beauty of Castle Hill*, *La France*, *H. Cannell*, and *Percy Surman*.

Mr. T. S. Ware, Tottenham, staged an exquisite group of double and single *Begonias*. The display formed by them was particularly striking, and formed a diffusion of colouring that was almost bewildering. It would be difficult to describe the many beautiful specimens staged; amongst a host of others were noticed *Duchess of Teck*, *Golden Empress*, *Moravia*, *Miss Jennie Fell*, *Beauty of Belgrove*, *Victory*, *Snowdon*, *Bexley White*, *Fairy*, *Bexley Gem*, *Leviathan*, *Viscountess Cranbrook*, *Claribel*, *Maid of Kent*, *Miss Emily Childs*, *Dean Swift*, *Empress of India*, *Duke of Teck*, *Pride of Bexley*, *Lord Byron*, *Samuel Pope*, *Princess of Wales*, *Sir Thomas Acland*, *Beauty*, *marginata*, *Zanda*, *alba magna*, *white Camellia Challenger*, and *Picotee*.

An excellent group of *Caladiums* was staged by Mr. Hunt, gardener to P. Ralli, Esq., Ashted Park, Epsom. The plants were exceedingly well grown, the foliage being large and effective, while in distinctness of variety they were all that could be desired.

A magnificent group of *Calceolarias* was staged by Messrs. J. James and Son, Farnham Royal, Slough. The plants displayed a high condition of cultivation, the colours being exceedingly delicate and diversified. Messrs. Collins Bros., Waterloo Road, sent plants of *Carnation Jane Collins*, a good yellow variety, but unfortunately destitute of scent. A fine group of *Pelargonium Glory* of the West was staged by Mr. W. J. Godfrey, Exmouth—an excellent decorative variety, and its good qualities were well displayed in the group.

*Tricolor Pelargonium Duchess of York*, which received an award of merit, was sent by Mr. J. Prewett, Hammersmith. Mr. Empson, gardener to Mrs. Wingfield, Amptill, sent plants of *Dracaenas ducetti* and *australis variegata*.

Messrs. F. Sander & Co. staged a large collection of rare plants, many of which were particularly fine. Amongst others were noticed the *Rex hybrid Begonia Sander's Masterpiece* (award of merit), and *B. Rajah*, *Dracaena Sanderiana*, *Begonia Lady Annesley* (award of merit), *Heliconia illustris rubricaulis*, *Nepenthes* in variety, and also *Anthurium Andreanum* in variety, together with *Dracaena Godseffiana* (first-class certificate), *Sonerilas ornata* and *Mr. H. Walters*, and *Arisæmas* in variety.

A charming display of hardy alpine flowers was exhibited by Messrs. Paul & Son, Cheshunt; the flowers were tastefully arranged on a diminutive rockwork made especially for them, and which showed them up to advantage. Amongst others were noticed *Aubrietias* in variety, *Phlox frondosa*, *Androsace sarmentosa*, *Phlox stellaria*, and *P. G. F. Wilson*, *Silene pusilla*, *Geum miniatum*, *Potentilla rupestris*, and *Saxifraga muscoides purpurea*.

Messrs. G. Jackman & Son, Woking Nursery, sent half a dozen splendidly grown plants of new *Clematises*, including *Countess of Onslow*, *Sir Trevor Lawrence*, *Duchess of York*, *Grace Darling*, *Duchess of Albany*, and *Crimson Beauty*.

Messrs. H. Cannell & Sons, Swanley, sent a remarkably interesting exhibit, comprising splendid *Gloxinias* in named varieties, and amongst which *Princess of Wales* was prominent, receiving an award of merit. These were charmingly interspersed with *Ferns*. *Cannas* were also shown by the same firm, but the effect was somewhat marred by the stiff arrangement. *Begonias* from Swanley also made a brilliant display, and amongst the best of which were *Lady Carter*, *Mary Cornhill*, *Miss Fisher*, *W. Marshall*, *Mrs. C. West*, *Mrs. Jenkins*, *Lord Rosebery*, *Lady Whitehead*, and *Miss E. Clarke*.

Messrs. James Veitch & Sons staged a superb collection of *Streptocarpus* or *Cape Primroses*. The plants were well covered with bloom, and displayed many very brilliant colours. *Gloxinias* were well shown by the same firm, very distinct and of excellent substance, composed chiefly of varieties *Duchess of Connaught*, *Sidonie*, *Brilliant*, *Radiance*,

Irma, Mars, Cicely, and Clarinda. In the same exhibit flowers of hybrid Phyllocactus claimed attention, as also did a group of cut hardy flowers, amongst which were Pyrethrums Dorotheus and Princess of Wales, Irises germanica, tolmiana, and florentina. Darwin Tulips in great variety were included, together with many charming Dodecatheons—namely, *D. maximus*, *D. Media*, Premier Gladstone, and others. Ferns also claimed attention, the firm staging well grown plants of *Lastrea atrata variegata*, *Adiantum Lambertianum* and *A. Weigandi*, *Osmunda japonica corymbifera*, *Davallia fijiensis*, *Pteris reginæ*, *Adiantum macrophyllum albo-striatum*, and *Davallia elegans polydactyla*, together with many others, all of which presented a healthy appearance.

Mr. Whillans, gardener to Duke of Marlborough, sent plants of a new seedling perpetual flowering Carnation Blenheim Beauty; the flowers are of enormous size, and prettily marked, but unfortunately devoid of the scent which makes these flowers so popular. Mr. T. S. Ware staged a very varied collection of hardy flowers, comprising *Spiræa plumosus*, *S. japonica*, *Phlox canadensis* (fig. 80, page 457), *Lilium longiflorum*, *Pæonies*, *Thermopsis montana*, *Trollius asiaticus*, *Iris florentinus*, *Heuchera sanguinea*, *Iberis Garexiana*, *Aquilegias*, *Saxifragas*, and many others. From Messrs. W. Cutbush & Son, Highgate, came flowers in variety. These were arranged on a long table, and the effect was admirable. Most prominent in this exhibit were superb flowers of Malmaison Carnations, rich both in colour and scent; *Spiræas*, seedling Carnations, *Lychnis dioica rubra plena*, *Dielytra spectabilis*, *Pæonies*, *Ranunculuses*, *Saxifragas*, *Choisya ternata*, *Heuchera sanguinea*, *Trollius*, *Lupines*, and some charming hardy *Primulas*.

Mr. J. R. Box, Croydon, also showed hardy flowers in great variety, and of high quality. These were well arranged, and each kind showed up to advantage. Conspicuous in this exhibit was *Houstonia cœrulea*, *Menyanthes trifoliata*, *Saxifraga granulata flore-pleno*, Iceland Poppies, *Aquilegias*, *Doronicums*, *Ranunculus acris fl.-pl.*, *Arisæma protoscedum*, *Heuchera sanguinea*, *Pyrethrums*, *Androsace sarmatosa*, *Irises*, *Cornus canadensis*, and Carnations Uriah Pike, Blush Malmaison, Mrs. Leopold de Rothschild, Germania, and Gloire de Nancy. Hardy flowers from Mr. B. Ladhams, Sairley, Southampton, were very charming and greatly diversified. *Aquilegias*, *Trollius*, *Centaureas*, *Aponogeton distachyon*, *Pyrethrums*, *Achilleas*, *Primula japonica fl.-pl.*, *Pæonies*, *Lilacs*, *Geums*, *Heuchera sanguinea*, *Irises*, *Anthericum*, *Thermopsis fabaca*, *Doronicums*, and Pink Ernest Ladhams.

*Pæonies* were sent by Messrs. Kelway & Son, Langport, in first-class condition, and comprised both single and double varieties. From the same firm also came single *Pyrethrums* and glowing *Cannas*, with softly tinted *Irises* for variety. *Aquilegia cœrulea* from Langport was also good, and the same may be said of the *Lupines* and other flowers from the same source. Carnation Uriah Pike in good condition was exhibited by Mr. James Pike, Park Road Nurseries, Acton, and which attracted much attention.

A most artistic display of hardy alpine flowers was exhibited by Messrs. J. Backhouse & Son, York. The diminutive blooms looked perfectly natural peeping out from the crevices of sandstone, in which they had been distributed with great taste. Amongst a host of these charming plants were *Alyssum alpestre*, *Gentiana verna*, *Dianthus calizonus*, *Linum alpinum*, *Saxifraga valdensis*, *Veronica prostrata*, *Globularia nana alba*, *Phlox subulata compacta*, *Primula auricula marginata*, *Silene acaulis*, and *Genista pilosa*. Cactuses in flower were also exhibited by the same firm, as was a large case of Ferns containing many exquisite varieties, including *Trichomanes exsectum*, *Hymenophyllum cruentum*, *H. obtusatum*, *H. crispatum*, *H. flexuosum*, and *H. candiculatum*. Especially worthy of mention were pans of the elegant little *Sibthorpia europæa aurea* (award of merit), with its pretty drooping habit. Orchids and *Azaleas* also came from this firm.

*Viola* blooms were exhibited in great variety and pleasing form by Messrs. Dobbie & Co., Rothesay, and considering the flowers had travelled from Scotland they were very fresh. Amongst numbers of others Miss Gibbon, a recent addition, is worthy of mention, being of a very delicate shade. In the older varieties were noticed Little Langtry, Duchess of Fife, Countess of Hopetown, Peter Barr, Ravenswood, Cherry Park, Laverock, Columbine, Gipsy Queen. Amongst the fancy Pansies were Ceres, Madge, George Anderson, Neil McKay, Wm. Ross, and Pilrig, together with several others of almost equal merit.

Messrs. Paul & Son, Cheshunt, staged an effective collection of hardy flowers, which were very striking, amongst others being *Doronicum plantagineum excelsum*, *Pyrethrum Ceres* and *Ne Plus Ultra*, *Centaurea montana sulphurea*, *Ranunculus acris plena*, *Thalictrum aquilegifolium roseum*, *Centaurea montana* and *C. montana alba*, *Geum miniatum*, *Spiræa confusa*, *Pyrethrum Perfection* and others. Very effective in the group were Lilac flowers in variety, double and single. Amongst the former Madame Lemoine is a fine double white, and of the latter Souvenir de Louis Spathe is a splendid variety.

Mr. M. Prichard, Christchurch, Hants, sent hardy flowers in variety, including good examples of double and single *Pyrethrums*, *Aquilegias*, *Phlox amœna*, *Polemoniums*, *Irises*, *Lupins*, *Scillas*, *Narcissi*, *Trollius*, *Geums*, *Pæonies*, *Eurybias*, *Ranunculuses*, *Euphorbias*, *Hemerocallis*, *Euonymus*, *Thermopsis montana*, and others.

Very beautiful indeed were the *Primula Sieboldi Pluto*, *P. S. Prella*, and others staged by Messrs. Barr & Son, King Street, Covent Garden. *Irises*, light and dark, large and small, also came from this source, and the single *Pæonies* in the exhibit were amongst the most gorgeous in the show. *Thalictrums*, *Liliums*, *Lychnis*, *Iberis*, *Pyrethrums*, *Geums*, *Gladioli*, *Scillas*, *Sweet Peas*, *Violas*, brightly coloured and quaintly formed Parrot Tulips, chaste Darwins, and singularly beautiful florists'

or-English Tulips also lent valuable aid in forming variety in this exhibit.

Messrs. J. Carter & Co., High Holborn, staged a very choice selection of hardy flowers, in which *Doronicums*, *Liliums*, Parrot Tulips, *Irises*, *Saxifragas*, *Anemones*, *Violas*, *Gladioli*, *Narcissi*, *Lupines*, hardy *Primulas*, *Pæonies*, *Geums*, and numerous others were very noticeable.

On each side of the entrance to one of the marquees were large groups of well-grown plants of Carnation Uriah Pike, exhibited by Mr. G. May, Upper Elmington, the tall spikes of which, crowned as they were with large flowers, looked particularly striking. A large and effective group of mixed plants was staged by Mr. H. B. May, Upper Elmington, the plants all being in healthy condition, and composed of *Coleus Decorator*, *Crotons Comtesse superba*, Baron Frank Sellière, Nestor, Formosa, and Mayi; *Coleus Crimson Gem*, and *C. Surprise*, together with *Pandanus Veitchi*, *G. oxiniæ* splendidly bloomed, and many other plants.

Messrs. Hugh Low & Co., Clapton, staged an effective group of plants, in which *Caladiums* predominated; amongst other varieties were *Charlemagne*, *Xeres*, *Queen of the Isles*, John Peed, and Mrs. Laing. It would be difficult to speak too highly of the above firm's magnificent collection of *Cannas*, which in form and flower were near perfection. Amongst many others were Charles Moore, Charles Henderson, L. E. Bailey, Florence Vaughan, and Alphonse Bouvier. In the same group were also included plants of the new perpetual flowering Mignonette Bush Hill White, together with Ivy-leaved *Pelargonium The Bush*. Large trusses of *Rhododendron* blooms were sent by Mr. Comber, gardener to J. H. Johnson, Esq., M.P., Bignor Park, Pulborough. A large group of magnificent *Caladiums* was staged by Mr. W. Leeton, comprising several fine varieties. Several diminutive Orange plants in flower, and bearing fruit were included in the exhibit.

Messrs. Sutton & Sons, Reading, staged a group of Giant *Mimulus*, plants of bedding *Begonias*, and a magnificent collection of *Calcearias*, which for size of flowers and delicacy of colour it would be difficult to excel, whilst the general substance of the plants proved that their culture had been of the best. Amongst other varieties the bright yellow Cloth of Gold was particularly striking; it is an excellent kind and well worthy of cultivation. A collection of well grown Palms was also sent by the same firm, together with *Azalea mollis*; as also were hardy flowers, comprised of Sutton's Giant *Anemone*, Sutton's Giant *Ranunculus*, Parrot Tulips, *Narcissi*, double white *Jonquils*, and many others. *Gloxinias* were also well represented with well flowered plants of Sutton's Prize. A pleasing spectacle was formed by a huge clump of Lily of the Valley flowers—Sutton's Giant. Included in the collection were well flowered plants of *Saintpaulia ionantha*.

Mr. D. Campbell, The Priory, Reading, sent plants of *Clerodendron A Priori*, which appears to be very profuse in flowering. A pot of *Adiantum Karlakei* was exhibited by J. B. Karlake, Esq., Reading. Messrs. John Bolam, Alnwick, sent double *Polyanthus* flowers, and Mr. J. T. Robertson, Ramsgate, sent blooms of a seedling *Pelargonium*. Messrs. R. Wallace & Co., Colchester, staged a collection of *Irises* and *Camassia Casicki*. Amongst the former were *Florentine*, *Princess of Wales*, *Germanica major*, and *Germanica violacea*. A large and varied display of hardy flowers came from Messrs. J. Cheal & Sons, Crawley, consisting of *Rhododendrons* in variety, *Syringa Charles X.*, *Doronicums*, and others. *Violas* were well represented with flowers of Oriel, Lord Beaconsfield, Profusion, Duchess of Sutherland, Duchess of Fife, Countess of Hopetoun, Quaker, Royalty, Joy, Goldfinch, and others.

Messrs. Wm. Paul & Son, Waltham Cross, sent fine trusses of Lilac flowers, amongst others being Marie Lequay, Souvenir de Louis Spathe, together with *Rhododendrons* and other hardy flowers. A fine display of hardy flowers came from Messrs. Geo. Jackman & Son, Woking, conspicuous in the collection being blooms of *Pæony Mountan*, *Phlox amœna*, *Pyrethrum Mont Blanc*, *Centaurea montana rosea*, *C. m. alba*, *C. m. rubra*, *Heuchera sanguinea*, together with flowers of *Cypripedium calceolus*, *Phlox canadensis* (fig. 80), and others, all of which were very fine.

A large and exceedingly varied group of Ferns was staged by Messrs. W. & J. Birkenhead, Manchester, all of which bore signs of being well grown. Very attractive in the collection were *Gleichenia rupestris*, *Davallia aculeata*, *Adiantum Waltoni*, *Davallia tenuifolia Veitchiana*, *D. fijiensis elegans*, *Adiantum speciosum*, *A. tinctum*, *Osmunda cinnamomea*, and others. Mr. Perkins, gardener to the Hon. W. F. D. Smith, M.P., Henley-on-Thames, sent an excellent group of *Amaryllis* interspersed with Palms and *Dracenas*; the plants were well grown and diffuse in variety. Mr. Downes, gardener to J. T. Bennett-Poë, Esq., Holmewood, Cheshunt, staged an excellent group of splendidly flowered plants of *Streptosolon*, which were very effective. Mr. Downes also sent a number of plants of double *Polyanthus Cloth of Gold*.

An attractive collection of *Violas* was exhibited by Mr. Septimus Pye, Garsang, Lancashire, and included many charming varieties. Amongst those of late introduction were Butterfly, Florizel, Border Witch, Dorothy Stokes, Annie Wood, Duchess, Cecilia, Robin, and Constance Smith; and of the older kinds Princess Beatrice, Queen of the May, Star, Purple Empress, and several others were very conspicuous.

Messrs. B. S. Williams & Son, Holloway, staged a small but effective group of *Amaryllises*, containing many of the best varieties. The same firm also exhibited a charming floral display, which comprised bouquets, baskets of flowers and sprays, in the make-up of which many delicate Orchids and other flowers had been used to advantage. Mr. W. Joy, Hill Lane, Southampton, sent a number of plants of double tricolored *Pelargonium Ada Joy*. Several well-bloomed plants of *Spiræa Van Houttei confusa* came from the nurseries of Messrs. George Bunyard and Co., Maidstone.

Mr. Prewett, Hammersmith, exhibited rustic designs for table decoration which were exceedingly light and attractive. An effective floral arrangement was exhibited by Mr. L. A. Calcutt, Stoke Newington, in which elegance in display had evidently been the object in view, and in this respect left little to be desired. Messrs. Phelps & Co., Cardiff, staged magnificent shower bouquets, in which Roses, Odontoglossums, and *Pancreatiums* were predominant.

The floral designs of Mr. J. R. Chard, Stoke Newington, were in every respect worthy of merit, the flowers and colours being pleasingly discriminated. Messrs. Perkins & Sons, Coventry, staged shower bouquets, sprays, and floral designs such as might have been expected from this well-known firm. They were all beautiful, but one representing a harp and another an anchor, were worthy of an especial word of praise. From the Horticultural College, Swanley, came tastefully made bouquets and small but effective table decoration. Mrs. Hodgkins, Didsbury, Manchester, exhibited an attractive display of botanical anatomy in which the tissues of many skeletonised leaves were shown in perfection.

Noticable in one of the beds in the lawn were a number of admirably furnished specimens of the Umbrella Pine of Japan, *Sciadopitys verticillata*. They had been planted a day or two previously by Messrs. Veitch & Sons from their Coombe Road nursery. It is rare to find this distinct Conifer in such deep green colour. They were grown with *Rhododendrons* in soil which contains naturally a good deal of peat or vegetable matter. This, then, is what the Umbrella Pine needs to make it flourish. The specimens alluded to had no protection whatever during the arctic frost of February, and they sustained not the slightest injury.

#### CERTIFICATES AND AWARDS OF MERIT.

*Begonia White Camellia* (T. S. Ware).—This is an admirably named double variety (award of merit).

*Begonia Lady Annesley* (F. Sander & Co.).—This is a silvery-leaved form, with dark veins and a dark green blotch at the base (award of merit).

*Begonia Rex Sander's Masterpiece* (F. Sander & Co.).—The leaves of this *Begonia* are somewhat small in size and of a dull crimson shade, with dark green blotches at the edges (award of merit).

*Begonia Samuel Pope* (T. S. Ware).—This is a charming *Begonia* with cream coloured blooms, each petal being edged with rose (award of merit).

*Caladium Rose Laing* (J. Peed & Sons).—This is a large-leaved variety of greenish-white colour with rose marking towards the centre (award of merit).

*Caladium Henry Irving* (J. Veitch & Sons).—This is a dwarf-growing variety with medium-sized leaves. The centre colour is silvery grey with broad bright green edge and rose veins (award of merit).

*Caladium Lord Derby* (J. Veitch & Sons).—The leaves of this *Caladium* are of rosy red shade with broad green veins and edges (award of merit).

*Cattleya Mendeli dellensis* (H. Ballantine).—The sepals and petals of this handsome form are delicate rose pink in colour, while the beautiful lip is deep purplish rose with a yellow throat, in which are crimson veins (first-class certificate).

*Cattleya Lawrenceana atro-rubens* (Jules Hye).—The petals of this *Cattleya* are rich deep rose, the sepals being much paler in colour. The lip is very beautiful in form, and of a deep velvety crimson purple shade (award of merit).

*Cattleya Mossiæ Prince of Wales* (F. Sander & Co.).—The sepals and petals of this *Mossiæ* are of good substance, and deep rose colour. The lip is deep rosy purple with a paler edge and white mottling. The lip is yellow and crimson (award of merit).

*Cattleya Mossiæ Lady Wigan* (Sir F. Wigan).—This is a very distinct variety, with almost pure white petals and sepals. The lip is white mottled and flushed pink, with yellow blotches in the throat (award of merit).

*Cattleya Mendeli grandis* (Hugh Low & Co.).—The broad petals of this flower are very faint blush in shade, the narrow sepals being of a somewhat deeper hue. The lip is fine with a rosy purple central blotch, and white margins with a yellow throat (award of merit).

*Clematis Duchess of York* (G. Jackman & Son).—The tubular flowers of this variety are of fine shape and delicate pink colour (award of merit).

*Cypripedium Stonei platytanium* (W. H. White).—This superb variety is a great improvement on the type. The dorsal sepal is white with purplish black lines. The petals are dull yellowish white, heavily blotched very deep purple towards the tips. The lip is of peculiar form and rosy colour (first-class certificate).

*Dracæna Godseffiana* (F. Sander & Co.).—This is apparently a variety of the old *D. surculosa*, and has bright green leaves with white spots (first-class certificate).

*Gloxinia Prince of Wales* (H. Cannell & Sons).—The handsomely formed flowers of this *Gloxinia* are velvety crimson in colour (award of merit).

*Incarvillea Delavayi* (W. Bain).—This is a Chinese plant of recent introduction, having beautiful rose-coloured flowers very much resembling a *Gloxinia* in shape. It is an herbaceous perennial, and said to be perfectly hardy in our gardens, and if such proves to be the case will certainly become popular. *I. Delavayi* is depicted in the woodcut, fig 75 (first-class certificate).

*Lælia purpurata Bella* (W. L. Lewis & Co.).—This is a grand purpurata with white sepa's, petals, and lip, the latter towards the throat

having crimson purple blotches, with veins of the same shade (award of merit).

*Masdevallia Shuttryana*.—This is a hybrid of dwarf habit with reddish salmon flowers, having yellow tails. The bloom is of a medium size (award of merit.)

*Masdevallia Harryana miniata* (W. H. White).—This is a very rich bright scarlet form of the type, with perfectly formed flowers (award of merit.)

*Miltonia Bleuiana virginialis* (Jules Hye).—This is chastely beautiful, with pure white sepals, petals, and lip. The base of the petals has a charming flush of rose (first-class certificate).

*Odontoglossum Fescatorei La Perfection* (Ch. Vuylststeke).—The flowers of this variety are of almost perfect shape. The ground colour is white, slightly flushed rose, and with deep rosy purple spots (award of merit).

*Pæony Lord Iveagh* (Kelway & Son).—This is of the tree section, and has superb flowers of a rich rosy red colour (award of merit).

*Pelargonium Duchess of York* (J. Prewett).—This, a very brightly coloured tricolor *Pelargonium* of dwarf habit (award of merit).

*Phyllocactus Excellent* (J. Veitch & Sons).—This is a very beautiful variety with orange scarlet flowers. The margins of the petals are crimson (award of merit).

*Sibthorpia europæa aurea variegata* (J. Backhouse & Sons).—This is a charming yellowish green form of the type (award of merit).

#### FRUIT AND VEGETABLES.

Some difficulty was experienced in giving anything like a systematic report in this section, inasmuch as the collections were not separately arranged. Some exhibits consisted of vegetables alone, some of fruit and vegetables, and in others plants and flowers were also included.

Prominent in this department was a remarkable contribution of produce from Messrs. Sutton & Sons, Reading—remarkable in extent, variety, excellence, and, it may be added, novelty. It is not too much to say that a similar display has never been seen at any show in any country. For instance, a row of Peas, and a splendid row too, in full bearing, is quite an innovation at a "flower" show in May, while *Runner Beans* 6 to 8 feet high is a fresh start in the art of exhibiting. The *Beans*, it may be said, were Sutton's *Tender and True*, four plants grown in 12-inch pots, each plant with its stake, and bearing splendid pods from base to summit, like fine examples of *Canadian Wonder*. These pillars of *Beans* were both useful and ornamental, and arrested much attention.

The "row of Peas" first mentioned was formed by a number of plants grown in large pots and then placed side by side. They were bearing a very full crop of fine pods to a height of 3 feet of Sutton's *A1*, and were timed to the day. A dwarf Pea, Sutton's *Favourite*, 18 inches high, was bearing prodigiously, the plants moreover being as green and healthy as if growing naturally in the open ground. Still a dwarf Pea, about the height of *American Wonder*, but with pods thrice the size, was equally well represented, as, too, were the taller varieties, Sutton's *Empress of India* and *May Queen*. These were not confined to one or two pots of each variety, but were in sufficient number to form rows. All were admired, but perhaps the *Sturdy Dwarf* with its large pods was the favourite with the public, and it has, no doubt, a good future before it.

Then we pass to the *Tomatoes*, of which it is impossible to speak in too high terms of approval. The several varieties were admirably grown in pots, the heavy crops of fruit being ripe or ripening. The long racemes of Sutton's *Dessert*, with its Plum-like red fruits, and *Golden Nugget*, with fruits of similar size, the racemes trained upright to a central stake, were in their way unique; but all the same the effect was artificial, and it would perhaps have been well to have shown some of the plants in their natural character.

Among other varieties plants of Sutton's *Abundance* had clusters of large fruits within 3 inches of the pots, and to a height of a little more than 2 feet. *Maincrop* plants were a little taller, and fruits perhaps a trifle larger. The tallest plants were of a new variety, *Princess of Wales*, magnificently grown, bearing large clusters of handsome scarlet fruits from within 6 inches of the pot to a height of 4 feet or more. Still there were more. Sutton's *Tender and True*, a dwarf crimson variety, bearing prodigiously; *Sunbeam*, with golden egg-shaped fruits of great beauty, and Sutton's *Best of All*, perhaps the gem of the collection, the plants 2 feet high, and fruits large, smooth, symmetrical and attractive, some of them almost or quite touching the soil. We have said enough to justify our remarks as to the character of this imposing exhibit without dwelling on the grand display of *Calceolarias*, *Begonias*, *Gloxinias*, and other flowers, by which the vegetable crops were flanked.

The next objects which we came near, or rather stood under, were umbrella-trained *Cucumber* plants, grown by Mr. H. W. Ward, of Longford Castle—variety *Carter's Earliest of All*, apparently of the Cardiff Castle type, bearing abundantly well-shaped fruits of the first table quality. The *Cucumber* pots were "plunged" in a groundwork of *Carter's Harbinger Lettuce*—a curled-leaved, light green, tender-looking variety, suggesting a touch of *Endive* in its composition. *Cos Lettuces* and very fine *Radishes* in several varieties were included in the group, of which, however, Mr. Ward's "tree" *Cucumbers* were the prominent feature. They were well grown, and must have been skilfully packed to arrive in such fresh condition.

Mr. W. J. Empson, gardener to Mrs. Wingfield, Amptill, arranged an extensive and excellent assortment of vegetables, including *Carter's Model Broccoli*, very fine; large *Leeks*, as well as superior *Potatoes*, also *Tomatoes*, *Carrots*, *Beans*, *Asparagus*, and almost everything in

season, brightened with a few Apples and good dishes of Strawberries. Mr. J. C. Waite, Glenhurst, Esq., exhibited large bunches of very fine Asparagus, also first-class fruits of Carter's Model Cucumber. Mr. R. J. Steel, Brentford, staged a fine collection of salads, also superior Carrots, which some gardeners concluded had been "grown in France."

Mr. G. Wythes staged what may be called a choice assortment of vegetables appropriate for a nobleman's table, all kinds in season being included, not large but of choice quality. Mr. Wythes also had a stand of excellent fruit, including Grapes, Melons, Peaches, Nectarines, Figs, and Strawberries, all of the best dessert quality.

Mr. George Bunyard, Maidstone, arranged a wonderfully fine and well-kept collection of sixty-five varieties of Apples. A few of the finest were King of Tomkins County, Sturmer Pippin, La Pontoise, Striped Beefing, Annie Elizabeth, High Canons, and Newton Wonder.

Mr. J. Friend, The Gardens, Rook's Nest, Godstone, staged excellent bunches of Foster's Seedling Grapes, considering the earliness of the season; also very good Black Hamburgs. Mr. G. Featherly, The Vineries, Gillingham, Kent, had a splendid market basket of Black Hamburg Grapes, fine Cucumbers, excellent Kidney Beans, and good Peaches. Mr. Osman, gardener to W. J. Brown, Esq., Ottershaw Park, exhibited capital examples of Black Hamburg Grapes; good bunches of this variety, as well as of Foster's Seedling, coming from Thomas Statter, Esq., Stand Hall, Manchester. Also excellent Grapes, Melons, and Figs were exhibited by Mr. Messenger, gardener to C. H. Berners, Esq., Woolverstone Park, Ipswich.

Last, but certainly not the least worthy of notice, was a number of Nectarine trees in pots laden with brightly coloured fruits from Messrs. T. Rivers & Son, Sawbridgeworth. Though these trees were arranged in the chief Orchid tent, with a magnificent bank of Orchids in front of them, and flanked on each side by specimen Roses and Caladiums, the trees lost nothing by the contrast; they really made a pleasing break or change to the rich masses of floral beauty. They consisted of two varieties of Nectarines only—namely, the valuable Early Rivers, and another Sawbridgeworth seedling of the same bright colour. This is appropriately named Cardinal. The fruits are not so large as Early Rivers, but they ripen nine or ten days sooner, and this is something when they realise 36s. a dozen, and 2½ dozen are borne on one bush tree. However, trees of Cardinal are not likely to be put in commerce, as the variety is only of value for early forcing, and then needs special care, whereas Early Rivers grows as freely as Lord Napier, and produces larger and brighter fruits, rendering it the first and best early Nectarine for general cultivation. There was nothing more meritorious in the show than this fine group of trees, studded with rich red fruits.

LIST OF AWARDS.

*Gold Medal.*—T. Rivers & Son, Sawbridgeworth, for Nectarines in pots.

*Silver Cups.*—J. Veitch & Sons, King's Road, Chelsea, for Streptocarpus and other plants; Sander & Co., St. Albans, for Orchids and new plants; Baron Schröder, The Dell, Egham, for Orchids; Sir Trevor Lawrence, Burford Lodge, Dorking, for Orchids; Paul & Son, Cheshunt, for pot Roses, Cannas, and others; C. Turner, Royal Nurseries, Slough, for Roses, Pelargoniums, and Azaleas; Sir Frederick Wigan, Clare Lawn, East Sheen, for Orchids; Sutton & Sons, Reading, for Gloxinias, Begonias, Lilies, Tomatoes, and Cucumbers; J. Backhouse & Son, York, for Filmy Ferns, Alpine, and herbaceous plants; Richard Smith and Co., Worcester, for specimen Clematises; Wm. Iceton, Roehampton, S.W., for Palms and Caladiums; Wills & Segar, Onslow Crescent, South Kensington, for decorative Palms; G. Bunyard & Co., Maidstone, for Apples; Pantia Ralli, Esq., Ashted Park, Epsom, for Caladiums; J. James & Son, Farnham Royal, for Calceolarias; H. Low & Co., Clapton, for Orchids, stove and greenhouse plants; and Perkins and Sons, Coventry, for floral designs.

*Silver-gilt Flora Medals.*—W. Batchin & Sons, Hassocks Nurseries, for Leschenaultias; P. Barr & Son, Covent Garden, for cut flowers; J. T. Bennett-Poë, Esq., Cheshunt, for Streptosolen Jamesoni; W. & J. Birkenhead, Sale, Manchester, for Ferns; H. Cannell & Sons, Swanley, for Begonias and Gloxinias; J. Carter & Co., High Holborn, for cut flowers; Charlesworth & Co., Heaton, Bradford, for Orchids; James Cypher, Cheltenham, for Orchids; J. Gurney Fowler, Esq., S. Woodford, for Orchids; W. Fromow & Sons, Chiswick, for Japanese Maples; Geo. Jackman & Son, Woking, for pot Roses; J. Kelway & Son, Langport, Somerset, for hardy flowers; W. L. Lewis & Co., Southgate, N., for Orchids; W. Paul & Son, Waltham Cross, for Roses; J. Peed & Sons, Norwood Road, for Caladiums; Leopold de Rothschild, Esq., Leighton Buzzard, for Carnations; T. S. Ware, Tottenham, for Begonias and cut flowers; B. S. Williams & Son, Upper Holloway, for Orchids; and John Waterer & Son, for Acers and Rhododendrons.

*Silver-gilt Knightian Medals.*—Welbore S. Ellis, Esq., Hazelbourne, Dorking, for Orchids; Earl Percy, Syon House, Brentford, for fruits and vegetables; and Mrs. Wingfield, Amptill, for vegetables.

*Silver-gilt Banksian Medal.*—C. H. Berners, Woolverstone Park, Ipswich, for black Grapes.

*Silver Flora Medals.*—L. H. Calcutt, Stoke Newington, for table decorations; Chard & Co., for cut flowers; Malcolm S. Cooke, Kings-on Hill, for Orchids; W. Cutbush & Son, Highgate, for Azaleas and cut flowers; Dobbie & Co., Rothesay, for Violas; H. J. Jones, Lewisham, for Pelargoniums; B. Ladhams, Shirley, for cut flowers; H. B. May, Upper Edmonton, for Ferns; G. Mount, Canterbury, for cut Roses; Sir J. W. Pease, Bart., M.P., Guisborough, for fruits; Earl Percy, Syon House, Brentford, for Orchids; W. Rumsey, Waltham Cross, for pot Roses; and the Hon. W. F. D. Smith, M.P., Henley-on-Thames, for Hippeastrums.

*Silver Knightian Medals.*—I. J. Baker for Grapes; and Earl of Radnor, Salisbury, for Cucumbers.

*Silver Banksian Medals.*—John R. Box, Croydon, for cut flowers; J. Cheal & Sons, Crawley, for cut flowers; Horticultural College, Swanley, for table decorations; M. Prichard, Christchurch, for cut flowers; Phelps & Co., Queen Street, Cardiff, for bridal bouquets; S. Pye, Garstang, for Pansies and Violas; and Wallace & Co., Colchester, for hardy flowers.

We were very glad indeed to see the show such a success, and also to learn at the time of going to press that the attendance far exceeded that of previous years. The secretaries and managers of the show are deserving of hearty commendation for the excellent manner in which they performed their duties.

ROYAL NATIONAL TULIP SOCIETY.

THE exhibition (at the Temple) as a whole was far in advance of last year's show, though the season has been by no means so propitious. The feathered flowers were of very high excellence, whilst the flamed varieties were but moderately good—another illustration of an apt

FIG. 75.—INCARVILLEA DELAVAYI.

saying of old growers, "We shall have some good 'feathers' after this hard frost." Universe, a seedling of Dymock's, was beautifully feathered in Mr. C. W. Needham's pan of six, and was awarded a certificate as premier feathered flower.

An unknown feathered byblømen, like Mrs. Cooper, in the third pan of twelves of Mr. Needham's was very meritorious. Heroine, an old Dutch sort, was exhibited by Mr. Haynes in his stand of six. General Grant, as shown by Mr. Bentley, was a very fine bizarre—gold cup with a dark red feather, well pencilled.

Sir Joseph Paxton, an almost perfectly flamed bizarre, shown by Mr. Haynes of Warwick in Class 4, was awarded the certificate as premier flamed flower. Dr. Hutcheon, a very telling, well-marked bloom, was seen in the Rev. F. D. Horner's stand in Class 4. The breeders were rather small, but of good quality. The seedlings of the Rev. F. D. Horner were excellent, and very striking in their richness and purity. Fairy, a byblømen, and Rosy Morn, a fine dark rose breeder, were quite attractive.

Class 1, twelve dissimilar rectified Tulips.—First prize, silver-gilt medal, Mr. J. W. Bentley, Stakehill House, Castleton, Manchester, byblømens, flamed, Chancellor, very good, and Talisman; feathered, Friar Tuck and Elizabeth Pegg; bizarres, flamed. Dr. Hutcheon, fine, and Hepworth's Seedling; feathered, General Grant and Masterpiece; roses, flamed, Mabel and Rose Celestial; feathered, Julia Farnese, quite pure, and Comte de Vergennes. Second prize, silver medal, Mr. T. Haynes, Warwick, roses, flamed, Mabel and Aglaia; feathered, Rose Hill and Heroine; byblømens, flamed, Amazon and Alice Maud; feathered, Adonis and Mrs. Pickerill; bizarres, flamed, Sir Joseph Paxton and

Ajax; feathered, Masterpiece and Sir J. Paxton. Third prize, Mr. C. W. Needham, Royley Royton, near Manchester, roses, flamed, Aglaia and Lady C. Gordon; feathered, Hilda and Modesty; byblœmens, flamed, Carbuncle and Friar Tuck; feathered, Trip to Stockport and a seedling; bizarres, flamed, Masterpiece and Wm. Wilson; feathered, Masterpiece and Luke Ashmole.

Class 2, six dissimilar rectified Tulips.—First prize, silver medal, Mr. C. W. Needham, Royley, Royton, Manchester, with bizarres, flamed, Sir Joseph Paxton; feathered, Luke Ashmole; byblœmen, Universe feathered and Universe flamed; roses, Lady Catherine Gordon flamed, Annie M'Gregor feathered. Second prize, Mr. T. Haynes.—Flamed byblœmen, Adonis; rose, Heroine; bizarre, Sir J. Paxton. Feathered, Bessie, Mabel, and Sir J. Paxton. Third prize, Mr. J. W. Bentley.—Feathered byblœmen, Beauty of Litchurch; rose, Annie M'Gregor; bizarre, Masterpiece. Flamed, Charlemagne, Aglaia, and Masterpiece. Fourth prize, Mr. G. Edom, Horeham Road, Sussex, with Dr. Hardy, flamed, Sir J. Paxton, feathered, bizarres; Universe, feathered, and Bessie, flamed, byblœmens; Aglaia, both a feathered and a flamed rose.

Class 3, three feathered Tulips.—First prize, Mr. J. W. Bentley. A fine exhibit, comprising Coningsby Castle, General Grant, and Comte de Vergennes. Second prize, Mr. T. Haynes, Sir J. Paxton, Mabel, and Adonis. Third, Mr. C. W. Needham, Modesty, Ashmole, Bessie. Fourth, Mr. G. Edom.

Class 4, three flamed Tulips.—First prize, Mr. T. Haynes, with a grand pan consisting of Universe, Sir J. Paxton, and Mabel. Second prize, the Rev. F. D. Horner, M.A., Lowfields, Burton-in-Lonsdale, with three excellent blooms of Dr. Hutcheon, Hepworth's Seedling, and Mabel. Third prize, Mr. T. W. Bentley, Mabel, Bessie, Duke of Devonshire. Fourth, Mr. C. W. Needham, Dr. Hardy, Bessie, and Nanny Gibson. Fifth, Mr. G. Edom, with Sir Joseph Paxton, Aglaia, and an unknown byblœmen.

Class 5, six di-similar Tulips.—First prize, silver medal, the Rev. F. D. Horner, Lowfields, Burton-in-Lonsdale, with Fairy and Desdemona, byblœmens; Mrs. Barlow and Rosy Morn, roses; Dragonfly and Storer's 3A, bizarres. Second prize, Mr. T. W. Bentley, Sir Joseph Paxton and Goldfinder, bizarres; Elizabeth Pegg and Glory of Stakehill, byblœmens; Mabel and Hepworth's Seedling, roses. Third, Mr. C. W. Needham, Sir Joseph Paxton, and Goldfinder; Glory of Stakehill and Elizabeth Pegg; Madame St. Arnaud and Lloyd's Seedling. Fourth, Mr. T. Haynes, Rose Hill and Mabel; Doctor Hardy and Sir Joseph Paxton; Beauty of Litchurch and Talisman.

In Class 6 there was a very close competition for the Samuel Barlow Memorial prize, for one feathered and one flamed Tulip of any class. First prize, Mr. C. W. Needham, with Elizabeth Pegg, feathered; and Sir Joseph Paxton, flamed. Second prize, the Rev. F. D. Horner, with a seedling byblœmen, feathered; and Mabel. Mr. T. Haynes was quite a close competitor with Masterpiece, feathered; and Sir Joseph Paxton.

In the competition for groups of amateur English Tulips, J. T. Bennett-Poë, Esq., Holmewood, Cheshunt, was awarded the first prize silver medal for his collection of well-grown blooms, in which were fine specimens of Sir Joseph Paxton, Sulphur, Mabel, and Annie MacGregor. A few more breeders would have brightened the exhibit. Second prize, Mr. J. W. Bentley. Third prize, Mr. G. Edom. The group exhibited by Mr. C. W. Needham being next in order of merit. The afternoon of Tuesday being rather dark, the blooms were hardly seen to the best advantage, some of them closing as the afternoon waned.—C. W. N.

WEATHER IN LONDON.—During the past week the weather in the metropolis has been very cold, the winds being particularly harsh and unfavourable to vegetation. A few drops of rain have fallen at intervals, while equally rare glimpses have been caught of the sun. It is hoped that a change will soon be experienced. Yesterday (Wednesday) was bright, though a little milder.

— WEATHER IN THE NORTH.—The weather towards the close of last week was cold and ungenial, and snow fell in both the north and the south of the country. Sunday was also cold, and the hills to the north were slightened whitened on Monday morning. With the advance of the day on Monday there was a return of milder weather.—B. D., *S. Perthshire*.

— GARDENING APPOINTMENT.—Mr. Wm. M. Moir, gardener to the Rev. Dr. McLeod (Chaplain to Her Majesty) at Glenfeulan, Dumbartonshire, and formerly at Rosshall, Paisley, has been appointed head gardener to J. D. Fletcher, Esq., Rosehaugh, Ross-shire.

— VIOLA CONFERENCE AT BIRMINGHAM.—The second annual Conference of growers and others interested in Violas will be held on the first day (29th inst.) of the Pansy and Viola show in the Edgbaston Botanical Gardens at four o'clock in the afternoon. Mr. William Cuthbertson will be Chairman, and the following papers will be contributed:—Professor Hillhouse, "The Genus Viola;" Mr. Richard Dean, "Older Varieties of Violas;" Mr. J. D. Stuart, "Viola Sports;" Mr. E. Burrell, "Violas That Do Well in Surrey;" Dr. Stuart, "Newer Varieties of the Violetta type;" Mr. A. J. Rowberry, "The Winter Treatment of Violas."

— COLCHESTER ROSE AND HORTICULTURAL SOCIETY.—The summer exhibition of this Society is announced to be held in the grounds of East Hill House, Colchester, on Thursday, June 20th, when excellent prizes will be adjudged for Roses, general plants and flowers, vegetables and fruit. The show will be divided into sections to meet the positions of all growers, and should prove a great success. The Chrysanthemum Show is fixed for Thursday, November 7th. Full particulars, with schedules, may be had from the Hon. Sec., Mr. O. G. Orpen, West Bergholt, Colchester, and Mr. P. R. Green, Colchester.

— SHIRLEY GARDENERS' AND AMATEURS' IMPROVEMENT ASSOCIATION.—A meeting was held on the 20th inst. at the Parish Room, Shirley, Southampton, when the President (Mr. W. F. G. Spranger) presided over a good attendance of the members. Mr. Jesse Jones, The Gardens, Terrace House, Polygon, Southampton, read a paper on the "Cultivation of the Melon." The increased fruitfulness of plants raised from seed two or more years old, compared with plants from quite new seed, was advanced; but no definite conclusion on the point appeared to be arrived at. A vote of thanks was accorded to Mr. Jones for his interesting and instructive paper.

— PEARSON'S "VINE CULTURE."—This little shilling work on the Vine maintains its popularity, as is evident by the issue of a sixth edition, published by Messrs. Forman & Sons, Nottingham. Written by one of the soundest of horticulturists in his generation, the late Mr. J. R. Pearson, and revised and edited by his son, Mr. C. E. Pearson, this handy little book may be regarded as a safe and sound guide for those busy people who want the greatest amount of information in the least space and at the smallest cost. It is a *multum in parvo* on the cultivation of the Vine, and the prevention or destruction of its enemies. It would be no great task to get the matter "off by heart," and those who should do this will have knowledge worth many shillings, and it may be pounds, stored in their minds.

— FLORAL DECORATIONS AT WARWICK CASTLE.—These were carried out on an extensive and elaborate scale during the recent visit of the Prince of Wales to the castle of the once king maker. Hundreds of splendid Maréchal Niel and Catherine Mermet Roses were employed, as well as large quantities of Lily of the Valley and Malmaison Carnations. Perhaps the chief feature of the floral arrangement was a large group of choice Orchids displayed with great taste, and intermingled with *Asparagus plumosus* in the fine drawing-room. On every hand Mignonette and Lily of the Valley filled the atmosphere with perfume. In the grand old hall, for which the castle is famed, stately Palms spread their arching fronds high above banks of vivid scarlet, the whole arrangement producing an effect not easily forgotten, and must have entailed an immense amount of work on the part of Mr. H. Dunkin, Lord Warwick's head gardener, and his assistants.—G. H. S., *Warwick*.

— GARDEN TULIPS.—The note on "Gardeners' Tulips" (page 422), by Mr. Brotherston, is opportune, and leads me to make a note about what I term garden Tulips. I allude to those that are grown solely in gardens, and which I call old fashioned Tulips, as being distinct from any of those cultivated in pots. In this neighbourhood much attention is paid to these Tulips by the cottagers, and hardly a garden can be seen that does not contain a good number. It is surprising what a range of colouring is to be found, from pure white to the darkest of red, embracing all conceivable shades of yellow, pink, and carmine. No one ever dreams of disturbing the bulbs with the idea of improving them in any way. From the success attained hereabouts it is a plain proof that annual replanting of the bulbs is not at all necessary. In what we call the wild part of our garden there are a goodly number of both double and single Tulips of this section growing in the grass. To my knowledge they have not been disturbed for sixteen years, and they flower annually in profusion. The sweet-scented Florentine Tulip (*sylvestris*) is a great favourite. The bright yellow flowers are tinted with green on the outside, and last in freshness a long time.—E. M.

— A "PAT" DESCRIPTION OF THIRSTY IRELAND.—Parched with the drought. Last rain we had was a hailstorm on May Day.—PAT.

— BANDS IN THE LONDON PARKS.—A pamphlet recently issued by the Parks Sub-Department of the London County Council informs us that bands will play in various parks and recreation grounds on each day of the week from May 16th to September 8th, and that in eleven open spaces bands will perform on Sundays, commencing May 19th and ending September 8th.

— STAPHYLEA COLCHICA.—Though this pretty flower is extensively used for forcing it is not seen blooming in the open air in gardens so often as might be expected, and those who grow it under these conditions will testify to its usefulness. It is one of the most pleasing of all flowering shrubs, and having passed safely through the ordeal of the severe winter, may be seen in some gardens blooming profusely, its sweet-scented, creamy-white flowers being very conspicuous. It grows and blooms in almost any position with little attention, which fact alone is sufficient to recommend it.—H.

— MAKING PARIS GREEN MORE EFFECTIVE.—Paris green is soluble in ammonia and carbonate of ammonia, but experience teaches that whenever arsenic in solution is applied to foliage it injures the leaves; otherwise compounds of arsenic with potash, soda, and ammonia, might be used instead of Paris green. The fact that Paris green yields its arsenic slowly is protection against the destructive action of the arsenious acid. It is not unlikely that if some gum-like material were added to the Paris green mixture, to fasten it to the foliage, failures from its use might be prevented. It might be worth while to try adding a small amount of dextrine (British gum) for holding the green to the foliage.—C. A. GOESSMANN (in the "American Agriculturist.")

— RAINFALL IN PALESTINE.—From a paper on "Early Agriculture in Palestine," by Dr. H. Vogelstein, we learn the interesting fact that in the first two centuries of the Christian era, rainfall was measured by means of a receptacle. The Jewish "Mishnah" refers to two seasons, one wet and the other dry. In normal years the early rain fell soon after the autumnal equinox, and its importance to agriculture is frequently referred to in that document. The amount which fell at this season was about 21 inches, which agrees fairly well with the present measurements at Jerusalem, but the total annual fall is not stated by Dr. Vogelstein. Further particulars of this interesting communication will be found in the "Meteorologische Zeitschrift" for April.—("Nature.")

— A BIG ROSE.—The specimen of Lamarque Rose in one of the Californian cities is sufficient to make cultivators of Tea Roses in this country somewhat envious. The Rose was planted in the autumn of 1876, and has grown vigorously from the first, and during the past fifteen years has borne enormous numbers of flowers. At the present time the stem immediately above the surface of the ground has a circumference of 2 feet 9 inches, and the two branches that spring from the main stem are each 2 feet in circumference. The growth has been trained over a large arbour, and this is annually pruned somewhat severely, a wagonload of wood being, it is stated, cut away last autumn. A contemporary has been informed that the blooms have been counted for several years, and the average in the five seasons previous to this has been upwards of 14,000. This year the number produced in March and April was 21,640.

— FLORAL DECORATIONS IN JAPAN.—The perambulating florist, says an American journal, offers quite a contrast to our ideas, with his flowering branches standing in bamboo jars. The Japanese are great flower lovers, and the flower vendor is a familiar sight in the streets of their cities. They are very fond of flowering shrubs, cut sprays being much used in decoration. But their ideas of floral arrangement are very different from ours, and our choicest decorations would be coarse and inartistic in their eyes. All their floral arrangements have an underlying symbolism which we find difficulty in comprehending, though we can recognise the main principle—that of fidelity to Nature. A single branch of Cherry blossoms, standing in a bamboo flower holder, will be the result of as much thought as we give to an elaborate arrangement, and a mixture of incongruous bloom is never seen, being absolutely repugnant to them. The idea that a single Rose, thoughtfully placed so that stem and foliage as well as bloom show to advantage, is sufficient decoration for a table, an opinion offered recently by a lady of much taste, is certainly a move toward the Japanese ideal.

— WAKEFIELD PAXTON SOCIETY.—At a recent meeting of this Society Lieutenant Goodyear presided, and Mr. B. Whiteley was in the vice chair. Mr. J. Burton gave a most interesting lecture on the formation of the world. He illustrated his eloquent address, which was delivered extempore, by a coloured diagram showing the crust of the earth. Mr. Burton's lecture, which was of a scientific character, was most attentively listened to, much applauded, and provoked an interesting discussion.

— FRUIT IMPORTS IN GERMANY.—At a meeting of the Central Agricultural Bureau of South Australia it was reported that while it had been thought that Germany exported a large amount of fresh fruit, it had been found from an official paper of recent date that from 1884 to 1893, while they only exported 215,521 tons of fresh fruit, they imported 376,076 tons. The imports each were half a million sterling in excess of the exports. It was thought from these facts that a market for South Australian fruit might be secured in Germany.

— THE HARDINESS OF SCARLET RUNNER SEEDS.—Mr. Helmsley in his interesting paper on the "Vitality of Seeds," states (page 437) that "The Scarlet Runner Bean loses its germinative powers on exposure to slight frost." Some years ago, as not infrequently happens in gardens, a number of pods of Scarlet Runner Beans ripened in the plants. After these were dead the sticks to which they adhered were drawn and stacked for the winter, but through pressure of work the dead twiners were not removed at the time. They were, in fact, not removed until the spring, and the dried pods and beans were exposed to a month of severe frost, the thermometer on several consecutive nights registering only a few degrees above zero. After this ordeal, and the beans appearing sound, some of them were tested in the practical manner of sowing an extra row by the side of the usual number from purchased seed. It was not expected there would be many, if any, plants, but to the surprise of all concerned, every bean, which must have been frozen, germinated, and the plants grew as well and the row was as productive as any in the garden. The beans were taken from the pods on the ground and placed in the drill by the hand that writes these lines, and the facts are exactly as stated. Has Mr. Helmsley proved his allegation or relied on books for his information?—A GARDENER.

— ROYAL METEOROLOGICAL SOCIETY.—The monthly meeting of this Society was held on Wednesday evening, the 15th inst., at the Surveyors' Institution, Westminster, Mr. R. Inwards, F.R.A.S., President, in the chair. Mr. G. J. Symons, F.R.S., and Mr. G. Chatterton, M.Inst.C.E., read a paper on "The November Floods of 1894 in the Thames Valley," which they had prepared at the request of the Council of the Royal Meteorological Society. This consisted of a systematic description of the causes which led to the great floods of November last, and analysis of the records obtained from the Thames Conservancy Board, from the engineers of several of the towns along the river, and also from rainfall observers throughout the Thames watershed. The information was given chiefly in the form of tables, one of the first being a chronological history of floods in the Thames Valley from the earliest records down to the present time. This was followed by a short description of the damage wrought in November, 1894, which was illustrated by a number of interesting lantern slides. Details were then given of the levels reached at various places in all the principal floods from 1750 to the present time. The authors exhibited a map showing the relative elevation of all the parts of the Thames Basin, and then gave details of the rainfall for each day from Oct. 23rd to Nov. 18th, 1894. The results obtained by the Thames Conservancy Board showing the flood levels at each lock were exhibited on a longitudinal section from Lechlade to Teddington, and the hydraulic inclinations from lock to lock were shown in a tabular form. The volume of flood water, as gauged by the Thames Conservancy at Teddington, rose rapidly from 4,000,000,000 gallons per diem on November 12th, to 10,250,000,000 gallons on the 16th, 12,800,000,000 gallons on the 17th, and to over 20,000,000,000 gallons on the 18th, when the discharge reached its maximum. The last-named discharge is equivalent to 0.37 inch over the whole watershed of the Thames above Teddington Lock. Mr. F. J. Brodie also read a short paper "On the Barometrical Changes Preceding and Accompanying the Heavy Rainfall of November, 1894," from which it appeared that the latter half of October was characterised by unusually bad weather, especially in the more western and southern parts of the British Isles. The torrential rains of November 11th to 14th, which actually caused the floods, were due to two secondary depressions which developed a certain amount of intensity as they passed over the southern part of England.

## CATTLEYA MENDELI PRINCESS OF WALES.

AMONGST the charming Orchids staged at the Drill Hall on the 14th inst. none attracted more attention than *Cattleya Mendeli* Princess of Wales (fig. 77) exhibited by Mr. De Barri Crawshay, Rosefield, Sevenoaks. The flower was exceedingly handsome, with broad, rosy, white petals, and narrow sepals of the same colour. The lip was heavily fimbriated, and of magnificent form. The outer portion was intensely rich purplish maroon, the throat being clear yellow veined with crimson. The Orchid Committee accorded an award of merit to this variety.

FIG. 76.—CYPRIPEDIUM CHAMBERLAINIANUM.

## ORCHIDS AT CHELSEA.

THE annual exhibition of Orchids, which has been such a feature of Mr. W. Bull's establishment for so many years, is now on view. This season is no exception to the rule of high quality that has become so general here, and in a future issue we shall give a more lengthened notice. In the meantime visitors to London are recommended to make a journey to Chelsea, as we are confident they will be well repaid for the time and trouble.

## THE DELL.

WHEN one thinks of Orchids, and especially *Odontoglossums*, one's mind instinctively becomes occupied with the name of Baron Schröder, than whom no amateur has a better or more complete selection. In its formation money has been brought to bear, as also has knowledge, which is of equal importance, for without its money will most likely be absolutely thrown away in buying Orchids, and this with very little trouble. These two requisites have been and are still being found by the Baron and his efficient gardener Mr. H. Ballantine.

It is no superficial interest that the owner takes in this superb collection, for his acquaintance with it may be termed little short of remarkable, conversant as he is with every plant and every flower. Considering that twenty-two structures do not afford any too much accommodation for these denizens of other climes, it will be acknowledged that in saying "remarkable" there is not the least exaggeration. These houses are all beautifully built, and kept scrupulously clean throughout. Each pot, each stage, each rafter, each pane of glass, is in the best of condition, and shows the unremitting attention and care that are devoted to them. Another notable point is that each plant is properly and legibly labelled, and every possible precaution taken to preserve correct nomenclature, an example that might well be followed in establishments where plants other than Orchids are accorded a primary position.

Perhaps if this collection is celebrated more for one section than another it is for the *Odontoglossum crispum*. Comprising this are probably all the best varieties in cultivation, and many to be seen here cannot be found elsewhere, at any rate in England. Hundreds, nay thousands, of pounds probably would not purchase many of these. The colours are extremely varied, as also is the form and substance; but almost, if not all, may be said to possess one or more points of more than ordinary merit. Here the form is the point, there the colour, and yonder, again, the substance. But no matter what may be the merits, each receives the same cultivation, and this is of the very best, all being done to insure success that intelligent thought can devise or money purchase.

From amidst such a plethora of splendid flowers it seems an overwhelming task to make a selection; but such is in reality not the case, as some stand so very much in advance of the others, good though all the latter undoubtedly are. The chief difficulty lies in the decision as to which section shall be accorded the premier position, taking it in this instance as the place of honour, and following with others as noted and not in any particular order of merit. Many kinds, too, are not now in flower, and these notes must therefore be taken as representative of the flowering section at the present time, and not of the collection as a whole. An opportunity may arise of seeing these Orchids at another season, when doubtless numbers of others will be found worthy of note.

Surely no one will object if we put the *Odontoglossum crispum* at the head of the list, for of these the selection is well nigh, if not quite, perfect. First of all we must mention *O. c. apiatum*, probably the finest spotted variety in cultivation. The form, substance, and colouration of the blooms are superb, and the same may well be said of the spike. *O. c. Lowianum* is of a very much smaller size, but of a beautiful colour, and may yet improve. Another pleasing variety of this section is *xanthotes*, which has occasional yellow spots on a creamy white ground. Others there are all good, and worthy of mention, but which must be excluded on account of the scarcity of space and adjectives, both absolutely essential in dealing with these Orchids.

But the *Odontoglossums* cannot be quite so briefly dismissed, as there are many of other than the *crispum* section of singular beauty. A grand form of *luteo-purpureum* attracted much attention, as also did *Wilckeanum*. Such *Odontoglossums* as *coronarum*, *ramosissimum*, *cirrhosum*, and *excellens* are well known and deservedly highly appreciated. With these we must leave the section, and pass on to others that if not quite so perfect are still worthy of the best possible attention. All these plants, it may be mentioned, are in the most excellent health.

Let us now glance at the *Cypripediums*, which it is perhaps superfluous to say are extensively represented by all the best varieties and hybrids in cultivation. Prominent here is *C. Lawrenceanum Hyeannum*, with its green and white flowers of grand shape, and which compel admiration. Then we have the charming *bellatulum*, the superb *Stonei*, the beautiful *laevigatum*, and the popular *Lawrenceanum*. Beyond these may be noticed a handsome flower of *C. Chamberlainianum*, a variety that varies greatly in the twisting of the petals, and a good form, of which is portrayed in the woodcut (fig. 76). In addition to these *macrochilum*, *grande*, *Schröleræ*, *Mastersianum*, and *calanthum* were all conspicuous for some good point or other, in one perhaps of colour, and another of form. Though not in flower, some splendid plants of *Stonei platyænum* are well worthy of a line as denoting such health as makes good blooms a certainty.

Placed on a stage in a cool house were a few Orchids in flower, and a *Cattleya Mendeli* amongst these was grand indeed. The petals were 3 inches in width, and of a charming shade of rose, this also being the colour of the sepals. The lip was of very intense deep rose, the yellow of the throat being edged white and striped with chocolate brown. It was also very finely fringed. In the same structure was a plant of *C. Skinneri alba* carrying large numbers of flowers. The *Mossiæ* section of the *Cattleyas* was replete with many varieties, and several of the plants were blooming admirably. A plant of *C. Wagneri* was also conspicuously attractive.

*Lælias* made a really grand display, the flowers being large and exceptionally rich in colour. Here again we are beset with diffi-

is amongst the best, but is said to be difficult to grow. *D. infundibulum*, *D. macrochilum*, *D. m. Deeri*, *D. Farmeri*, and *D. densiflorum* are all very beautiful, and mostly fairly well known. There were in addition to these many others, notably the chastely beautiful *D. Bensoniæ xanthinum*, with which we must leave the section.

Passing on we come to the *Masdevallias*, which make one of the brightest displays of all. The colouration is so good, so diversified, and the plants so well grown that they make a show of themselves. All the best forms are to be seen, and one of the most striking is *Houtteiana*. A plant of this in a 12-inch basket is carrying upwards of 220 blooms. Others are *Kimballiana*, *Harryana* in variety, *Veitchi grandiflora* (superb), and *amabilis*.

FIG. 77.—CATTLEYA MENDELI PRINCESS OF WALES.

culties of one kind or another, so must pass on briefly. Of course, *L. purpurata* in variety are the most showy, but *L. elegans* made a most pleasing diversion. *L. purpurata Sanderiana delicata* is a very beautiful variety with too much name, while *L. pumila* is a pretty flower with one much handier. *Lælio-Cattleya Hippolyta* represents the bigeneric hybrid section, being the result of a cross between *L. cinnabarina* and *Cattleya Mossiæ*, both of which may very readily be seen, but especially the former, in the sepals and petals.

It was unfortunate that many of the *Dendrobiums* had passed their best when we visited The Dell, but sufficient remained to give an idea of what might be seen at various times. *D. nobile* and *D. Wardianum*, of which all orchidists who know it will say Baron Schröder's form, as depicted in fig. 78 (page 454), is one of the best, are found in numbers. *D. McCarthiæ* of those now in bloom

*Vandas*, of course, are to be seen in goodly array, *suavis*, *tricolor* and the charming *teres* being in magnificent condition. A little gem is *Vanda cœrulescens Boxalii*, while a white variety of *teres* grown here would be very difficult to beat. Most prominent among the *Oncidiums* was *macranthum*, a plant of which has flower spikes several feet in length, and *fuscatum*. The Fox Brush Orchids are beautiful, especially *Aërides Fieldingi*.

Of the *Cœlogynes* little can now be said, but the celebrated plant of *Dayana*, that attracted such an extraordinary amount of attention at the Temple Show last year, must have a word, and as for the plants of *cristata* varieties, they have doubtless been a perfect picture a short time ago. Plants of the well-known *Ada aurantiaca* may be seen affording variety. Useful for this purpose is *Epidendrum James O'Brien* with its richly hued blooms, and

*Spathoglottis Kimballiana*, which is very bright yellow in colour. A specimen of *Sobralia xantholeuca* throwing up a perfect forest of growths is said to be the largest known, while another of *S. macrantha* is but little less in size.

The *Phalænopsis*, though not now in flower, are in the best of condition, and full of promise for future beauty. More curious than pretty is *Marmodes Medusæ*, but *Trichopilia suavis alba* is really charming. With *Saccolabium ampullaceum* we must conclude our notes. Again let us express the hope that an opportunity will arise for The Dell to be revisited, when it cannot be doubted that "The Baron" and his genial gardener, Mr. Ballantine, will have done their best to keep this collection in the unique position that it at present occupies amongst Orchids.

#### BURFORD LODGE.

EVERYONE interested in Orchids, even to the smallest degree, will have heard of Burford Lodge and its genial owner, Sir Trevor Lawrence, Bart., to whom the Royal Horticultural Society, of which the Baronet is the energetic President, and Orchid growers generally owe so much. There is rarely a meeting passes at the Drill Hall at which Sir Trevor may not be seen, and Temple show time usually finds him at his busiest in earnest endeavours to make everything a success. This interest in the society is most praiseworthy, and it is to be hoped that the R.H.S. will long have the benefit of it.

Nestling under the side of a hill clothed with trees Burford Lodge is naturally an ideally situated estate, and well worthy of the attention that is bestowed on it by Mr. W. Bain, the head gardener. Though the visit was to see the Orchids, the opportunity was taken of a glance at the outdoor flowers and also at the glass department, and all was found in a very creditable state. Amongst the plants were noticed many of which may be termed botanical curiosities, and are very rarely to be seen in general cultivation in private establishments. Curiously enough the only fruits

FIG. 78.—DENDROBIUM WARDIANUM, BARON SCHRÖDER'S VAR. (See p. 453.)

grown under glass are Peaches, Nectarines, and Strawberries, and the fine condition of these testify to the ability of the grower.

Entirely distinct is the department devoted to the Orchids, and it may be said that these occupy a very large proportion of the glass houses on the place. Here Mr. White reigns supreme, having the complete charge. On our arrival we found him busily engaged preparing plants for the Temple show, and many readers of the *Journal of Horticulture* will, ere now, have seen the splendid group he staged, and which so well upheld the name of Burford Lodge and his own as a first-class cultivator. Apparently he was relieved when he learned that the visit was to be a brief one, as it was evident he was anxious to return to his work. Not that there was any hurry; on the contrary, no one could have been more courteous and attentive than was Mr. White in giving all the information in his power. When the time for departure arrived we left with a feeling of regret that the stay could not have been longer, but brightened by our conductor's invitation to repeat the visit any time we liked. This was good, and we shall take him at his word.

As we found Mr. White so busy amongst the *Masdevallias* we cannot do better than give them first attention, especially as they occupy the leading page of some almost unreadable notes. Though the latter are bad the plants are good, and occupying as they do a little lean-to structure to themselves make a surprisingly bright and pleasing show. The freedom with which they flower, combined as it is with strong growth, is exceptional, as it frequently occurs that strong plants produce very few flowers. Here, however, the attention and culture are so good that the plants leave little to be desired. The varieties are extremely numerous, and include the rare *Shuttleworthi*, the charming *lutea oculata*, the peculiar shaped *conchiflora*, besides *miniata* with its scarlet flowers, the well-known *Veitchi fragrans* with its sweetly perfumed flowers, and the hybrid *Mundyana*. But enough of these. We must pass on.

Turning to the Slipper Orchids, we must place *Cypripedium Stonei platytænium* in the premier position, for undoubtedly it is well worthy of the honour. The Burford Lodge plant is splendid indeed, and carrying flowers the superior of which we have never seen. Close by we see *Stonei*, with which the preceding was imported, and the difference is as marked as it well can be. Passing on we stand shortly before what is probably the finest specimen of *C. grande* in the kingdom. Owing to the freedom of the growths we could not measure the pot; but it was evidently well over 27 inches in diameter. This big receptacle was placed on a revolving pivot so that the plant could be readily turned to allow of all sides being readily approached. *Hookerae volonteum*, *Swansianum superbum*, *tonsum*, *Lawrebel*, and *Elliottianum* were also seen in our perambulation.

*Dendrobiums* are here seen in splendid condition and also in goodly numbers, many varieties, of course, not now being in bloom. Still, several remained that were worthy of note. Of these *D. Jamesianum*, a well known and highly esteemed variety, *D. Parishii*, and *D. secundum album* may be mentioned. Before turning to other flowers a word of mention must in justice be accorded to the winter-flowering section of the *Calanthes*. The plants of these have recently been potted, and the strong growths that are now pushing denote the splendid health of the plants, and give ample promise of an abundance of flowers in the proper season.

Now to the *Odontoglossums*, which have a home indeed at Burford, that is if strong growths, leathery leaves, and handsome spikes may be taken as a criterion, and certainly we do not see what more need be desired. Particularly beautiful are several plants and forms of *citrosimum*, of which the range of colouration is very wide, the flowers and spikes being of good size. Several forms of *O. crispum* are grown, and, what is more, thoroughly well. One of the best *Odontoglossums*, and which attracted a great amount of attention a short time back when exhibited by Sir Trevor, is *O. Ruckerianum splendens* (fig. 79, page 455), which, as may be seen, is a charmingly spotted form. *Andersonianum* is also very fine, and the same may safely be said of *maculatum*, *Pescatorei*, *Halli*, and *polyxanthum*. In the *Odontoglossum* (*Miltonia*) *vexillarium* sections there are a good number of plants, all looking remarkably well, and many carrying good spikes of bloom.

Of course *Cattleyas* are very extensively grown, and comprise all the best forms procurable in the various sections. *C. gigas*, though not in bloom, are in the best of condition. *Mendeli* are now in grand form, and many cannot fail to attract attention and elicit admiration, and to *C. Mossiæ* these remarks are equally as applicable. Worthy of special note are the *C. Lawrenceana*, of which some superb flowers were noticeable. The colour and form of many of these were alike particularly good. It is unfortunate that more space cannot now be devoted to these *Cattleyas*, they being so well worthy of more extended attention; but it cannot be helped, so we must dispose of them in this curt manner for the present at least.

A richly coloured variety of *Lælia purpurata*, justly named *nobilior*, next claims notice and laudatory expression, for its flowers are amongst the finest we have seen. This form is also represented with other varieties of merit, but these cannot have individual attention. Very charming is the rose-hued form of *L. majalis*, while the *Lælia* *Cattleya* tribe is well shown in *Phœbe*. *Aërides Fieldingi* and *Kimballiana* with *Phaius Sanderianus* each give strength and variety to the collection already so complete in its diversified beauty.

"That plant has been constantly in flower since last Temple show," said Mr. White, pointing to a specimen of *Epidendrum Wallisi*, and what could we do other than make a note of it? There must have been many hundreds of individual flowers, and more remarkable still is the fact that there are yet many to expand. Equally interesting is a plant of *E. Stamfordianum*, carrying thirteen handsome spikes. Going now from fine plants to fine names we have *E. Frederici Wilhelmi*, which may safely be said

FIG. 79.—ODONTOGLOSSUM RUCKERIANUM SPLENDENS. (See p. 454.)

to have a distinct German twang with it. Two more only were noted—namely, *E. bicornutum* and *E. Randi*, both of which are charming.

With one or two others we must draw to a close. *Vandas suavis* and *tricolor* are grown in such a manner as to allow one to say that they are perfect, as also are the *V. teres*. In addition to those enumerated there are numerous kinds that ought to be accorded a position, but space forbids. Let us hope that when next we make a pilgrimage to Burford Lodge we shall find Mr. White less busy, and also that we shall have no Temple show in the foreground to preclude our giving the amount of space that is so thoroughly deserved.—W.

#### DENDROBIUMS AND CATTLEYAS.

PLEASE inform me how *Dendrobiums* showing for flower should be watered, and what temperature ought to be maintained. Must the stems be syringed occasionally? I should also like to know if establishing imported Orchids, or those which get into a bad condition, is a chance operation. I have been trying to re-establish a *Cattleya*, but there is no sign of a root, although I keep the crocks moist. What more can I do?—W. C.

[*Dendrobiums* when showing for flower, especially the section with long cylindrical stems like pseudo-bulbs, ought not to have much moisture, either at the roots or in the atmosphere, until the flower buds can be distinctly seen, after which a little more is necessary. Many of the deciduous species, such as *D. Wardianum* or *D. Bensoniæ*, *D. crassinode*, or even *D. nobile*, must have very little water until the growths are well advanced and are commencing to root. The evergreen kinds, as *D. densiflorum*, *D. thyrsoflorum*, or *D. chrysotoxum*, will need more, or shrivelling of the pseudo-bulbs will take place, thus weakening the plants. The stems during hot weather may frequently be lightly syringed with advantage, especially at closing time, but never until the buds can be seen nor after these are showing colour, the former tending to the production of growths instead of flowers, the latter causing spotting of the blossoms. They must never be syringed on dull days or watered more than is absolutely necessary. A suitable temperature will be 60° by night, 70° to 75° by day with sun heat.

There is a great difference in establishing a newly imported *Cattleya* and resuscitating one that has got into a bad way under

cultivation. The former plants have a good deal of innate vigour, and are simply shrivelled for want of heat and moisture; the latter, on the other hand, has perhaps borne years of ill-treatment and gradually got into a weakened condition, from which they seldom recover. *Cattleyas* and *Lælias* are possibly more difficult to bring round from this condition than any other Orchid, and it is often the best plan to throw them away, procuring healthy plants, which may be purchased at a very reasonable rate. If, on the other hand, your plants are newly imported you have only to carry out the instructions given from time to time in this Journal, and with a little patience all will be well. Very often the growths come in advance of roots, and when the former are a couple of inches in length you may place a little peat and moss over the crocks, watering carefully at first, and screening the plants from bright sunshine.]

#### APPLE BLOSSOM.

Now that signs are becoming apparent of the vegetable and fruit garden being made more than it has been a place for sweet flowers, the need of studying the capabilities of the Apple as a decorative subject is forced on us. Whether employed as espaliers, bushes, or as standards, those selected for borders by the sides of walks will require to be carefully chosen. I planted the sides of a 400-foot walk three years ago, and the trees are now sufficiently grown to be most effective, and at the same time to show that for this purpose one good variety is better than a number. While I write the flowers are studded thickly from base to tip of the little trees, and without break from one end of the row to the other. If more than one sort had been planted, and the various shades of blush and of white chosen, it would have been necessary to have arranged them so as to have the whole mixed in the same way all through; and, above all, to plant those only that would flower simultaneously.

There are, however, some kinds, free and certain croppers, that also stand out in a prominent manner for the beauty of their flowers, and it is from these that particular portions of the garden ought solely to be planted. No varieties are more beautiful than *Lord Suffield*, *Keswick Codlin*, *Manks Codlin*, *Adams' Pearmain*, and *Cornish Aromatic*. The first and last named have large flowers, the other smaller, and each possesses something of the beauty of the wild Crab. There are many varieties with blossoms of a faint blush which are also very beautiful; some of these have flowers of a very large size. Amongst the best I name *Stirling Castle*, *Warner's King*, *Ganges*, *Loddington*, *Ribston Pippin*, and *Tower of Glamis*. Those white, or almost so, are, as a rule, not so effective as the blush kinds, and of course they, in the degree that the white is pure, differ in an essential manner from Apple blossom as a shade. *Ribston Pippin* is sometimes white, *Early Julyan* nearly so, as also *Lord Grosvenor*, but this is not certain every year to flower profusely. *Duchess of Oldenburg* is fine, but the finest white of all is *Devonshire Quarrenden*. Its long shoots are wreathed with clusters of pure white. This, with *Keswick Codlin*, *Lord Suffield*, *Adams' Pearmain*, and *Manks Codlin* are the finest out of a very large number grown here.

I have seen it somewhere remarked that green-skinned Apples possess coloured flowers, and highly coloured Apples white blossoms. This, indeed, obtains to some extent, but it is not a constant rule. *Queen Caroline* and *Lord Grosvenor* are examples of white-flowered varieties, and *Irish Peach* of a blush kind. There are a number of late-flowering sorts that come in towards the end of the Apple-blossoming season. These are certain croppers. They include *Fearn's Pippin* and *Court Pendu Plat*, though their flowers are not effective; *Alfriston*, pretty; *Northern Greening*, the blooms of which when expanded are flat and not cupped like other Apples; *Stewart's Seedling*, a very dark flower; and *Nelson's Codlin*, perhaps the most attractive of all the late-flowering kinds. *Rymer* has the largest blooms of all the Apples we grow; the tree, moreover, scarcely ever misses a crop, but the foliage is so early that the clusters are almost hidden. Some kinds, again, produce flowers that are, to say the least, not very attractive. Among these are such popular sorts as *Worcester Pearmain*, *Winter Hawthornden*, and *Ecklinville Seedling*.

I may be allowed to note the great beauty of the strictly decorative Apple, *Pyrus Malus floribundus*, which has much the darkest flower among these.—B.

#### TWICE TEN THOUSAND TULIPS.

NO; "alliteration's artful aid" is not brought into requisition in the headline for the purpose of effect, nor as a mere freak of fancy, but because it represents a simple fact in condensed form, which, being interpreted in prosaic amplification, means that 20,000 Tulips were seen flowering in the Long Ditton nursery of

Messrs. Barr & Son towards the middle of last week. "Then, why not have said so without so many tinkling 't's'?" That, it may be assumed, is what some sharp critic of the "Saynor" type may be asking. Well, let him try to accomplish the literary feat, and if he succeeds not, to at once admit the necessity of the predominating consonants in the interests of veracity. But, again, it may be urged that the number of Tulips indicated is nothing extraordinary, that nearly as many may be seen in some of the London parks earlier in the season, and more in some market growing establishments, to say nothing of the hundreds of thousands of blooms glittering in the sunshine in the bulb farms of Holland. Granted, but with an important qualification, that they are not the real, true, genuine, English florists' Tulips, of which the Ditton collection numbers nearer 30,000 than 20,000, or probably the largest assortment in the world.

Yet two other questions may be asked. 1, Why are they grown in such numbers? 2, Why are they accorded the specific designation—English? To the first question it may be said that they afford much pleasure to the senior bold bulbarian and to his son Mr. William Barr, who knows them and grows them so well. But this is not all, for others, many others, enjoy them too, and find their way to the canvas-covered beds at Tulip time. Nor is that quite all either, for it would seem as if a compact had been entered into and a determination arrived at to popularise these very distinct, often erratic, certainly beautiful, and in some respects wonderful flowers, and to distribute them far and wide. And why not? The desire is perfectly legitimate. It was, to say the least, a bold step to buy collections, large or small, named and unnamed, at home and abroad, wherever obtainable, when the flowers were, if not on the down grade, certainly *not* in demand.

And then the after labour in marking, sorting, selecting, rejecting, classifying, and naming has been such as few could conceive, and not one man in ten thousand would undertake and carry out as Mr. William Barr has done. Only an actual deep-seated love for the flowers and a sense of duty in attaining the object in view could have impelled him to persevere with untiring persistency year after year, for assuredly he could have spent his time more profitably if profit had been his immediate object. If ever this highest type and most distinguished class of Tulips should become popular and generally grown in gardens the result will be due to the critical acumen, care, patience, activity, and industry of this ardent young Tuliparian more than to any other man; and if, perchance, he should at some distant day find the pursuit a commercial success, it will have been so well won that no one will begrudge him its enjoyment.

But to the second question, Why are these particular Tulips called English? The answer is very simple: Because they *are* English. All the best florists' Tulips at Ditton and elsewhere have been raised by English amateurs. They are the result of fertilisation and years of care in preservation and waiting for the development of their final characters. There are florists' or amateurs' Tulips in their "broken" form, as bizarres, with their golden ground and rich crimson to black markings; bybloemens with their violet, purple, or maroon colouring on a white ground; also the translucent roses, the white of which is more or less covered with the most delicate tracings of rose crimson and soft scarlet—there are varieties of all these, not of English but Dutch origin; but it is rare to find one having the short smooth cup and clear basal disc of yellow or white that invests the flowers with value. Some of the Dutch flamed and feathered Tulips are showy enough, but in most the petals are too long, thin and irregular, while the flakes of colour run down to the base of the cup. These are faults which the true English fancier cannot endure. The clear central disc is the hall mark of excellence, and while the seedlings are in the self stage imparts to them their value and beauty—in fact some of them are so charming that it seems almost a pity they should change. Yet change they will, and do, sooner or later; but no one knows when nor what they will be when the mysterious transformation occurs. This breaking is sometimes a sudden, sometimes a deliberate process. In rare instances the colouring is first seen as if through a cloud; in others one or more petals may gain a year's start of the rest, then comes the period of rectification. Moreover, there is to the trained eye a change in the leaf when the breaking is in process, and then does the florist watch with interest the unfolding of the petals, as he may have a gem of the first water, or on the contrary he may have simply lost a charming "mother" flower by this change.

Just as Tulips are slow in showing their true character, so are the majority of persons who admire the flowers for decoration slow in turn to appreciate their highest attributes. It is as well so, or what would become of the varieties that are lacking in some of the essential properties which the advanced amateur seeks? These, in many respects beautiful fugitives, may be regarded as so many letters in the Tulip alphabet which play an initial part in

floral education. The learner of music does not at first purchase the most costly instruments, but is content with those of moderate price. So it is with flowers, including Tulips, and these are classed to meet the means of beginners in their culture. Time and the superior examples exhibited by experts at shows, or in home collections, do the rest, and the new growers, if their love is strong, gain knowledge as they go, and eventually "break" into florists. There is choice enough in Tulips in the Ditton collection, not alone in the English florists' varieties in the various grades, but in the gay "Darwins"—valuable for borders and cutting, the gorgeous Gesnerianas, the delicate "Picotees," the quaint "Parrots," and sundry others, but while all are beautiful, and have their admirers increasing in number yearly, the refined and correct English florists' Tulips bear the palm, or did a week ago, but they are practically over now. Varieties cannot be usefully named here, as price is a governing factor, and both the cheapest and the rarest can be found in lists which all who may desire can obtain and make their own selections.

## BOTHIANA.

### HABITS.

(Concluded from page 422.)

RELEVANT to the subject of bothy studies, and not unconnected with this, is the necessity of working on a plan—a system. This has been previously alluded to. I refer to it again, as it is a matter in which I should like to assist you. Yet it is one for which no hard and fast lines can be laid down, so varying in character are persons, places, and circumstances, and in all cases, for obvious reasons, it must be more or less of an elastic nature. This is its weak point. To counteract this do not fail to mark progress periodically, weekly or monthly. Pause on these occasions; sit in judgment on yourself and your efforts. This habit of reviewing will be of material assistance, and enable you to continually adjust the burden to your strength and opportunities. Do not let your mind be deprived of that rest which is its due on the seventh day, nor allow the freedom of bothy life to lure you from the observance of those duties you have paid respect to at home.

We are advised not to judge the man by the coat that he wears. This advice will never prevent criticism. Then court the verdict of common sense. Choose some good, honest tweed, suitable to your work and your means. Never allow the want of clothes to present itself to your mind until the means of payment is in your pocket. Have nought to do with the credit system. Pay as you go for everything, and you will pay the least and obtain the most for money. Acquire the habit of neatness in dress, and of tidiness pertaining to your belongings in the bothy. This is too often disregarded, but means much to all concerned.

I do not think a young man is rightly imbued with that respect due to himself and to his superiors, who turns out morning after morning with dirty boots and a general appearance of deshabelle, daily increasing till Sunday brings a grand cleaning up. Clean up those boots every night, lad! Are they wet? Have two pairs, one off, one on. This is economy. You cannot afford to despise economy. Endeavour to have a margin over your expenses, however small.

"If youth but knew what age would crave,  
How many a sixpence it would save."

Ah! but age is a long, long way off, you will say. True, but remember the subject: Habits.

Have you ever heard of the Gardeners' Royal Benevolent Institution? Inaugurate, when bidding farewell to the bothy, your new dignity by becoming a member of it. Do, I beseech you, for your own sake, for pity's sake, of some worn and weary brother, whom you can aid with your votes. Am I anticipating? This is not relevant to bothy life. Then make it so; begin at once and you will not begin too soon. Anyway, let it be a thank-offering when you become a head gardener, and a tangible possibility to lean on in the future. It appeals to the highest and noblest of human feelings. It has a moral claim on your sympathy. I cannot think that you, you that have followed my humble endeavour to assist you in your journey through bothydom, are devoid of this feeling. No, it cannot be! Then you will not refuse.

My bothy career was commenced when a wave of the temperance crusade swept through the county where I had migrated to. I was engulfed in it, became one of "them teetotalers," and remained so for the bothy period. After many years, now, in calm reflection I come to the conclusion this was not a mistake. The subject is one of principle, but embraces a far wider field than that of temperance; that phase of the question may present no temptations to you, nor did it to me. Here I offer

not any advice to you. Take my moral for what it is worth, and draw your own conclusions.

Other points there are I would fain have touched on, but must not further encroach on space. In conclusion, I ask your indulgence for any weak expression of those thoughts which have prompted this; some, indeed, are too deep for words. I can but hope some help has been afforded you to arrive at that stage of the journey where "the high seal of character is set," where the "Olympic prize" awaits you. If so, you can then stand a little aside from the hurry and crush of a restless world, seeing things as they are, not as they seem; neither discouraged by petty vexations nor unduly elated by success. Wisdom shall guide you through the deeper waters you are entering on, whose "ways are ways of pleasantness," whose paths "are paths of peace."—AN OLD BOY.

### BLACK STRIPE IN TOMATOES.

THE affected specimen arrived in good condition for examination, and being a full-sized fruiting example, with some of the fruit commencing to ripen, is characteristic of the Tomato plant as affected with the disease known as "black stripe," which corresponds with "the Tomato rot" of the United States pathologists, an excellent account of which may be found in the 1888 report of the United States Department of Agriculture, pages 339-346, by Mr. B. T. Galloway. The disease, however, was known in this country long before that, our first acquaintance with it being in the year 1873, when we had it very disastrously on some Tomato plants grown in pots in Peach houses, and still worse in 1875 on plants outdoors.

The plant examined was perfectly normal at the roots. There was no trace of eelworm, but on the stem where the radicle issued from the seed there was a dark stain, and it extended upwards, being ultimately lost in the vascular tissues. Following the stem upward the dark stripe or long blotch appeared here and there, being most pronounced at the ties, but beyond the discolouration of the tissue and the destruction of the epidermal cells there was nothing discernible. The hairs, however, were very abnormal and much contorted, the cellulose or cell wall appearing as fine threads, and mentioned, as they must not be confounded with the prostrate hyphæ or filaments of fungi.

Passing on to the leaves, each consisting of several leaflets, we came to the yellow stripes or blotches. On subjecting a section through this to microscopic examination we found the cells permeated by a streaming body, slightly darker in colour than the cell fluid, and easily detected by anyone conversant with cell structure and cell contents. This tissue ultimately becomes brown or black. The streaming is that of an amoeboid-like body, but it is more that of the micro-organism. There is no hyphæ recognisable in these cells, but I have no doubt the micro-organism is the plasma of a fungus, which may or may not at a subsequent stage develop hyphæ, and from this erect filaments or outgrowths, producing the characteristic reproductive organs and seeds (spores). This is a new phase of fungus life, some may say, but it was noticed by the Rev. M. J. Berkeley in 1848, and it certainly is that of a myxomycetes growth, which indicates the evolution of fungi from the slime fungi, so-called, or myxomycetes.

Examining tips of the young shoots we came across the same organism as discovered in Mr. Iggulden's specimen a short time ago, and this is *Plasmadiophora tomati*—the "drooping disease" of the Tomato plant, and known in the case of the Vine as "brownure" or "browning," about which I have nothing "new" to relate, but the procedure given on page 360 will render a good account (to the cultivator) of this micro-organism, and possibly of that known as "black stripe." Indeed, it may ultimately be shown that the "drooping disease" is merely a stage in the development of "black stripe," but the fact remains that "brownure" or "browning" cannot be transformed from a myxomycetes into a fungus. A myxomycetes can only produce a cell—a surrounding wall of cellulose to the contained protoplasm, which emerges as a zoospore; while "black stripe" gives rise to hyphæ within the tissues and to outgrowths from these, which produce conidia, and finally resting spores—the characteristics of a fungus. This indicates that the "drooping disease" as produced by *Plasmadiophora tomati* is not the same as that wilting of the young growths caused by the plasma of the "black stripe fungus."

Passing on to the fruit we find the same plasma or body streaming through the cells. There is no hyphæ whatever, and the whole thing is extremely bewildering. But it is all made clear in the generalisation, namely, the disease began (in this case) at the root (Mr. Iggulden pointed that out some time ago), it passed up the stem, appearing here and there, then became manifest in the leaves and finally in the young growth, these wilting and perishing. The fate of the plant is thus practically sealed, but Nature is strongest in that of reproduction, and the struggle for existence begins between the plant on the one hand and the parasite on the other. The fruit, therefore, shows the "black stripe," the tissue becomes discoloured down to that of the embryos of the future seed of the Tomato plant, and the fruit attains to a certain degree of perfection, but is of no value for useful purposes. The germs—so far as I have been able to ascertain these are confined to plasma—of the disease enter the Tomato seed and attach themselves to the testa or part corresponding or near to the protrusion of the radicle on growth taking place in the seed. Thus the disease is carried over from year to year,

and is in that respect hereditary. This characteristic of the "black stripe" has been pointed out by several Tomato growers in the *Journal of Horticulture*, being confirmed by Mr. Iggulden and now by your correspondent, Mr. Arabin.

Now I will ask your readers to go back with me to the Potato crops in this country before the outbreak (?) of the Potato disease in 1844. I can well remember a disease my grandfather called "dry rot," and what he told me of its disastrous effects on the Potato crops at the latter part of the last and beginning of the present century, and his description of "dry rot" exactly coincided with that I have endeavoured to give of "black stripe" in Tomatoes, the "stripe" being as clearly defined in the Potato apple as in the Tomato fruit. The Potato sets only produced a weak haulm, and often collapsed before any tubers were formed but generally the "dry rot" was confined to a plant here and there which produced a few very small tubers, known in the Humber Valley, both in Lincolnshire and Yorkshire, as "chats." They were perfectly sound. The rest of the Potato crop attained the ordinary development of haulm, but sometimes the tops became brown at the tips, the leaves curled, turned brown, and then black, fell off. The tubers were smaller than usual in consequence, and some of them, usually the largest, had

FIG. 80.—PHLOX CANADENSIS. (See page 447.)

reddish marks in them when cut. Such "sets" sprouted very weakly, sometimes produced no growth above ground after setting, or only grew a few inches high, the plant collapsing by the time it was usual to earth up the crop that had grown properly. The "sets" simply rotted in the ground, and as it was early in the summer was called "dry rot" to distinguish it from "wet rot," which occurred about digging up or after they were placed in the "pies." I use the term prevalent in the Ouse (Yorkshire) Valley.

The disease taking the tops of the Potatoes was the "curl," and it was carried over in the seed "sets" and in the "apple," for we grew Potatoes from seed in those days. Then the "curl" died out as small sets were used.

This malady does not materially affect the small tubers; but it gets into the larger and is carried over from year to year, sometimes very little damage being done, and in others no perceptible mischief happens. But under certain conditions the disease does great injury, and being accompanied by the Potato fungus (*Phytophthora infestans*) is apt to be overlooked. American observers have long suspected this fungus as a cause of great loss to Potato growers in America, and it was put forward last year as a "new" disease. It is nothing more than the British "curl" fungus (*Macrosporium commune* var. *Solan*), and the "black stripe" on Tomatoes is only that form of it called *M. c. tomati*.

As the outgrowths of the fungus are only produced at certain stages,

and not even that in some cases, I will pass over that part, as it is not essential for successfully contending with the disease. This is carried over with the seed of the Tomato, and the thing is to begin with that. This is a very difficult matter, as the fungal plasma is internal; but much can be done by saving seed from perfectly disease-free fruits. It may also be possible to destroy the plasma within the seed by steeping the seed in a solution of corrosive sublimate, sulphate of iron (not sulphate of copper), or even nitrate of soda or kainit. Anyone can test the matter for himself by using (1) corrosive sublimate, finely powdered, 2 grains (apothecaries weight) to 1 gill (quarter of a pint) of water, bearing in mind that this solution is a terrible poison; (2) sulphate of iron, three-quarters of an ounce (avoirdupois weight) to 1 gill of water, allowing the seed to remain in the respective solutions one hour and a half, then remove and sow at once, treating in the usual manner. If, as I anticipate, the plasma of the fungus is within the outer coat of the seed it may take a longer time to reach it; but as a rule the time named is sufficient to effect its destruction, especially when the integument is thin, as it usually is, where the fungus lies dormant.

As regards soil treatment there is nothing better than a peck of air-slaked, or even freshly slaked lime per rod, distributing it evenly and pointing in lightly, or not that when likely to interfere with the roots of the plants. For the part of plant above ground, air-slaked lime, 100 parts, and carbonate of copper (precipitated) one part, thoroughly mixed and distributed over the foliage with a bellows apparatus, so as to coat every part of the plant with the finest possible film, will give a good account of any outgrowths, thus preventing the spread of the disease, also making sure that no fungus whatever can germinate externally and push the germinal tube of its spore into the Tomato plant. If a liquid is preferred, use Bordeaux mixture, half strength.—G. ABBEY.

#### A VISIT TO THE REV. F. D. HORNER, M.A., BURTON-IN-LONSDALE.

BRIGHTLY was the sun shining as we approached the houses wherein were staged some of the most beautiful of Flora's gems. Directly we got inside and viewed the Auricula bloom generally the mind was deeply impressed with the exquisite display of rich tints and soft shades.

The blinds allowed a little sunlight to stream in here and there, lighting up the colours and showing charming variety of tint and depth of colour, though the subdued candlelight of last night's preliminary peep was more favourable to a careful examination of the merits of the flowers, as it was to the due appreciation of their delicious aromatic fragrance.

The season having been such an unkind one the plants were by no means so healthy as is usual at Mr. Horner's, appearing flabby and short of stamina, due to stunted root action. Though the date was May 4th very many of the green-edged varieties were not open; indeed, much of the bloom excepting selfs was not fully expanded.

Amongst the grey edges, Lustre appeared to be the best. The tube perhaps may not be quite so rich as "Lightbody;" but it has more body colour and is a better balanced flower. In addition to a fine truss of Geo. Lightbody, we noticed Lapwing, Fairy Ring, Harbinger, and Hypatia—all excellent.

Of the white edges, Miranda was most prominent, then Luna, Magpie, Bull's-eye, a new seedling—Bean Blossom, and a very promising Heather Bell; with the portly Meiklejohn nodding close by, apparently about to awaken and open his eye.

Of green-edged varieties, a grand truss of the Rev. F. D. Horner was easily discernible, Chloe and Viridiflora (both seedlings of Mr. Simonite of great merit), and T. E. Henwood were in good form.

Mr. Horner this year seems to have struck quite a group of green-edged seedlings of the highest quality, patient and persistent endeavour on the most scientific lines thus being rewarded. We noticed Verdant Green, the Rev. G. Horner (a fine specimen), Bull Dog (a bold dashing bloom), a fine light green Sparkle, Ossian (very good), and a shapely flower that bids fair to prove a regular Adonis.

Amongst his selfs, Mr. Horner had many of high excellence; indeed, one may safely say of his seedlings generally it is difficult to find a second-rate flower. As the trusses were for the most part fully expanded they were very telling amongst the groups of Auriculas. Favourite, a lustrous violet, one specimen we saw, a sturdy plant, carrying no less than sixteen pips, and towering above its neighbours; Melaine, dark maroon; Rosy Morn, a lovely light shade of cherry red; Enchantress, a fine purple; Black Swan, a chocolate brown with a beautiful tube and clear paste; Charmer, velvety red; Iolanthe, purple; and Florence, grand violet, were very conspicuous. Heroine was past its best. This variety gives its best bloom from a maiden plant. We noticed a wondrous light lavender self with a clear round paste, but a wee bit green in the tube; Symmetry, a beautifully formed flower of light rosy purple, on a healthy mealy plant; Midnight, a magnificent blue with a purple sheen, circular paste, and good tube, amongst the latest of Mr. Horner's seedlings.

Considerations of space prevent more than a passing reference to the glories seen in Mr. Horner's Orchid jungle.

As our authority on the Tulip, Mr. Bentley, was one of the party, it is perhaps needless to state that our host's collection of Tulips was eagerly and closely scrutinised, and pronounced well grown and full of promise. Just a touch of colour was seen on one or two buds, and pious

hopes were indulged in that his crack seedlings may be seen at their best on the exhibition table at the National show.

An evening spent round the fireside, where our quartet of florists met and talked over the flowers, descanted on their beauties, condemned the faults of various sorts, dealing first with Auriculas, then with Tulips, next with Carnations, back to Auriculas, and on went the "gossip of the garden," with many a story of the florists of old and their methods, and many new ideas for crossing suggested, memories recalled of florists that were, until it was time to glance again at the pets in the Auricula house ere we dropped into sleep.—C. W. N.

#### CUCUMBERS.

THE resolve at which the Fruit Committee of the Royal Horticultural Society has arrived, to invite the Council to have next year a thorough test trial of Cucumbers at Chiswick, is one that must be commended, although no doubt there are some raisers of new varieties to whom the resolve may give pain. The resolution has been arrived at only because it has been found impossible to deal justly with Cucumbers, seeing that what are no doubt new varieties, yet bear to older ones such exceeding resemblance, it is not possible to say from a cursory notice of the fruits whether they differ materially or not.

But whilst with many growers of these assumed new sorts singularly hazy notions seem to prevail as to what constitutes quality in Cucumbers, samples sent being often of the most ungainly and coarse description, some others have thoroughly realised what is quality in these fruits, and have during the past few years put before the Committee sorts of such exceeding excellence, such unquestioned beauty and quality, that it seems as if little or no room really was left for improvement. I almost think that there can be very little such room, because it is difficult to see where improvement can come in. What improvements there are yet to be considered can barely be in colour, form, length, or beauty of the fruits. It is only in growth or cropping qualities that improvements may be looked for, and it is evident that only through a good trial conducted at Chiswick can these improvements be ascertained.

Some twenty years or more have, I believe, elapsed since a similar trial of Cucumbers took place at Chiswick, hence it is about time another was conducted. It is to be hoped that only recognised good old sorts will be grown, as it is evident for summer uses not a few of the old sorts have been quite superseded. There we should like to see not only seedlings shown for the first time this year, but all varieties certificated or put into commerce during the past ten years. Even with this limitation a large trial must take place. It is hoped that all interested in Cucumbers will do their best to make it a success.

Obviously now that the Fruit Committee has come to this resolution it will be difficult, to my mind impossible, to grant certificates to any new sorts this year. That seems to be the only logical outcome of the proposal. One result of the trial it is hoped will be to give to the Chiswick Gardens greater interest in the estimation of the Fellows and horticulturists generally. Whilst testing of various products should constitute the principal work of the Gardens, it is obvious that this work does not receive at the hands of Fellows one tithe the attention it deserves. It seems perhaps too much to ask of the Committees, but it would be well were it possible for these bodies or portions of them, to meet at Chiswick very much oftener than now. Indeed to keep pace with growing produce it seems as if meetings there once a fortnight during the summer would not be too often to enable what is being there grown to be thoroughly examined and dealt with.

Perhaps there may be some desire expressed on the part of Cucumber raisers to learn what sort of excellence the Fruit Committee look for in new varieties. Well, before any person sends out as new anything they may have raised from seed, they should purchase and grow a few of the recognised best sorts in commerce, and thus ascertain for themselves what existing excellence is. Possibly such a home trial would do very much to help raisers to arrive at more correct conclusions. The more recently certificated varieties have given to us fruits ranging from 15 inches to 20 inches long, and these are indeed long enough for any purpose. Dark green in colour, very smooth and even from heel to point; in fact, as perfect as it would seem Cucumbers apparently can be. It is not possible with such sorts in mind to give any sort of recognition to fruits that even if of fair length are almost of large dimensions, very ribbed, wanting colour, and uneven in form.

Then, again, Cucumbers, if ever so handsome and prolific, may be in the estimation of the Committee too short. Thus one of our most successful raisers exhibited the other day a variety that was without doubt singularly prolific, yet the fruits, very handsome, averaged only 12 inches in length. A better variety for home use perhaps could hardly be found, but it was not long enough for market, and to that test chiefly now are Cucumbers brought. But then with regard to prolificacy, there seems to be no doubt but that Cucumber plants have limited powers of production, short fruits being numerous, long fruits much fewer. The short prolific sorts no doubt are best for winter culture, but still the winter culture of Cucumbers is very limited. Generally we have to regard them as summer products, and in that respect good average length must always constitute an important qualification.—A. D.

## ROSE SHOW FIXTURES FOR 1895.

- June 19th (Wednesday).—York.\*  
 „ 20th (Thursday).—Colchester.  
 „ 25th (Tuesday).—Isle of Wight (Cowes).  
 „ 26th (Wednesday).—Richmond.  
 „ 27th (Thursday).—Gloucester (N.R.S.) and Canterbury.  
 „ 28th (Friday).—Exeter.  
 „ 29th (Saturday).—Windsor.  
 July 2nd (Tuesday).—Diss, Maidstone, and Sutton.  
 „ 3rd (Wednesday).—Brockham, Croydon, Ealing, Farningham, Lee,† and Sittingbourne  
 „ 4th (Thursday).—Eltham and Norwich.  
 „ 6th (Saturday).—Crystal Palace (N.R.S.).  
 „ 9th (Tuesday).—Westminster (R.H.S.), and Wolverhampton.\*  
 „ 10th (Wednesday).—Chelmsford, Farnham, Hitchin, and Redhill (Reigate).  
 „ 11th (Thursday).—Great Malvern (Hereford Rose Society), Helensburgh, Woodbridge, and Worksop.  
 „ 17th (Wednesday).—Derby (N.R.S.).  
 „ 18th (Thursday).—Canterbury (Kent Hospital Fête) and Halifax.  
 „ 20th (Saturday).—Manchester.  
 „ 23rd (Tuesday).—Tibshelf.  
 „ 24th (Wednesday).—Chesterfield and Newcastle-on-Tyne.\*  
 „ 25th (Thursday).—Trentham.

\* A show lasting three days. † A show lasting two days.

I shall be glad to receive the dates of other Rose shows than those named above for publication in future lists.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

## MARÉCHAL NIEL ON THE SOLFATERRE STOCK.

WOULD you kindly name the enclosed Rose? We have in the conservatory here a Maréchal Niel that has been budded many years ago. The circumference is 10 inches 1 foot from the ground, length upwards of 30 feet, and is quite free from canker. It has been in flower since January, and both varieties flower at the same time. The Maréchal Niel grows excellently. I think the result of such a combination should be more generally known. The “stock” flowers come in clusters, sometimes as many as eighteen in one spray, occasionally five or six being open at once, and others in bud. There were some dozens of shoots like the one sent. The Maréchal is now over.—R. W. SMITH, *Raby Castle Gardens.*

[Mr. William Paul, who has seen the samples, says it is quite clear that this is a case of a Maréchal Niel established on a Solfaterre stock.]

## THE N.R.S. SOUTHERN PROVINCIAL SHOW IN 1897.

At the Committee meeting of the N.R.S., held on Tuesday, May 14th, a letter was read from the Town Clerk of Portsmouth conveying the invitation of the Town Council of that borough to hold their southern show there in 1897, and the invitation was accepted with the thanks of the Committee.

## ROSES AT THE ROYAL BOTANIC SHOW.

WE notice in your report of the flower show of the Royal Botanic Society, held on the 15th inst., it is mentioned “Messrs. Wm. Paul & Son, Waltham Cross, came second with a group of little less merit,” &c. This is a mistake, which we shall be glad if you will rectify in your next issue, as we did not exhibit in that class, but were given the highest award for our group of Roses—a silver-gilt medal.—WM. PAUL & SON.

## MARÉCHAL NIEL ROSE UNDER GLASS.

THE system of growth recommended by “W. R. Raillem” (page 406) is the correct one for this Rose, no matter what “H. R. R.” says (page 430) to the contrary. I can speak with confidence, having tried many plans extensively. At a time when I had an important object in view plants budded on strong Briar stems gave the only good and lasting results, and from these I have cut upwards of 19,000 flowers in one season. Grafted plants gave a few flowers, never so good in quality as the others, and for this reason they never made such free growth.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham.*

## EXPRESS GRAPE GROWING.

I HAVE to thank Mr. Innes for his kindly remarks in the *Journal* of May 16th. With much that Mr. Innes writes I agree, but in one point I cannot see as he does. He says, “The only difference in Mr. Thomson’s case and mine was that he did not fruit his permanent Vines and I did, and was rewarded with a crop of first-class Grapes.” Now I see a vast difference in Mr. Innes’ case. He planted his Vines in the middle of August; poor, starved canes, out of 3-inch pots. We planted ours in

May, June, and July, all in splendid condition for planting. They received no check, and did splendidly; all could have borne a good crop the next year if we had wished. I repeat that the remarkable feature in Mr. Innes’ case is, that Vines planted so late, and in such a poor condition, should do so well that they were able to bear a heavy crop the next year. Everything seemed against them at first. Poor little canes out of 3-inch pots, planted late in the season, they yet did so wonderfully well that they bore heavy crops the next season!

We prepared our Vines in the best possible way, had them strong, and splendidly rooted, planted them in good time, and gave them every chance. That they could all have borne a heavy crop the next season is just what we consider the natural result of our treatment; but Mr. Innes’ case is different. The Vines he planted had much against them, and the results he recorded in connection with their vigour, and the crops they bore the very next year after being planted in such a poor condition and so late in the season, are really remarkable. “Market Grower” remarks that the recent articles on “Express Grape Growing” “are of great interest to market growers, showing the wonderful crops that Vines well grown can carry.” I would remark that Mr. Innes’ first article was of greater interest because he showed what wonderful crops Vines, badly grown, could bear the next season after being planted so late as the middle of August. When I say “badly grown,” I am only judging from the description of the Vines given by Mr. Innes himself. Had they been “well grown” they would have been considerably thicker than straws by the middle of August, and 3-inch pots would not have contained them. However, “all’s well that ends well,” and we must regard these Vines as wonderful samples of Mr. Innes’ skill as a Grape producer. “Market Grower” draws attention to a point in Grape culture for market that I have several times referred to when writing to the gardening papers, and that is the vast difference between well ripened and finished Grapes and badly ripened ones. They are as different as possible, and the British public that only knows the taste of an overcropped, badly ripened Black Alicante or Gros Colman can have no idea what a splendid fruit a well-grown Grape really is.

Alicante at best is not a high-class Grape, but Gros Colman can be vastly improved by good culture. If well finished Muscats Duke of Buccleuch, Black Hamburg, Madresfield Court, and others that could be named, are placed before people, then, and not till then, will Grapes be properly appreciated. Of course it may be urged with much reason that cheapness is much looked to by the public, and that if they get Grapes of any kind cheap they are satisfied. Until the public taste becomes sufficiently educated I fear they will be inclined to rest content with badly finished Alicantes and Gros Colmans, when they might have the same in better condition if they knew to encourage the proper culture of these varieties, and to refuse to be supplied with samples of them that contain little of the virtues they might possess if well grown.

Gros Colman is much more capable of being improved by proper culture than Black Alicante, yet even the latter can be made more palatable by good culture, and it should be put before the public in as good a condition as possible. Over-production seems looming in the immediate future in connection with Grape culture, but it would lessen the over-production of inferior quality Grapes if the public were able to discriminate between well grown and badly grown samples. As one who desires that Grapes of all kinds should be supplied to our markets in first-class condition, I hope that the future will see a great improvement in the style of those generally sent forward for sale, and that every year less of the inferior quality of Grapes at present so much in evidence may be placed before the public.

If Mr. Innes will exert himself in this direction he will be assisting to benefit the public at large. My desire is to see them well supplied, not only as regards quantity but quality.—JOHN THOMSON, *Clovenfords.*

[A communication from Mr. Innes did not arrive in time for insertion in our present issue.]

## FRUIT AND EARLY VEGETABLES IN THE CANARY ISLANDS.

THE usual monthly dinner and conversazione of the Horticultural Club took place at the Hotel Windsor on Tuesday evening last week. There was a good attendance of members, the chair being occupied by the Rev. W. Wilks. The discussion after dinner was opened by Dr. Morris with a very interesting address on the “Cultivation of Fruit and Early Vegetables in the Canary Islands for the English Market.” Of these the principal were Tomatoes, Potatoes, and Bananas. Oranges also are cultivated, but at present not to any large extent. Those produced are of a very superior quality, allied to St. Michael, if not identical with it. He described in detail the Tomato culture, the manner of packing, and the arrangements made with the growers for the sale and exportation of the fruit. He also described the method of irrigation, the most essential point of the whole culture in the Canary Islands; the care which was taken, the laws that regulate it, and the way it is supplied. The Tomato has, however, there, as in other places, been subject to disease, which threatens seriously to interfere with it, and therefore he regarded it as simply of temporary culture. The Canaries have been subject to these changes.

Their palmiest days were when the cochineal insect was the great industry. The discovery of the aniline dyes completely extinguished it, as effectually indeed as did the Coffee fungus the chief industry of Ceylon. Dr. Morris stated that there can be no doubt that the fungus

which attacks the Tomato is identical with that which plays such havoc with our Potato, both being allied plants. He also spoke of the cultivation of Potatoes, and stated that the chief variety used was the *Magnum Bonum*. In many places the culture of the Banana had been introduced very successfully. He does not know how it may be in the future, but at present the smaller subjects for garden cultivation, such as Lettuces, have not been attempted.

A very brisk and animated discussion took place afterwards, in which most of the members present joined, especially Messrs. Webber and Monro, who gave some interesting information as to the prices obtained for these articles in Covent Garden. A friend of the latter, who had been a resident in the Canaries, gave some very valuable information with regard to the laws relating to tenure, as bearing upon the production of various vegetables. A cordial vote of thanks was awarded to Dr. Morris for his interesting paper, as also for his kindness in sending samples of the Tomatoes and Potatoes for the dinner; as also to Mr. Webber for some Tasmanian Apples for the dessert. Probably no more interesting meeting of the Club has ever taken place.

## ROYAL HORTICULTURAL SOCIETY.

MAY 14TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters, F.R.S. (in the chair); Dr. D. Morris, C.M.G., Rev. W. Wilks, Mr. A. Michael, Dr. Russell, F.R.S., Rev. G. Henslow, Hon. Sec.

*Wellingtonia with Tumourous Growth*.—Mr. Bunyard sent a specimen of a young plant which had produced a large globular woody growth at the base. It was perforated by some beetle, but this was apparently of subsequent occurrence, and had nothing to do with the cause. A very similar structure had formerly been sent in a *Taxodium*. It was forwarded to Mr. Blandford for further examination.

*Fungi in Soil*.—A sample of soil was received from Mr. Hooper, Cambridge, Waikato, New Zealand, with a communication, stating that the roots of fruit trees which penetrated the places where the fungus appeared to reside became infected, the fungus penetrating the tree from base to summit, and ultimately killing it. It was referred to Kew for investigation.

*Nemophila Seedlings*.—Dr. Masters called attention to a peculiarity in the cotyledons and some of the leaves of this plant—in that the epidermis appears to become detached in places from the underlying tissue, and gives the appearance of white spots, as the chlorophyll becomes invisible.

*Cattleya Malformed*.—He exhibited a flower reduced to its lowest terms in having two sepals only, an anther with two (instead of eight) pollen masses, and no pistil, the "inferior ovary" being represented by a stalk only.

*Rhododendron hirsutum*.—Sir Ed. Loder sent a specimen apparently dying, with the observation that others appear to be in the same condition. Mr. Michael remarked that he had observed how this species is confined to limestone districts, while *R. ferrugineum* is indifferent, and grows both on limestone and granite in the Alps of Switzerland. It is possible, therefore, that the plants require lime, if it be deficient in the garden in question.

*Black Currant "Jaundiced"*.—Mr. Fish sent specimens having a very yellow-green foliage, with a communication of which the following is an abstract:—After referring to several assumed causes—*e.g.*, "sudden changes from heat to cold, drought to drowning, &c."—this case differs from most in the following particulars:—"The jaundice is limited to Black Currants of two or three years of age. The cuttings last year were free from the disease. The field is well drained, and of excellent quality for fruit trees and bushes. I hear at Meldreth that this new disease is more or less prevalent over very wide areas in Cambridge-shire." The best remedy to be tried was thought to be a solution of sulphate of iron, and if this failed only to grow those kinds which appear to resist the complaint—*e.g.*, Black Champion, Lee's Prolific, and the Cut-leaved Black Currant.

*Colours of Flowers*.—Some discussion arose as to the question of the influence of mineral salts in the soil upon the colours of flowers, Dr. Russell observing that many interesting and profitable results would undoubtedly follow from experiments in this direction. The change from blue to red in Hydrangeas was spoken of when they are removed from maritime to inland places, the general experience being that blue specimens grew mostly by the seaside, and were not altogether attributable to iron in the soil. Dr. Russell suggested the use of a dilute solution of ferro-chloride to test the conversion of the red to a blue colour.

*Influence of Salt*.—A further discussion arose on the effect of salt. That on maritime plants is well known, being a cause of succulency in many of them, but the injury due to its presence in the case of S.W. winds has been felt at great distances inland, as at Bagshot, upwards of fifty miles away. Dr. Masters described the remarkable result on a Japanese Maple in Mr. Waterer's grounds, in that while one half of the tree on the leeward side grew vigorously and never flowered, the other half exposed to the wind was greatly checked, and as a consequence blossomed, and so enabled seed to be procured from it.

*Tulip Abnormal*.—Mr. M. Mills of The Gardens, Combe House, Croydon, sent a Tulip of abnormal size and growth, consisting of three peduncles fused together, with leaves 15 inches by 5 inches, the whole being nearly 3 feet in height.

*Primroses, Blue-tinted*.—Mr. Wilson exhibited (at the meeting held on April 23rd, but accidentally omitted from the minutes) a fine bowl

full of the best of the blue-tinted Primroses; showing a great improvement upon the original forms when first raised.

*Photo of Fig*.—Dr. Masters showed a photograph of a Fig, possibly *F. Isiela*, *Roxb.*, with its roots forming a perfect network over the stem of a Mango. It was taken in a grove near Lanowlee, Western Ghats, by Mr. G. Marshall Woockrow, College of Science, Poona.

*Rosa multiflora, Photo*.—M. Vilmorin sent a photograph of a dwarf plant of this Rose, the seed of which was sown on January 15th, and the plant was in blossom on April 11th.

*Tendrils on Vines*.—Dr. Masters showed the results of his observations on the occurrence of tendrils on branches of Vines containing seven leaves in succession; only certain of the leaves had tendrils opposite to them, but there is no rule as to which should have none. Of seventeen examples, three leaves and one leaf had tendrils five times, or about 30 per cent. Tendrils occurred with four leaves, two leaves, or not at all, twice, or about 12 per cent. In no case did every leaf have a tendril, nor did six out of the seven ever have one at all.

## ARGON.

AS I see no possibility of saying anything on this subject calculated to please Mr. W. Dyke, I beg to simply direct his attention to a few facts.

1, I did not state in the original article on "Plant-Forming Elements" that "argon enters into the composition of plants," but that "the elements derived from the air are carbon, hydrogen, oxygen, argon, and nitrogen" (page 332).

2, No definite statement has been made by me that "argon is found in plants" (page 435).

3, I have not "quoted" or said that "plants in the first instance lived in an atmosphere of nitrogen" (page 435), but "Evolution points to a primitive atmosphere of absolutely pure nitrogen, there not being any free oxygen, and with only such carbonic acid and water as were evolved from volcanoes, which extended over the greater part of the earth's surface before the first organised beings came into existence" (page 412).

To all the statements given in the articles on the "Plant-Forming Elements" (page 332 and 354) and in that on "Argon" (page 412) I strictly adhere.

Professor Ramsey has not said that argon does not exist in plants, but he says that "probably the process adopted was not suitable for detecting the new element." It took quite a century to detect argon in the atmosphere after its presence had been indicated by Cavendish, and that a similar element obtains in the nitrogen of plant analysis is well known to "anyone with the most elementary knowledge of chemistry." What is this element but argon—extremely inert nitrogen?—G. ABBEY.

[We prefer discussions by practical men on subjects with which they are directly acquainted to second-hand arguments on argon that can be of small service to our readers.]

## FRUIT FORCING.

*Vines.—Houses of Ripe Grapes*.—When the Grapes are quite ripe fire heat will only be needed to prevent the temperature falling below 60°, admitting of a free circulation of air, and allowing a little constantly to insure a change of atmosphere and prevent the deposition of moisture on the berries. Do not allow the border to become very dry, but keep it moist and mulch with rather dry litter from which the manure has been removed, and the material sweetened by exposure for a few days to air and rain. The mulching being thin air will enter the border, evaporation, however, being lessened, and the uniformity of the moisture preserves the roots in good condition. Moderate atmospheric moisture is not injurious to the Grapes but highly beneficial to the foliage, which must be kept clean and healthy. Allow a little lateral growth, as this will favour root action and tend to the preservation of the principal leaves, while if anything happens to them it will afford an outlet for the sap, and prevent the starting of the principal buds. If the Grapes are required to be kept some time place a double thickness of herring nets over the roof lights, especially where Black Hamburgs are hanging, in order to enable them to keep their colour. Foster's Seedling and Buckland Sweet-water are also benefited by the netting, as brownish streaks sometimes appear on the golden skin, and more or less deteriorate the appearance.

*Early Muscat Houses*.—Vines of Muscat of Alexandria started at the new year will be swelling the fruit rapidly, and the berries on the upper side of the bunches exposed to the direct rays of the sun are somewhat liable to become scorched or scalded, hence a single thickness of pilchard or a double thickness of herring nets placed over the roof lights breaks the fierce rays of the sun sufficiently to prevent the injury, whilst not materially interfering with the admission of light. The netting also obviates any danger of damage to the foliage where the panes of glass are large and the means of ventilation inadequate for effecting the requisite change and amount of air in very bright weather,

and the preservation of the foliage in good condition is essential for the perfecting of the crop and the formation of the buds for next season's bearing. Ventilation should commence with the acting of the sun on the house, so that the Grapes will be heated equally with the surrounding air, then there cannot possibly be any scorching, a moderate amount sufficing, by which there is no loss of solar heat; as by increasing the ventilation with the advancing sun the temperature will rise to that required, it being kept at 70° to 75° by artificial means, and 80° to 85° or 90° from sun heat, reducing the ventilation so as to retain this amount during the afternoon. Muscats like a generous regimen, profiting by top-dressings of phosphatic, potassic, and nitrogenous manures, such as obtains in the advertised fertilisers, using 2 to 4 czs. per square yard at intervals of three weeks or a month, washing in moderately after duly moistening the soil and applying the fertiliser. This does little good on dry soil, and leaving it on the surface means the evolving of ammonia from the organic matter and its dissipation in the atmosphere, whilst the other substances cannot be diffused through the soil. Allow a fair amount of lateral growth, as this insures a due extent of root activity, supply of nourishment, and its appropriation. Damp the paths and similar surfaces in the morning and at closing time, or towards evening, allowing the temperature to fall to 65° through the night.

**Succession Houses.**—The Vines being in full growth, and the weather more or less sunny, fire heat will only be necessary to prevent the temperature falling below 65° at night, though it may recede to 60° on cold nights, and to maintain it at 70° to 75° by day. Admit a little air as soon as the sun acts powerfully on the house, but maintain it at 80° to 85° from sun heat, allowing the temperature to rise to 90° or 95°, closing the house at 85°, then sprinkling the paths and borders. By admitting air early in the morning the moisture condensed on the foliage during the night is dispersed before the sun's rays act powerfully, and thus scorching is obviated.

**Watering.**—When the known requirements of the Vines or borders are acquired from long experience, stated intervals for watering answer in all but the variable circumstances that upset the calculations. Thorough supplies are usually afforded at starting to insure the moistening of the border materials to the drainage. This is necessary, but it may be overdone, and any approach to soddenness does considerable mischief, as root formation is not favoured by wet, but healthfully moist soil. All that is needed is water sufficient for the solution and diffusion of the stored matter, for rootage in Vines does not precede but follows the breaking of the buds. If a dressing of some approved fertiliser is given at the start it will be in proper condition for absorption by the roots when these push fibres freely, and another before the Vines come into flower will push the Grapes ahead after setting. During the first swelling more need for water arises, as the foliage has a large expansion, and is fully capable of performing its functions. Stimulating food may then be supplied, such as top-dressing of the advertised manures or waterings of them in liquid form. When stoning, phosphates or mineral matter is most needed, afterwards nitrogenous substances favour the increase of the flesh and juices, but when colouring commences phosphates, potash, and reduced amount of nitrate or ammonia are most beneficial. The amount to be given depends upon circumstances, soil, conditions of Vines and crop. Loose and light soils require more manure than compact and strong, weakly Vines more frequent and greater amounts than sturdy and vigorous, heavily cropped than lightly burdened Vines. Likewise in watering the supplies need to be regulated by circumstances, always making weekly examination of the border in the case of light soil, and fortnightly where heavy, and supplying it whenever required, but only then. Over-watering is as bad, or worse, than under-watering, but neither are good, there being more failures from insufficient than over-watering where the borders are properly constructed and the drainage complete. Watering twice a week in the case of Vines with roots in restricted borders, and once a week for those that have a good run of border, is not too much after the Grapes are formed until they are changing colour. Some loams are naturally very loose, sandy, or gravelly, and they have the usual opening materials added, as lime rubbish and charcoal, which makes them still more sieve-like, the consequence is the greater need of moisture. Retentive soils will require water far less frequently, but in no case must there be any lack at the roots throughout the swelling period.

**Late Vines.**—The latest will be in flower in most places. Maintain a temperature of 70°. Shaking the rods once or twice a day will be sufficient in most cases to distribute the pollen effectively, but in that of the shy-setting varieties artificial fertilisation must be resorted to, going over the bunches carefully with a camel's-hair brush. All large berried, free-setting varieties, such as Gros Colman and Gros Guillaume may be thinned whilst they are in flower, and with those that are liable to have closely set berries it is a good plan to thin before the flowers expand, as a practised eye can tell which buds by their vigour are likely to set, and the removal of the weaker strengthens them wonderfully. Whilst the Vines are in flower do not pinch or stop the laterals, but fairly set remove the needless growths, so as to prevent overcrowding, not allowing more to remain than can have full exposure to light.

**Planting Growing Vines.**—Those raised from eyes in February or March, and grown in pots or turves, may from now to the early part of June be planted out, watering with tepid water to settle the soil about the roots, mulching the surface with a couple of inches thickness of short rather lumpy manure, and shade from bright sun until they become established.

**Figs.**—**Early Forced Trees in Pots.**—When the first crop fruits are all gathered remove the loose portions of previous mulchings, and supply well sweetened rich compost, which will induce the formation of

active feeding roots, and assist in the perfecting of the second crop. If the trees have become infested with red spider or scale cleanse them by means of any approved insecticide. Syringe twice a day so as to keep down red spider. Although a second crop is serviceable, a good first supply is much more valuable, therefore be content with a few fruits, or none at all if the trees have been severely taxed by the first crop. Growth after this period will require frequent attention to stopping and training, as the best Figs are always produced on sturdy young shoots fully exposed to light and air.

**Planted-out Forced Fig Trees.**—The fruits on trees started at the commencement of the year are swelling for ripening, and must have a higher temperature and drier atmosphere, but care must be taken to afford an abundant supply of tepid liquid manure and to syringe the foliage regularly, as any sudden check is against the fruit finishing well; besides, a dry atmosphere induces attacks of red spider. As the fruits ripen it will not be advisable to wet them, nor is it necessary, as atmospheric moisture can be secured by keeping the borders and paths properly damped, and the moisture arising from this can be prevented condensing on the fruit by maintaining a steady circulation of air with moderate fire heat. When grown in a hot dry house the trees soon become infested with red spider and scale, and as a consequence the ripening period is shortened, the trees resting because exhausted, consequently the second crop is puny, rusty, and unsatisfactory; but trees treated liberally, ventilated freely, exposed fully to the sun, and syringed so as to keep them clean bear successionally. Planted-out trees succeed best on the extension system, allowing the leading shoots to extend without stopping until they reach the extremity of the trellis, when they are cut away after fruiting to make room for others succeeding them, some fruit being also borne on spurs, which are encouraged where there is room for them, not otherwise. Thus the trees are kept constantly well furnished with bearing wood, always of a character affording the finest fruits. The temperature should be kept at 60° to 65° at night, 70° to 75° by day artificially, and 80° to 85° or 90° from sun heat.

**Unheated Fig Houses.**—The trees are showing abundance of fruits, and these, with favourable weather and management, afford an acceptable supply of ripe Figs in August and September. If in restricted borders of suitable materials they will require copious supplies of water and due syringing. In cloudy weather an occasional syringing suffices, but in bright effect it every afternoon, and sufficiently early to allow the foliage to become dry before night. Ventilate early, insuring a free circulation of air, for it is important that the leaves be well developed. The temperature may rise to 95° or 100°, but in a close atmosphere the Fig produces nothing but leaves. Train the young shoots a good distance apart, stopping unruly growths, but late stopping is not good, as it results in a number of shoots which may not ripen properly, even when duly thinned, and it is on well matured growths that the Figs are borne. Secure, therefore, firm short-jointed wood, and allow the points to grow up to the glass without touching it, in which position they will form a number of Figs ready for swelling in the spring.

**Melons.**—In houses, when the fruit is cut from the earliest plants the old stem may be shortened to a strong shoot near its base, removing as much of the old soil as can be picked out from amongst the roots, adding fresh in its place, strong, rather lumpy, and well pressed down, giving a good watering. If a moist atmosphere is maintained and the plants are syringed in the morning at about 4 P.M. they will soon start freely, showing fruit in much less time than by starting afresh. If they have healthy growths they need not be cut down so closely, but laterals taken at suitable distances and the old shortened or cut away, the fresh laterals will show fruit at a few joints of growth. If, however, the plants are affected with canker or from carrying too heavy a first crop, a deficiency of water or attacks of insects, are enfeebled, it is better to remove them, thoroughly cleansing the house, placing strong plants in ridges or hillocks of fresh soil. Maintain 70° as the minimum temperature, though 55° or even 60° will do no harm when the nights are unusually cold and the days bright, 70° to 75° being secured by day artificially, admitting air at the latter and increasing it with the sun heat, allowing an advance to 85° or 90°, closing at 80° to 85°, yet so early as to raise the temperature to 90°, 95°, or 100°. Keep abundance of moisture in houses containing young growing plants or those swelling their fruits, gently damping the foliage, walls, and floors, closing about 3.30 P.M., or as early as is safe. Feed plants liberally that have their fruits swelling, not allowing them to suffer through insufficient supplies of water, and afford weak liquid manure. Fertilise all pistillate flowers daily, ensuring a somewhat dry condition of the atmosphere, not using the knife during that period, but pinch out the points of the shoots at one or two joints beyond the fruit. Earth plants that have set their fruits, and examine them frequently for the removal of superfluous growths, not allowing these to interfere with the principal foliage. Shade as little as possible, and only to prevent flagging.

# THE BEE-KEEPER.

## APIARIAN NOTES.

### STRONG SWARMS.

I NEVER heard of any bee-keeper finding fault with large swarms of bees, but, on the contrary, speaking always in favour of them. Yet many persons do not even give hives a chance to throw off large swarms by keeping bees much too small for their requirements. Large hives very often swarm as early as undersized ones, and as a matter of sequence are more able to gather greater quantities of honey than smaller ones.

Admitting that small hives may swarm a few days earlier than full-sized ones, the former may have from 1000 to 1500 hatching daily, while the latter will have from 3000 to 4000 daily. At a week later it will have 20,000 more than the small hive to go with the swarm, and as many more which constituted the hive before swarming; while the old stock and after swarms are proportionately larger, and consequently in a good season more profitable.

It is entirely owing to bringing up my hives to full strength, regardless of the fate of queens, that I have secured the big yields of honey I have from time to time recorded, and that, too, at times when undersized hives' yield were nil. It is an easy matter for those who have not given the different methods a fair trial to do so the coming season, but to bear in mind the queens must be those of the year previous. It is no use working with queens two years old; they may be fair, but not (unless in exceptional cases) good, at least I have never found them so.

### PUNIC *versus* BRITISH BEES.

For reasons previously explained, my apiary in the future shall be stocked with Carniolan bees only. Pushing forward that state of matters I gave away many of my Punic queens with bees during the autumn of 1894.

There is perhaps not much in that to the casual observer, but the trait came in well when a lecturer appointed by the County Council lately advised bee-keepers to keep the old British bees, as "they were the best." One auditor supported him in this theory, because his British bees were doing by far the best. He was rather surprised and taken aback when I informed him the bees he was boasting of were not British but Punic, North African bees, and those I gave him in the autumn. These facts apply, in my opinion, to all who say they have the British bees, and to every place in the United Kingdom.

### WIND AND WATERPROOF COVERS FOR HIVES.

An effective wind and waterproof roof for hives not provided with these may be made with two slates and a piece of zinc ridging. The zinc is bolted to the slates, which ought to be large enough to give proper protection, and the zinc while holding both together affords ventilation at the apex. The weight of the slates is sufficient to resist a very high wind, and may be said to be everlasting. Some made thirty years ago are as good as ever they were.—A LANARKSHIRE BEE-KEEPER.

### SEASONABLE NOTES.

IF not already done, arrangements should at once be made for obtaining full benefit from the honey flow when it comes. A careful examination must be made of all stocks, and a note made of those that are intended for working sections of comb honey, and those that are required for extracting purposes, as it is much the best plan to work them separately. I never extract honey from the brood comb, and strongly advise others to follow the precedent.

As it is not advisable to place all your eggs in one basket, it is better to work for both comb and extracted honey than to produce it only in one form. In some districts there is a great demand for well finished sections. In others honey in the comb is a drug and almost unsaleable. Extracted honey is often more useful for domestic purposes, consequently a more ready sale is obtained if neatly bottled in 1 lb. glass jars, which may be made attractive by using the producer's own label. A greater weight of honey per hive can be obtained by extracting than is usually had by working sections, but as the latter is of more value per pound the result is much the same. The reason sections take longer to finish is that every cell must be sealed over or they will drip. This is the objection that dealers have in handling sections, whereas the combs that are extracted from are taken from the hive when partly sealed over; the honey is ripe, and a day or two is saved, which is a great consideration in a season like last year, when the honey flow only lasted about a week. The 1 lb. section I consider

preferable to any other. A few years ago sections to hold 2 lbs. of honey were often used, but latterly the smaller size has been in most request.

The one-piece section with the four bee way is to be preferred, as it is a very easy and quick process to prepare a quantity for use. Commence by folding them into shape, and as the ends are dovetailed a slight tap with the hammer will make them secure. If the wood is very dry they will sometimes break at the corners during the folding process, but if slightly damped there will be no danger from this cause. Some bee-keepers prefer to use whole sheets of foundation for sections, but except for exhibiting purposes this is quite unnecessary. All that is needed is to fix a strip of foundation to the top of the section to act as guide comb for the bees to work from, as the midrib of comb is always less where the bees make it themselves than when foundation is used.

If the sections are prepared and placed in crates ready for use when required, it will be an advantage and a saving of much valuable time, as with favourable weather strong stocks in forward districts should soon be ready for supering. At the present time it may appear rather premature to speak of supering bees, with the wind blowing a gale from the north-east, doing much damage to the fruit trees that are in full bloom, and the temperature only a few degrees above freezing. Should the threatened frost come it will do a great amount of damage, as all vegetation made rapid growth during the spell of hot weather recently experienced.

Verily, bee-keepers, as well as gardeners, require a great amount of patience and forethought. Even then their best laid schemes may be dashed to the ground in a single night. But let not bee-keepers forget the busy workers who are short of stores; they can at any rate make them secure by covering them and giving a little thin syrup whilst this spell of bad weather lasts.—AN ENGLISH BEE-KEEPER.

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Propagating Her Majesty Pink (*Sussæ*).**—You can pull off the pipings and insert them singly in thumb pots in sandy soil, and place them in a hand-light or under a bell-glass outside. The most certain way is to turn the plant out of its pot and plant it outside, then layer the growths the same as you would Carnations. A quicker way is to insert the plant in a cool frame, and then layer the growths in it, lifting and potting singly, or planting out when rooted.

**Rooting Tree Carnations (*Haywards Heath*).**—It is immaterial whether the cuttings are cut just below a joint or whether they are split. Some follow one practice and some another. Very much depends on the cuttings; if short and somewhat soft they are best cut below a joint, if fairly firm it does not matter. The principal thing is to insert them in sandy soil and keep them practically air-tight until they are rooted. Water when inserted in sandy soil, and shade from bright sunshine.

**Peach Tree Growths Blistered (*Somerset*).**—The shoots and leaves are badly diseased, being what is known as "blister." It is caused by a fungus (*Saphrina* or *Exoascus deformans*), the leaves ultimately withering and falling. The recent cold weather has been singularly favourable to the development of the fungus, it not being possible for it to exist under certain atmospheric conditions; hence it is culturally avoidable by means of a glass coping and protective material in front, such as scrim canvas or wool netting, being so contrived as to be let down or drawn up as required on the appearance and departure of frost. This would be the best thing, and should be provided ready for another year, and then you may defy the fungus. This year you may remove the worst infested leaves and the young shoots, but not defoliating the trees too much at once, yet gradually, so as to remove every part of the diseased leaves and shoots, and when fine weather comes the young growths will not be affected. As the saying is, the trees will grow

out of the disease; the reason is the conditions under which the fungus cannot thrive are produced naturally, or artificially by protection from cold winds and frost.

**Aleppo Pine (Somerset).**—This is, no doubt, the species to which you refer. Its botanical name is *Pinus halapensis*. It is of very wide distribution, being found in the Mediterranean region from Portugal to the Levant, throughout Western Asia, on Mount Hebron in Palestine, and other parts of Syria. Sow the seeds in sandy soil containing a good amount of vegetable matter in a cold frame, shading for keeping the soil uniformly moist until germination is effected, then admit light with free ventilation preparatory to full exposure of the plants.

**Bossiaea tenuicaulis (Young Gardener).**—Several *Bossiaea*s are in cultivation, but they are comparatively rarely seen except in large collections of plants. Yet they are well entitled to a foremost position among the best of the Australian Leguminous plants, as they are mostly free in growth and astonishingly profuse flowerers. Two of the most handsome and useful are *B. linophylla* and *B. tenuicaulis*, the latter being represented in the illustration (fig. 81). *B. linophylla* is a slender shrub with linear leaves and bright yellow flowers, which are produced from

FIG. 81.—BOSSIAEA TENUICAULIS.

May to September. *B. tenuicaulis* is rather more straggling in habit, with ovate leaves, the flowers being rich yellow streaked with red. It also flowers earlier than the other—usually during April and May. Both these, like all the others, thrive in a greenhouse temperature, a compost of peat and turfy loam and sand, with good drainage, being all the attention needed.

**Black Stripe on Tomatoes (St. Julien Arabin).**—Your letter describing the progress of the disease is extremely interesting and valuable as showing under what conditions the fungus (*Macrosporium tomati*) thrives best, and what are inimical to it. You are quite right; you began too late. Steps ought to be taken with the seed, not using any but from perfectly healthy plants, disinfecting all before sowing, then practising spraying with Bordeaux mixture before the plants come into flower, and at fortnightly or three weeks intervals afterwards. Mulching with strawy matter must be avoided, and heavy dressings of stable manure should not be applied to the soil. If you do not like Bordeaux mixture use the lime and carbonate of copper mixture, or you may employ anti-blight powder or McDougall's patent anti-mildew or fungus powder, the thing being to begin in time and follow it up. The disease usually first becomes noticeable when the fruit is about half grown, appearing at the blossom end, but often at the stem end, as a small blackish spot or streak, that increases in size as the Tomato develops. The tissues beneath the spot are destroyed by the fungus, so that the fruit becomes flattened where affected, and the inside of the Tomato is blackened. The fungus also appears on the stem, but mostly

on the fruit, usually involving the whole fruit and plant (more or less), producing a shivelling and blackening, which, as you say, is appalling. See page 457.

**Packing Forced Strawberries (A. S.).**—There are a variety of methods of packing Strawberries for market. Some salesmen prefer them packed in round and square punnets; others in boxes that will hold about 1 lb. We generally pack in boxes of various sizes. Some are 18 inches in length, 1 foot wide, and 2 inches deep; others 12 by 12 by 2; others 2 inches narrower; others 10 by 10 by 2; others 10 by 8 by 2; and others 1 inch narrower. We place at the base of the box a layer of cotton wool, or very fine willow shavings, the thickness varying according to the size of the fruit. Over this a sheet of tissue paper, then a layer of Vine leaves or Spinach, or failing these each fruit in a Strawberry leaf on the tissue paper. Lime leaves are capital at this time of the year, so are the soft leaves of Spinach; over the top a good layer of leaves, and then the lid. The box must be full.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (W. C. B.).—*Bryophyllum calycinum*. (R. J.).—1, *Spiraea prunifolia flore-pleno*; 2, *Doronicum caucasicum*; 3, *Myosotis dissitiflora*. (Obeido).—The *Spiraea* is a variegated form of *S. japonica*; the other specimen is *Cyrtodeira rosea*, if it has rose-coloured flowers. (O. E.).—1, *Ornithogalum longibracteatum*; 2, *Salix lanata*; 3, *Ame-lanchier Botryapium*. (F. G. S.).—*Solanum Seafortianum*. (P. W.).—1, *Thunia alba*; 2, *Odontoglossum citrosimum*; 3, a poor form of *Cattleya Mendeli*; 4, *Oncidium macranthum*. (G. I.).—1, *Dendrobium thyrsoiflorum*; 2, *Cattleya Mossiae*, good variety; 3, *Odontoglossum Pescatorei*. (F. P. V.).—1, *Iberis sempervirens*; 2, *Cheiranthus alpinus*; 3, *Kerria japonica flore-pleno*; 4, *Stachys lanata*; 5, *Corydalis lutea*; 6, *Doronicum austriacum*. (M. T. D.).—*Statice profusa*. (H. M. H.).—The specimens you send are seedling variations from the common Holly, *Ilex aquifolium*. (J. M.).—1, *Lycium europaeum*; 2, *Veronica gentianoides*; 3, *Anemone sylvestris*; 4, *Tiarella cordifolia*; 5, not in flower, perhaps *Heuchera sanguinea*. (J. Harris).—The specimens you send are florists' varieties, not species of plants—see above.

### THE MANAGEMENT OF YOUNG STOCK.

LAMB weaning is a reminder to us of the special care required in the treatment of young stock, and of the frequent applications which we have for help in this matter. For the lambs when weaned tempting food, and abundance of it, at some part of the farm where they cannot hear the bleating of the ewes, is the best thing. In most springs they run forward on the Swedes, clearing off the green tops, and making no inconsiderable mark on the roots, also long before weaning time. This year Swedes left out in the open were very generally destroyed by the great frost. Some good work was done in folding the ewes and lambs first of all on Swedes from covered heaps, and then on Rye, some crushed Oats being used in the feeding troughs for the ewes, and some mixed corn crushed for the lambs.

It is customary on some farms to separate all small or weak lambs from the others, and to sell them. We do not do so, but prefer leaving the whole of them together for the present, and to keep all of them going briskly by folding on Sainfoin or Tares, and still giving a little corn in troughs. In due course we shall select a certain number of the best ewe lambs to add to the breeding flock; all strong wether lambs will be reserved for autumn and winter folding, and the smaller lambs will be sold. We are convinced that early maturity is a golden maxim in flock management, pointing literally to golden profits.

Calves have to rough it, and suffer more from exposure and a low diet than any other stock of the ordinary farmer. To keep them healthy, well nourished, and going briskly they require perfect shelter and a perfect dietary, altogether different to that which they generally have. At the present time there are numbers of calves to be seen out on pastures, taking their chance with older stock, or if kept separated they receive no special care other than some gruel twice daily. It may seem and is right enough to see them now out on the fresh succulent herbage by day, but at night cold wind and cold showers prove very trying for them. It is altogether better to shut them in a snug yard or hovel at night, and so to avoid any risk of exposure to cold and wet. Every home farm should have one or more calf hovels, each having its separate yard and paddock.

Corrugated iron sheeting answers admirably for sides and roof of the hovel and for sides of the yard. It is cheap, durable, and affords perfect shelter, and the calves are then kept thoroughly in hand, nothing being left to chance. If they still have milk it is thickened with oatmeal; if it is separated milk, some boiled linseed may be used to replace the missing fat, but we find a liberal mixture of oatmeal and crushed Oats answers well, and always avoid cake or linseed bills if we can. No animals repay one better for careful tending, for good food, shelter, and kindly treatment than calves, and yet there are none among which losses are heavier from negligence and mismanagement.

Young pigs may be helped early by having a slip board in the side or front of the enclosure in which they are kept with the sow, so that as soon as they begin feeding they may have access to some milk thickened with oatmeal or barley-meal. If kept going with this milk and meal after weaning they are soon out of hand, 1 lb. of meat for 5 lbs. of meal being the usual result. Breed well, feed well, and shelter well tells

with por'ers to a certain profit, either at 60 lbs. or twice that weight. Our experience is decidedly in favour of the lesser weight provided the porkers are really first-class. Dealers are then eager enough to have them; it is the second and third-rate animals which they dislike, and which pull down market returns. Keep them on a clean dry floor or one well littered with dry litter. They often suffer from cramp, caused by having to lie down on a damp floor. Dairy farmers having to buy all their straw and litter are very guilty in this matter, and suffer from losses accordingly. Cold and wet are the two things to avoid, and when young animals are shut in let it not be forgotten that they require a dry floor as well as a dry roof.

### WORK ON THE HOME FARM.

Wonderful was the heat and brisk the growth of everything till the 14th, when the weather became somewhat colder. Rye rushed up into ear in southern counties, where it was being mown for green fodder. Never have we found this crop more useful both for mowing and sheep folding. The dry weather has been highly favourable for keeping down weeds among crops and for clearing land, but it has rendered root-sowing somewhat difficult. As ploughing of late-folded land has been done harrows and drills have followed closely, and where land has been thrown up in ridges seed-sowing has been done and the rollers passed over before the soil became too dry for the work. On fruit farms horse and hand hoes have been kept going briskly. The land is clean, and from Strawberry fields to orchard trees the abundant blossom gives promise of an abundance of fruit. Caterpillars are rampant on the trees, and sprayers are already in full action.

As the ewes are separated from the lambs for the weaning they are turned on some rather poor upland pasture for awhile, and then all over-age ewes, and those with faults or blemishes rendering them unfit for breeding again, are separated from the flocks, and they will go into folds on pasture early in the autumn, to be brought into saleable condition, and at the same time to do some good to the land. It is quite useless folding such old sheep on roots to pull out their teeth on food which they cannot consume. Much better is it to reserve the roots for the hoggets. See that the sound ewes, or rather the breeding flock, has all due care bestowed on it now and onwards through the summer. After the shearing has been over sufficiently long for any wounds inflicted by the shears to heal, and after, not before the weaning, let the ewes be dipped in Cooper's dressing to destroy ticks and other parasites, and then let them have really good grazing for the three or four months intervening before attention must again be given to breeding matters. All such matters of detail depend as to time and locality, there being a difference of months between flock work on arable and dairy farms, and between north and south.

### REMARKS.

- 12th.—Hazy, close, and frequently cloudy day, threatening in afternoon, and a slight shower between 4 P.M. and 5 P.M.  
 13th.—Hazy and cloudy early, generally sunny during the day, but cloudy at times and rather close.  
 14th.—Warm, and a little hazy, alternate sunshine and cloud.  
 15th.—Generally cloudy till noon; sunny afternoon.  
 16th.—High wind and alternate cloud and sunshine.  
 17th.—Overcast almost throughout and chilly, spots of rain in evening and showers at night.  
 18th.—Rain from 1 A.M. to 5.30 A.M., overcast; with occasional spots of rain till noon, occasional gleams of sun after.

More than 3° between the maximum in the shade on the 12th and on the 17th. Monday, 13th, was warmer than an average July day, and May 17th had about the temperature usual at the end of March. This cold spell in May is an almost invariable occurrence, and generally occurs in the second or third week. Happily this year the nights have generally been cloudy, and so we have not yet had actual frost.—G. J. SYMONS.

# DICKSONS' NEW IRISH ROSES.

ALEX. DICKSON & SONS

Have pleasure in announcing for distribution in May a further series of their

**CELEBRATED PEDIGREE ROSES,**  
HELEN KELLER (H.P.), Rosy Cerise, superb .. 10/6 each  
MAVOURNEEN (H.P.), Silvery Flesh, first rate 10/6 ..  
MARJORIE (H.T.), White, Pink centre, very pretty 7/6 ..

ALSO  
The Best of the NEW FRENCH & BRITISH ROSES.  
Descriptive Catalogue Post Free on application,

**NEW (H.T.) ROSE BELLE SIEBRECHT** (Mrs. W. J. Grant).

Raised by ALEX. DICKSON & SONS, distributed by SIEBRECHT and WADLEY, New York.

The most valuable introduction of the past ten years. This superb variety has gained the highest awards wherever exhibited in Great Britain and America, chief among these being the National Rose Society's Gold Medal.

Valuable alike for exhibition, decorative, and forcing purposes. No collection, however small, complete without it.

PLANTS IN POTS IN MAY, 10/6 EACH.

Full Descriptive Particulars Post Free on application to  
**ALEX. DICKSON & SONS,**  
ROYAL NURSERIES,  
NEWTOWARDS, CO. DOWN,  
SOLE AGENTS FOR EUROPE.

**C. COX,** Horticultural Engineer,  
TUNBRIDGE WELLS.

THE HERCULES.—Design Registered.  
**TENANT'S FIXTURE PORTABLE SPAN-ROOF CURVILINEAR CONSERVATORY OR GREENHOUSE**

No brickwork required. These houses are made of the best materials, painted four coats, and glazed with 21oz. clear sheet glass, a flat painted stage is fixed on each side and one end, and slatted path up centre.

CASH PRICE, Carriage Paid to nearest Station in England & Wales, within 100 miles of Tunbridge Wells—fixed free:—

## FLORISTS' FLOWERS AND HARDY BORDER PLANTS.

FORBES' NEW CATALOGUE for 1895 is enlarged to about 150 pages, and very materially improved, embracing everything—new and old—worth cultivating in the way of FLORISTS' FLOWERS and HARDY PLANTS, with accurate descriptions and prices. Copious notes as to their origin, how and where best to grow, a full index of the common or popular names of HARDY BORDER PLANTS, and a vast mass of other valuable information that cannot be had elsewhere, which renders this the BEST, MOST RELIABLE, and COMPLETE CATALOGUE ever issued on this popular class of plants. Free on Application.

**JOHN FORBES,** Nurseryman,  
HAWICK, SCOTLAND.

## JACK FROST

Has caused many losses that can be made good in an easy and cheap manner by purchasing the following Bulbs and Plants, which I can strongly recommend as being first class:—

**BEGONIAS, SINGLE,**

20,000 Grand Bulbs, Mixed Colours, finest ever offered at the price. 3s. per dozen.

**PELARGONIUMS, SHOW & DECORATIVE.**

Fine Plants in Best Kinds, 6s., 9s., and 12s. per dozen.

**ZONAL PELARGONIUMS,**

Best Kinds only. 6 for 2s. 6d., 12 for 4s.

**IVY-LEAF PELARGONIUMS.**

A very Choice Lot. 6 for 2s. 6d., 12 for 4s.

**DOUBLE PETUNIAS,**

Extra fine New Kinds. 6 for 3s. 6d., 12 for 6s.

Send for Catalogue, Free.

**H. J. JONES,** Ryecroft Nursery,  
HITHER GREEN, LEWISHAM.

## STRAWBERRIES.

Special low quotations for quantities for market growing. In small pots for fruiting first year. Open-air runners very cheap. All the leading varieties, new or old.

**FRUIT TREES**  
OF ALL KINDS. SEND FOR LIST.

**JOHN WATKINS,**  
Pomona Farm Nurseries,  
WITHINGTON, HEREFORD.

## Journal of Horticulture.

THURSDAY, MAY 30, 1895.

### HARDY FLOWER NOTES.

SO fair and beautiful are the hardy flowers in the bright days of early summer that it is a constant delight to be among them. Long as we waited for winter to depart we have since been recompensed with no churlish hand, and since early in May the attractions of the garden have been almost bewildering.

Tulips, which seem to have stolen from the most radiant sunsets their brilliant hues, up-reared themselves above the galaxy of gems with which they were surrounded. Alpine Phloxes have been mounds of bloom from white through lilac and blush and pink to the bright red-purple of one of the hardiest of all—P. setacea atro-purpurea. The great clumps of Alyssum saxatile compactum which, when winter was but passing away, seemed forlorn and holding forth little hope of beauty, blossomed forth into masses of purest gold. White Saxifrages and purple Aubrietias have allied themselves together and combined to take our hearts by storm. Violets and the more brilliant Violas nestled here and there among other flowers in the borders or stood boldly out from more conspicuous places on the rockwork.

Specially noteworthy among these have been Violas William Niel and that sweet and refined flower Pride of Etal. Primulas and Auriculas, too, have made charming pictures; the varieties of P. Sieboldi, of which I have now some good clumps, having been specially favoured with calm weather to enable them to yield us longer pleasure by their elegance. A few of the best Alpine Auriculas, the gift of an old florist whose acquaintance I have the honour of having, have been very charming; although grown in a border and not cultivated in a frame in the orthodox manner. These are flowers to study and not to glance at; refined creations of the taste and skill of men who have done much to advance the noble and gentle art of gardening. But besides these flowers, which from their numbers attracted a greater share of attention, there have been many others which in the eyes of the true lover of flowers have been no less delightful, and one would like for once to cast aside all considerations of space and utility and roam from flower to flower, saying a little about

each as we roamed, and telling something of its beauty and its wants and ways. Yet this cannot be done; and as one has so often to do in this world of ours, we must check our inclinations and limit ourselves to speaking of a few.

The Tulip, "the fop of the parterre," as the poet unworthily dubs it, must as usual at this season come in for more particular remark, not, however, to trespass on the domains of those versed in the English varieties nor even to detail the beauties of the brilliant early and late forms which are so decorative in almost every garden, but to speak as usual of some of the less known species or varieties.

One of those which has attracted considerable notice here bears the name of *T. Kolpakowskiana*, and, like *T. Kaufmanniana*, comes from Central Asia. It is to be feared that its name is neither euphonious enough nor brief enough to commend this Tulip, which must thus stand or fall on its own merits, and it is likely enough that these are great enough to enable it to make its way into our affections—and our gardens. In its early stages of growth a feeling of disappointment is almost inevitable. The plant is "lanky," and after the flower-stem attains some length it bows down towards Mother Earth like some other Tulips but in a more pronounced way. While at this stage it is a somewhat odd looking object, and when it becomes erect and the flowers begin to open one's admiration is but faint. In a few days, however, its beauty is better recognised and we can admire its bright flowers with their acutely pointed segments. The flowers are a good size, and vary in colour from scarlet to yellow, the red form being almost self-coloured. It grows nearly 2 feet high, and the flowers on their long stems seem to follow the course of the sun. It came into flower with me in April and lasted for some time in bloom.

Another Tulip which has been longer in my garden and which I originally received from Bithynia is *T. Biebersteiniana*, which, as has been well said, resembles *T. sylvestris*, but is smaller and less robust in habit. It is bright yellow inside, the outside being duller in colour, and opens out flat in the sun, when open looking rather like a tall *T. persica*, although hardly so attractive as that graceful little species. *T. Biebersteiniana* does not appear to open much before one o'clock, even in full sun. I have watched it for several days together, and this has been about the time at which the flowers expanded. It grows to nearly 1 foot in height, and seems to be suited for a permanent place in the border or rockery.

A few notes on such pretty Tulips as *Buonventura*, *Picotee*, *Gesneriana alba marginata*, *Golden Beauty*, and others must be deferred until another time.

A rather attractive looking plant on one of the rockeries has been *Vesicaria utriculata*, one of the "Bladder Pods" or "Bladder Seeds." This is a perennial which grows about 1 foot high, and has racemes of bright yellow Wallflower-like flowers. It is rather a pretty plant, and when the flowers are over the inflated seed pods are interesting. The leaves are smooth and bright green, the lower ones being somewhat ciliated. *V. utriculata* may be increased by seeds or division, and will grow in ordinary soil in the border. It seems, however, to be more attractive on the rockery than in the border. Although introduced from the South of Europe as long ago as 1730 it is but seldom seen, and is worthy of a little more attention than it has hitherto received from those who care for hardy plants. *V. græca*, another species, is occasionally met with as *Alyssum utriculatum*, and is thus liable to be confused with the one under notice. *V. arctica*, a North American species, I have not yet had the pleasure of seeing.

Several visitors to my garden have lately been much attracted by a little *Fritillaria*, of which our generous friend Mr. Edward Whittall of Smyrna kindly sent me a number of bulbs. Few of the *Fritillaries* are showy plants, but many of us confess to some admiration of them, and look on them in much the same light as Mr. Benson seems to do in his poem, "Fritillaries." They are, in truth, "rare outlandish things for such as love them," but mostly having the fault that the prettiest markings are inside, and that

the flower has to be turned up to see these. The species I am now speaking of is not, however, "spotted like an ocelot's skin," nor even "streaked like the banded viper," to quote Mr. Benson again but is of almost a sea green outside and a peculiar greenish yellow inside. The flower is more cone-shaped than most of the *Fritillaries*, and its colouring makes one almost wonder wherein its attractions lie. Still attractions it has, and ladies seem to admire it, which is surely a sufficient answer to any expressions of disapproval. I suppose the name of *citrina* has been given to this Snakeshead Lily on account of the interior colouring, although it is hardly of the shade that one usually associates with the word. *F. citrina* cannot thus be said to be attractive to the multitude, and yet it is but faint praise to say that it is more pleasing than a considerable number of the plants of the singular genus to which it belongs. I do not know how widely *F. citrina* is distributed, as no mention of it appears in my works of reference. Some bulbs of this species collected in Samos came in 1893, but like many other *Fritillaries* this season these established bulbs did not flower, and those which flowered were sent me in 1894. Several of my friends with whom I have correspondence have a similar experience in the way of disappointment with the non-flowering of many of the Snake's-head Lilies this year. I understand Mr. J. G. Baker is the authority for the specific name of *F. citrina*.

The many persons who have been experimenting with the *Oncocyclus* Irises may be interested to learn the result of another season's trial of these singularly beautiful flowers. It is, I am sorry to say, an unsatisfactory report that I have to submit, as the only one likely to flower is *I. lupina*, which flowered here last year, and is now open. This seems a more robust and satisfactory grower than the majority in my garden. Of the others *I. lupcens*, *I. paravar*, *I. Gatesi*, and *I. Helenæ* seem the best growers, the first two being hybrids, raised by Professor Michael Foster. *I. atropurpurea* and some others seem to be going back instead of gaining in strength. After the flowering season they were kept quite dry until October, when the lights, which had been placed over them, were removed.

During the severe frost they were covered with litter, which was removed when the frost had quite gone. I have seen several Irises of this section in other gardens this year, and in all these the results are decidedly unsatisfactory. I suppose we must, however, brace ourselves for a fresh effort in hope of being able to overcome the mysteries which baffle those who wish to grow these flowers in our northern lands.

I had intended to say something about the results of my experimental planting of *Calochorti*, but this must be deferred from considerations of space. Some are in flower and others are in bud, so that soon several of these attractive *Mariposa* Lilies will add to the pleasures the garden yields.—S. ARNOTT, *Dumfries*.

## FOOD REQUIREMENTS OF THE GRAPE VINE.

MUCH has recently been written in the *Journal of Horticulture* on "Grape Growing," but so far nothing has been said about the food requirements of the Vines, and the best manures to apply to suit their wants. Being a good time of the year to apply top-dressings, either of natural or chemical manures, to Vine borders, it would be advisable to see which are the best substances to use for this purpose, for many Vines are partly ruined through heavy cropping, and being insufficiently supplied with the necessary ingredients to finish the crop, and to produce suitable wood for fruiting the following year.

It has been shown in the *Journal of Horticulture* ("Plant-forming Elements") that certain elements are essential for the growth of plants. Which of these are needed most by the Vine? This can only be shown by an analysis of the Vine and its fruit. One ton of Grapes will yield on burning 18 lbs. of mineral matter or ash, which show the following selected constituents:—Potash 60 per cent., phosphoric acid 16 per cent., lime 15 per cent., magnesia 5 per cent. The manurial requirement of the Vine to produce 1 ton of Grapes is potash, equal to 19 lbs. of sulphate of potash; phosphoric acid, equal to 10 lbs. of mineral superphos-

phate; lime, equal to 5 lbs. of carbonate of lime; and magnesia, equal to 3½ lbs. of sulphate of magnesia. The nitrogen contained in 1 ton of Grapes is 8½ lbs., equal to 54 lbs. of nitrate of soda.

The wood on the Vines sufficient for the production of one ton of Grapes (I am speaking of laterals only) would weigh about 200 lbs., and requires for its formation nitrogen equal to 8 lbs. of nitrate of soda, potash equal to 2 lbs. of sulphate of potash, and phosphoric acid equal to 1 lb. of mineral superphosphate. The leaves when weighed would be about 130 lbs., and would require nitrogen equal to 3 lbs. of nitrate of soda, potash equal to 1 lb. of sulphate of potash, and phosphoric acid equal to 1 lb. of mineral superphosphate.

To produce a ton of Grapes in theory would require 65 lbs. of nitrate of soda, 22 lbs. of sulphate of potash, and 12 lbs. of mineral superphosphate; but from a practical point of view much more would be required. It has been shown by experiments that never more than 60 per cent. of the manure applied becomes available for the crop. The compound which ought to be in excess of the actual requirements of the Vine is the phosphoric acid, for it combines readily with some of the compounds of the soil to form insoluble phosphates, which are of very little value as plant food.

Farmyard manure is not suitable as a top-dressing for Vine borders, the amount needed to supply the necessary quantity of food being so great as to make its use impractical where large numbers of Vines are grown, for 1 ton of the best farmyard manure only contains about 12 lbs. of nitrogen, 12 lbs. of potash, and 6 lbs. of phosphoric acid, and this would only become available for the plant by the slow decay of the manure.

Undoubtedly the best results are obtained at the present time by the judicious use of suitable chemical manures, for they are concentrated, easy to apply, and can be given in a soluble form, which is very essential when we know that nearly the whole of the food constituents of the Vine is taken from the soil before the berries begin to colour. The manures I mentioned were only to show the requirements of the Vine, and may be substituted by others for some soils with advantage. For sandy soils kainit could take the place of the sulphate of potash, 100 lbs. being used to supply the necessary amount of potash, for it is an advantage to use this manure on sandy soils, because of the property it has of absorbing moisture; it would be better to use half the amount of nitrate of soda and substitute for the other half dried blood. On stiff clayey loams 42 lbs. of sulphate of ammonia could be used with advantage instead of the nitrate of soda.

It should be remembered that for the successful use of a chemical manure the Vine border must be in a good condition, that if the soil be of a sandy character it will not retain plant food like a clayey soil, consequently will require more frequent dressing of manures, and that it is always better to apply them in small dressings and often rather than in large quantities at any one time.

Perhaps a few remarks on the amount of chemical manure to use, and the best time to apply it, may be of use to many. If the soil be of a sandy character, poor in organic matter, manures like guano and kainit (2 lbs. of the former to 3 lbs. of the latter) will have the best effect. The guano will supply the nitrogen and phosphoric acid, and the kainit the potash. On sandy soils rich in organic matter the following will be a good mixture:—1 lb. of nitrate of soda, 2 lbs. of superphosphate, and 3 lbs. of kainit. The nitrate of soda to supply the nitrogen, superphosphate the phosphoric acid, and kainit the potash. The amount to use in both cases is 1½ oz. to the square yard, every week from the formation of the shoots to the colouring of the berries, when all feedings should cease.

On loamy or clayey soils the following will be found a more suitable mixture:—2 lbs. sulphate of ammonia, 6 lbs. superphosphate, and 1 lb. sulphate of potash, to be applied at the rate of 2 ozs. every fortnight during the period of growth above mentioned.—W. DYKE.

## CROWDING, THINNING, AND ASSISTING CROPS.

WE are always more or less at the mercy of the weather, and so are all who practise horticulture in any part of the world, but all the same those persons succeed the best who adopt the best methods. Take the case of Potatoes. Plenty of the men know they are acting foolishly in crowding the plants in the way they do, and they are also aware that miserable little sets are a mistake.

Very rarely, if ever, are really heavy crops obtained from crowded rows, and if the shoots come up thickly I should advise an early drawing of some of these weakly growths. The heaviest crops are invariably had from extra strong branching haulm, only one or two stems springing from each strong set planted. It is at the ends of the rows where the best crops are usually found. A loose, deep root run is most favourable to the production of

Potatoes, and if the ground was lumpy when the planting was done extra pains should be taken in fining it down afterwards. Canterbury, or two-tined hoes, are excellent for this purpose. This hoeing checks the growth of weeds, breaks up the clods, and lets in the warmth and air, and those who take this extra trouble may reasonably expect better crops than those who do not. A dressing of soot applied before the first hoeing would not be wasted, but a very light surfacing of nitrate of soda would be even more effective on medium and light soils.

Will the bouillie Bordelaise, or preparation of sulphate of copper and lime, ever become popular as a dressing to prevent the Potato disease? I think not. There is too much ceremony and bother in the preparation; yet the Warminster experiments, which cost but 12s. per acre and gave an increased yield of from 3 tons to 5 tons per acre, must be considered most satisfactory. For smaller plots Mr. Robert Fenn's remedy, a powder known as anti-blight, is much to be preferred. Mr. Fenn distributes this over the haulm as often as needs be by means of a hair sieve. I shall use it extensively, and the Malbec bellows will be the means of distribution. Lime alone seems fairly efficacious against Potato and kindred diseases, but two parts of this to one of sulphate of copper in a powdered state is more effectual. There is yet another preparation that is likely to be effective against Potato disease as well as mildew generally, and this is recommended by a French expert, M. Louis Lipière. It is known as lysol, is prepared in Germany, and briefly described as an alkaline liquid readily soluble in water. I intend spraying it over Potato haulm twice during the season, the first time about the third week in June, and again a month later. It will be applied at the rate of one pint of lysol to 30 gallons of water, and I calculate the cost of two dressings of a 20 perch breadth of Potatoes will be about 3s. This means a heavier outlay than would be the case if the lime and copper mixture was used, but there will be far less ceremony about it and less likelihood of clothes being spoilt, and if we only arrest the progress of the disease I shall expect crops considerably enhanced in value accordingly.

Turning to other crops. With the medium to heavy soils it is of the greatest importance that the surface be kept free and open, and where possible cracking should be anticipated, as it is more easily prevented than cured. Directly the rows of Onions, Carrots, and such like could be traced hoeing ought to have commenced, whereas many growers delayed this important work till the ground became too hard to be stirred. If hoeing were done before weeds are plainly discernible, and with far greater frequency than is customary, there would be a marked improvement in the progress of the crops, a fine loose surface preventing the loss of heat and moisture without excluding the air, while weeds would never have a chance to become a nuisance. Where the hoe cannot be worked—that is to say, between small plants, the surface can be prevented from cracking by means of a strong pointed stake.

The overthinning of root crops results in coarseness, while if the plants are left in a crowded state the other extreme follows—poor produce. What thinning is necessary ought to be done while yet the small plants draw readily—that is to say, when they will neither break off short nor, in coming out, greatly disturb those to be left. Caught at the right time the work can be done much more expeditiously than it could be later on, and the results be more satisfactory in other respects.

Crowded rows of Peas already present a yellow appearance. The midseason and late varieties ought certainly to have good room, or they fail to branch and crop continuously. I find it next to useless to preach thinning out, but the rows would in many instances pay for this timely attention. Unless the haulm branches the crop is so soon over that it scarcely pays for the cost of staking. It is much the same with Runner Beans. An intelligent cottager whose garden it is a pleasure to walk through adopts a very different method of growing Runner Beans to that generally in vogue. Instead of sowing his seed in rows he prefers to sow in patches about 3 feet apart each way. Three plants are eventually left at each station, and as many strong stakes used. From these few plants he obtains abundance of pods, and very frequently takes prizes from growers of repute.—W. IGGULDEN.

## FLORAL FACTS AND FANCIES.—10.

DURING what has been called the fighting period of English history, our ancestors, or at least some of them, took more notice of the appearances of Nature than we perhaps suppose, and they frequently connected the return of certain flowers with persons, or events. Even upon those who paid little heed to the notes of birds the sonorous cry of the cuckoo made a decided impression, hence several flowers that opened just about the time it was first heard came to be associated with it—for instance, the Arum or Cuckoo

Pint and the Cuckoo Flower (*Cardamine pratensis*) to which I have already referred. Many of the flowers of May were also dedicated to the Virgin, because this was regarded as her month, so that it will always be an open question, when the old name of a flower is a compound of "lady," whether it alludes to the fair sex generally or to Our Lady in particular. Then the Cuckoo Flower is the Lady's Smock as well. A friend wishes to know why. Possibly the name arose from the display made amongst the grass by its white blossoms, especially along the banks of streams, where people sometimes laid their linen to bleach. Some correspondent of a scientific journal has suggested that "Lady's Frock" would be an improvement! Two pretty varieties of this flower that flourish in moist borders are a rosy purple and a double lilac.

The Marsh Marigold, also Lady's Bud, was called Cuckoo Bud too, flowering, says an old botanist, "when the cuckoo doth begin his pleasant notes without stammering." In our day it usually blooms before the cuckoo is heard or the Virgin's month arrives. 'Twas later perhaps when the winters were colder, on the average, than now, and yet old records tell of spring flowers being picked earlier than we usually get them out of doors. It has been said that the large golden flowers are suggestive of "desire for money," not an uncommon peculiarity in all ages. An old belief was that the cuckoo ate flowers to clear his voice. Amongst these the true Sorrels were mentioned, especially the Wood Sorrel, which, with several other names, had that also of Cuckoo's Meat and of Alleluia, because presumably it was coming into flower about the time this was sung in the churches. Possibly the oxalic acid these plants contain might be good for any throat. Formerly a green sauce made from them was eaten with fish. The evidence seems conclusive that the Wood Sorrel is not the Shamrock of Ireland, though some have argued for it. A species of Clover is probable, and as the Wood Sorrel is a symbol of "joy" it is not specially appropriate to the history of Erin.

Yet another flower of cuckoo name is the Ragged Robin (*Lychnis flos-cuculi*). We infer that arose from its being seen in flower just when the cuckoo is noisiest; but we have garden species of *Lychnis* or *Campion* which bloom through the summer, so, too, does the white *Campion* of hedgerows, with an evening fragrance like that of the *Petunia*. Some folks have fancied in the Latin name an allusion to the use of the down of a *Lychnis* for lamps; 'tis more likely to have arisen from the brilliancy of the flowers. We are told the Ragged Robin represents "wit," and no doubt this article is quite as frequently associated with ragged attire as with stylish dress. "Enthusiasm" is the meaning of the purple and scarlet varieties we see in gardens. Allied to these are the species of *Silene* or *Catchfly*, and, owing to the propensity of the leaves to ensnare small insects, in floral language they have a sinister meaning. The plants generally tell us of "snares," and a white *Catchfly* is symbolic of a traitor or betrayer. Curious is the legend of their classic name. We read how the wise goddess *Minerva* had an attendant—*Silene*, whose duty was to obtain flies for her owl. But one day she caught him napping instead of fly hunting, and she changed him into a plant which should continue to catch insects in all the ages.

Pinks and Carnations form an important group of garden flowers related to those just mentioned, and their many varieties have had numerous meanings given to them, only a few of which I can notice. The name of the genus, *Dianthus*, is significant of the regard in which the flowers were held at an early period—flowers that had something divine about them, and people often infused them in wine to extract a flavour resembling their aromatic perfume. Evidently the old name of *Gillyflower* given to our familiar native species was only a perversion of that of the month July, when the flowers were mostly in bloom. Near the end of the sixteenth century the first garden *Carnation* arrived in Britain from Poland, the flesh-like hue suggesting the name. Good old *Parkinson* in 1629 reckoned that he had about fifty sorts of *Carnations* and *Pinks*, and the *Carnation* became for many years the more popular, so that in 1702 *Rea* could enumerate 360 sorts, but shortly after our Scotch friends gave the *Pink* a new start. As a flower it has favourable meanings attached to it; people used to say figuratively that a person was the "pink of perfection," and a garden *Pink* of that colour represents "pure love;" while a white *Pink* is both a token of "beauty" and of "ingenuity," some say, and the mountain variety tells of "aspiration;" but "refusal" is implied by a variegated *Pink* or *Carnation*. The tall variety of the latter shows "dignity," a deep red *Carnation* is a symbol of "sorrow," and in a yellow one we see "disdain." It is probably owing to its rarity that one native annual, the rosy tinted and curious *D. prolifer*, has received no special meaning; but the wild *Castle Pink*, that mounts high on venerable walls, serves as a reminder of "courage." Many are the memorial specimens of it that have been taken from *Rochester Castle* and *Fountain Abbey*.

What shall we say about the *Harebell*, or *Hairbell*? Here we

have somewhat of a puzzle, but we can start with the fact that the plant originally called *Harebell* was not any of the *Campanulas*, it was the familiar *Bluebell* of woods, the wild *Hyacinth*, *Scilla nutans*. If we ask, "Why was it so named?" the probable explanation is, that it was prompted by the abundant growth of the species in coppices where hares were often seen, rather than by the notion that it furnished them with food. When the name was applied to the other group, which is also possessor of that of *Bluebell*, we cannot ascertain; and the spelling is debateable, the advocates of "harebell" think the growth of the flower suggested a comparison between them and the timid quadruped, but the supporters of "hairbell" point to the hairlike character of the stalks generally. Others yet think it may have been "airbell," because the *Campanulas* have something aerial about them; this we can hardly consider as more than a fancy. Cultivated in gardens they are often called *Canterbury Bells*. The particular species that seems to be best entitled to that name is *C. trachelium*, the *Nettle-leaved Bluebell*, long ago observed in profusion about *Canterbury* and other parts of *Kent*. "Acknowledgment" is put down as its meaning, and it acts certainly as if it had an acknowledged right to spread, for I have noticed how it multiplies on waste ground where it has got possession. *Clare*, the poet, tells us it was once a favourite trick with boys to introduce glow-worms at night within its purple bells. It was the *Throatwort* of our ancestors, and considered to be a good remedy for hoarseness.

One of the earlier species grown in gardens (perhaps *C. persicifolia*) was called the *Virgin's Violet* 300 years ago, *Viola Mariana*; and the dwarf *C. alba* appears to be the species that was known in France by the name of "Nun of the Fields." This, and other kinds that are white, are said to represent "gratitude;" but the blue and purple *Campanulas* tell of "submission" or "grief," the drooping flowers of most kinds suggesting the idea. No one disputes that the *C. rotundifolia* is the "bonnie *Bluebell*" of *Scotland*, though abundant also in the south; then the odd name of *Venus's Looking-glass* is believed to have been first given to our native *C. hybrida*, since then it has been transferred to several garden varieties. In the *Rampion*, *C. rapunculus*, we have one of the tribe which furnishes an edible root, formerly cultivated as a winter salad.—J. R. S. C.

#### DISBUDDING PEACH TREES.

THE Peach tree being generally grown on the extension principle, a great deal of disbudding is required on healthy free-growing examples before the number of shoots is reduced to the proper limit. In this operation, like all others, there is a right and a wrong way of performing it. Some few years ago I saw a gardener disbudding his Peach trees; the growth of the shoots were 5 or 6 inches in length, and these he was pulling off wholesale, and very often a long strip of bark from the branch as well. This is undoubtedly a wrong way, for it would be a serious check to the trees to be denuded of so much foliage at one time, and the force expended on these useless shoots ought to have been concentrated on those required for the following year's fruiting.

Disbudding should be commenced early, say when the growth has extended about an inch or so, or even sooner, the growths then being very numerous. It should be done gradually, the fore-right shoots and those growing towards the wall may be rubbed off first, the others by degrees, until sufficient only are left for furnishing the bearing wood for the following season. A few extra may be allowed in case of accidents. A great mistake is made by leaving too many, some of which would have to be cut away at the winter pruning. No more should be allowed than can receive the full benefit of the sun and obtain abundance of light and air; then we may expect, other things being equal, firm well-ripened wood in the autumn, which we all know is one of the great secrets of success in fruit-growing.

It is a common practice to leave at the extremity of the current year's fruiting wood a growth for the purpose of drawing up the sap to the fruit. This shoot is stopped when a few inches of growth is made, if it is not required for the extension of the tree. Another growth is left as near to the base of the shoot as possible, to be laid-in for fruiting the next season. All the shoots between these two are removed unless the growth is a long one, when more will be left; but this will depend in some measure to the distance allowed between the main branches.

My own practice for the last four or five years has been rather different, as I am inclined to think that it is not a good plan, in all cases at any rate, to remove the whole of the growths between those left for the following year's fruiting. In disbudding our trees all growths at right angles to the wall are of course taken off in the ordinary way, but instead of removing all the others not required for furnishing the tree some of them are allowed to grow a few inches, and then stopped at the third or fourth leaf, and all subsequent growths pinched at one leaf. Should these be found to make the tree too dense, as the main growths extend some of them can be reduced, or cut away altogether. These are cut clean off when the trees are pruned or in the autumn, so that the light and air may have free access to the wood that it is necessary to retain. I do not suppose that this is anything new, but mention it to ventilate the subject. My reason for working on these lines is because I think the fruit swells more evenly and quickly in its early stage; and

in young trees that are likely to produce very strong wood, which does not as a rule give the best results, it allows more outlets for the sap.

In conclusion, a word about disbudding young trees. I have seen cases in which too many branches have radiated from the centre of the tree, and so closely together that no young growths could scarcely be laid in between them. This is a mistake that can very easily be made, unless attention is given to training when the tree is quite young. The branches may be trained closely together at first, but in a year or two the wood should be laid-in in such a way that some of the smaller branches may be removed and cut off close to the stem; the growths on these can be stopped at the third or fourth leaf, and a few more may be allowed on branches that it is intended should remain to take the place of the temporary ones when the latter are cut away. As the tree increases in size subsidiary branches should be trained from the main one, and in such a way that they will not be less than 1 foot apart.—J. S. UPEX.

### LINARIA MACEDONICA.

THE correspondent who sends flowers of this plant will be glad to know that many species of Linarias, or Toad-flax as they are often called, make charming plants when grown in pots for a cool house. The genus being a large one, including both hardy herbaceous and annual kinds, it is rather difficult to make a selection; but *L. macedonica* (fig. 82) is highly ornamental, and might be used with good effect. It commences to bloom in early spring, and continues for a long time. Like most of the Linarias it is of easy culture, requiring only some rich soil and a light position in a cool house or frame. It freely reproduces itself from seeds, growing about 18 inches high, and flowers profusely in a short time. The flowers are of a bright orange colour and very attractive.

### IN A SCOTTISH MANSE GARDEN.

I AM writing this article for the *Journal of Horticulture* on the 20th of May, a day which last year was fatal to the hopes of horticulturists, and especially of rosarians in many regions where plants were much exposed. What a contrast we have been experiencing to-day. To sit in this garden beneath the lustrous leaves of the wide-spreading Sycamore, and contemplate the glories of the early summer flowers—the classic Narcissus, the Viola, the Myosotis, and fragrant Auricula; while the odour of the Sweet Briar ever and anon comes floating to my consciousness is surely the purest and sweetest experience that mortal man can know. What affluence of blossom there is on the Apple, the Pear, the Cherry, and the Plum! Conspicuous among these are the Morello Cherries, which look as if they were covered with a shower of snow. On such a day as this I feel inclined to echo in my heart those beautiful words of Alexander Smith, one of the truest poets and most thoughtful essayists that Scotland has produced—

“Daisies are white upon the churchyard sod,  
Sweet thoughts the clouds lean down and give.  
The world is very lovely. O, my God,  
I thank Thee that I live!”

Though this memorable day, now fading into twilight to the music of the merle and the passionate thrush, has been one of the most beautiful within the range of my remembrance, its immediate predecessors have not been equally blessed with brightness and peace. North-easterly winds have of late been our frequent experience, too often touched at night with the bitterness and stern severity of frost. As a natural consequence, that interesting transformation has been in my garden very seriously affected—the development of the flowers into the embryonic fruit. The Early Rivers, Black Eagle, and Werder's Cherries have suffered most because more greatly exposed than others to the northern blast. For these at least a more benignant atmosphere has come too late. But, on the other hand, the Pitmaston Duchess and Early Crawford Pears (the latter of which is preferred by Dr. Hogg to Citron des Carmes) the stately Czar and Early Rivers Plums, and most of the Apple trees have providentially escaped. It is quite possible that the imperfect evolution of the Cherries I have mentioned, and their manifest susceptibility to adverse atmospheric influences, may be to a large extent attributable to the fact of their somewhat recent introduction. When more strongly established they will doubtless exhibit greater hardiness of constitution and more absolute assurance of productive strength.

Rose trees are fully a fortnight later than they were last year. The earliest here will be *Rosa Harrisoni*, the Austrian and Persian Yellows, the Penzance Briars, *Gloire de Dijon*, A. K. Williams, Crimson Bedder, *Gustave Piganeau*, *Souvenir d'un Ami*, *Anna Olivier*, *White Lady*, and *Margaret Dickson*. All of these will be in bloom this summer before *Maréchal Niel*, usually the earliest variety in my garden. Though growing on the south wall this grandest of Noisettes has been at least a month later than usual in unfolding its delicate virginal leaves. On the other hand, and as if by way of compensation, the Oriental Lilies are farther advanced than ever I have seen them at this period of the year. This is especially true of *auratum*, *excelsum*, *candidum*, *chalconicum*, *Szovitzianum*; *speciosum Kraetzeri*, *Henryi*, and *giganteum*, of which the last-mentioned Lily has a stem 8 inches in circumference, and is

making magnificent growth. It would be worth growing if only for its foliage, which is exquisite in shape and exceedingly effective, more glittering than that of *Aralia Sieboldi*.

This is the result of my horticultural observations, that late flowers are early, and early flowers are late. For example, I have had during the last three weeks a unique combination; the Queen of Spain Daffodil and *Narcissus poeticus* blooming side by side. The Snowdrop and the British single Daffodil were also for some time contemporaneous this year. Violas are later, and *Aquilegias* somewhat earlier than usual; *A. coerulea hybrida* is already in flower, and *glandulosa*, *chrysantha*, *canadensis*, and *californica* are rapidly preparing to follow in its train. There are few herbaceous flowers more impressive than these. I recommend them as admirable substitutes for Orchids, to those who cannot

FIG. 82.—LINARIA MACEDONICA.

afford the expense inseparable from the cultivation of the latter aristocratic flowers. They would, I doubt not, be equally admired were they only as rare.

I should perhaps have mentioned in previous contributions that I am greatly interested in the open-air culture of the Magnolia, of which I possess the following varieties:—*hypoleuca*, *purpurea*, *Watsoni*, *stellata*, *parviflora*, *purpurea*, *Lenne*, *Soulangeana nigra*, *macrophylla*, and the famous *conspicua*, perhaps of all these the most universally known. Though natives of Japan and South America, they are of sufficiently vigorous constitution, only requiring, when grown in our gardens, a sheltered situation, southern exposure, and a moderately fertile soil. They are sometimes cultivated in shrubberies with considerable success, but when hemmed in on every side by Azaleas and Rhododendrons, as they almost invariably are in such a position, they have not an equally commanding effect. Here they are grown on a long open border, protected by a lofty hedge of Hawthorns from the northern winds, where, alternating along its whole length with Japanese Lilies, and overlooked by lines of Noisette Roses, which scale the south wall, they find themselves naturally, to use the language of Herbert Spencer, in correspondence with their environments.

Among my latest acquisitions are certain plants of Oriental extraction, and bearing the following remarkable names:—*Embothrium coccineum*, *Hamamelis Zuccariniana*, *Eucalyptus ficifolia*, *E. citriodora*, and *Physalis Franchetti*.—DAVID R. WILLIAMSON.

## MODERN GRAPE GROWING.

### PLANTING.

(Continued from page 425.)

We will suppose that a house is ready for planting by the first week in March, that it has an inside border, that the soil has been prepared as previously directed, and is in good workable condition, neither too wet nor too dry. The Vines shall have been grown in the manner I have suggested, either on the premises or bought from a trustworthy source. They ought not to be of more than one season's growth, short jointed, quite round, moderate sized canes with large plump eyes, and thoroughly ripened not later than the previous September. For the uninitiated I may say that moderate sized canes should measure about 1½ inch in circumference, and the eyes or buds average about 4 or 5 inches apart.

It may be necessary to say once more that although most of the cane will be cut off, it is advisable to be thus particular about its condition, as it generally affords an index to the condition of the roots. The Vines should be procured not later than the beginning of November, and they may be ordered much earlier, as growers will always select and mark them for early purchasers. If a cold house is not available they may be kept outside for a time with the pots plunged or covered in some way merely for the protection of the pots, for if the Vines are thoroughly ripened frost will not harm either tops or roots. Some time before or about Christmas, when the weather will permit, they should be taken under cover where the frost can be merely kept from them, and not later than the beginning of January they should be cut down to the desired length. The length they are to be left is governed by the situation in which they are to be planted. For planting in any of our houses they would be cut down to two or three eyes, but in some cases it is necessary to leave them 4 or 5 feet long.

If, unfortunately, there is a dead wall in front of where the Vines are to be planted, or anything else to obstruct the light, they must be left a sufficient length that the sun will reach the point where the new growth of stem commences. Even then they will be under a disadvantage compared with those on which the sun can shine quite down to their base, but we must do our best with such materials and erections as are placed at our service. Mr. Tillery, when gardener at Welbeck, while some costly vineries were being built, offered a little advice which was unheeded, turned away and said, "Well, if your Grace builds me a barn I will grow you some Grapes." I do not advise anyone to speak to his employer in this way, though very often there is a great temptation to do so, but to try and do his best whether he has vineries or barns to deal with.

The canes being cut to the proper length should still merely be protected from severe frost, and towards the end of February, or whenever there is a suspicion that the eyes are likely to start swelling, they should be kept in a light position, and the stems, if any, should be tied erect. Early in March they will start into growth naturally, and when there are visible signs of movement they should have a minimum temperature of 55°, and when they have made 2 or 3 inches growth they will be in the best possible condition for planting.

Now as to the position for planting. There seems to be a very general idea that the nearer to the front wall of the house you can plant the better, but I am of opinion this is about the worst position you can choose. If there are one or two hot-water pipes near the wall and another set about a yard or 4 feet from it, then the middle between these two sets of pipes is the proper place to plant. There need not be any waste of room, for it is an easy matter after training the main stem upwards to allow a growth from it to go downwards and fill up any space there may be; and even if the position is not good enough for a bunch of Grapes to grow, the space will well repay for filling with leaves, provided they get the full benefit of the sunshine on them. None of our Vines is less than 18 inches from the wall, many of them are 3 feet, and I prefer the greater distance.

Next, as to the manner of planting. The soil should be entirely shaken away from the roots, which is an easy matter at this stage, for root action, or more correctly, perhaps, root growth, has not yet commenced. The roots should be spread out evenly all round, slightly covered with pulverised soil, and trodden rather firmly; then a little more loose soil must be scattered over, and when the surface becomes sufficiently dry, say in a day or two, according to the weather, it should be watered to settle the soil between the roots. If the stem is buried an inch deeper than it was in the pot it will be quite sufficient.

As to distance, ours are very little less than 5 feet apart, and if large bunches of fine fruit are wanted this is not too much room, and even for ordinary fruit they should not be nearer than 3 feet. Shade is seldom required when Vines are planted in this condition, and they may be treated as to temperature and moisture at once like established Vines—a minimum temperature of 55°, and a damping of the floor at the time of opening the ventilators, and once or twice while they are open during the early portion of a bright day.

If a house has to be planted at any time after the beginning of April a different mode of procedure is necessary. One plan is to have one-year-old Vines cut down to one or two eyes, started into growth,

repotted into 10 or 12-inch pots, and grown on till such time as the house is ready for them.

If this is any time before July the roots will not have become matted, and it is best to plant the balls entire. This is done by making a hole sufficiently large to lower the pot into it; then break the sides of the pot with a hammer and take out the pieces. It will do no harm to leave the bottom in. Then press the soil carefully round the ball as if repotting a plant. Water when necessary, and the Vine ought to go on growing without feeling the shift.

Young plants of the current year's rooting are also very suitable for planting from May onwards, and if planted in a growing condition before they become pot-bound they should also be planted with the balls entire, and being in smaller pots they may be turned out into the hand and the pots saved.

If the planting has to be deferred till August or September, plants of the current year's rooting that have been kept in small pots and have their lower part ripened are very suitable. In this case they should be shaken out of the soil and have their roots well spread about, and they will make sufficient new roots before winter to establish themselves and be in the best possible condition in spring to make a good and early start after being cut down at the new year to one or two eyes.

When the Vines have to be planted in an outside border the operation is best performed at the end of February or beginning of March before the buds have made much progress. It is best to have good, medium sized, well ripened canes for this purpose, and cut them to the required length about Christmas time. In this case, too, all the soil should be shaken off the roots and the latter well spread out in the border, which it is presumed will have been covered to prevent it becoming too wet.—WM. TAYLOR.

(To be continued.)

## QUESTIONS AND ANSWERS.

As it was suggested a few weeks ago that some readers might possibly like to indulge in a little home exercise in answering the questions propounded by the Royal Horticultural Society to students in the recent examination, I have been trying my hand at the task, and send the results. I will deal with questions in Division B another week.—E. D. S.

### DIVISION A.—ELEMENTARY PRINCIPLES.

#### QUESTIONS.

- 1 (a), What substances do plants absorb by means of their roots? Explain the process of absorption by the root.
- (b), What elements do plants obtain from the air, and by what agency do they obtain them?
- 2, Explain the effect on flowering plants of an adequate, a deficient, or of an excessive amount of heat.
- 3, How are "cuttings" made? Describe the changes that occur during the process of "striking."
- 4, What are the objects sought to be obtained in digging the soil?
- 5, Write as full and orderly a description as you can of any plant in common cultivation, through all stages of its growth, from the germination of the embryo to the formation of the seed.
- 6, What organs of the plant are represented respectively by an Onion, a Cabbage, a Potato, Beet, Turnip, and a pea-pod?
- 7, Describe the mode of growth of the common Mushroom.
- 8, What is meant by "green fly"? What is the best application to rid plants growing out of doors of this pest?

#### ANSWERS.

1 (a), Plants absorb by means of their roots organic and inorganic elements consisting of carbon, oxygen, hydrogen and nitrogen, sulphur, potash, lime, iron, magnesia, silica, and soda. These elements are either absorbed alone or enter into combination with one another, forming chemical compounds, which enter the roots by their surfaces, root hairs, or spongioles, at the extremities, passing upwards through the stems to the leaves, where under the action of sunlight certain changes are undergone, some elements being retained and others given off again into the atmosphere.

(b), Plants obtain the organic elements, carbon, oxygen, hydrogen, and nitrogen from the air, chiefly in a gaseous form, but also in a liquid state, as well as by chemical combination of organic with inorganic substances. The leaves absorb a certain amount of the organic elements in a gaseous form, but the bulk is absorbed by the roots.

2, When plants have an adequate amount of heat at the flowering period, with the roots healthy and numerous, moisture sufficient in the soil and atmosphere, as well as a due supply of air, the flowers develop boldly and in a perfectly regular manner.

When heat is deficient the roots are comparatively inactive, hence the forces which sustain and nourish the blooms are incapable of developing them to the fullest extent, which may cause their decay prematurely.

An excessive amount of heat incites the development of flowers unduly, but frequently produces wood growth at the expense of bloom, and this will be of a weak unripe nature. It may also, especially in the absence of a due amount of moisture, invite, if not cause, the attacks of insects.

3, "Cuttings" in the majority of cases are prepared by securing suitable portions of wood with foliage, young and succulent in many

cases, half ripe in others, cutting the stems immediately below a joint from which the leaves usually spring, removing the two lower leaves, and possibly the pair above, retaining four good leaves and a healthy growing point. Cuttings of many deciduous plants may be prepared and inserted in spring and autumn, at the first period selecting young firm shoots or short stubby growths, taken off with a heel of old wood attached. In autumn young ripened wood is selected and cut into suitable lengths with the lower leaves removed, so that a clear portion is obtained to insert in the soil, which should be of a sandy character in a sheltered position or where the protection of a hand-light or frame can be afforded. The process of rooting is as follows:—First, a portion of the sap or organised matter contained in the cutting descends to the base, collecting there, and forms a callus. From this callus, sooner or later, roots emerge, take hold of the soil, extend and increase, the rooting thus being accomplished. In the case of autumn-inserted cuttings—for instance, Calceolarias, Carnations, and Roses—roots are seldom produced before the days begin to lengthen. The callused cuttings retain their freshness as if rooted. Cuttings of many hardwooded plants and spring-propagated Roses are best callused under cool conditions, then incited to root by the assistance of a gentle bottom heat.

4, The objects to be obtained by digging the soil are its deepening and amelioration by the thorough mechanical division of the particles and their exposure to the atmospheric elements, whereby a freer admission of air, moisture, and warmth is secured, the whole being rendered more available by the roots of plants.

5, A Pea placed in the ground absorbs moisture from the soil, and with the assistance of heat the substance of the seed swells. The vital part within which is the embryo proceeds to develop. It throws out from its apex a green point, which is termed the plumule or growing point; from the base the radicle, which subsequently forms the root. Attached to the embryo are the cotyledons, which serve to feed the embryo during its early stages of growing existence, or until the first leaves are formed and young roots originated, when they decay. The plant is then established in the soil, and gradually develops larger stems and leaves. This is carried on rapidly under favourable circumstances, the plant also throwing out tendrils by which it may cling to objects for support. On attaining to the normal height of the variety the plant begins to flower, the blooms becoming fertilised by the action of the wind or insects distributing the pollen from one flower to another. After this the petals fall and the pods commence to form. Each pod contains the seed closely attached to the inner epidermis. The seed derives support from and is protected by the pod, which draws its sustenance from the plant. The final stage is reached when the haulm turns yellow. The pods are also affected, eventually drying and cracking, and the fully developed dried Peas are seen.

6, The Onion represents an underground stem in the form of a bulb. A Cabbage consists of leaves more or less closely folded together. A Potato is a thickened part of an underground stem or branch, and is termed a tuber. Beet and Turnips are the thickened fleshy parts of roots in which material for future growth is stored. A Pea pod is the seed-bearing organ.

7, The origin of a Mushroom takes place from the white thread-like filaments called the mycelium, which spreads rapidly in a favourable medium of soil or manure. At certain parts the forces contained in the mycelium combine and form cells, which multiply and enlarge with extraordinary rapidity, terminating in the development of a Mushroom.

8, "Green fly" is the common term for aphides of that colour, insects which infest plants outdoors and under glass. A solution of six parts of water to one of tobacco juice, thoroughly mixed and applied with a syringe or sprayer, is one of the many best applications for ridding plants outdoors of these pests.

### GROWING PEAS AND PREVENTING MILDEW.

I KNOW it is a common plan amongst gardeners to practise and advise that Peas, especially those for late crops, to be sown in trenches somewhat after the method pursued with Celery. The main object in the trench culture of Peas is the prevention of mildew by providing what is considered adequate moisture, by affording a root run into a mass of manure in the trench. Too often have I seen Peas growing in such trenches infested with mildew to a serious extent to consider the plan a good one.

A trench 15 inches wide is dug out, and as much, or more in depth; manure 9 inches thick is put in the trench, trodden down quite firm, a few inches of soil is laid on the manure, the Peas sown. By the time the Peas are several inches high the soil is some inches below the surface, affording space for a good supply of water. My objection to the system is this, the roots quickly take possession of the manure, and owing to the wall-like sides of the trench they do not spread into the surrounding soil, but are contracted as it were to the narrow space in the trench. As may be imagined, during a spell of dry weather, unless water is very often supplied, the roots quickly absorb what moisture the manure contains, and then comes their suffering in consequence of an insufficiency of supply, with the usual result of a full crop of mildew.

How often do we see the haulm of Peas attacked with mildew after a spell of dry weather. It is one of the most difficult matters imaginable to check the spread of the fungus when once it has obtained a thorough hold. As a rule drought at the roots is the main cause of the attack, and I always apply a 3-inch mulching of half-decayed horse manure on the approach of dry weather.

It is generally considered that Peas in light land suffer much more from mildew than those growing in heavy land. My experience does not altogether confirm this theory. Directly the rows are earthed we apply the mulching, first digging the soil, as if it is trodden on when wet it kneads together surprisingly. All practical gardeners know the advantage gained by having the soil in a loose friable condition for the roots to run in, as well as a means of retaining moisture. Half-decayed horse manure is probably the best material for mulching purposes, though decayed vegetable refuse mixed with wood ashes, old potting soil, and leaves answers admirably. Even if mulching with any material is not practicable the next best thing to do is to keep the soil, for at least 1 foot on each side of the plants, well broken up, so that the surface cannot crack and allow the moisture to escape, and thus save the crop by retaining the moisture in the soil.—E. M.

### SINGLE DAHLIAS.

AT this period of the year summer bedding is the uppermost thought in the minds of most gardeners, and during the next few weeks these operations will be in full swing. Stern recollections of the severe frost on the 20th of May last year will have been sufficient to advise all not to be in too great a hurry, but rather be the gainers by waiting until all danger of frost is over. In many large gardens the question of producing a supply of plants sufficient for the demand is one of much consideration, and to meet this Dahlias are largely called into requisition, and the bright display which they afford is ample recommendation for their use. The number of pretty Cactus and fancy varieties that have been introduced during recent years is very large, and truly many of these are extremely beautiful and worthy of a place in any garden.

It is my intention, however, of speaking of a class which do not appear to be cultivated so largely as they deserve—namely, the singles, which, for producing abundance of elegant flowers, have no superiors. Strange to say, in this class the old varieties still hold full sway, as few of the additions are very far in advance of those of earlier introductions. They are especially suitable for the adornment of gardens where the landscape is undulating and of natural formation. Another point in their favour, often found wanting in the double varieties, is that they throw up their profusion of brightly coloured blooms well above the foliage, this adding much to their value from a decorative point of view.

So simple is their cultivation that any notes on this is unnecessary, and for varieties I have proved from experience that the scarlet Formosa is one of the very best. The flowers are bright and effective, and produced in such large numbers that a small bed makes quite a feature. It is in groups of three or four that they are seen to the greatest advantage, and so planted add much to the beauty of any garden even during the most unfavourable of summers. The elegance of the long spikes of flower also renders them very useful for decorative purposes.

Negress is a variety growing taller, and of a very dark velvety colour almost approaching to black, which in the sunshine is very pleasing. In growth Negress differs from any other variety, the leaves being cut and fimbriated. The "White Lady of the Lake" is almost indispensable in any collection of singles, as it produces abundance of pleasing flowers which form a charming contrast to any other colour. It is very useful for forming the outside rows of beds planted with mixed kinds. The single yellow is likewise pretty and useful, as, like all of the class, is extremely floriferous, and almost indifferent with respect to situation and weather. Juno is a tall growing kind of a bright purple colour, and suitable for forming the back lines of large masses, for which purpose it is mostly used.

Another useful scarlet variety is Mrs. Beauman, with flowers larger than Formosa, though not borne in such profusion. Edith is of a pretty salmon tint, and commendable for contrasting. Though there are many other varieties all worthy of a place in addition to the above I have refrained from mention of them, as fewer kinds of decided colours are preferable to growing too many, in which case there is danger of confusion and clashing of shades. In conclusion, I would add that single Dahlias are well worthy of a place where they can be accommodated in large numbers, by which the effect of their graceful beauty is shown to the greatest advantage.—G.

### THE TEMPLE SHOW.

No doubt this very fine exhibition has ere now undergone enough criticism. Nothing in this world, not even a Temple show, can be perfect, and if there be criticism no doubt it is not at all unkindly meant, but is rather a product of that earnest yearning which so many people have for ideals that may never be realised. Thus from an artistic point of view the show was a failure, but that is inevitable because of the surroundings. No man, however great his capacity to design or to execute, could accomplish more under existing conditions, although in relation to individual groups perhaps much more might have been done even with such surroundings.

But if artistic skill in grouping was lacking, the show was all the same one of very remarkable excellence. It showed to the world, though in a limited degree, how great are our horticultural resources, and what a magnificent display of a floral nature can be produced even when the surroundings are not of the most helpful. Very likely there were some who went only to see, who wished they could have had a free hand in arranging some of the collections. Furnished as most of the material is

by members of the horticultural trade, it is but natural they should wish to stage things in their own way for business purposes, and that way is too often far from being attractive. Any attempt to compel certain styles of arrangement would be productive of a revolt, and therefore, even if the surroundings did admit of it, the production of artistic effects would be out of the question.

It would be most unjust to assume that grace and elegance in the grouping of plants is not an attribute of the British people. That we are not in the concrete a tasteful people there can be no doubt, but we have had in the past abundant evidence, that given a free hand, we have numerous designers in floral arrangements who would be hard to beat anywhere. But when obliged to take the form they must necessarily do at the Temple, it is obvious that any grower's flighty fancy has to be restricted, and the best made of the difficulty. The long tents have side tables, and the centre ones are too narrow and rather too high. It would be a distinct advantage to exhibitors in these tents were the side tables placed on each side of the centre one, and a trifle lower, as then a finer face could be given to each collection, much more scope for arrangement, and a far bolder effect produced.

The public would gain also in having only one face of plants or flowers to look at on either side, and thus save so much twisting of the neck as is now needful, and so much perambulation, as to see everything two turns round each tent are requisite, thus unduly crowding them, and making the visitor very tired. Even in the large tent, where the material was so fine and varied, very little of artistic effect was or could be seen. Where Palms or other common decorative plants were introduced naturally elegance could be combined with the grouping, but many things—balloon-shaped Clematises, large Caladiums, big pot Roses, Rhododendrons, Acers, and hardy flowering plants—do not present the most promising of material for grouping unless associated largely with other things. Mr. C. Turner's group of Roses, thanks to the free use of the beautiful Crimson Rambler, was undoubtedly very pleasing, and should furnish a valuable hint to others another year how to employ some graceful material if at hand.

Of all plants naturally suited to produce eminently light elegant arrangements Orchids are of the best, and yet of all the immense numbers present none were so utilised. Presumably it cannot be otherwise, as each grower wishes to show off the abundance of his Orchid riches rather than to make with their aid the most elegant display. I observe the Council awarded Mr. Rivers a gold medal for his group of Nectarines in pots—a triumph in cultivation and transit—but artistically of no merit. Would that next year a real award could be offered for the group of plants in the show, apart from intrinsic merit, that was most gracefully and artistically arranged. It should also be for groups in which not foliage plants such as Palms, but rather flowering plants comprised at least one-third. Such an award would, without in any way interfering with the present general arrangement, at least help to stimulate growers and exhibitors of groups in the direction of trying to do something artistic.

Of course the groups in the large tent would have the best chance, but then, so far as practicable, all exhibitors who wished to compete for the medal should have the first claim on the spaces in that tent, and they should in each case be rigidly restricted to a certain area, very much room is therefore some encouragement to those who set up such fine but still generally muddled groups of hardy flowers. These are invariably mere conglomerations, and it is feared that whilst permitted to be so exhibited in endless quantity, these collections will never be other than conglomerations. Messrs. Backhouse & Sons showed in a very beautiful way, and Messrs. Paul & Sons strove in the same direction to show how artistically alpine plants may be staged, but cut hardy flowers seem to baffle ingenuity. Anything that served to illumine with grace the present long monotonous banks of these flowers would indeed be welcome.—A. D.

#### STRAWBERRY AUGUSTE NICAISE.

FOR gentle forcing this is a very fine variety, and some growers can command success by subjecting it to temperatures sufficient to mature them early. As a rule, however, the finest fruits come from midseason or later plants. Well grown in pots it is equal to any variety I know of in point of crop and weight, but outdoors I do not find it nearly so prolific as Sir Joseph Paxton, Noble, President, James Veitch, and others here.

As Strawberries vary so much in different soils, this failing with us may be quite unknown elsewhere. As I had no previous experience with it as an outdoor variety, I can only invite the opinion of other readers who may have had the opportunity of proving it. Two acquaintances of mine grow the variety largely in pots; indeed, it commands greater space and favour with both than any other sort, and judging from the results obtained they appear to be fully justified in their choice. It has been said that berries weighing  $3\frac{1}{2}$  ozs. each have been grown at Leighton, but I have never had the statement verified by Mr. Mann, the gardener, and therefore have never accepted it as an established fact. I saw a large number of plants there in the month of April, and the ambition for very large fruits was clearly apparent, as a few strong plants in 7-inch pots were permitted to carry only four fruits each.

Of Mr. Robinson's plants in pots of the Auguste Nicaise I have previously written, and the attainments of this season have been fully up to the old standard. In a good dish gathered during the past week, there were twenty berries that weighed 2 ozs. each and over, the largest which would cover the palm of the hand, weighing  $2\frac{1}{2}$  ozs. Such fruits

cannot fail to give satisfaction at the dinner table, and the fact of its being an annual attainment proves that it is no mere accident, but that the grower fully understands the cultural treatment the variety requires.

Whilst in bloom the plants occupy a low sunk pit with moveable lights, and these are tilted in front so as to allow a current of air to play on them—a valuable aid in securing a good set. Individual attention to the opening flowers is also given, and light top-dressings of chemical manures given occasionally promote the requisite vigour for carrying them on to the ripening stage. That they are never allowed to suffer for want of root moisture no further evidence than the uniform excellence of the crop is required. From seven to nine fruits are allowed on each 7-inch pot, and small berries, of course, are unknown. Before the stems are brought down by the weight of the fruit small twiggy supports are given to keep them in a natural position. The colour is very bright and glossy, and such a dish as I have described would be considered creditable to any grower.—W. S.

#### ROUND PECKHAM RYE.

WITH the inhabitants of South London the above name is a household word, the large expanse of open ground being looked on by the people as being entirely their own, and so far as freedom of use is concerned such is certainly the case. To see the famous Rye in the glory of its popularity it is necessary to pay a visit on some Bank Holiday, when there is ample scope for anyone of that turn of mind to study many different grades of society. It is on such occasions that the jolly coster and his "donah" are glad to escape for a short time from the environs of Covent Garden, and while away their few idle hours on this public playground.

Such a place, however, as a real park on the Rye was a few years ago unthought of, but through the energy of the London County Council a large tract of land was purchased, the skill of landscape gardeners brought to bear on it, and what was once wild and uncared for is now transformed into a pleasing landscape equal in every respect to the pleasure ground that surrounds many a nobleman's mansion. As it is but little over a year since the park was open to the public the flowering and ornamental shrubs are yet but small, and here, like everywhere else, many have suffered severely from the effects of the past cruel winter.

In spite of this, however, the walks, turf, and borders present a neat and well-kept appearance, which is in every way creditable to Mr. Ashmore, the superintendent, and his staff. A pleasing feature in the Park is its natural appearance, rendered so by its richness in forest trees, chiefly Elms, which were left undisturbed at the time of its formation. The landscape abounds in rustic peeps and delightfully shaded walks, one of which, known as the "Lovers Walk," struck the writer as being an ideal spot for a hot summer's day, covered as it is by a dense canopy of foliage, and proof against the rays of the brightest sunshine.

Long lines of sweet Hawthorn bushes abound on every side, now charming with their profusion of white flowers, emitting a perfume which cannot fail to remind one of spring time in country lanes. These have formerly done duty as hedgerows dividing meadows, and it was a happy inspiration that led to them being left in their natural form. In the centre of the Park are several acres of copse not yet in the hands of the Council, thickly studded with tall forest trees, under which there is dense underwood, where many wild flowers are to be seen blooming profusely.

From this spot comes the sound of the cuckoo's welcome voice, thrushes and other song birds build nests and raise their broods in perfect safety, and in the stillness of the night may be heard the lays of the nightingale. Perhaps some reader will say there is nothing extraordinary about this, if so I would ask him to remember that all this is within a short distance of one of the thickest populated districts of the metropolis.

In the more cultivated portions are to be seen in profusion of bloom, Lilacs, Guelder Roses, Spiræa callosa alba, Rosa rugosa, and many others, while, strange to say, Wallflowers have mostly passed safely through the ordeal of the winter, and now present a bright appearance. Long stretches of green turf look verdant and healthy, especially considering it is only a comparatively short time since portions of it were laid, and in one part lovers of the tennis racquet are free to display their skill, while in another wielders of the willow can indulge in their favourite sport.

As there is but little of that garden-like appearance here which characterises the neighbouring Park, Dulwich, formal flower beds are not a feature, nor would they be in character with the rustic surroundings. In spite of this, however, the borders have been recently gay with Narcissi and other bulbous flowers, pleasingly intermingled with the shrubs, and now may be seen in their places many patches of popular annuals just peeping through the surface, which give ample promise of a future bright display. The situation is everything that could be desired, the air being fresh and clear, while all round lies rich undulating scenery, the like of which adds so much towards making many London suburbs pleasant.

There are several small improvements yet to be completed, but with the consideration that it is only a little over twelve months since this pleasant spot was made a public resort, the general condition is truly creditable, and, it is gratifying to know, appreciated by the people, who have in this and other such places privileges unknown to London dwellers of but a few years ago.—WANDERER.

**EVENTS OF THE WEEK.**—In the provinces during the coming week at least three great shows will be held. On Friday the annual show at Manchester opens, on Saturday will be held the Tamworth Pansy and Viola exhibition, while on Monday (Bank Holiday) the Southampton Society will be holding its show.

— **WEATHER IN LONDON.**—During the afternoon of last Thursday there was a heavy fall of rain for about an hour in the metropolis, which caused visitors to the Temple show to rush quickly to the tents. Since that day, however, beautiful weather has prevailed.

— **WEATHER IN THE NORTH.**—During the week ending the 28th inst. the weather has been generally warm and fine. On some days thunder occurred, and two or three showers have fallen, but more rain would be welcome.—B. D., *S. Perthshire*.

— **THE PARIS EXHIBITION.**—The show of the National Horticultural Society of France opened in the Tuileries Gardens on the 22nd, and closed on the 28th inst., may be termed a success, all sections being fairly represented. Hardy flowers from Messrs. Vilmorin, Andrieux & Co., and Forgeot & Co. were exceptionally brilliant, Azaleas, Caladiums, and Palms being also well shown. Messrs. F. Sander & Co., St. Albans, staged a group of Orchids, *Dracaena Sanderiana* and other plants that attracted much attention, and which was adjudged a gold medal.

— **A ROYAL CEDAR AT WARWICK CASTLE.**—Before leaving Warwick Castle on Monday, the 20th inst., H.R.H. the Prince of Wales planted a young Cedar of Lebanon near the site of the historic old Cedars which were blown down in the recent gale. Although centuries must elapse before this young tree attains to the grand proportions of its pioneers, it is interesting to think, and hope, that many future generations will look with pleasure on its spreading branches, and ascertain by the inscription beneath it that it was planted to commemorate His Royal Highness's second visit to Warwick Castle, adding thereby another link in the long line of historic associations which cluster around the famous stronghold of the ancient midland town.

— **KEW GUIDES.**—The following are the guides on sale at the Royal Gardens, Kew:—Key plan and index to the Royal Botanic Garden and Arboretum, Kew. Third edition. 1893. Price 2d. Official guide to the Museums of Economic Botany. No. 1: Dicotyledons and Gymnosperms. Second edition, revised and augmented. 1886. Price 4d. Official guide to the Museums of Economic Botany. No. 2: Monocotyledons and Cryptogams. 1894. Price 4d. Official guide to the Museums of Economic Botany. No. 3: Timbers. Second edition, revised and augmented. 1893. Price 3d. Official guide to the North Gallery. Fifth edition, revised and augmented. 1892. Price 6d. Guides to Museums and North Gallery in one volume, cloth boards. Price 1s. 9d. Hand-list of trees and shrubs grown in Arboretum. Part I.: Polypetalæ. 1894. Price 8d. Hand-list of Ferns and Fern allies cultivated in the Royal Gardens. 1895. Price 6d.

— **TENTH NATIONAL CO-OPERATIVE FLOWER SHOW.**—The schedule of this show, just issued, repeats the offer of about 800 prizes, including £300 in cash, many bronze, silver, and gold medals, special awards and consolation chances. Most of the prizes are, as usual, offered for the produce of workmen's gardens and labourers' allotments, each section of the kingdom having separate offers. The Council of the Agricultural and Horticultural Association seeks this year to enlist art students in the improvement of town gardens by offering prizes of £10 for designs of the "Workman's Garden of Taste," contrasted with the "Workman's Garden Run to Waste." The competition designs are to be exhibited at the Crystal Palace on the 23rd and 24th August, when the show takes place in conjunction with the Great National Co-operative Festival. Schedules of the show can be obtained without charge from Edwd. Owen Greening, the Hon. Sec., 3, Agar Street, Strand, W.C.

— **FRUIT FROM THE ANTIPODES.**—The "Oceania" arrived on the 18th instant, bringing the following fruits:—Four boxes from Sydney, 9247 from Hobart, 894 from Melbourne, and 130 from Adelaide—or a total of 10,275 boxes of Apples.

— **DEATH OF DR. H. F. C. CLEGHORN.**—The death is announced of Dr. H. F. C. Cleghorn, well known for his work in connection with the organisation and development of the Forest Department of India. He was for some years President of the Royal Scottish Arboricultural Society, and examiner in forestry to the Highland Society. He also took a leading part in the founding of the forestry lectureship in the University of Edinburgh.

— **FRUIT IN KENT.**—The prospects of the Raspberry crop in Kentish grounds are this year, says a local contemporary, very poor. The severe frosts of the past winter seem to have affected the canes a great deal, and they are now bursting very poorly. Cobnut trees are generally looking very well, and the show for fruit is a capital one. With regard to Plums, reports state that it is mostly trees of the Dauphin variety which are showing very patchy for blossom.

— **FINE FRUIT PROSPECTS ON THE CONTINENT.**—The orchards in the districts round Paris now present a mass of bloom such as seldom has been witnessed. Pear, Cherry, and Apple trees are alike loaded with flowers. The season is unusually late, but there is every prospect of a splendid crop, unless indeed there is any frost. The system of protecting fruit trees from frost at the critical moment of fertilisation of the pistil by lighting fires in orchards, so that the smoke may have the same effect as a cloudy sky, is in some cases being resorted to. Gooseberries and Currants are sufficiently advanced to render an abundant crop almost a certainty.

— **A GOOD WHITE COLUMBINE.**—Seen in a large number of strong plants carrying fine heads of bloom a fine pure white Columbine of the garden hybrids is a telling feature beside a garden walk at Woodhatch, Reigate. The flowers have longer spurs than are usually found on the common strain, and indeed it should not be difficult, by careful selection and intercrossing, to develop from it a pure white long-spurred form, after the style of chrysantha. Columbines are very elegant as found in true species, or even in many of the numerous hybrids that have come from intercrossing *A. chrysantha* with *A. cœrulea* or *Skinneri*, but none of these have yet given us a pure white form. The one at Woodhatch therefore merits wide cultivation.—A. D.

— **STEPHANOTIS AND RIPENED WOOD.**—If you think appropriate and likely to produce thoughtful consideration I should like to refer to the controversy that was under discussion in the columns of the *Journal of Horticulture* last autumn, on the question of "Ripened Wood." In the issue of November 15th, 1894, page 444, "A Sceptic" states that a correspondent "makes a remarkably bad shot considering that *Stephanotis floribunda* blooms on the young growth." True it does, but it also blooms on the old growth if well ripened. I am sending you a length of 1894 autumn growth with four fully expanded trusses on it, with young growth from the same showing other trusses.—F. W. B. [The examples were as stated. They were clean and healthy, but not novel. It is common enough to find *Stephanotis* flowers on growths of the previous year, and sometimes at nearly every joint.]

— **THE EFFECTS OF THE WINTER.**—In one important respect horticulture this spring is, says the "Derby Mercury," suffering somewhat severely from the severe winter, the ravages of snails and similar ground insects being more than ordinarily destructive. The reason is that the lengthy frost, instead of retarding the operation of these little pests, has actually favoured them, for it has almost completely annihilated the mistletoe thrush, whilst song thrushes are nearly as scarce. These birds in early spring—and, indeed, all through the winter in open weather—feed on numbers of snails and their eggs. Early Peas, it is said, have suffered greatly by the small white snails, and in many gardens even the Asparagus heads are taken before they can fairly break through the ground. The robin, too, though a hardy little bird, has also considerably diminished in numbers, and other indigenous insectivorous birds have suffered to an equal degree. It is consequently to be hoped that the present warm weather will continue, and that an abnormal number of migratory birds—most of which are insectivorous—will assist to make up the deficiency. More rain is at present very much needed, the ground having been considerably dried by winds. The fruit blossom is setting well, and if severe frost keeps off the season will be one of the finest for fruit we have enjoyed for some time.

— THE ANNUAL SHOW OF THE HEREFORDSHIRE FRUIT AND CHRYSANTHEMUM SOCIETY is fixed for 5th and 6th November.

— NARCISSUS BIFLORUS.—This is worthy of a place in the wild garden or in the herbaceous border if only to prolong the display of this section of bulbs. The blooms are borne in pairs on stout stalks, dull white in colour, and fragrant.

— WE are requested to announce that Mr. J. Williams, late gardener at Penwortham Priory, Preston, and Brooklands, Garstang, has commenced business at Bowgreave, Garstang, as seedsman and florist.

— RICHMOND HORTICULTURAL SHOW.—The schedule of the annual show of this Society, to be held in the Old Deer Park, Richmond, on Wednesday, June 26th, is just to hand, and contains particulars of several classes, in which excellent prizes are offered. We hope the exhibition will be as great a success as in previous years, and as the good management of it so thoroughly deserves. Anyone desiring information should write to Edwin Pragnell, Esq., London and County Bank, Richmond.

— THE GOLDEN-CRESTED WREN.—Though the smallest of British birds this is a great friend to both gardener and farmer, destroying as it does myriads of troublesome creature pests, which infest cultivated plants. By watching its habits at this season it may be seen busily feeding on the aphid, or green fly, which is one of the most troublesome of insects. By looking in the right place the nest of the golden-crested wren will be found in some Honeysuckle or such like bush.—B.

— DAPHNE CNEORUM.—Always an uncertain little evergreen here, says the "Garden and Forest," it seems to have come through the winter unusually well, and is now covered with its fragrant pink blossoms, and there is nothing better than this trailing shrub for rock-work. Flowering at the same time, but a good deal more hardy and trustworthy, are the half-shrubby perennial Candytufts. The flowers of these Candytufts are white as snow, and since the plants resemble the Daphne in habit the two make admirable companions.

— THE VITALITY OF SEEDS.—I was interested in the article, page 436, on the vitality of seeds. It appears to me the vitality of many seeds is destroyed by storing, where at certain seasons they absorb moisture from the atmosphere or the receptacle they are stored in. Once seeds begin to germinate and are checked they make no further progress, while at the early stages of germination they are easily killed. In the spring of 1894 I took soil from a depth of 4 feet from which several plants sprung, one a Lathyrus or Pea, a new kind to me, and I have observed Charlock spring from material many fathoms deep.—W. T.

— RESTORING THE INTERIOR OF A TREE.—A process of restoration has been carried out in the interior of the famous "Rollo's Oak," which is to be seen within an easy distance of Rouen, France. It is so old that it has completely lost its inside, and was liable to collapse at any moment. It has now been relieved of this liability. An arboricultural genius has, according to a contemporary, fitted it with a solid new inside of masonry. The masonry is made to follow and fit every turn and twist, and gnarl of the patient; and there is the veteran, solid as a rock again. Then the fissures and cracks on his exterior have been neatly filled up with cement, and the cement has been artistically coloured, so that you would hardly know it from the natural bark. It is expected and believed that the tree will not know the difference either, and take to flourishing again as it did a few centuries ago.

— SOME FEATURES OF PLANT LIFE.—Professor T. Johnson delivered a lecture on "Some Features of Plant Life," in the Royal Dublin Society's Buildings, Kildare Street, recently. There was a very good attendance, and the lecture, which was adapted to a juvenile auditory, was closely followed by those present. The lecturer at first dealt with the main groups of flowering plants. He then described the Bean or Flax plant, and the Oak, as illustrations of dicotyledons. The structure of the stem was minutely referred to, after which the arrangement, nature, and functions of the veins or vascular bundles were dwelt on. The other portions of the lecturer's discourse were concerned with the tip or growing point of stem, buds, or tree trunk, and its mode of formation, the root system and its function; the food of a plant; the "stringiness" of some roots, and the "bleeding" of the Dandelion root. The lecture was listened to with great interest, and its different points were fully appreciated.

— By a printer's error, the address of Mr. G. May, who showed Uriah Pike Carnations at the Temple show, was given in our report as Upper Edmonton instead of Upper Teddington.

— MESSRS. B. S. WILLIAMS & SON write:—"We have much pleasure in informing you that the Lord Steward has appointed us nurserymen and seedsmen to Her Majesty the Queen. The warrant conferring the appointment is dated 8th of May, 1895."

— HORTICULTURAL BUILDINGS.—Mr. C. Cox, Tunbridge Wells, has favoured us with handsome reproductions from photographs of the structures he builds, and which clearly depict lightness and elegance with substance and utility. All forms of glass houses are represented, from the small frame to the ornate conservatory. Amateurs are not forgotten, as several "tenants' fixtures" are portrayed, and amongst which "The Hercules" appears everything desirable.

— WISTARIA FLORIBUNDA.—In spite of many new additions to the floral world, we have no creeper more beautiful at this period of the year than Wistaria floribunda. When recently passing a cottage in a London suburb I was struck to see the walls covered with large clusters of its purple coloured blooms, and could not help thinking how many bare walls might be made beautiful if covered by this old but charming creeper. Considering the ease with which it may be propagated by layering the long shoots, it is somewhat surprising that it is not grown to a greater extent.—G.

— PRIMULA SIEBOLDI PLUTO.—Amidst the wealth of hardy flowers and plants shown at the Temple few kinds more readily arrested the attention than did a group of this beautiful hardy Primula blooming profusely in small pots, and exhibited by Messrs. Barr & Son. The flowers were of good size, partially lacinated, a very desirable feature in these flowers, and of a rich reddish magenta hue. How effective would clumps of such a hardy Primula as this is be in 6-inch pots in a greenhouse if well grown! the colour is uncommon and the effect charming. Primula Sieboldi, to have it in good form, should have the root crowns divided every year, the best selected and potted, whilst the weaker may be grown in pans to make strong crowns for the following season.—D.

— FATAL VIOLETS.—A well-known botanist says the root of the fragrant Violet is so poisonous that a very little of it causes nausea, interrupted heart action, difficulty of breathing, and other organic complications, which may result in serious illness. In this connection it is significant that an intimate relation has been discovered between the strong perfume of the fragrant Violet and the venomous qualities of its root, for the root of the scentless, or Dog Violet, is not venomous. More recently, cases of heart failure and defective circulation have been traced to the influence of Violet perfume. Since the fragrant Violet and its extracted perfumes are becoming all the vogue, it might be well, in view of these sinister reports concerning them, to consider the propriety of their indiscriminate and lavish enjoyment, particularly as they seem liable to injuriously affect not only those who use them, but also susceptible persons who may be in their immediate neighbourhood.

— NYMPHÆA LAYDEKERI ROSEA.—This is one of the best of the small-flowering Water Lilies for general use either as an ornamental plant or for cut flowers. While it grows as freely as any of the other kinds, it has baffled all attempts at propagation, so far as known. The plants keep growing from the same crown, forming a thick succulent stem, the lower part of which is continually decaying as the top makes new growths. I have tried to increase it in various ways, but never have succeeded in even starting a lateral growth, and the worst of it is, the plant usually dies if disturbed too much. I have killed four plants already, and am as far from a solution of the problem as ever. Several other people have tried to propagate it, with like results. It sometimes produces seeds, but they do not come true. I am inclined to believe that the best way to raise it is to cross-fertilise the two parents every time seed is wanted, and thereby renew it in the same manner in which it was originally produced. Its parents are said to be the Chinese Nymphæa pygmæa, fertilised with pollen from the pink variety of N. alba. I am the more inclined to believe these to be its parents, because for want of the flowers of the last-named kind, I have tried pollen of a dark form of N. odorata rosea on flowers of N. pygmæa with successful results. The flowers of this hybrid are nearly of the same colour as those of N. Laydekeri rosea; there are more petals to the flowers and the shape is more star-like.—G. W. OLIVER (in "Garden and Forest.")

— TWO ACRES OF CABBAGES at Pensham were sold by auction the other day at Worcester, the price obtained being at the rate of £38 per acre.

— WE learn that Mr. George Murray has been appointed Keeper of Botany in the British Museum, in succession to Mr. Carruthers, who retires on superannuation.

— BIGNONIA CHIRERE.—For a cool conservatory having a lofty roof no climber is better adapted for beautifying that part of the house than this Bignonia. Allowed to hang downwards, the current season's shoots produce a fine effect when freely studded with the orange red, tube like blossoms. Unless the branches are well matured the previous autumn, and the current season's shoots pinched a joint or two beyond the cyme-like flower trusses, a full crop of blossoms cannot be expected. Abundance of moisture at the root is important.—E. M.

— IRIS RUBRO-MARGINATA.—The flowering season of the rhizomatous Irises commences in April with the flowering of this little Central Asia Minor Iris. *I. rubro-marginata* is allied to *I. pumila*, which is very familiar in gardens as a dwarf border plant, usually flowering in May. The leaves of this species are 2 to 4 inches high, usually margined with red. The rhizomes are short, and short-creeping. The flowers are small, of beautiful compact form, with large standards and of a peculiar vinous colour, with metallic reflections. They are borne in profusion, and the plants at flowering time are quietly, rather than strikingly, handsome.—A. C.

— SINGLE-FLOWERED PÆONIES.—Were it not that the blooms have so fleeting an existence they would run their double-flowered competitors a hard chase for popularity in a decorative point of view. Many of them are very showy, flowering more abundantly, and are less tall in their growth as a rule than the double sorts. These single-flowering Pæonies make a bright display in the herbaceous borders during the month of May, and take less time to establish than do the double-flowered varieties. *Officinalis splendens* (brilliant purple) and *tenuifolia* (brilliant crimson), with another variety of a pleasing pink colour, form a trio well worthy of attention by anyone interested in hardy flowers.—M.

— THE ABSENCE OF SLUGS.—Here with me, and in a walled-in town garden, a conspicuous feature is at present an almost entire absence of slugs. For six weeks we have had in the South of Ireland little or no rain. This may be one of the causes, but I attribute the chief cause to the severe winter, and chiefly the heavy snowfall. Great cold they avoid by burying themselves in the soil; but snow and snow water they cannot escape, as it trickles and percolates after them, and close observers say kills them in myriads much more than great cold. The crops look exceedingly well notwithstanding the persistent drought, which I attribute in a great degree to the moisture remaining in the soil after the afore-mentioned heavy fall of snow.—W. J. MURPHY, *Clonmel*.

— VEITCH'S CLIMBING FRENCH BEAN.—This Bean should prove an acquisition for growing early in the year in vacant spaces in houses where it can have room to extend. Having some spare room in a late Peach house I decided to give it a trial. The seeds were placed in 10-inch pots early in March, four and five plants being finally retained. They were grown steadily, and when sturdy enough removed to the house in question, in which place abundance of ventilation is given at all favourable times. The plants have simply had ordinary attention, and are now turning in a very serviceable crop of Beans, a sample of which I forward with these lines for your inspection.—J. J. CRAVEN, *Allerton, Liverpool*. [The sample of Beans sent was an excellent one, and proves the truth of our correspondent's remarks.]

— THE MYRTLE OR PERIWINKLE.—In connection with the subject of plants that will do well in deep shade, it may be mentioned that few things are better for this purpose than the dwarf Periwinkle, *Vinca minor*. No matter how deep the shade, or how dry the earth may be under trees, this form of Periwinkle does admirably. It is found under the deep shade of Pine forests in the Old World. It is frequently used in America as a covering for graves. It then goes by the name of Myrtle, although very different from the true Myrtle of the poets. There are four marked varieties in cultivation; one is the ordinary blue, another pink, a pure white variety, and a double form of the pink. The flowers come up in early spring, immediately after which the old leaves die away and a new set of leaves take their place. In many respects there is not a more useful plant in the list used by lovers of gardening.—("Meehans' Monthly.")

— HORTICULTURE will be fully represented at the Paris Exhibition of 1896, and will be located on the banks of the Seine, between the Alma and Invalides bridges.

— THE USES OF EARTH-WORMS.—A contemporary says: "A number of years ago a piece of arable land on the sea border of Lincolnshire lost its fertility in consequence of the destruction of all its earth-worms by the breaking in of the sea, but regained its fertility in consequence of becoming again over-run with earth-worms, after the effects of the sea burst had ceased."

— RIBES AUREUM.—This plant, which is found in many old gardens, has a rather straggling habit, but it is among the earliest shrubs to show its flowers, and these are of a singularly clear yellow colour. The great value of this plant, however, lies in the delicious fragrance of its flowers. No other shrub at this season has any odour at once so pleasing and so penetrating, and it is well worth planting for this quality alone.

— AMELANCHIER FLORIDA.—This is a variety of Canadian Grape Pear, *A. canadensis*, flowering fully a month later than the type. It is perhaps less seen than this or the more showy Snowy Mespilus, although it deserves far more attention than it now receives. Cultivated as a standard by grafting it on the common Hawthorn or Quick is perhaps the way most suitable for displaying its attractiveness. If it can be associated with evergreen subjects, especially underneath, a fine effect is produced by half a dozen trees. The pure white blossoms thickly set in a luxuriant mass of green of its own foliage appear especially pure in colour.—E.

— BAPTISIA TINCTORIA.—For medicines *Baptisia tinctoria* has been found very useful. All medical writers, says "Meehans' Monthly," from Rafinesque down, have much to say about it in this connection. Rafinesque, however, gives in a few words the substance of most that has since been said of it: "It is a valuable remedy for all sorts of ulcers; must be used externally as a wash or fomentation, or in poultices with lard or cream." "It is one of the most powerful antiseptics in putrid disorders." "It stops gangrene, and is useful in putrid and typhus fevers." Griffith says, "A decoction is made by steeping an ounce of the root in a pint of boiling water."

## APPLES AND STOCKS.

THE closing paragraph of your able and interesting leader (page 419) makes a brief allusion to this subject, in which I heartily agree. As you say, some persons attach much importance to the stock on which the trees are growing, and really think that on this the whole secret of success hinges. This idea I do not concur in, because in some gardens excellent and equal results accrue from trees worked on three kinds of stocks—namely, the Paradise, seedling or free stocks, and, thirdly, the Crab. When all those named give equal results under exactly similar conditions of site, soil, and management, it seems idle to pin one's faith to any one of the three named.

I am acquainted with persons who say the Paradise stock is the best, while I might equally uphold trees established on seedling stocks. The latter are really the result of sowing the seed or "pips" from the cider mills. Some cultivators say trees grafted or budded on the latter do not come quickly into bearing. This I stoutly contradict, as I know from experience trees of various ages, from one year to ten years, will fruit the second year after planting, and many of them the first year if it were desired. This, I hold is a good argument in favour of seedling stocks from the cider mills. Take, again, the Crab as an illustration. Even standard-trained trees will give fruit the first year after planting. This is really much too soon to be desirable for the future and early establishment of full sized trees.

When trees are favourably started into growth their future cropping and growing propensities are largely governed by the method of management adopted. It is useless pruning hard every year trees that make vigorous shoots if the roots are not served in a similar fashion. This is a fact that needs little emphasising to practical men, but those who have not the benefit of experience find it hard to realise this truism.

I am watching at the present time an experiment that is being tried by a cottager on the Swanmore estate on the subject of stocks for Apple trees. From many sources he collected the seeds of Apples during the winter of 1892, both English and foreign being included. The seeds were sown out of doors; the trees grew rapidly, many of them making 4 feet or more of growth last year. Last month I grafted seventy of these stocks with various kinds of Apples, and with apparently good results, not a single graft having failed to grow. With a view of further testing the experiment I purpose budding an equal number during the coming season. The behaviour of the several kinds of Apples as stocks will no doubt prove interesting. Many of them at the present juncture appear all that could be desired as far as growth is concerned.—E. MOLYNEUX.

## GROS COLMAN GRAPE.

No Grape that I know of can be so much improved in flavour and general quality as Gros Colman. It really needs a high temperature to develop its best qualities, and this must of course be combined with a judicious amount of air. When this treatment is given to Gros Colman it is vastly improved. Under cool conditions you may secure a good colour and heavy bloom, but the edible conditions of the fruit are much inferior.

Gros Colman, when well grown, is a most useful and handsome Grape, possessing sufficient quality to make it an acceptable fruit on the dessert table. Noble in appearance, firm in flesh, and not wanting in flavour, it is a Grape worthy of the attention of all growers and consumers. Time was when Lady Downe's fetched a high price in the winter and spring; those days are gone, never to return. The bolder appearance of the Gros Colman has entirely put the Lady Downe's in the background, though the latter is most pleasant to eat when hung for a month or more after becoming thoroughly black.

One thing that greatly enhances the value of Gros Colman as a Grape for market growers is the comparative ease with which it can be thinned. Compared to the thinning of Black Alicante or Lady Downe's the thinning of Gros Colman is a pleasure—if only one thins them enough. When Colman Vines are in full vigour the amount of thinning the bunches require is wonderful. When one thinks that berries  $4\frac{1}{2}$  inches and even more in circumference can be had when the Vines are in prime order, the berries must be wide apart when thinned. The inexperienced thinner is often much deceived in this matter, as his mind's eye cannot picture the enormous berries that are to develop. I speak, of course, of Vines in the best possible condition.

Taken all in all Gros Colman is well worthy of the best culture that can be bestowed on it, as it is a most satisfactory Grape in many ways. Sometimes it happens, during a very sunny, hot summer, that the Colman is better for a very slight shade. A little whiting and skim milk squirted on the glass with a syringe has been found useful for this purpose. It prevents the foliage suffering and helps to keep down spider. For a Grape with a robust habit Gros Colman is—like Muscat of Alexandria—peculiarly subject to the attacks of red spider if not carefully watched and attended to.

Gros Colman hangs well on the Vine, but our experience of it as a Grape for keeping in bottles has not been favourable. It requires a long time to colour and ripen as a rule, and has a strange habit of colouring even as late as Christmas. All things considered, this Grape is deserving of the position it has acquired as a market variety.

The importance of an abundant supply of fresh fruits and vegetables is every year becoming more evident, and there can be no doubt that an ample supply of well-ripened Grapes is most important for the public health. Grapes are not only refreshing and sustaining, but most truly medicinal, and are calculated to assist very much in maintaining a generally good condition of health. Their value is vastly enhanced when high culture has been applied to them, and the more this is recognised the better for all concerned.—JOHN THOMSON, *Clovenfords*.

MILTONIA BLEUANA VIRGINALIS.

AMONGST the many superb Orchids staged at the Temple show none was more beautiful or attracted more attention than *Miltonia Bleuana virginalis*, sent from Belgium by Mons. Jules Hye. The woodcut (fig. 83) will convey some idea of its quality, the single bloom being almost exactly the natural size. The colour is a pure white, the base of each petal being flushed with rosy purple, while the lip has a blotch of rosy buff. The first-class certificate awarded was thoroughly deserved.

## ORCHIDS AT WOODHATCH, REIGATE.

ALTHOUGH there were such wonderful collections of Orchids at the Temple show there were numbers of others unrepresented, and amongst these the fine one which Mr. Haywood has at Reigate merits inclusion. Probably not so representative as many other collections in certain respects, because here it seems to be more desirable to have certain species or families in big groups,

hence we find houses devoted respectively to *Miltonias*, *Phalænopsis*, *Odontoglossums*, *Cypripediums*, *Masdevallias*, *Vandas*, *Dendrobiums*, *Cattleyas*, and *Lælias*, of each of which sections there is an almost immense number, and in every case all are in the most admirable condition.

Houses and Orchids alike are extremely clean, and the latter are most healthy and robust. A rare form is *Miltoia Daisy Haywood*, one of the finest whites there is, and of great beauty. *Phalænopsis grandiflora* is well represented by several grand spikes. A noble and most effective Orchid. There are many very fine varieties amongst *Cypripediums*, such as *Lawrenceanum*, *Rothschildianum*, *caudatum Wallasi*, with very long appendages; *Victoria Marie*, and beautiful *bellatulum*s.

In many respects the bulk of the collection is past blooming, but in such variety something interesting may always be found. Mr. Salter mentioned that he had during the long spell of hard frost in the winter a very anxious time, as it was most difficult to maintain anything like a suitable temperature and keep the houses from becoming thickly coated with ice.—D.

## ACINETA HUMBOLDTI.

THIS singular and pretty species with its pendant scapes of purple spotted flowers is very attractive while it lasts, but the evanescent character of its flowers is a great fault. Like all the genus this species may be grown in wire baskets suspended, but to leave them, as is too often done, in one position all through the year with very scant attention is to court failure.

I find that *Acinetas* enjoy a very high temperature during the growing season, and in order to keep the foliage in good condition, and red spider and other insects in check, the syringe must be constantly plied about the plants, as the atmosphere is frequently drier close under the roof than in the body of the house. The roots, too, if in a rough open compost, delight in copious supplies of moisture until well on in the autumn. A frequent mistake made with pseudo-bulbous Orchids is diminishing the water supply too soon, in fact just as the roots are actively searching for it at the time of finishing up the pseudo-bulbs. The species in question is almost aquatic in its needs from the time the growth is well on the move until about the beginning of October, when the supply must be diminished, the temperature also being lowered. In the winter very little will suffice if the atmosphere is fairly moist, and a minimum temperature of 50° will be found suitable.

Good peat fibre, loam, and sphagnum moss in equal proportions, with a good sprinkling of rough nodules of charcoal, will be found a suitable compost. *Acinetas* dislike frequent disturbance at the roots, therefore the drainage must have very careful attention, some large pieces of charcoal being first laid in the bottom to insure the safe passage of any spikes that may be pushed down through the compost. If fairly wide baskets are used the plants may be kept in good health for a number of years by removing a little of the top compost yearly and substituting fresh. It is a native of Venezuela, and produces its flowers freely when well established from the base of the robust-looking pseudo-bulbs. Its flowering season is during March and April, and the blooms usually last about ten days only.—H. R. R.

## ORCHIDS AT CHELSEA.

THE famous nursery of Mr. William Bull is at the present time more than usually gay, owing to the fact that the annual exhibition of Orchids in bloom is now open. The display this year is quite equal to any of its predecessors, and the view on entering the large span-roofed house which is used for the above purpose is one of exceptional beauty. The name of Bull is synonymous with that of new and rare plants, so that one expects to find something out of the ordinary when paying a visit to this establishment. In this respect no one need feel disappointed, as amid the large army of flowers there are many which can only be seen in very choice collections. The plants are tastefully arranged along the centre and side stages of the house, and form a picture of gorgeous beauty that would be difficult to excel.

The most striking in this maze of flower are the *Cattleyas*, *Lælias*, and many well-furnished plants of *Odontoglossums vexillarium* and *citrosimum*. Amongst the former was noted a fine specimen of *Cattleya Mossiæ fimbriata*, with flowers of most pleasing form and very sweetly scented, while scarcely less beautiful is a good example of *C. Mossiæ Lawrenceana*. A feature, however, amongst the *Cattleyas* is the many magnificent specimens of the different forms of *C. Mendeli*, giving a good idea of the variety that is obtained in this charming flower. Time did not allow of a close inspection, but amongst many others *C. Mendeli Empress*, with its large white sepals and petals and very deep crimson lip, called forth acclamations of praise. Of an equal standard of merit is *C. Mendeli majestica* of a like colour, but with a long and delightfully fimbriated lip. Another pleasing form is that of

*C. Mendeli Rex*, with its large petals and sepals of the purest whiteness, and lip of a rich crimson. An exceptionally fine plant was noted in *C. Mendeli chelense*, one of the most superb in the whole group, having petals and sepals equalling in purity those of the former, with a long lip pleasingly fimbriated, and in colour of the deepest crimson.

As already mentioned, *Lælias* form a feature, and one fine plant of *purpurata* was noted carrying twenty-two large flowers. Amongst others of this charming variety *L. purpurata Victoria* is

different shade, being rosy red. Very distinct in character to the above are many well-grown plants of *O. citrosmum*, and amongst these particularly worthy of mention are *O. citrosmum punctatum*, a beautifully spotted form; *O. citrosmum sulphureum*, with large buff-coloured petals and sepals; and *O. citrosmum concolor*, which has one deep shade of pink throughout the whole flower.†

*Cypripediums* are well represented in the show, chiefly with small plants placed here and there in groups. Among these are *C. grande*, *C. Curtisi gigantea*, *C. Lawrenceanum superbum*, and

FIG. 83.—MILTONIA BLEUIANA VIRGINALIS.

very conspicuous. This is a magnificent form, bearing large substantial flowers with petals and sepals of the purest white and lip of very deep crimson fading into the throat, which is of a bright canary yellow prettily striped. Another fine plant is that of *L. purpurata rosea* with several spikes carrying six blooms of fine character, and shaded with rose throughout. Not so striking as these, but still very pretty, are *L. purpurata Russelliana* and *L. purpurata Bella*, a form of much lighter shade.

A large number of well-flowered plants of *Odontoglossum vexillarium* adds much to the beauty of the show, and amongst these *O. vexillarium albescens* is particularly effective with its fine white flowers of extraordinary size slightly shaded with crimson. *O. vexillarium rubrum superbum* bears excellent flowers of a much

exceptionally fine forms of *C. niveum majus*. *Cymbidium*s are likewise conspicuous, amongst others being a fine specimen of the rare variety *Cymbidium concolor*, together with many handsome spikes of *C. Lowianum*. Several well flowered *Oncidium*s claimed attention, amongst others being *O. macranthum*, *O. Marshallianum*, *O. pulvinatum*, with bright blooms of the pretty *O. Kramerianum*, or the Butterfly Orchid.

Mention must be made of the rare and exceedingly pretty little *Phaius bicolor*, with its chocolate coloured sepals and petals and lip of delicate purple. *Masdevallias* were also noted, amongst others being the pretty though miniature form of *M. Schroderiana*, together with *Comet*, one of the brightest flowered of its class. Many curiosities are also displayed, such as *Scuticaria Hadweni*, with

its chocolate coloured blooms barred with yellow, and the long drooping flowers of *Cœlogyne Dayana*. All plants in what may be termed the reserve houses, and from which the foregoing are drawn, are in excellent condition of health and throwing numberless flowers, by which the exhibition may be kept up for a considerable time.—G. H. H.

### EXPRESS GRAPE GROWING.

YOUR correspondent, "Market Grower," in his letter on page 225 (May 16th) appears rather sceptical about the result of these crops of Grapes which he has been reading of lately in the Journal. He points out what he considers a most significant omission—viz, "the price these Grapes realised per pound." He also states that it is not enough to say they carried so-and-so, and finished well, when opinions differ so much as to what is a good finish in a house of Grapes. This certainly is a most significant statement. I have long been under the impression that among practical Grape growers, at least, the term "finished" was thoroughly understood, being a very comprehensive term, and required no further explanation or definition. When I hear one say the Grapes were good and well finished, I at once understand them to be at least medium sized, compact bunches (not necessarily large), berries good and well coloured, and of good flavour whatever the variety may be.

If I were to give "Market Grower" the prices he asks for he may again say it is not enough to say they realised so and so, or that the crop was so and so. But as photography cannot be accused of exaggeration, and may be trusted to convey the truth so far as the weight of crop is concerned at any rate, I shall be pleased to forward a photograph of the Gros Colman house I referred to on the 9th inst. in the Journal if "Market Grower" will kindly communicate his name and address to me. The photograph represents the entire crop of 1891, which was cut in February, 1892. The house as described by me is 100 feet in length by 24 feet in width, and 18 feet rafters planted with eighty-two Gros Colman Vines, 2 feet 4 inches apart. Each Vine carried twenty-two to twenty-three bunches of first-class, well-finished Grapes, and averaged 3s. 4d. per lb. We began selling at 3s.; after a few days we made 3s. 6d. The house was cleared in a fortnight. During the eight years referred to in my letter on the 9th inst., page 408, *Journal of Horticulture*, the average price from this house during that period was 3s. 6d. The first four years, from 1887 to 1890, the crop averaged 4s. 6d. per lb., and the last four years, from 1891 to 1894, 2s. 6d. per lb. The highest price realised during the first four years was 7s. 6d. per lb.; but great changes have taken place since then in the price of Grapes. The prices given are, of course, wholesale market prices, but I do not think prices prove much, as "Market Grower" may possibly have discovered that prices are guided by supply and demand, and also the period of the year the Grapes are sold. I have frequently sold Grapes at 1s. 9d. and 2s. per lb. that would have made nearly double that amount three months later.

"Market Grower" gives a sad account of a house of Gros Colman Grapes he saw last year. The house was 300 feet in length and carried 2700 bunches, which, he states, was the heaviest crop he ever saw of any Grapes. "Market Grower" does not give the number of Vines in the house; but, assuming they were planted 2 feet 6 inches apart, there would be about 240 Vines in the house, which would give an average of a little over eleven bunches per Vine, averaging about 1½ lb. per bunch, on a rod 12 feet in length, which would be about 1 lb. 6 ozs. per foot run of rod. I do not think there are many who would consider such a crop a very extraordinary one. "Market Grower" also states that all the bunches were left on the Vines, many of the shoots carrying three and four bunches. It would not require many such shoots to carry eleven or twelve bunches. There surely must have been a great many barren ones. "Market Grower's" statement, in my opinion, points to thorough mismanagement throughout.

I am deeply gratified by the fact that Mr. Thomson in his letter on page 459, May 23rd, agrees with me on some points at least, but he appears rather cynical about the result of my "poor little starved Vines" as he is pleased to term them. My little Vines were by no means so good as they might have been, but not starved, as stated by Mr. Thomson. They were healthy, sturdy little canes, and were possessed of that which is of the highest importance in a young Vine for planting—viz., abundance of fine, healthy, fibrous roots. It is true they were not grown or prepared on the orthodox principle, nor planted at the appointed season. Mr. Thomson states that their Vines were prepared in the best possible way. I think this proves how wonderfully accommodating the Grape Vine is. My little Vines had no coddling before planting. The eyes were plunged in the propagating pit until rooted, when they were removed and placed on a cool border in a Tomato house, and received regular supplies of water when necessary until they were planted on the 11th or 12th of August, and by the middle of September these poor little Vines were travelling at the rate of 3 or 4 inches a day.

Surely Mr. Thomson (even if he has never tried the experiment) is not so prejudiced as to think it impossible for Vines planted in a good border in a lean-to house, and under moderately good treatment, to make as good growth as Vines would planted earlier in the season. We frequently have some of the brightest weather in the year during the autumn months, although the days are shorter. With respect to the ripening of the wood that is merely a question of time and management.

I heartily agree with Mr. Thomson that we want quality as well as quantity, and I have been exerting myself in this direction for a long

time in trying to produce the best Grapes possible, both in quantity and quality; but whether I have succeeded in doing so perhaps it is not for me to say.—W. INNES, *Derby*.

### TOWN VERSUS COUNTRY GARDENING.

MY experience for a very long time had been wholly in the country, and when three or four years ago we took up house and garden in a good-sized, much-frequented country town, within easy distance of London, one knew that the conditions of gardening must be very different from those to which one had been accustomed to formerly. A good-sized raised bed facing south, protected by the back of the house from the north, a piece of rough turf or grass about 30 feet long running down to a walk about 10 feet long and 4 feet wide dividing the main garden from a little belt of Victoria Plum trees rather wider than the bed I have spoken of as being immediately beneath the windows, a walk on one side, right of the turf, a border filled only by old and decrepit evergreens on one side of the walk dividing it from a neighbour's garden, and on the other side, filled in the same fashion, but backed by a decaying wooden fence, completed the unpromising picture. And if the outside aspect was unattractive, the nature and character of the soil was discouraging in the extreme. The bulk of the ground was all but pure clay—cold, tenacious—nothing could grow; no roots could expand. Let us make an exception in favour of the bed beneath the windows, where luxuriated two great Laurel bushes, beneath whose sombre shade, with hardly a pretence of concealment, reposed every variety of disused and discarded rubbish, whole and broken, while rubble and rough stones, and broken brickbats, made up about the most disheartening field for a lover of flowers to work and cultivate that it would be possible to find.

I must not make this communication too long for your columns in case you should admit it, but as an old subscriber and sometime contributor to the Journal I should much like to send you some further notes on town gardening under difficulties, and these are greater than at first appear. Many of them might, I am convinced, be obviated, and the general advantages of having cultivated disinterested labour to assist the amateur would go far to develop a more intelligent and discriminating race of jobbing gardeners, to the great satisfaction of the employer and the unspeakable health and adornment of the garden.—A. M. B.

### THE PANSY,

ITS CULTURE, AND DIFFICULTIES MET WITH BY AMATEURS.

(Prize Essay.)

IN connection with the Tamworth Pansy and Viola Show, held on Saturday last, a silver medal was offered for the best essay on the "Difficulties of Pansy Amateurs, and How to Deal with Them." After carefully reading six essays the judges awarded the medal to Mr. Robert Hannah, Atherstone, whose prize contribution is herewith published:—

There are few flowers in which the effects of cultivation are more marked than in the Pansy. In an early description of this flower, given by Loche, I find he describes it as a kind of Violet, no doubt at the time a fair and proper description, but what a description if applied to the Pansy of the present day.

EARLY CULTURE.—I have looked through several old works, and so far as I can ascertain, the first record of its actual cultivation in this country was in the year 1812, at Walton-on-Thames, by a Mr. Richardson, gardener to Lady Mary Elliott, daughter of Lord Tankerville.\* Mr. Richardson appears to have brought out some of the fine qualities of the flowers, for shortly after it was noticed, and took a place amongst florists' flowers. Since then wonders in its development have been accomplished, and the Pansy of the present day has become as perfect a flower as can well be imagined.

ATTRACTIVE IN GROWING IT.—It is both attractive and artistic, and there is no flower grown that opens out so wide a field of interest and amusement to the amateur in horticulture. The question may be asked, Why? Simply because it possesses so many general advantages over most other flowers. It is most hardy. Inexpensive. Little trouble to raise from seeds or cuttings, and with fair management you may have it in bloom for fully eight months out of the twelve, and it may be grown by anyone and under almost any reasonable conditions.

Then, again, in the culture of this flower the amateur need not be very far behind the professional. It may be argued that the professional has the advantage over the amateur by his greater knowledge of its culture, and his skill in hybridising. Here I may say that the art of hybridising may be acquired in a single lesson. True, but it does not follow that plants raised from the professional's hand-crossed seed show in the long run very much better results than those raised from self-crossed seed providing that the seed is taken from a bed where only first-rate varieties are grown. There is at all times the chance of raising a specimen superior to the parent plant. That fact is really one of the things that adds so much amusement and interest in the culture of this flower. There is another thing—whatever plants you raise from seed you can depend on the blooms being at least pretty, and, as I have already said, there are at all times the chances of finding something really good amongst your seedlings.

HINTS AS TO ITS CULTURE.—In the successful culture of this flower it is only necessary to carry out a few simple rules, such as I have

worked on, generally with satisfactory results. The first rule I should like to impress on my fellow amateurs is to grow nothing but first-rate varieties. Get rid of all plants not coming up to that standard. Keep either to the "Fancy" or the "Show Pansy," in other words do not grow both, unless at the opposite ends of the garden, for satisfactory results. I certainly recommend the former. You will soon discover the varieties that are best suited to the soil of your garden, and from such plants take the best of your cuttings for the next year's display. Root them where you intend wintering them, in a cold frame in the autumn. Keep the lights off until the severe weather sets in; do not be afraid of giving the young plants abundance of air on every favourable occasion, and bring them up as hardy as possible. After a severe frost, if the snow has thawed from the glass, shade them from the sun by means of a little straw or mats over the lights until the ground has thawed. If the weather is open plant out towards the end of March. Should a cold easterly wind set in before they are properly rooted shelter each plant by means of an inverted flower pot.

**PREPARING THE GROUND.**—In preparing the ground for them commence if possible in the autumn, by first digging in a good dressing of leaf mould, followed by a dressing of short well-decayed cow manure. Get both well incorporated with the soil, then turn up roughly, so that the frost can get well into it. If the weather permits in the early spring give the ground a good dressing of soot, and turn over. In February follow with a dressing of salt, about quarter pound to the square yard.

**IF FOR EXHIBITION.**—If growing for exhibition give your plants abundance of room, strip side shoots, stake the leader, and do not allow the plants to bloom until about a fortnight or three weeks to the time you require the blooms; do not pinch a bloom off, but break it off with a slight jerk to the right, close to the stem. So much for its culture. We will now turn to a few of the difficulties that are sometimes met with by amateurs and others.

**THE WIREWORM.**—The first and about the greatest enemy to the Pansy is the wireworm; it is to be found in most gardens, and is too well known to need any description. Sufficient to say there are several species of them, and nearly the whole family are pests in the true sense of the word. They are the larva of the click beetle, and it is said they remain in the soil in a larva state for the space of five years. To get rid of them I recommend the following remedies:—If space and time will allow, sow the intended bed thickly with white Mustard seed early in the autumn, destroy all weeds near. This pest, it would appear, cannot eat the roots of the Mustard plant, most probably from its acidity, and no other roots being in the soil near on which they can feed, the inference is they die for want of the necessary support. Be that as it may, they disappear.

Another plan is to plunge full grown Carrots into the soil of the bed about 8 or 10 inches apart, and examine them every other day; nothing more is required than to remove the worm and replace the Carrot. This may be followed up when the plants are bedded out. It seems that the wireworm prefers Carrots to almost anything else. Another remedy that I have tried with great success is a perforated galvanised iron trap. Such traps may be obtained at a trifling cost from Mr. W. Sydenham, Tamworth. Bait them with pieces of Carrot, Potatoes, Turnips, or linseed cake. These traps are not only useful in ridding your soil of the wireworms, but numbers of other insect pests find their way into them. Occasionally watering with lime or soot water renders the roots of the plant distasteful to this foe as an article of diet.

**THE LEATHER GRUB.**—The presence of this pest may be too quickly seen, by finding one or more of the plants hanging dead or withering up. Examine the stem, and you will find that it has been gnawed through. At once make a careful search in the soil at and around the roots of the plant that has been attacked, the possibilities are that you will find the culprit. It is a grub of a dirty grey colour, large enough to be easily seen. Both soot and lime water are distasteful to this pest.

**SLUGS.**—Of these there are several varieties, but the most destructive to the plant and bloom are the small black slugs. They bury themselves during the day in the soil and under the leaves of the plant, and come out in the night time to feed.

**REMEDY.**—Take some fresh lime in a powdered state, put it into a coarse bag, and in the evening or early morning well dust between the plants.

**LIME WATER.**—Lime water can be used, and may be made by pouring water at the rate of 3 gallons to a pound of lime in lumps, as fresh from the kiln as possible. Stir well, and allow it to stand for a few days; it will then be quite clear. Use through the rose of a watering can. This should be done in the evening when the slugs are out feeding. Lime or lime water will destroy every slug it reaches. Do not be afraid to use either remedy. Probably you may spoil a bloom or so, but you will not in any way injure the plant; in fact, lime has the reverse effect.

Soot and soot water will keep them away if it does not kill them. To improve the colour of the bloom there are few things better than soot if you use it dry. Be sure that it is not too fresh.

**SOOT WATER** may be made as follows:—Enclose soot in a coarse bag at the rate of about 1 quart to every 3 gallons of water. Place in the bag containing the soot a brick to sink it. Allow it to stand a few days before using.

Another good and easy way is to strew a few fresh Cabbage leaves about the bed in the evening. In the morning the chances are that you will find many of these slimy pests adhering to them.

**APHIDES** (plant lice or blight bugs).—This numerous family are at home in almost all kinds of plants. The aphid that generally attacks

the Pansy is of a dark reddish-brown colour. Its presence may be detected by the unhealthy appearance of the foliage, or by the blooms being disfigured with spots.

**REMEDY.**—Syringe with a solution of softsoap and water in the evening, and the following morning before the sun is on them, with clear water or tobacco water. A solution of boiled quassia chips, or a dusting with snuff or tobacco powder, are all useful in destroying this pest. The lady bird (*Coccinella*) renders great service in destroying myriads of these troublesome pests.

**SHADING AND SHELTERING.**—It is an easy matter to obtain perfection in the colour of a bloom, but to retain it there just at the time it is most needed is one of the greatest difficulties a grower has to contend with. To retain any of the beauty in the bloom, the plant must be protected from the hot sunshine and heavy rain. The best modes with which I am acquainted are as under:—

Utilise your frames in hot weather, substituting a canvas awning for the lights. Another way is by having a few frames something after the clothes horse pattern, over which canvas is stretched, hinging two together on the top, thus—(fig. 84).

FIG. 84.

Another cheap and useful shade may be made by taking a piece of stout paper, say 20 inches by 10 inches, and cut it as shown in fig. 85, and form it into a cap, thus—(fig. 86).

FIG. 85.

FIG. 86.

Secure the sides by means of a couple of paper fasteners, insert around the plant you intend protecting three or four slight stakes in a slanting direction to receive the cap. It will be an advantage to give the paper (before forming the cap) a coating of boiled linseed oil, to which is added a little white lead.

Another excellent method by which shade may be obtained from the midday sun, and shelter from the rough winds, is by sowing not too close to the bed on the south side from east to west a row of Sweet Peas.

[The six essays, all of which contain useful hints, will, we are informed, be published in pamphlet form at 3d. each. \* The late Mr. William Dean states in his "History of the Show Pansy," in Mr. James Simkins' excellent work, that Lord Gambier collected wild Pansies in the fields, and requested his gardener, Mr. Thompson, to cultivate them in the gardens at Iver, near Uxbridge. This was done, and improved varieties were soon obtained. Mr. Dean mentions the Walton-on-Thames case, but he believed, with Dahl, that "it was at Iver that the improvement of the progeny of the wild Pansy was first made."]

A TEXT—POWDER.

I FEEL the sermon has been owing to these pages for some considerable time, but *non possumus!* During the last six months—times of transition—when a man found himself blessed with two parishes, in the shape of acting overseers' and surveyors' work to do, you can doubtless give a pretty near guess how things have been sailing with him in his ship-shaping and piloting course through delectable gulfs of the modern parish meetings. However, I have nearly weathered the storms, escaped the quicksands, and I retain all my old offices in their new arrangement. I conclude with a highway survey audit and a vestry for church purposes this week, which will relieve me, I hope, to give more attention to the *Solanum tuberosum*. For three years I have been successful in warding off the Potato disease through the application of Tait and Buchanan's anti-blight powder. I pin my faith to the mystic No. 3, therefore allow me to advise those who wish to preserve their crops of the noble tuber, and its congener, the Tomato, to order at once a quantum of the powder from Messrs. Barr & Son, 112, King Street, Covent Garden, W.C., who are among your advertisers, and therefore entitled to mention here.

I have, as our worthy Editors can guarantee, kept my Potato and Tomato haulms perfectly free from disease, and consequently the tubers, by constantly dusting them with the powder from their infantile state, to allow no loopholes on the foliage for the fatal spores to take possession. I consider the dusting application far more important and convenient in its application for horticulturists than the sloppy

mixtures, which, after all, merely mean the powder submerged—a *bouillabaisse*—the nasty mess. I use the Malbec bellows, which no garden should be destitute of, for greenhouses and wall work, though I can more expeditiously go over my Potato breadths by using a horse's baiting sieve, with an extra addition directly lying on the wicker-work mesh, namely, a piece of perforated zinc or coarse muslin. Fasten a forked stick under the sieve, allowing sufficient length to serve as a handle. Suspend the sieve by the aid of this handle over the Potato foliage, walk rapidly, or run if so inclined, and keep tapping the rim or side of the sieve with a short piece of stick. An impalpable even smother of the powder will become deposited on the surface of the leaves to defy all microbes, and it at once can be decided whether the bellows or the sieve is to win. At any rate, I never rode post for a patent, so there you are.

Well, our Editors, that is my text. No doubt if I live the sermon will follow, which I trust may prove effective; and so, to make a beginning, I will firstly say a paragraph for yourself—and the philosopher. It may not perhaps be an unmixed blessing that I have not been enabled to cause the bending of the printers' backs in Fleet Street till now, when this subject will be less likely to be cast aside, and be more likely to be read, as the Murphies are approaching their nervous state of greenery. Let your readers know also that they need not fear about the "sticking" properties of the anti-blight powder. It will do so without the aid of softsoap or other nostrums, which I see are theoretically, as advice, creeping in. I have undertaken the Berkshire part of the plan of experiments with manures for Potatoes for the University Extension College, Reading, Agricultural Department, so what with this and the anti-blight experiments, which I propose to adhere to, I think I shall be enabled to afford you and the philosopher a lively quarter of an hour, should you elect to come and "sit under me" by-and-by.—ROBT. FENN.

#### THE AMERICAN CHRYSANTHEMUM ANNUAL.

THIS work, which is far more pretentious than the N.C.S. Year Book, has just been published. It is edited by Mr. Michael Barker of the Horticultural Department, Cornell University. It is admirably printed, and contains excellent portraits of celebrated American growers of blooms and new seedlings, but the pen and ink reproductions do not do them justice. It also contains illustrated articles on diseases of Chrysanthemums. Papers on historical and cultural matters are included by writers of acknowledged ability from all parts of the world. England is represented by Mr. C. E. Shea, who discourses on the past season; by Mr. Shoemith, who tells of the cultivation of American varieties in England; and by Mr. Harman Payne, who at some length acquaints the American reader with the origin, rise, and growth of the English National Chrysanthemum Society, from the earliest times to the present. A portrait of Mr. John Thorpe appears as the frontispiece, and there are other eminent growers given, including the officers of the American N.C.S. The book is published by the Mayflower Publishing Co., Floral Park, N.Y.

#### THE IMPERIAL CHRYSANTHEMUM SHOW.

In the "Pall Mall Magazine" for the present month is an article entitled "The Imperial Family of Japan." This article is illustrated with portraits of the reigning family, their crests, &c., and contains a reference to the annual Chrysanthemum show in the Emperor's gardens, upon which a few remarks may be interesting to horticultural readers.

The writer in the "Pall Mall Magazine" says:—"Every autumn the Emperor gives a birthday ball, and a few days later a Chrysanthemum garden party. It was my good fortune to be present at both these gatherings in 1892. The invitations to the ball and garden party were in French, engraved on a large Chrysanthemum-bordered card."

As I happen to have a card of invitation to the Emperor's Chrysanthemum party, which was sent to me by a friend in Japan some five or six years ago, and who had been present on more than one occasion, I was rather surprised to find that the invitation was in French. Pierre Loti, the author of "Madame Chrysanthe" and "Japoneries d'Automne," gives in the latter work a very full and interesting account of this Imperial function, but his record of the ticket of invitation corresponds with the one in my possession.

The ticket is of ivory white, very thick and gilt-edged. It measures about 6 inches in length by 8 in width, and has a gilt border of Chrysanthemum foliage and flowers placed at regular intervals. Intersecting the top of the border is a large gilt figure of the Kiku-mon or Chrysanthemum crest, composed of a flattened sixteen-petalled single-flowered type. The wording of the invitation is in the Japanese character and in perpendicular columns, being read from top to bottom and from right to left.

My friend's description of the fête, which was published in the columns of a contemporary some time since, agrees substantially with

that in the "Pall Mall," so that little or no alteration in the proceedings appears to have taken place.

It is—or perhaps it would be safer to say that this fête was—one of the very few occasions on which the Empress was seen in public. The flowers are wonderful examples of cultural skill, and exhibits of huge single-stemmed plants with only one bloom on a plant, and monstrous pyramids, with 300 or 400 blooms on a plant, are on view beneath tents of purple silk supported by bamboo frames. Invitations are difficult to obtain, and the visitor's presence is accounted equivalent to presentation at Court.

Some of the continental raisers are stated to have procured seed from varieties grown in the Imperial gardens, and one variety, named M. Foukouba, who occupies the position of Director of these gardens, and which was raised from seed emanating from this source, is being put into commerce this spring.

In California there are now Japanese nurserymen engaged in the importation of native novelties into the United States, and when we consider the commercial enterprise of the inhabitants of the Land of the Rising Sun we should not be surprised to find some of them settling down in this country, which, in spite of all competition, is the Eldorado of the Chrysanthemum raiser.—C. H. P.

#### AN APRIL CHRYSANTHEMUM SHOW.

THE annual show of the Auckland (New Zealand) Chrysanthemum Society took place in the Choral Hall on April 18th, 19th, and 20th. The show was opened by His Excellency the Earl of Glasgow, who was accompanied by Lady Glasgow and a large party from Government House. In his opening remarks the Governor referred to the fact that the soil and climate of Auckland are specially favourable to the production of large and bright flowers, and this opinion was borne out by the testimony of one of the members of the Society, who described the leading stands in Japanese cut blooms as surpassing what he saw at the Crystal Palace and Westminster Aquarium in November last. The number of blooms staged was not so great as last year, but there was a general consensus of opinion that no such examples had previously been seen in Auckland.

One of the most attractive displays was the dozen stands of six blooms of Japanese in one variety. Mr. Handley was first with six perfect Sunflowers, Miss Carnott second with Domination, and Mr. Tibbs third with Vivand Morel. Mr. Jones also had a grand six of E. Molyneux. The greatest display of all, however, was the six stands in the amateur class for twenty-four Japanese. The growers had evidently put all they knew into this contest, and the Judges had a very difficult task to settle the merits of the lovely stands. Mr. Tibbs was first, Mr. Wells of Cambridge second; and Mr. Tibbs had a second stand highly commended. Mr. Tibbs' twenty-four were the following:—Back row: Charles Davis, Vivand Morel, International, Amos Perry, Miss D. Shea, Miss A. Harts-horn, The President, Mrs. C. H. Payne. Middle row: Mdlle. M. Hoste, yellow (?), Beauty of Exmouth, John Farwell, Stanstead White, Illuminator, The Queen, Harry Reay. Front row: W. Seaward, Florence Davis, Excelsior, Mrs. J. W. Tibbs (white L. B. Bird), Sunflower, L. B. Bird, Col. W. B. Smith, and Charles Shrimpton. Conspicuous among Mr. Wells' flowers were Eda Prass, Duke of York, and E. G. Hill.

The N.C.S. medals were awarded as follows:—Professional, thirty-six varieties, Japanese and incurved, T. Whiteley; twenty-four incurved, T. Whiteley; twenty-four Japanese, D. Hay & Son; N.C.S. certificate, T. Whiteley. Amateur, thirty-six Japanese, incurved, W. Handley; twenty-four incurved, T. Wells; twenty-four Japanese, J. W. Tibbs; N.C.S. certificate, T. Wells. The championship.—Dewe's challenge cup and N.C.S. silver medal were won by J. W. Tibbs, with W. Handley and T. Whiteley equal for second place.

#### BLACK STRIPE IN TOMATOES.

I AM exceedingly obliged to Mr. Abbey for his very clear article on "Black Stripe" (page 457, May 23rd), and I hope you will convey my thanks to him, and also let me thank you for your remarks. There is one point, however, which Mr. Abbey does not touch, and it is perhaps the most important from the grower's point of view, and that is "infection." Mr. Abbey assigns its origin to diseased seeds. This was also the conclusion I was driven to, as I could find no other to account for the outbreak; but it seems also clear to me that infected plants infect sound plants. How is this done?

Every plant I have examined has had the disease all up the stem, so apparently it must have started under the soil. How has the infection been conveyed then? I have had two supplies of seeds. No. 1 came from three sources, one French and two English. The whole is infected, and I have lost quite nine out of every ten plants. No. 2 came from two sources, both English. They were brought up apart from No. 1, being much later. One house of No. 2 has had the disease very badly, caught, I believe, from the adjoining house of No. 1. This house of No. 2 is the one I referred to in my letter to you of the 16th, when I said the disease had affected one side but not the other. On the very next day (Friday) I found some affected plants on this side, however, and by Monday had turned out twenty-seven diseased ones. Since then I have not had another bad plant in this house. It really looks as if the disease took some days to cross the 15 feet of width, and then attacked every susceptible plant simultaneously. Now, how was this infection conveyed to attack the plant underground?

I have three other houses planted with No. 2 seeds, one of them of the same supply as in the affected house, and I have only had one plant diseased as yet; but in these houses a few plants of No. 1 were put out. Nearly all of these have been diseased and destroyed. If Mr. Abbey could throw any additional light on this question of infection it would be of immense value to growers. Now would these affected houses be safe to plant in next year? Does the poison start only for the seeds, or may it remain in the soil?

What Mr. Abbey writes upon "dry rot" in Potatoes is very curious. Last year all my early Potatoes had a disease which shrivelled up all the haulm. All the Potatoes were only the size of Walnuts. My foreman declared it was that late frost (on May 20th, I think) that caused this; but to me it appeared quite different to frost-bite. A new house (not for Tomatoes) was built where these Potatoes grew. Some soil was moved for the foundation. This soil may have been used in potting up the No. 1 Tomato plants. Would this have infected them? My late Potatoes last year, grown adjoining these diseased ones, were perfectly healthy.—ST. JULIEN ARABIN.

IN order to comprehend how infection of healthy Tomato plants is effected it is necessary to give a brief description of the fungus producing "black stripe." The *Macrosporium tomati* attacks the leaves, stems, and fruits extensively, spreading over their surfaces (internally) and ultimately destroys them, and the fruit is small, discoloured, or blackened and worthless. There is an absence of the rapid decay and stench so noticeable in the case of Tomato plants affected with the Potato disease fungus (*Phytophthora infestans*). At first a small greyish brown spot is visible on the leaves, stems, or fruit, and this extends in concentric rings; these become brown, and ultimately much darker or black. The hyphæ, threadlike branches of the mycelium, are brownish, somewhat curved, and septate. From these spring the conidiophores, or erect hyphæ or outgrowth bearing the conidia, which (fruits) are oblong, pointed, and divided by transverse and longitudinal septa, as shown in the illustration (fig. 87). From these the conidia fall out when fully ripe, and are distributed far and wide, giving rise to the "black stripe" on the leaves, stems, or fruits of Tomato plants on which they fall, germinate, and push the germinal tube into the internal tissue. Thus the disease spreads from plant to plant during the growing season.

It is said that the conidia from this form (*Macrosporium tomati*) may rest for the winter on the decayed leaves, stems, and fruits of Tomato plants, and on the ground. Mr. Wead of the New Hampshire College, United States of America, states positively that *M. solani*, an allied species, winters in the dead leaves and stems of Potato plants, and my experience is that *M. tomati* is only a form of that species.

Mr. Arabin's experience tends to confirm the view expressed. The spores of the fungus (*M. solani*) from the Potato plants seized on the Tomato plants at the root, for in the plant examined the disease had certainly ascended the stem. This confirms Mr. Iggulden's view, also that of the foreman, who attributed the collapse of the Potato tops to the May frosts, as these would tend to produce that condition of the haulm favourable to the development of the fungus, backed by the damp weather following, for this fungus certainly delights in damp and somewhat cold weather, and which respect it differs from Potato fungus (*Phytophthora infestans*).

**Bordeaux mixture.**—This is a recognised preventive of the disease, but to be effective must be applied when the plants are 6 inches high, and should be repeated at fortnightly intervals, so as to coat the growths as made with a thin film of the mixture. For reasons of easy application and less danger from use powder applications are the most desirable for use under glass. There are several such powders in the market, not advertised (as they should be) and in consequence are little known. I shall not say more about them for obvious reasons.

To prepare precipitated carbonate of copper. Dissolve separately in warm water 1 lb. of sulphate of copper, and 1½ lb. of washing soda, when dissolved mix the two solutions together well, when carbonate of copper will be precipitated, then pour off the water and dry the copper carbonate—that is, the sediment. Weigh the carbonate of copper when dry, then take 100 times its weight of air-slaked lime, quite dry and in the finest possible powder, and add the copper carbonate, mix thoroughly, passing several times through a hair or very fine wire sieve, and after mixing keep in air-tight vessels in a dry place. Use with an ordinary sulphur duster or bellows. It is most important to begin in time.

As regards disinfecting the soil, there is nothing better than quick-lime, about one-tenth mixed with the compost being sufficient, or a peck per rod in the case of borders. The lime acts promptly on any vegetable matter in the soil, such as partially decayed or strawy manure, which should not be used, either as manure or as mulching, for it forms the best nidus for the fungus, which is equally capable of existence, growth, and reproduction as a saprophyte or a parasite; indeed it produces its fruits more freely as the former than the latter, and those having it are in a great measure responsible, as it cannot possibly live where there is not organic matter, hence such substances as basic slag are far better than dressings of stable or farmyard manure, though there is little danger in that provided it be thoroughly decayed. A dry and well ventilated atmosphere is also of consequence in avoiding the disease, as it is damp and cold (relative to the subject) and organic matter that fosters the disease. Clean seeds and cleanly structures are also of the first importance in dealing with the low forms of vegetable life.

There was not anything in Mr. Arabin's specimen but plasma—no mycelial hyphæ or conidiophores. This was stated in the reply to his letter, and, of course, puzzled him, as *curl* in Potatoes and *black stripe*

in Tomatoes have the authorities, to know how the disease was infectious. I also stated that the fruits affected might or might not produce the fungus, for no one can tell what a plasma will bring forth. Sometimes nothing follows, yet the plants collapse and the fruit is worthless.

I have expressed the view that our enemy is nothing more nor less than the so-called saprophyte *Pleospora herbarum*, its conidial condition being *Macrosporium commune*, which has several forms according to climatic conditions and host. Indoors, and as a parasite, the conidiophores and conidia are long, drawn, and pointed; outdoors, and as a saprophyte, the conidiophores are very short and very blunt in the conidial part, so much so as to appear quite distinct. This *Macrosporium* is the product of the self-same mycelial hyphæ, and is produced

FIG. 87.—Black Stripe fungus (*Macrosporium tomati*) from Tomato plant under glass:—a, mycelial hyphæ; b, conidiophores; c, conidia; d, summer spores fallen out.

from the spore of *Pleospora herbarum*, and it seldom goes further than *curl* in Potatoes and *drooping* in Tomatoes. Occasionally, however, the *curl* is followed by the wholesale collapse of healthy Potato plant tops, and the destruction of Tomato plants and fruit by *drooping*, *stripe*, and *blotch*.

The fungus (*Macrosporium tomati*) figured is as I first saw it in 1873 at Grinkle Park, and certainly was accelerated by syringing the Peach trees, as in another house kept warmer and unsyringed there was not any disease in either the plants or fruit. Occasionally since that year I have seen the Potato top collapse disease and the Tomato rot—all

FIG. 88.—"Black Stripe" (e) and "Blotch" (f) on Tomato, caused by *Macrosporium tomati*.

the same thing—the conidial condition of *Pleospora herbarum*. *Macrosporium commune*, as a saprophyte; *M. solani* and *M. tomati* respectively as a parasite.

Strangely in 1895 I received, through the *Journal of Horticulture*, a specimen Tomato fruit with both *stripe* and *blotch* (fig. 88) from Saltburn-by-Sea (about ten miles distant from Grinkle Park), and on May 25th the outgrowths of the fungus broke through the blackened epidermis of the blotch, appearing as a greyish or white mould—the *Macrosporium solani* or *M. tomati*. The mycelium is discernible around the edge of the blotch, it growing in concentric fashion, and slightly raises the margin surrounding the destroyed cells. Keeping this fruit under daily observation, and transferring the spores to living plants, as well as decaying ones, an insight is got into the characteristics of the fungus as a parasite and as a saprophyte, in both of which it certainly originates from, and ultimately develops into *Pleospora herbarum*. Possibly, however, there are two forms of this; but whatever confusion exists botanically there is no mistaking Nature as revealed by the microscope.—G A.

## BELVOIR CASTLE.

## SPRING GARDEN.

To my mind there are no flowers more beautiful than those of the spring. How rich, how fragrant is a garden filled with them! My love for spring flowers was largely fostered at Elsham House, Grantham, from 1871 to 1873, and it has unmistakably increased as the years have gone on. I have that beautiful garden in my mind's eye at this very moment, and the spring gardening conducted by Mr. Samuel Ellis will never be effaced from my memory. Either in 1873, or the following year, Mr. Allis, now at Old Warden Park, described that garden in the *Journal of Horticulture* as a "veritable fairy scene."

Belvoir Castle stands out in the landscape as a power of its greatness and strength in the past, and can be seen for miles, while from its massive towers, and even the terraces, there are commanding views of the country, on a clear day, for thirty to forty or more miles. The view from Belvoir across that fertile stretch of country to Lincoln could not probably be surpassed: If we were to describe Belvoir in one sentence it would be "it is a grand old place," and worthy of the traditions of the noble family who inherit it.

For twenty-five years I have had a longing desire to visit the spring garden, and that desire year by year seems to have intensified. The various articles that have appeared in the *Journal* have added in no small degree to that desire. How long spring gardening has been carried out at Belvoir I cannot say, but it was in full swing at the time to which I have alluded. It is questionable if a more charming spot could be found for a spring garden in this country. It is practically in a valley, and appears to be well sheltered on every side. The greater part of the beds and flowers are arranged on the southern slope of one of the hills, with a background of forest trees. The spring garden proper comprises many acres of ground, and may be described semi-circular in shape. There is a large space at the bottom of the slope planted with many choice flowering evergreen and deciduous shrubs, while thriving Conifers tower up suitably amongst them. It is a capital finish to the higher rocky slopes that are almost covered with spring flowers. Although so well shaded, light and air, both essential to the flowering of alpine and other spring flowering plants, are not shut out in the least. The whole has been grandly conceived, and bears abundant evidence of good taste and careful thought on the part of the late Mr. Ingram, or whoever made this portion of the grounds.

Those who have never seen these slopes must not think that it is a mass of spring flowers arranged on the neat principle that one finds in some geometrical design in close proximity to a mansion. Such is not the case. The object has been to give it a natural, even rustic, and in places a semi-wild appearance. Belvoir spring garden, so it struck me, if short of one thing, it is rock, and I have been thinking if some of the bold massive rocks of Dovedale could be transplanted there the picture would be enhanced in boldness and beauty.

Such, however, cannot be the case, the labour already having been enormous. On entering these slopes, practically levelled into the hill-side, are a number of beds charming with spring flowers of various kinds, well designed and the colours beautifully blended. Then on the same side trees of many species come almost close to the circular walk. On the opposite side are other beds, well arranged, carefully sloping down the hill in terrace-like fashion, with a number of bolder beds at the base, and to all appearance on the level. On lower levels still are series of beds, geometrical in design and charming with a variety of spring flowers.

A compact form of *Arabis alpina* is freely used for white flowers; but unfortunately this plant is somewhat too early. We want a white flowering plant that will come in with *Aubrietia* and others. *Primrose Harbinger*, when a stock can be raised, will certainly replace it to a large extent; but on rocks of a bold character, where it grows and hangs down gracefully, it is hard to find a substitute. The old *Aubrietia græca* is very effective and largely used; but the darker and best of all forms, *A. Leichtlini*, is most conspicuous, and is used in several beds in masses. *Phlox amœna* is a glorious plant for the spring garden. *Primroses*, fancy and laced *Polyanthuses* abound in every conceivable shade of colour.

Wallflowers are indispensable, and the beds filled with a variety of these and edged with dwarfier plants were very effective, and the fragrance simply delightful, the plants having passed the winter well. Near these beds, and in partial shade, was a delightful bed of the late-flowering *Violet Lady Hume Campbell*, which was one mass of its large mauve coloured, highly fragrant flowers. The spring garden at Belvoir entails much labour and thought.

Many good hardy plants abound on the slopes amongst the spring flowers, and when the beds are filled with their summer occupants this part of the grounds is still gay and attractive. Two acres out of the seven in the walled-in garden are devoted to a general collection. The top portion near the main range of vineries and Peach houses being quite gay with various spring-flowering plants. *Narcissi* are represented in this part by a very large collection. *Iris concolor* and others were gay, as also were many plants too numerous to mention. Large borders had been filled with *Carnations*, and others with *Violets* for autumn, winter, and spring flowering.

It was scarcely the time to see the kitchen garden. *Asparagus* beds looked well; *Asparagus Kale* had passed the trying winter, as also had *Chou de Burleigh*. Large plots of spring *Cabbage* were ready for cutting. The wall trees looked well, with a good promise of abundant crops if the weather proved favourable. The bush and pyramidal fruit trees had been crowded, but their branches have undergone a severe thinning.

This bird's-eye view of Belvoir must be brought to a close by saying that these renowned gardens are safe in the hands of Mr. W. H. Divers, and unmistakable signs of progress are visible. I have not the least doubt that the reputation of the gardens will be well maintained, and I shall be surprised if we do not hear more of Belvoir—after a time—in the future than we have done in the past.

My very best thanks are due to Mr. Divers for showing me all in the gardens my time would allow, and thus gratifying the wish of years. His hospitality to me—a stranger to him—will not be forgotten. What a brotherly feeling there is amongst gardeners! long may it continue.—  
WM. BARDNEY, *Osmaston Manor*.

## REFLECTIONS.

I WONDER if many of your readers reflect as I do on Thursday evening that Friday morning's post brings the *Journal*, and that means a bit of pleasant profitable reading. I anticipate it much, and so I think does my friend, who gets it second-hand. I want to say a word about the lavishness of funeral flowers. We are rejoicing in the fact that common sense forbids the fearful display of *crêpe* and weepers tolerated in the days gone (not so far gone by either), but is there not a fear of the excess taking another form? To whom do the flowers give comfort? Not to the "happy dead," and the sorrow of the survivors surely cannot be much mitigated by wreaths and crosses of costly exotics. Personally, I think the flowers should go to the living.

Do not we all know decayed gentlewomen and friends of reduced means to whom *ls.* is too valuable to spend on flowers. I think of some who have been bred in the country, and now in their old age are finishing life's journey in a hot dusty street. I know two old ladies (out of the many) who for forty years lived in a pleasant country vicarage. Circumstances have driven them to a large town, and they have often told me how the sight of a box of country flowers would affect them to tears. The charm is greater if there should happen to be a flower the like of which they knew at home. Do not I know, and do not you know, Mr. Editor, how a posy even of common flowers from this remote village would touch the tenderest feelings of a heart in Fleet Street? I do not plead here for hospitals and the sick poor. Happily they are in most places well cared for. It is the members of the lower middle class who are neglected.

There is another class of people to whom a few flowers would be a great pleasure, and that is the great army of shop assistants. In most towns now these folks enjoy a half holiday, and many of them, far more than you would suspect, spend that afternoon over their scraps of garden. Here in our market town the best *Carnations* are grown by a watchmaker; splendid "riculars" by a journeyman cabinet maker; and *Begonias*, bad to beat even in London, by a signalman. Could not some pleasant, kind ladies occasionally, when their gardens are at their best, invite the humbler members of the great trading body to spend the afternoon with them? There would be benefits both given and received, to say nothing of the cultivation of a kindly spirit. I speak from experience.

There is a note, too, in last week's issue about the beauty of common flowers—or rather, I should say, inexpensive ones—for decorative purposes. On a farmhouse table I saw the other day an arrangement that struck me as being pretty. In the centre, in a large two-handed greenish yellow mug, were placed the fresh bronzy leaves of *Sycamore*, with a handful of some inexpensive *Daffodils*. At the four corners were small glass globes full of wild lavender-shaded scentless *Violet*, a *Violet* which is, to my mind, of beautiful habit. The week following *Narcissi* and *Beech* leaves occupied the centre, with *Forget-me-not* at the corners. I am writing in the May week, which is here a time of holiday and rejoicing for working lads and lasses, and the general wedding time. The bouquet of a rural bride I thought pretty the other day. Centre three pinky yellow *Tulips*, set in a crowd of *Narcissi*; a border of pink *Pelargoniums*, principally *Bride* and *Nordi*, begged from a friend's greenhouse; an edging of the pretty green *Corydalis*; and then a finish of pale and white *Lilac*. Flowers are flowers here, and we do not stick at a bit of colour, even for a bride.

Another friend (page 427) speaks of his *Lettuce*. I trembled for mine. A new experiment on a sunny border with no covering but snow; 130 were planted. The gaps that exist the salad bowl accounts for. So crisp, so refreshing; and the seeds also hailed from Reading, but the plants were grown, I think, farther north than the specimens that were sent to you. This may have been an advantage because of the heavier fall of snow than fell in the balmy south during a certain period early in the year.—THE MISSUS.

[A gardener in the "balmy south" basking, or rather brushing in a temperature approaching zero, swept what snow he could, and piled it in ridges over some rows of *Lettuces* and young *Cabbages*. These rows have of late given valuable produce, whereas the plants uncovered melted away.]

## RYECROFT NURSERY.

THE name of Mr. H. J. Jones, of Lewisham, and the ever-popular "mums" is so synonymous, that to think of one is but to bring the other quickly to the memory; but as June is hardly the time to speak of these plants, except in a growing condition, though, indeed, they are for ever in the mind of gardeners, it was not to obtain any information of these that a recent visit was made to the nursery of this energetic florist, but rather to see another class of flowers, for which

he is no less famous—those of the beautiful, though perhaps somewhat under-estimated, fancy Pelargoniums.

After seeing Mr. Jones's creditable exhibit of these brilliant flowers at the recent Temple show, it was with the expectation of seeing something out of the ordinary that the journey was taken to Ryecroft, and in this respect we certainly were not disappointed, as the large exhibition house in which they were staged presented a mass of bloom that would be extremely difficult to excel.

Owing to their aptitude to become infested with aphides, fancy Pelargoniums are not found adorning greenhouses to the extent their beauty merits, but that they can be and are grown in first-class style entirely free from green fly may be proved by paying a visit to the collection under notice, where excellent cultivation may be easily seen in each sturdy plant. So great was the density and variety of bloom presented that it was an impossibility to give each the amount of admiration due to it, as in one the form of flower and delicacy of colouring was so exquisite that we were apt to conclude that perfection was reached, until our attention was taken by another with some particular mark of beauty peculiar to itself. Such being the case former decisions had to be reconsidered until, after some further attempts had been made at picking and choosing, we felt obliged to give it up, and be content to admire the whole *en masse*.

This was doubtless the best course to take, and in passing along many familiar varieties were recognised, while through the courtesy of Mr. Jones we were enabled to note other new and beautiful additions, for whose introduction he is in many instances responsible. Should the mode of cultivation, such as is practised at Ryecroft, become more general, we have no hesitation in suggesting that Pelargoniums will again be accorded a deservedly high position amongst greenhouse plants.

Amongst the recent additions Mrs. W. Wright is well worthy of a high position, being one of the most beautiful Pelargoniums in cultivation. When first opening the flower is of a pleasing rose shade, passing in later stages to pale blush. The blooms are well formed and slightly crisped at the edge, while the plants are robust and sturdy in habit. Of no less merit is Mrs. H. J. Jones, whose large and conspicuous flowers of blush-white blotched with crimson are particularly attractive. Eucharis carries large masses of pure white flowers, and in addition to its decorative qualities is one of the best for affording cut blooms. Mr. Jeffrey is of a colour most uncommon in Pelargoniums, being of a deep purple, while the truss is large and the habit of the plant dwarf and compact.

One of the most profuse flowering varieties in cultivation is Mr. H. J. Jones; in colour it is a bright rosy red, with a maroon crimson blotch on the upper petals. Another novelty is May Queen, of a soft salmon-rose, heavily blotched with dark crimson. Very different in colour is Agnes Cook, which is of dwarf habit, and carries a profusion of pale lilac flowers. Edward Perkins is a pleasing orange-scarlet, with a maroon blotch on the upper petals. Quite a feature in the collection was Lady Folkestone, a free-flowering variety of a charming rosy pink, with beautiful crimped edges. Very attractive also is Rose Queen, of an exquisite shade of blush pink, with upper petals blotched red.

Amongst the "Regals" were noticed as being particularly striking Bush Hill Beauty, with large flowers of a mottled rose shade; Duke of Fife, a clear lake with white margin; Lady Duff, a rich red sport from the former; Madame Thibaut alba, a charming pure white, as its name implies; Prince of Wales, a bright vermilion with light centre and large trusses; and Queen Victoria, of a somewhat similar colour, but with a dark blotch on the upper petals.

Worthy of a special note are several varieties not yet introduced—namely, Ladas, a delicate salmon pink with dark blotch in the centre; Duchess of Portland, Euclid, and Miss Alice Love. The single Zonals were only accorded a passing glance, though their merits warranted much closer attention, and a group of some 500 double Ivy-leaf Pelargoniums presented a mass of bloom, which to see meant to admire. Close attention to the hybridisation of these popular flowers has resulted in the production of many beautiful specimens, and we shall perhaps not be wrong in according Ryecroft Surprise the post of honour in this class. It has a bold vigorous habit, with blooms of a distinct shade of salmon pink clustering round the plant in great profusion. Of a different colour, though equally charming, is Flambeau, which is brilliant scarlet. Congo is very distinct, being of a light lilac shade with silvery white edge. Ryecroft Scarlet is described in the name; it bears very large flowers, and is perhaps the best of its colour. Others in the group, each with its own particular attraction, were Prince of Wales, Jersey Beauty, Jeanne d'Arc, Liberty, and La France.

Further attention was claimed by a large span-roofed house filled with single Begonias, all in excellent condition and giving ample promise of a bright display later on; but as the flowering period was only in its infancy we shall pass over these with but a few brief remarks. Like all other flowers grown in the nursery these have had their full share of attention in regard to raising new varieties, with the result that Mr. Jones is responsible for the introduction of many charming novelties.

Several already in bloom were noted as being exceptionally fine, of good substance and varied in colour; the plants gave evidence of sound cultivation, being sturdy with flower stems sufficiently stout to dispense with the customary stake.

In addition to the above there are about 150,000 seedlings raised this spring in various stages of growth, and the large space of ground set apart for exhibition was in preparation for planting.

The Chrysanthemums will be heard more about in due season, but

still their healthy appearance merits a word of approbation. Faint attempts were made to obtain some idea of the number grown, but it had to be given up, as they were to be seen everywhere and in all stages. Numbers already in their flowering pots with stems clothed with stout foliage looked everything that could be desired, whilst thousands of others in small pots and boxes were waiting their turn for removal. A large number of new seedlings are being closely watched by Mr. Jones, from which he hopes in the coming season to obtain several fresh novelties, and in this alertness he is equally matched by Mrs. Jones, who appears to understand the flowers almost as well as her better half.

It was with reluctance we left this exhibition of flowers, for so it may be justly termed, fully satisfied that this energetic florist is at any rate doing his share towards popularising, not only the Chrysanthemum, but also the Begonia, and the somewhat neglected but singularly beautiful and varied "fancy" Pelargonium.—G.

#### FRUIT FORCING.

**Peaches and Nectarines.—Early Houses.**—The earliest forced trees of Alexander and Early Louise Peaches, Advance and Early Rivers' Nectarines are, or nearly, cleared of the fruit. The shoots on which the fruit has been borne, if not required for the extension of the trees, must be cut away to the successional growths from the base. This will admit light freely to the foliage, and the access of water for cleansing purposes. Syringe forcibly to free the trees of red spider, and if this and scale continue troublesome the prompt application of an insecticide will be necessary to eradicate the pests. It is highly important that the foliage be kept healthy, and to prevent over-maturity or premature ripening it is necessary to keep the structure cool by ventilating to the fullest possible extent, when the weather is mild, after the fruit is gathered. The borders must be duly supplied with water, and in showery weather remove the roof lights. Keep gross laterals stopped, but avoid checking the growth by removing a large quantity of foliage at one time, as this has a tendency to hasten the ripening of the wood, and when this is the case the trees will be swelling their buds through over-development when they should be resting.

Trees of Hales' Early, A Bec, Early Alfred, Early York, Dr. Hogg, and Early Grosse Mignonne—all second early Peaches of good colour and first-class quality, with Stirling Castle, Royal George, and Dymond in the same house or in a house to themselves, which is the best, will now be ripening their fruit, and must not be syringed, though if the trees become infested with red spider a thorough syringing may be given when there is a prospect of a fine day; but with the water hanging on the fruit for some time the skin is liable to crack, even in fruits partially ripe, while those that are nearly ripe will be much deteriorated in quality; indeed, they acquire a very unpleasant musty flavour from the attacks of minute fungi. The trees must have sufficient water at the roots, but any excess at this stage has a tendency to cause splitting at the stone, especially in the case of vigorous trees.

**Houses Started in January.**—The trees of the very early varieties will be cleared of their fruit, or nearly so, while second early varieties will be ripening; both should be treated according to the preceding advice. The standard forcing varieties, such as Stirling Castle, Royal George, Grosse Mignonne, Dymond, and in some cases Alexandra Noblesse, with Lord Napier, Stanwick Elruge, Goldoni, and Dryden Nectarines are now advancing fast towards ripening. The leaves will have been turned aside, and the fruit raised on laths placed across the trellis with its apex to the light. This insures the fruit colouring well and ripening evenly. If the weather proves cold and wet gentle fire heat will be necessary to secure a circulation of air constantly, the temperature being maintained at 60° to 65° artificially at night, and 5° to 10° rise by day, in order to keep the fruit in steady progress. Cease syringing as soon as the fruit begins to soften or assume the ripening tint, and take care to have the trees free from red spider before the syringing ceases, or the pest will increase so rapidly as to seriously affect future prospects. See that there is no deficiency of moisture in the borders, and if necessary give a thorough supply of water, mulching with some light material, such as partially decayed manure or spent Mushroom bed refuse, about an inch thickness sufficing.

**Succession Houses.**—Do not hurry the trees during the stoning process, but allow time for the satisfactory completion of this exhausting and essential work, aiding the trees in effecting it by a dressing of superphosphate and potash manure. Allow a rather free extension of the laterals as an encouragement of root action, but be careful not to crowd the principal foliage, and keep insects in check by syringing twice a day. When the stoning is completed remove all the surplus fruits, and turn the others with their apexes to the light to insure their even colouring. Give thorough supplies of water, mulching the border lightly with partially decayed stable litter, and supply liquid manure liberally to weakly trees. Vigorous trees will not need more than a surface

mulching, as high feeding will only cause grossness, and must be studiously avoided. Ventilate early in the morning and close in the early part of the afternoon, with abundance of atmospheric moisture, so as to raise the heat to 80°, or 85° or 90°, and ventilate a little afterwards for the night, the temperature being allowed to fall to between 60° and 65°. This procedure must not be practised until the stoning is completed, and only when it is desired to accelerate the ripening or secure fruits of the largest size.

**Late Houses.**—Young shoots that are to carry next year's crop must be tied in and allowed to extend as far as space admits, taking care to avoid overcrowding. Pinch all side shoots that are not wanted for next year's fruiting or for furnishing the trees, and stop any gross shoots, so as to cause an equal distribution of the sap. In thinning leave a few more than will be required for the crop. A Peach to every square foot of trellis covered by the trees is ample for the large-fruited varieties, but the medium-sized and Nectarines may be left a little closer. Keep the foliage clean by syringing twice daily in fine weather, and always sufficiently early to allow the foliage to become dry before night. Water thoroughly when necessary, and always sufficient at a time to moisten the soil through to the drainage. A light mulch of short partially decayed manure will save watering. Keep the surface moist and supply some nourishment. Ventilate early, and increase the ventilation with the sun heat, closing early if the ripening is to be accelerated; but if the fruit is wanted late keep as cool as possible by free ventilation day and night except when frost prevails.

**Young Trees.**—Those in course of formation for covering their allotted space must be properly disbudded, leaving the main branches or shoots for forming them 15 to 18 inches distance apart, and the bearing wood at a similar distance along them, training the extensions their full length and pinching the side shoots not required for extending on last year's wood to two or three leaves, so as to form spurs, and to one of subsequent growth. Laterals on the current growths should be pinched at the first joint and subsequent spray as made.

**Pines.**—Plants of these under good management yield, as a rule, the finest fruits and the only profitable return when they show them ten to twelve months from the time the suckers were first potted, but some allowance must be made for autumn suckers, which were then potted and have to make their growth under adverse circumstances. Plants finally potted last September are now showing fruit. If any of that age are not fruiting subject them to about four to six weeks' comparative rest, lowering the heat at the roots to 75°, admitting air fully at 75° to 80°, and let the temperature fall to 75° before closing the house for the day. Little fire heat will be necessary, but it must be afforded, if necessary, to prevent the temperature falling below 60° at night. Do not allow the plants to become excessively dry, but whenever a plant needs it afford water liberally. The smaller suckers of the plants referred to potted this spring must be kept growing until the pots are filled with roots, when, if necessary, they can be subjected to the same course of treatment as advised for the larger plants, and these will afford a successional supply of fruit.

**Suckers Potted in March.**—The strongest of these should now be in their fruiting pots. If they are not yet potted do not tolerate farther delay, as to retain them longer in small pots is detrimental to their after growth. Let recently potted plants have a regular bottom heat of 85° to 90°, and be duly supplied with water, if needed, after potting, not giving any more until the soil becomes dry, as it is necessary to exercise more care than usual at this stage, the state of the soil of individual plants being ascertained before its application.

**Routine.**—Young plants are making rapid progress, and must be regularly attended to, allowing sufficient space for development, as it is inimical to sturdy plants to crowd them, especially in the early stages of their growth. Ventilate early in the day, always at 75° to 80°, to render the foliage dry before it is affected by the sun. Discontinue shading successional plants, but for fruiting ones with the crowns in close proximity to the glass a slight shade from powerful sun will be beneficial.

**Cherry House.**—When the crop is wholly ripe the chief consideration will be to keep the fruit fresh and prolong the season as long as possible. Shading will do so, but it is only desirable where the fruit is exposed directly to the sun owing to the limited foliage. Free ventilation must be accorded, and in hot weather a sprinkling of the surface of the border in the hottest part of the day will assist in keeping the fruit fresh. The supply of water at the roots must not be neglected, for dryness is inimical to the formation of the buds for the ensuing crop of fruit and the health of the trees.

**Cucumbers.**—Plants in houses that have been in bearing since the beginning of the year may be cleared out, and the house cleansed preparatory to replanting with young plants or Melons for a late crop. If, however, the old plants are fairly healthy and Cucumbers are still insufficiently supplied from pits and frames, they may be kept in bearing a time longer by removing the surface soil with a small fork, and supplying some lumpy loam, afterwards surfacing with decayed manure, giving a top-dressing of some approved fertiliser, and a good soaking of tepid water, or the fertiliser in liquid form. Thin out the old growths, and encourage young in their place. Shade from powerful sun, syringe both ways in the early morning and afternoon, and damp down before nightfall. Admit a little air at 75°, increasing with the advancing sun, keeping through the day at 85° by solar heat, and close early, so as to run up to 90°, 95°, or 100°. Employ fire heat only to prevent the temperature falling below 60° to 65° and to insure 70° to 75° by day.

**Pits and Frames.**—Plants in these should be ventilated from 7.30 to 8 A.M., and in the hottest part of the day a slight shade from the fierce rays of the sun will be beneficial, and keeping through the day at 85° to 90°; close at 85°, increasing 5° to 10° with sun heat. Keep them watered as required, about twice a week will be necessary in bright weather, and sprinkle on fine afternoons. Avoid overcrowding the foliage, thinning well, keeping up a succession of bearing wood, removing bad leaves, stopping one or two joints beyond the show of fruit, and avoid overcropping. If straight fruits are wanted place them in glasses or nail pieces of half-inch deal together, so as to form open ended troughs about 3 inches wide, introducing the fruit, and having the troughs slightly inclined so as not to hold water.

**Strawberries in Pots.**—Copious supplies of water are needed in the early stages of the fruit swelling; indeed, if the plants but once lack that essential element the plant or fruit may be so impaired as to do little good afterwards. Abundant supplies of water and nourishment at the roots are necessary to secure well swelled berries, with a somewhat moist condition of the atmosphere, therefore avoid drying currents of air, especially when cold. Water the plants two or three times a day, according to the weather, and supply liquid manure two or three times a week until the fruit commences ripening, after which give water only sufficient to prevent the foliage flagging. This, with abundance of air, improves the flavour.

**Plants in Pits and Frames.**—When the Melons are ripening they should be fully exposed to the sun by raising them on inverted flower pots with a piece of slate intervening, as the moisture from the bed is apt to accumulate in the pot, and rising through the hole cause the fruit laid upon it to decay at that part. Admit air freely, and water only to prevent flagging. If a second crop is desired encourage about four shoots from the base of each plant, and when the fruit is cut the old growths may be removed and young shoots substituted. These will show fruit on the first laterals, every alternate one being rubbed off to prevent crowding. If a top-dressing of fresh compost be given, supplemented with a good supply of moderately weak liquid manure at 90°, the plants will be assisted to make a vigorous second growth. A useful crop of Melons may be obtained by making up beds now of any spent material, which, with mixing and turning, will generate a gentle warmth, placing over it frames that have been used for Potatoes and bedding plants, placing in each light about a couple of barrowfuls of any strong loam mixed with some old mortar rubbish or road scrapings if deficient of grit, and pressing it down firmly. Into this, when warmed through, turn out a strong, healthy plant, pressing the soil about the roots and giving a good watering. If the weather be bright shade for a few days after planting. Seeds may yet be sown to raise plants for frames at present occupied by tender bedding plants.

#### THE FLOWER GARDEN.

**Bedding Out.**—A great deal of this is done, but much remains to be completed. June is soon enough for planting the more tender kinds of plants and flowers, such as Iresines, Coleuses, Alternantheras, Amaranthuses, and Begonias.

**Tuberous Begonias.**—What these should have is ample room and a fairly rich, moist root run. Planted thickly they soon overrun each other, and the beauty of the foliage is lost, while if the soil is poor and non-retentive of moisture the results will never be satisfactory. Old Mushroom bed refuse or other short manure should be freely mixed with the soil. The plants take to their fresh quarters more quickly when moved out of boxes or beds, and in any case they should be in a moist state at the roots when transplanted. If the varieties are good and also mixed they would prove most effective planted not less than one foot apart each way, with a carpeting of variegated Mesembryanthemum or other neat trailing plants, and a few Cyperuses, Dracenas, or Palms dotted among them would further add to the general effect. A mulching of either cocoa-nut fibre refuse, leaf soil, or short manure should always be given Begonias. Without it they will fail in many positions. Begonias raised too late to bed out may, later on, be planted in nursery beds. They will form good tubers for next season. Fibrous-rooted species, several of which bed out admirably, are best massed together.

**Fuchsias.**—Plants in large pots move out of these badly. In some instances plunging answers best, the roots finding their way through the drainage and over the rims of the pots into the surrounding soil. Specimen Fuchsias also look well plunged in the turf. Standard plants are particularly effective in the centres of Begonia and other beds. For massing, quite young plants are perhaps the best, and these should be planted out in fairly rich soil.

**Various.**—Antirrhinums, notably the compact growers, are admirable for bedding out, and they stand both dry and wet seasons remarkably well. Quite small plants will produce a moderately strong spike, and this cut early will be followed by a mass of smaller ones. Pentstemons are also effective in beds. If small, plant in moderately rich soil and somewhat thickly, or they may be dotted among Violas, Lobelias and Musk. Heliotropes are fine in masses, and a bed of a dark flowering variety with straight young plants of Abutilon Thompsoni dotted among them never fails to give pleasure. Violas ought to have been replanted a month ago.

**Filling Vases.**—These ought to be emptied of old or very dry soil and a rich loamy compost substituted. Mixtures are not nearly so effective as a mass of one variety with a trailing edging of some kind. Zonal Pelargoniums are among the best plants that can be used, and none surpasses Henry Jacoby in a mass with an edging of blue or white

*Lobelia*. If either *Fuchsias* or tuberous *Begonias* are used make the soil extra rich and give abundance of water. White *Marguerites* edged with pink-flowered *Ivy-leaved Pelargoniums* are effective. Much the same remarks apply to window boxes.

#### THE KITCHEN GARDEN.

**Celery Trenches.**—If not already done, no time should be lost in getting trenches ready for the main and late crops of Celery. Some soils are simply unworkable for several weeks after they are dug, or say till baked by sunshine, and then well moistened. In this case, then, early digging of trenches is imperative, and early preparation of trenches where the soil is of freer working nature is also desirable. If wanted extra fine one row of plants in a trench is enough, but for ordinary purposes very large "sticks" are not altogether to be preferred. Even in this case nearly or quite as many plants may be grown in single rows as are usually put out in double lines, and the former can always be the more readily and effectively moulded up. Trenches for single rows may be 15 inches to 18 inches wide, and they ought to be fully 20 inches wide for the double rows. Where possible allow 4 feet spaces between the trenches, and some of the soil from the trenches being evenly distributed over this, Lettuces, Kidney Beans, and dwarf Peas may be grown on them to perfection. Shallow rather than deep trenches are the best for heavy soils and cold lying positions.

**Celery Beds.**—Where space is limited there is much to be said in favour of growing Celery in beds. Open a shallow trench 4 feet to 5 feet in width and distribute the soil on each side, then fork in good solid manure. In this instance the rows must run across and not lengthways of the trench, or otherwise earthing-up will be a difficult undertaking. The rows may be from 12 inches to 15 inches apart, and the plants in the rows from 6 inches to 8 inches apart.

**Planting Celery.**—Market growers in many instances move the plants to the trenches direct from the seed beds; but in this case the trenches are not deep, and have been got out well in advance of planting, or long enough to have become warmed somewhat. In cold, deep trenches a very poor start is usually made by small plants moved without a ball of soil about the roots. Any pricked out in boxes or on old hot-beds ought not to become badly crowded before they are moved to the trenches. Pass an old knife round them or through the lines three or four days prior to transplanting, and from the long roots thus cut through numbers of root fibres will spring, a compact mass of soil and roots being had accordingly. A good soaking of water ought always be given well in advance of the moving, and then, if not allowed to become tall, the plants will scarcely show any signs of a check. Naturally they would move the most satisfactorily in dull, showery weather; but there should be no waiting for this if by so doing the plants become drawn and weakly. If dry soil in trenches is moistened before planting, and a good watering is given afterwards, there will be little or no flagging. Plants in single rows may be disposed from 6 inches to 8 inches apart, allowing rather more space if extra fine produce is desired; while those in double rows should be from 10 inches to 12 inches apart and 5 inches clear of the sides of the trenches. Plant the white-stalked varieties principally for the earlier supplies, the coloured varieties keeping better.

**Tomatoes.**—In some districts planting of these against sunny walls has already commenced. Early planting is recommended in the case of any starving in small pots, as these must have time to become well established in their fresh quarters before they will commence fruiting. Those raised late and not badly root-bound should be kept a few days longer in cold frames, or where they can be protected from heavy rains and cold weather. Sunny walls and fences are the best positions for these crops. The low front walls of forcing houses, allowing the plants to trail a little way over the roof, answer well for Tomatoes in favourable seasons, but it should be added that in such exposed sites they are more liable to disease than are the plants less exposed to the rains. Neither a very rich root run nor any particular soil is needed. Freshen up stale or very poor soil with a little loam, solid manure, and burn-bake, while a wholly fresh or temporary border may be formed with good garden soil, with a little manure and fresh loam. A sprinkling of Thomson's or other special manures may be used in either case with advantage in preference to applying it later on. If plants are plentiful dispose them 12 inches apart, and confine to a single stem, but if somewhat scarce arrange them from 2 feet to 3 feet apart, and lay in two side growths in addition to the unstopped leader.

**Tomatoes in the Open.**—In moderately favourable seasons Tomatoes succeed well quite in the open, the fruit commencing to ripen only a little later than those on plants against walls. The plants might be put out among early Potatoes, arranging them from 2 feet to 3 feet apart each way, or they may be planted 1 foot or rather more apart in rows running from north to south and 3 feet or rather more apart. Rows of runner Beans might be made to form screens on the coldest sides. A very rich soil is undesirable, but the other extreme should also be avoided. Ruby, Earliest of All, Laxton's Open Air, Conference, and Conqueror are among the best varieties for open air culture. In each and every case see the soil is moist prior to planting, and also that the balls of soil and roots are neither dry when put out nor allowed to become so afterwards.

#### PLANT HOUSES.

**Crotons.**—Plants that are growing too tall for table decoration may be notched and bound with a little moss. If kept moist roots are quickly emitted, and well furnished heads can be established without the risk of losing the lower foliage. The plants operated

on should be stood by themselves so that they can be liberally syringed, and the house kept close and moist. Heaths of a smaller size may be inserted in small pots and placed under hand-lights in a warm house. If stock is wanted allow the old plants to break, and when the side shoots are large enough they may be rooted. Keep growing plants free from scale and thrip, and syringe liberally. Sponging is an evil that must be avoided as much as possible. Many varieties cannot be done, however carefully, without injury to their curled foliage.

**Dracænas.**—To grow these plants well they must never become stunted; from the time the heads are rooted, or the plants raised from portions of stem, they should be kept growing. If unduly confined at their roots the plants are checked, the lower foliage falls, and they rarely do well afterwards. In potting these plants all that display signs of stunted growth should be discarded. All kinds need careful watering after potting until they are rooting freely. For stove sorts a warm moist atmosphere is necessary, and shade for a few hours during the hottest part of the day. Cool kinds make the greatest progress when grown in heat; under cool conditions they are too long on hand. When once they are fairly started an intermediate temperature with abundance of moisture and shade suits them admirably. From root cuttings some grand table plants can be grown if inserted in heat at the present time. In from 3 to 5-inch pots the old *D. congesta* makes capital shapely plants, and a good number of small plants for many purposes will be found useful.

**Gardenias.**—Where a young stock was raised last August or September the plants should be growing freely in 6-inch pots, and old stunted plants that have flowered may be thrown out. The shoots of the young stock should be pinched to induce them to branch freely. Grow the plants fully exposed to the sun in a warm moist house. The soil should be kept moist but not saturated, or these plants become sickly and stunted. When well rooted a little chemical manure may be applied to the surface once a fortnight. Old plants that it is necessary to keep may be cut down and started again into growth in brisk heat. If bottom heat can be given all the better.

**Cyperus alternifolius.**—Young plants raised from seeds and established in thumbs should not, if wanted a useful decorative size in 5-inch, be grown in too warm a temperature. When placed into 5-inch give them cool treatment. They are very useful for cutting, and are very effective hanging out loosely from amongst flowers. When plants are needed for this purpose they may be grown on, so that their stems attain to 3 or more feet in length. *C. distans* may be given similar treatment. It is a useful Grass for grouping and also for cutting.

**Poinsettias.**—Those rooted from eyes in small pots may be placed into 3-inch size. Pot firmly and grow the plants close to the glass. Admit air to them daily and increase the supply, so that firm sturdy growth will be made. It is a mistake to grow them too soft in their early stages. They generally run up tall, and the foliage fails sooner or later. Cuttings that have been rooted from soft shoots may be treated in a similar way. Old plants, if needed, may be cut down at once and started into growth. As soon as they break shake away all the old soil, and repot into smaller sizes. When established grow with the young stock.

**Medinilla magnifica.**—If grown in the stove proper this plant will be in flower. If more root room is needed pot it as soon as the flowers fade. It will do well in three parts good loam, with the other part composed of leaf mould and manure; coarse sand may be added. Pot firmly, and allow the plant to make its growth in a close, moist, shady atmosphere, when growth has been completed expose it to the sun to ripen the wood.

**Begonias.**—For winter flowering *Begonias* may be rooted without delay. Insert them singly in small pots, so that they can be grown without disturbing them when rooted. Once they are rooted gradually harden to cool airy treatment. The foliage is very liable to rust when grown in a close confined atmosphere. Old plants may be cut over, allowed to break from the base, and then placed into larger pots.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### CHLORIC DROPSICAL FEVER.

I HAVE had this disease several times in my apiary since 1858, and have given my observations in the *Journal of Horticulture*. From the first I have never been able to alter my opinion of it, unless in a number of cases in 1894, where the hive survived after being reduced to less than a cupful of bees. One of these without any assistance survived the winter, and at the present time is a good strong hive. That the disease is hereditary, and not owing to anything in the hive, I am positive, as I am that feeding or an inflow of honey stays the disease, for not in a single case has it done so with me.

A good illustration supporting my views has occurred with me this spring, and I have experienced many similar cases. A Carniolan queen was joined to a Punic stock in October of last year. The disease manifested itself early in April amongst the Punic

(a strong stock), and they are now all dead, while not a single Carniolan is affected. If an inflow of honey or feeding would have stayed the scourge then these bees would have been cured, because they had both.

My opinion of the origin of the disease is, either the ova becomes affected or the queen contracts some disease in her sperm sac, because drones do not die of the disease, which both may be brought on by some peculiar feeding which affects the ova or eggs. Certainly it is not, as some say, infectious, or the Carniolans would have succumbed as well as the Punics. My opinion is further supported by the fact that the disease is virulent only amongst bees laid between certain dates, those laid before and after having an entire immunity from it.

#### THE APIARY.

For two weeks from the 1st of May the weather has been drouthy, frosty at night, and lately cold, the night temperature being repeatedly at freezing, and the day temperature on the 17th was 45°. The fruit trees, so beautiful in their mantles of white and pink blossoms, in one night were browned, so piercing were the north-west winds.

Honey gathering has been very limited since May came in. I shall, to keep up breeding and prevent backgoing, feed a little daily till the weather is favourable for honey gathering. A few pence spent on each hive from now till honey flows will turn the scale in favour of the bee-keeper to pounds instead of a loss. Many young bees are hatching daily, which consume much honey. When no honey is to be had the young bees are often expelled the hive.—A LANARKSHIRE BEE-KEEPER.

#### A RETROSPECT.

BEE-KEEPERS, like other people, must have their growl, and during the past few months they have had more cause than usual to complain. First it was the mild weather experienced until the new year. Stocks were strong in bees which consumed more than their usual supply of stores, which I find always happens more during a mild autumn than when there is an extra spell of cold weather. Then of a sudden extreme cold sets in with the thermometer down to zero, or within a few degrees of it, for several nights in succession. Low temperatures prevailed for the first two months of the year; many stocks in the hands of negligent bee-keepers, who through various causes had omitted to supply their bees with sufficient stores in the autumn, succumbed.

A few days ago I visited an apiary where last year there were several good stocks of bees in well-made frame hives, from which very little surplus store were taken. These were left to take their chance, and the result is that only one stock is now alive, a practical proof, if such is needed, that all stocks should be thoroughly examined in the autumn, and those that are short of stores should have their requirements attended to. Another bee-keeper who had upwards of forty stocks, chiefly in straw skeps, and whose bees had the swarming mania during the few really fine days last summer when honey was coming in freely. On being appealed to not to neglect them, as many were very weak and could not possibly live through the winter without some assistance, he rejoined, They must take their chance, as owing to several bad seasons in succession it would not pay to feed them.

This, I need hardly say, is a great mistake, as it is a long lane that has no turning, and good honey seasons will come in the future as they have done in the past. It is much better to keep a few stocks and attend to them well than attempt to keep a greater number and neglect them. After the long winter the usual changeable weather set in till the early days of May, when summer appeared to come all at once. Day after day the sun shone from an almost cloudless sky. Bee-keepers began to predict a record year. In the apiary stocks that had wintered well were making great headway, and as honey and pollen were coming in somewhat freely from the many spring flowers and fruit trees.

In the hives breeding was going on apace, some of the most forward colonies being nearly ready for swarming, and preparations were made for supering, when the wind suddenly veered round to the north-east, and for ten days the minimum reading of the thermometer placed 4 feet from the ground registered only a few degrees from freezing, the maximum reading of the same varying 50° to 55°. In several places snow fell; fortunately it did not actually freeze, but the high winds played sad havoc with the blossom, and much damage has been done to the fruit trees, the fruit crops in some exposed positions I fear being nearly ruined.

During the past twenty-four hours (May 25th) heavy showers have fallen, and the weather being much warmer there is now a better prospect. The cold caused a temporary check to breeding; a great number of drones in the grub state were cast out of the hives, but no workers were disposed of, and with the return of warmer weather, of which there is every appearance at present,

bees will again make headway. Stocks on the whole are much later than usual, and there will be very few May swarms to chronicle.—AN ENGLISH BEE-KEEPER.

#### TRADE CATALOGUE RECEIVED.

Acme Chemical Co., Bolton, Lancashire.—Weed Killer:

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Cucumbers (S. G. R.).**—The plant reached us too late for an examination to be made for this issue, but it shall have early attention.

**Asphalt for Paths Without Boiling the Tar (G. C.).**—We have no recollection of the recipe you mention, and fail to find it in our files. Can any correspondent oblige with particulars of making asphalt without boiling the tar by using quicklime in place of boiling the tar?

**Raising Begonias (Double).**—We are not able to state the particular varieties which the most successful raisers have found by experience to be best adapted for intercrossing for the object in view, and if we asked them they would have a way of their own in replying—very pleasant and courteous if not exactly what you would wish. Possibly they are a generation or two ahead of you in the way of parentage—we mean Begonia parentage of course, and what appears difficult to you seems easy enough to them.

**Mulching Roses (Ferndale).**—If the soil is of a light nature and liable to "dry out" in the summer, we should not fork in the long litter as it would make the ground still lighter, and the surface covering would be of service in preventing evaporation; but if the ground is very heavy it would be improved by the manure being pointed in, provided the roots of the plants are not disturbed, and even then a covering of short manure spread on the soil on the approach of hot weather would do good; short manure would be better than long also for mulching light soil.

**Steam Pan for Boiling Fruit (J. B.).**—The idea of filling the steam cavity with water is certainly novel and also dangerous. Even if you had an escape pipe there would be danger, but with the thing closed an explosion must take place. Besides, how is the fruit to boil in the pan if the water in the steam cavity is not made much higher in temperature than boiling water? This means steam, not water. There is no need for a steam-jacketed pan if you intend to put it on the fire, but an ordinary copper or enamelled iron pan would serve your purpose. Such are used in large establishments and answer well, but, of course, steam is better for general sale requirements.

**Shading Tomato Houses (A. F.).**—Tomato plants do not do well in shade, it not being possible to afford them too much light or air under favouring external conditions. As the plants, however, do not grow freely a slight shade as that of whitewash (whiting mixed with skim milk) brushed lightly on the glass outside would modify the sun's rays. It would be better to supply stimulating food at the roots, such as top-dressings of the advertised fertilisers, or bone superphosphate three parts, kainit two parts, and nitrate of soda one part, mixed after crushing fine, and using 2 to 4 ozs. per square yard at about three weeks' interval. The shading, if any, must only be temporary.

**Flies from Apple Trees (R. M.).**—The somewhat large black flies belong to the order Diptera, tribe Empidæ, and are known as *Empis tessellata*. Your specimens consist of both males and females, and had visited the Apple trees in quest of prey, which consists of insects of various kinds, especially the small leaf-roller moths, in capturing of which the perfect insects display wonderful assiduity and skill, their long legs embracing the victim, closing tightly around the body, binding together legs and wings, so as to prevent all struggling, and the sharp beak with which the mouth is provided is thrust deep into the body. Little is known of the larval condition of the *Empis*, but so far as we have observed the grubs do not feed on living vegetation, yet we have had them emerge from pupa contained in vegetable matter undergone decay.

**Forcing Kidney Beans (A. J. G.).**—Dwarf Kidney Beans succeed admirably when grown in borders in very light houses, not otherwise, and many are so grown; but there must be no obstruction whatever to the light from plants on shelves suspended from the roof. With the Beans grown in pots or boxes on such shelves other useful crops may be grown beneath. A great number of Beans are grown in pots on stages or shelves. Perhaps the majority of growers prefer 8-inch pots, but some find the 7-inch size answer the purpose. You will find much information that will be of service to you in some essays that we shall publish on the profitable occupation of glass structures in the winter, and for which essays silver medals will be awarded.

**Grubs Destroying Chrysanthemum—Dressing for Infested Soil (X. Y. Z.).**—Of the two grubs only one reached us, the other having vanished. It is the larva or grub of the daddy longlegs fly (*Tipula oleracea*), commonly called leather jacket, from its tough skin. For select plants, such as Chrysanthemums and other flowers, baits of Potato, Mangold Wurtzel, Turnip, or Apple, affixed to sticks and sunk 2 inches in the ground, should be used, pulling them up every day or two, and the grubs found attached to them, or in the soil close around, be removed and destroyed. For the land apply a dressing of two parts kainit and one part nitrate of soda, crushing the salts finely, mixing thoroughly, and using 3½ lbs. per rod, or 5 cwt. per acre. The mixture, in the reverse order of that given, acts better on the grubs, but you want a cheap mixture, which is in some respects better for the crop. It is difficult to advise when patients want medicine of their own choosing.

**Weevils Infesting Vines, Peach Trees, and Roses (W. C. D.).**—The swarm of weevils you sent in the box were glad to escape, and caused trouble in collecting and destroying. Fair samples are always desirable, but it is possible to have "too much of a good (or bad) thing." The pests are the grooved weevil, commonly called the black Vine weevil (*Otiorhynchus sulcatus*), and are very destructive to the foliage of various plants in their perfect state, whilst in the larval state they feed on the roots. You could not do better than capture as many of the pests as you can by placing sheets of white paper beneath the trees or plants and shaking them sharply after dark, when the insects drop on to the sheets, become visible, and are readily cleared away and destroyed. Houses should be entered very gently, and a light not used till the trees or Vines have been shaken. This plan is safe and better than poison for such fruits and plants as Vines, Peaches, and Roses.

**Leaves of Tomato and Melon Plants (G. G.).**—The Tomato leaf does not give trace of any parasite, but the appearance somewhat accords with that of plants suffering from eelworm at the roots, which you may ascertain by examination. If you find the roots knotted or thickened you may water them with soluble phenyle solution, using a wineglassful to 3 gallons of water, employing that quantity per square yard if the plants are set in the ground; but if in beds of about a foot depth use half the quantity, or 1½ gallon per superficial yard. The Melon leaf has some spots of a fungoid description, evidently a *Glaeosporium*, but there are no outgrowths, so that it cannot be determined. Is there not also eelworm at the roots? The leaf indicates this, and the fungus is not sufficient to account for the disfigurement of the leaves. If the plants are badly infested with eelworm it is not likely they will recover, as they do not push fresh roots so freely from the stem, hence cannot be restored by placing lumpy loam about the stems, as is feasible with Tomato plants. Nothing will restore destroyed tissue or that injured by eelworm.

**Tomato Fruit Spotted (G. N. S.).**—The fruit is affected with black stripe, or Tomato rot, in a very characteristic manner. It is caused by a fungus (*Macrosporium tomati*). There is no means of restoring decayed tissue, and but little chance of arresting the spread of the evil in the affected fruits, as the mycelium of the fungus is situated internally, and thus cannot be reached, or only partially, by outward applications. It may, however, be prevented spreading by spraying every fortnight or three weeks with Bordeaux mixture. Prevention should be the chief object. 1, Use only sound seeds from perfectly clean fruit. 2, Spray with Bordeaux mixture (a) as soon as the first trusses show, (b) when the flowers are formed, and (c) again before they expand; also (d) when the fruit is set. 3, Use nothing but thoroughly decayed manure, neither mulching with nor using strawy material. 4, Maintain a dry condition of the atmosphere, with judicious ventilation. If you prefer dusting use a 1 per cent. mixture of precipitated carbonate of copper and air-slaked lime, which is easily applied with an ordinary sulphur duster or bellows apparatus. Some cultivators find it quite as efficacious as the Bordeaux mixture.

**Questions from Sydney (A. Busby).**—1, *Gesneras*. These plants are best kept free from insects by preventive measures, as syringing is injurious to their beautiful foliage. Choose a convenient time for emptying the house and giving every part of it, whether visible or not, a thorough cleansing. Remember that insects lurk in the most unlikely places. They are often found, or rather hibernate, whether they are found or not, on the under sides of stages, in fissures in woodwork, cracks in walls, in dry soil near the walls and hot-water pipes—anywhere where they are most likely not to be seen. With a clean house, clean tubers, clean pots, and clean soil, these plants can be kept free from insects by good cultural management. The pots should not stand on dry open stages, but on a close base that can be kept moist in hot sunny weather; this must not be allowed to suffer by want of water—that is, the soil should never become so dry as to shrink from the pots. The

floors and walls ought to be syringed twice a day or more in the summer, as a fairly moist atmosphere promotes the growth of the plants, and checks the increase of their enemies. The plants should be shielded from hot sun, and must not have dry currents of air driving against them through side ventilators or doors. Under the conditions indicated they develop handsome foliage. Some good forms out of many are *Barlardi*, *chromatella*, *cinnabarina*, *Donckelaari*, *exoniensis*, *Lindleyana*, *nigrescens*, *refulgens*, *pyramidalis*, *rosea punctatissima*, *sceptre cerise*, and *zebrina splendens*. 2, The address for which you ask is Messrs. R. P. Ker & Sons, Aigburth, Liverpool. 3, *Tectorium*. There is a wire gauze gelatine material used for roofing where a subdued light is needed, and possibly the above may be its name. Some part of the Westminster Aquarium roof is, we believe, covered with it. We have also seen it used in one of the London parks for the roof of a potting shed. Mr. Moorman, the Superintendent of Victoria Park, says it answered that purpose well, admitting sufficient light without side windows; but he does not think plants would succeed under it. Possibly some kinds—such as Palms, Ferns, and even *Gesneras*—might answer where the light is more intense than in London. If you try it, do so experimentally. For verandahs it would be likely to prove suitable, as it is light and durable.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*Ross-shire*).—A, *Saxifraga muscoides purpurea*; B, *S. Aizoon minor*; C, *S. hypnoides*; D, *S. cotyledon*; E and F, Hybrid *Primulas*, that can only be named by comparison in a large collection. (*J. E.*)—Specimen crushed in the post; send fresh. (*W. H.*)—1, *Pyrus Aria* (White Beam tree); 2, *Thalictrum aquilegifolium*; 3, *Prunus Padus* (Bird Cherry); 5, dead. (*T. S.*)—*Aërides Fieldingi*. The *Dendrobium* is unrecognisable without flowers. (*Somerset*).—Possibly the plant may be *Gloriosa superba*, but until you are able to send a flower we cannot furnish the name with certainty. (*Junior*).—A well-coloured form of *Cattleya Mossiæ*. (*W. S.*)—*Sprekelia formosissima*.

## POULTRY.

THIS is the best time of the whole twelve months to make changes and improvements in the poultry of the home farm, having well in view all possible requirements of the household, and striving by the light of experience, of past success or failure, to render the supply of poultry and eggs perfect. Perfection in this matter being easily defined as numbers of chickens small in the legs with deep-fleshed, plump breasts, plenty of eggs all the year round, and a full supply of other poultry—Turkeys, Geese, Ducks, Pigeons, Guinea Fowls, each in their season, all of the best.

Easily said but not so easily done by any means, and in our connection with home farms we have had much difficulty in the maintenance of a really full supply at all, to say nothing of the high class produce which we have ever striven for, and in the obtaining of which there is no insuperable difficulty.

At the outset, or whenever reforms are set about in good earnest, ways and means must have due attention. If we would have quality in our chickens we must have plenty of Dorking hens, either coloured or white, and cross them with the Old Game cock. When young birds are purchased specially for this purpose they must be kept apart from all other breeds. This is so obvious that any mention of it might well be thought uncalled for. It certainly ought not to be required, but we once took much pains in the purchase of young birds for this purpose, and then found the home farm bailiff had turned them down with other breeds kept specially for their eggs.

With ordinary care the chickens from this cross are as entirely satisfactory as they are superior to all other chickens for table. In this matter mere size does not tell, heavy, coarse birds of whatever breed having no chance in competition with the Game-Dorking chicken. We, therefore, make it a special point to keep up an unbroken supply of them. The only way of doing this is to get a tolerably clear idea of the actual number required, and to allow a liberal margin beyond this for all possible contingencies, any surplus chickens being eagerly purchased by the higglers or poultry dealers.

Milk, oatmeal, and suet in mixture is the favourite food of the wholesale chicken fattener for market. We have used it with satisfactory results when the chickens have been shut up in fattening coops. But we are bound to say that we have had excellent chickens as plump and fat as heart could wish, fed on oatmeal made into paste with milk, and some whole maize, and they were not shut up at all, but were let run on grass with access to abundance of grit and dust, and had as much food as they could clear up when it was given to them. This requires a little judgment and care, so that no food is left lying about for sparrows and other pests after the chickens have done.

For eggs we certainly prefer Minorcas. We say this without prejudice, and with no wish to detract aught from the merits of

other breeds. To anyone wishing to start a yard of Minorcas or other pure breeds now, we strongly advise procuring a stock of young birds in sufficient numbers now to ensure a full supply of eggs when wanted. If winter eggs are required, then procure March, April, and May hatched pullets. But do avoid buying sittings of eggs. We were shown an Orpington cockerel recently which we were told had cost 15s., as it was the only living result of two sittings of eggs purchased from a famous Orpington breeder.

Purchased eggs for sittings are notoriously a doubtful quantity, and yet they are so tempting, and it seems so delightfully simple when one has broody hens. To listen to a certain worthy farmer's wife, as we did in a market train only an hour or two before sitting down to write this article, it all seems simple enough. Said she, "We set eighty eggs and got eighty chicks, an' we sold 'em about half-grown at five shillin' a couple." This to two other henwives with whom she was discussing practical "home" farming, and who appeared to receive her statement in perfect good faith. But they did raise doubts about the rearing of Turkey poults with anything like certainty, and we knew they were right in their preference for a barndoor fowl or any other good hen as a foster-mother rather than a Turkey hen, because she drags them about through long wet grass before they are old enough, causing serious losses.

## WORK ON THE HOME FARM.

Drier weather with strong cold wind has caused some difficulty in the sowing of Swedes and white Turnips. The only safe plan has been to plough, roll, and sow at once, making the complete work a daily matter. Though the plant does not come up quite together under such practice, there can be no serious objection to it. Good work has been done among the early sown Swedes and Mangolds, and though the cold weather has checked growth a bit the weeds have been got well under.

During the past fortnight the value of quick action in manure has been admirably shown in the brisk growth of the Wheat dressed with nitrate of soda, of spring-sown Oats drilled in with a well balanced mixture of chemical manure, and of pasture herbage similarly dressed three months ago. Glad are we to have got the Carrots singled and weeded. This is an expensive crop, but Carrots are so much in demand in the light horse stables, and are so useful among stock during the last three months of the year that we always have an acre or two of them.

Some slight damage may have been done by high, cold wind among fruit trees, but there appears to be no serious damage from this or any other cause. In Kent there is ample promise of a remarkably abundant fruit crop generally. Horse and hand hoes were kept going briskly among Strawberries till about a week ago, when the litter carts appeared, and the litter or long stable dung was thrown out of the carts by hand in small heaps, which were spread along between the rows by men with forks, women following with a stick in each hand about the length and size of a light walking stick, with which they worked the litter well up to and close around the Strawberry plants.

By this means all splashing of the fruit is prevented, and every shower cleanses the litter, washing its nutriment into the soil about the roots. The blossom is wonderfully strong and abundant, giving promise of abundance of really fine fruit, which is likely to become so cheap, that recourse will be had to jam making early in the season.

 Another dry week; thunder on 23rd.—G. J. SIMONS.

**THE NEW EARLY STRAWBERRY FOR 1895, STEVENS' WONDER.**

The earliest variety in cultivation and very prolific; solid fruit, good flavour, high perfume.

Awarded First-class Certificates, Royal Horticultural Society, and Royal Botanic Society, 1895. See *Gardeners' Chronicle*, March 2; *Journal of Horticulture*, March 14; and *The Garden*, March 16.

Having purchased the whole of the stock of this grand new early Strawberry from the raiser, we have pleasure in offering it as follows:—

**STRONG PLANTS**, in Pots, £5 per 100, 15/- per doz.  
**RUNNERS** .. .. £3 " " 9/- " "

Ready for delivery early in July. Early Orders requested as stock is limited. Further particulars upon application.

**WM. CUTBUSH & SON,**  
 HIGHGATE NURSERIES, LONDON, N., AND BARNET, HERTS.

**JACK FROST**

Has caused many losses that can be made good in an easy and cheap manner by purchasing the following Bulbs and Plants, which I can strongly recommend as being first class:—

**BEGONIAS, SINGLE,**

20,000 Grand Bulbs, Mixed Colours, finest ever offered at the price. 3s. per dozen.

**PELARGONIUMS, SHOW & DECORATIVE.**

Fine Plants in Best Kinds, 6s., 9s., and 12s. per dozen.

**ZONAL PELARGONIUMS,**

Best Kinds only. 6 for 2s. 6d., 12 for 4s.

**IVY-LEAF PELARGONIUMS.**

A very Choice Lot. 6 for 2s. 6d., 12 for 4s.

**DOUBLE PETUNIAS,**

Extra fine New Kinds. 6 for 3s. 6d., 12 for 6s.

Send for Catalogue, Free.

**H. J. JONES,** Ryecroft Nursery,  
 HITHER GREEN, LEWISHAM.

**C. COX,** Horticultural Engineer,  
**TUNBRIDGE WELLS.**

THE HERCULES.—Design Registered.

**TENANT'S FIXTURE PORTABLE SPAN-ROOF CURVILINEAR CONSERVATORY OR GREENHOUSE**

No brickwork required. These houses are made of the best materials, painted four coats, and glazed with 21oz. clear sheet glass, a flat painted stage is fixed on each side and one end, and slatted path up centre.

CASH PRICE, Carriage Paid to nearest Station in England & Wales, within 100 miles of Tunbridge Wells—fixed free:—

Length 9 ft., Width 6 ft., £15 0 0—Width 8 ft., £19 0 0

**HOW GARDENERS ARE MADE.**

FROM a cursory review of the swelling ranks of the great army of gardeners, conclusions may be drawn that the noticeable congestion is a natural result of the increase of population, a cause which by analogous reasoning should produce the same effect in all the various trades and professions. With some, indeed, it may to an extent do so, but not in any does it appear to be more acutely felt than in gardening. Without ignoring the waves of depression which periodically affect other classes of the community, they are more of the spasmodic kind than those which immediately concern us, which by their persistence may now be regarded as chronic.

The rising generation of our large industrial centres have to-day many new channels opened to absorb their energy, and, I think, the City boy bred and born under the more exciting conditions of life is apt to look on gardening as "rather slow." Hence, recruiting from this quarter is not a prominent feature in the question. Obviously, there are many reared under the same conditions who cannot be included in this category, yet are precluded by want of opportunity, or from absence of those hereditary intuitive influences pertaining to the more natural conditions of country life.

Setting aside this large portion of the population, which does not appear to materially affect this important question, whence comes the supply, which so much exceeds the demand, and from what cause proceeds the effect? To the first query, which is simple, the answer is plain—From the country districts. To the second, which is more subtle than simple, the reply may be—I think is found—in ambition. The ambition of the boy to be a little better than his father, and the unselfish parental desire that he should be so—a thesis applicable to and obtaining with all sorts and conditions of the human race.

From this one need not go far to seek, nor is it difficult to find the class from which this influx is derived—viz., the agricultural; nor is it needful to point to that depression, which furnishes an additional incentive for young Britain to escape from it. Any port in a storm,

particularly the nearest one; hence by the contiguity of horticulture to agriculture—the garden to the farm—relief is sought, the rush is made, and overcrowding the result.

Setting forth a fictional example, founded on facts furnished by many a rural locality, illustrating how some gardeners are made, we may note a cottage home plentifully bedecked with olive branches—a source of pride and anxiety to the worthy parents. The time arrives when the eldest of the apple-faced boys should be contributing something to the family exchequer, and to get him into the squire's garden is advancing by leaps and bounds over the head of father, who has toiled and moiled for years on the farm. Our young recruit and his parents arrive, with but little reflection, at the conclusion that if he can be enlisted on the staff at the Hall gardens, it is but a matter of time when he will attain to a similar high position as Mr. Prunewell, the squire's head gardener, who, as everybody knows, takes all the principal prizes at the Hortus-cum-Digwell flower shows. Should a fee be required to unlock the gates to these Elysian fields, it is cheerfully provided from the rainy day fund, which should be as powerful to invoke prospective blessings as it is to stave off future troubles.

Ambition now soars high, and tempts—which the passport if provided enables—him to go straight through the glass houses in his endeavour to reach the goal. Consequently but little, if any, practical knowledge of outdoor work is acquired. So many examples may be noted of this way in which gardeners are made that it need not be attributed to imagination, although there are happily to be found exceptions to this ill-balanced method, particularly in North Britain, where the importance of a sound drilling in outside work is duly recognised. Having launched our apple-faced hero on the sea of life, what more natural, or apparently more desirable, than that other developing pippins, still dependent on the parent stock, should be sent to the same market, irrespective of any consideration of a glut?

Now, gardeners—in the fullest sense of the word—are born, not made, although it would be presumption in localising their birth to any class or condition of life. Given all necessary qualifications to those who are eventually to rule successfully, these are those who by natural right should occupy the position they are qualified to adorn. It may be admitted that the majority of them do so sooner or later, but they are the class (not the cause) most acutely feeling this congestion in their trial by the ordeal of waiting.

Some time since, when this topic was touched on (editorially, as far as I recollect), some crumbs of comfort were afforded by the deduction (I am not quoting verbatim) that nine-tenths of the really good and capable men would find their legitimate level. Giving the matter that thought it deserves, the force of this truth—and I believe it to be such—is evident. Here is comfort for the nine, but what of the tenth? No hope! This fact has to be faced. The tenth does not look very formidable on paper, but embracing the area of our country the serious proportion it then assumes is not to be lightly passed over; nor is it, as plainly evidenced by the space given to this subject from time to time in the *Journal of Horticulture*.

Apropos of the silver medal which the authorities of the Journal are liberally bestowing for an essay on a matter of some importance, I would respectfully suggest to them that any expression of thought which would pave the way for remedial measures, either by restricting the supply or increasing the demand, would be worthy of a gold medal. Moreover, a practical solution of the puzzle initiating a golden age for good gardeners should prompt such a medal assuming the dimensions of Captain Cuttle's historical watch.

From this point of view—viz, the natural desire of self-preservation as a class, and the protection of that great minority, "the tenth," with a mitigation of the sufferings of the nine, we must charitably look on the other side from whence comes the crush. Competition in the field of horticulture is open to all, and the desire

of each generation to step onward and upward is not only enforced by circumstances but encouraged by education. May the latter ever be so! Not any selfish views may prompt us to shut out these considerations, nor fail to acknowledge the worthiness of those who bear the burden of agricultural labour. Rather would we, and do, hold out a helping hand to our hard-working brother by transplanting his olive branches into the gardening world, even though it be, and undoubtedly is, to our own detriment.

The decadence of farming has obviously much to do with gardening difficulties, and though our farming friends are straining every nerve to make two blades of grass or corn to grow in the place of one it is only to find that the virgin soil of "the West" is yielding three minus the handicapping they are subject to. But on this side of the subject it is needless to dwell, unless it is to point the moral that relief from this quarter—the supply—appears to be remote indeed.

Those immediately concerned—head gardeners—are so keenly conscious of the growing evil that we find them questioning the wisdom of training their own sons to follow in their footsteps. Although it is their gain not to do so, it can only be generally regarded as a loss to the gardening world. And, when we consider the moral force a head gardener has to give his son a push in his own profession, whilst prudence causes him to nip all horticultural tendencies in the bud and shunt him out of it, it clearly points to something rotten in the State of Denmark.

Passing from supply and how gardeners are made, there appears to be something to be said on the question of demand. Are there to be found here any rays of hope in the gathering gloom? I think there are; but in view of space and dreading the editorial scateurs I will at present defer it, and, if permitted, return to it under the heading of "Facing the Fact."—INVICTA.

### FREE GROWTH OF PEACH TREES.

WHEN first planted in a fresh border Peach and Nectarine trees are apt to grow too strongly to be productive, say during the next three seasons. Especially is this the case when the grower is free with the knife at the winter pruning, and either the finger and thumb or the knife during the spring and early summer months. There was a time when very few, if any, gardeners ventured to lay in sub-lateral or secondary growths in the case of trees under glass even, and would have scoffed at the idea of saving any on open air trees. All this, however, is being gradually altered.

Instead of removing all the sub-laterals or breaks on the current season's growths, and which only aggravate the evil of grossness, the better plan is to remove those straight from the trees and a portion of the remainder, leaving only what can be laid in on the upper side, and in some cases on both sides of the primary growths without undue crowding. I shall perhaps be told that these side growths cannot possibly ripen sufficiently to fit them either for fruiting purposes or assisting in laying the foundation of a serviceable tree, but not by those who have given the plan a fair trial. Where the houses are old-fashioned, that is to say very heavy and dark, also indifferently heated, I can appreciate the necessity for depending solely on the shoots first formed, but there are not many such structures to be seen, the great majority having very light woodwork and extra large squares of glass. Of these latter it cannot truthfully be said that the wood fails to ripen satisfactorily under them. On the contrary, it is sometimes necessary to shade lightly in order to prevent premature maturation of wood, and early loss of foliage by red spider.

In these light, and it may be freely ventilated, structures there ought to be no hesitation about laying in some of the sub-laterals now so freely forming on the stronger growths of young trees, as it is certain they will mature sufficiently for all purposes. Fail to do this and the chances are still more sub-laterals will be pushed out from the fattening laterals, with the eventuality of few or no fruit buds, unless it be at the extreme ends, which, if the practice is carried out in its entirety, will be cut off at the winter pruning. These much-pampered growths are very difficult to deal with the following winter, and prune how you will there is every likelihood of the breaks from them proving even grosser than the parent branch.

If the trees could be depended on to last one's lifetime in good health and vigour there would be some excuse for taking extra

pains in laying the foundations, but in many cases they are liable to fail just when they have attained to their most serviceable size. Sometimes this is due to faulty stocks, stem canker, gumming, and in others to certain local conditions that do not suit stone fruits of any kind, and not unfrequently the mischief might be traceable to over-pruning at the nurseries. In our climate the trees ought really to be prepared against warm walls, and in not a much-enriched soil, but as this cannot be profitably undertaken on a large scale by nurserymen, gardeners should train their own trees. Many years ago, Mr. W. Taylor, when at Longleat, initiated the plan of starting with maidens against the open walls, running them up quickly and making no attempt to form them into great spreading trees. Hitherto the Peach and Nectarine trees against the same walls had proved very disappointing. Whether or not Mr. Taylor anticipated that his smaller quickly grown trees would last longer than those previously planted had done I am unable to say, but am under the impression that he made up his mind that their lives would be "short and merry." Be this as it may, the fact yet remains that very few, if any, of those trees have died, and I can remember them for fifteen years, while the crops produced have been exceptionally heavy and good.

What would have been said, not so very many years ago, of trees only twice pruned producing two dozen fruits and upwards? Yet I can point to several trees planted as maidens in March, 1894, that are now carrying this number of fruit, some of the earliest already commencing their final swelling. Before the season is over some of these trees will cover a roof area of 12 feet square, but at what size and when would they have fruited so freely if we had not laid in sub-lateral growths freely? Those maidens were all extra strong and well matured, and were reserved with a clear stem of 2 feet in order to bring the head of the future tree to the roof trellis at once. This season the stronger growths are again forming side shoots, and the best placed of these will be saved, so that if all goes on well we shall have a roof nearly covered with fruiting wood, and almost a full crop of fruit.

Mr. Challis has done well at Wilton in this direction. We are "going one better." If strong maidens are cut hard back, or say to within 4 inches to the stock, the growths resulting ought to be, and usually are, so vigorous that they must be allowed to divide, and even sub-divide, freely, and in a good position in a heated house the third breaks ought really to ripen sufficiently well to fruit the following year. Even maidens growing quite in the open will branch and mature sufficiently to flower the following spring.

Recently I was shown some strong healthy trees against sunny open walls that had not nearly covered their allotted space, and asked how to treat the leading growths. These latter were branching freely, and I had no hesitation in advising a retention of a few well placed for laying-in, and the removal of the rest. The leading growths have, as a rule, abundance of room, and so also have the shoots laid in from them, and it will be a very sunless summer indeed if the latter fail to mature properly. Occasionally one or two first-formed growths take too strong a lead, and unless checked a lop-sided tree may be the result. Instead of reserving these to their full length, cut them back at once to where the wood is firm. This will largely divert the sap to parts of the tree more in need of it, and the two or three shoots that are soon put forth by the pruned growths will never be so strong as the parent growths, and are more likely to fruit than are the rank growths not summer pruned. Sappy shoots would in many cases have been removed with advantage, those with a little experience detecting them before they are many inches long. If a growth is wanted from near where they start, the timely removal of extra strong central shoots would have been the means of starting a less vigorous shoot from one of the outside wood buds.

I am aware that there is nothing very novel in this, and am equally well aware that many readers of the *Journal of Horticulture* are still inclined to move a little too cautiously in the matter of training Peach and Nectarine trees.—W. IGGULDEN.

ODONTOGLOSSUM PESCATOREI LA PERFECTION.

VERY beautiful indeed were the many *Odontoglossums* staged at the recent Temple show, and the form of *Pescatorei*, shown by Mr. Ch. Vuylsteke, and named *La Perfection* (fig. 89) was amongst the foremost as regards quality. The flower was of exceptionally good form, the ground colour being white very

delicately suffused rose in a few places. The spots, deep rosy purple in colour, greatly enhanced the general effect of this handsome form, which received an award of merit.

#### EPIDENDRUM POLYBULBOUS.

MANY of the smaller growing and flowering species belonging to this genus are in rather bad odour with growers, and it is true that some of them are weedy in appearance and very indistinct and unattractive in colouring. The present species is, however, well worthy of a place in representative collections, and especially on account of its free-flowering character. A small plant I saw growing in a hanging basket was crowded with small, starry, violet purple and white flowers.

The plant is small and creeping in habit, the rhizomes being sparingly set with tiny pseudo-bulbs, each bearing a pair of very

FIG. 89.—ODONTOGLOSSUM PESCATOREI LA PERFECTION.

small leaves. It thrives well apparently near the door in the *Cattleya* house, and on account of its habit it must be pegged down to the surface of the compost. It has been a long time in cultivation, and appears to be a widely distributed plant in and around Mexico, probably also Jamaica, for I believe Mr. H. W. Ward of Longford Castle imported it from there some time ago, but whether collected wild or from a botanic garden I am not sure.

#### STIMULANTS FOR ORCHIDS.

The practice of using manures of various kinds for Orchids is a subject that has been freely discussed from time to time in the horticultural press, and naturally divergent opinions are held by cultivators. That the practice is right, when all other details are carried out satisfactorily, there is no denying, but it is very easy to run to extremes, especially with the epiphytal section.

When writing of *Dendrobium nobile* recently "B. W." advised the use of loam in the compost, bones being mixed with it, and liquid manure also applied. No doubt "B. W." has had good results by these means, or he would not advise them for others; but I cannot think it would be advisable, or even safe, for beginners in Orchid culture to use liquid manure with such a stimulating compost, nor is it necessary if cultural skill is brought to bear. It is quite possible to grow *D. nobile* magnificently without any of these seemingly fertilising ingredients.

For all the medium-growing *Dendrobiums*, for *Cattleyas*, or any of the general run of pseudo-bulbous epiphytal Orchids I am convinced that an atmosphere more or less strongly charged with ammonia is decidedly more beneficial than the use of stimulants of any kinds at the roots. Strong-growing kinds there are, such as *Cymbidiums*, *Phaius*, *Zygopetalum Mackayi*, *Peristerias*, *Anguloas* and others that are better—both in the size of the pseudo-bulbs and number of flowers—for the application of some concentrated fertiliser, and probably such plants as *Oncidium Marshallianum* or *macranthum* may be benefited by a little when carrying a heavy inflorescence, but with the species in question and similar kinds, I am of opinion it is time and money wasted to use them to any extent.

Individual cases of successful cultivation by these means prove only that it is possible so to grow the plants. Whether they can be as well grown without them is the point, and I maintain that they can, other conditions being right. With regard to the best fertilisers for the other class of Orchids referred to, I have had good results by using well-diluted Peruvian guano. Ichthemic guano and various other fish manures have received strong testimony from many growers, but as I have used them only to a very limited extent I could not say whether they are in any way superior. A good change from the foregoing will be found in steeped cow-manure diluted until the water is hardly stained, and clarified soot water in equal proportions.

Liquid manure made from horse droppings, according to my experience, is the reverse of beneficial applied to the roots, though as an agent for supplying ammonia to the atmosphere it is first-class. Another point where I can hardly agree with "B. W." is in regard to watering immediately after repotting. He advises a thorough watering to settle the soil about the roots. As far as I have seen, the compost for Orchids generally, *D. nobile* included, settles itself only too quickly, the chief difficulty being found in keeping it in an open and aerated condition.—H. R. R.

### HOME-GROWN LILY OF THE VALLEY.

EARLY forcing is an important phase of a gardener's duty, and by superior art applied in growing plants for this purpose, flowers of numerous kinds are produced in profusion quite out of their natural season. Many that a few years ago were thought to be proof against the forcer's powers have been found to adapt themselves admirably to these conditions. Their name is legion, and amongst all the flowers which swell the number none is more popular than the Lily of the Valley. It is perhaps no exaggeration to say that in the growing and forcing of these the florist's art is displayed to a greater extent than in any other.

Perhaps the great public demand for Lilies is in a measure responsible for this, as whenever there is a clamour in the markets for any particular flower means are surely found to supply it. Such is the case with the one under notice, and to supply the English market with crowns assorted and suitable for forcing, Lily of the Valley growing in some parts of the Continent is quite an industry. The forcer's power is then brought to bear, with the result that by careful arrangement fine blooms are abundantly produced, and placed in the markets from some weeks before Christmas until they flower naturally out of doors. In almost every establishment in the country, large or small, Lilies are forced in some cases by the hundred, and in others by the thousand; and so general has this mode of cultivation become that any notes on it would almost appear superfluous.

It is, therefore, to the growing of the Lily of the Valley under its natural conditions that I will confine these remarks. Strange as it seems, it is nevertheless true, that in many instances the interest in this charming flower appears to cease at the close of the forcing season. Perhaps it may have never occurred to some readers in how few establishments outdoor Lilies are really grown. True, they may often be seen eking out a miserable existence in some out of the way corner of the kitchen garden, or perhaps making faint endeavours to bloom under some dense shrubbery; but as for being cultivated, that is a thing unthought of. Many are planted in such positions as above referred to, and left year after year without a thought of giving the attention due to them, until after abstracting all the supporting properties from the soil they either produce weak, dwindling spikes, which are hardly worth the trouble of gathering, or else they become so matted together that flowering becomes a thing impossible.

That outdoor Lilies pay well for the small amount of attention and labour that it is necessary to bestow on them is amply proved in the large numbers of magnificent flowers that are produced in establishments where they are considered worthy of this little extra care. By the systematic splitting of crowns and replanting it is also surprising the rapidity with which they will multiply, and for the benefit of anyone who may be desirous of effecting this the following notes may prove useful. In no aspect are they out of place, but for supplying early flowers a position near a south wall is undoubtedly the best. A bed with a north-easterly situation is suitable if it is desirable to keep them in bloom a considerable time; and last, but not least, a little shelter is necessary, such as would be afforded if planted in the shade of bush or pyramid fruit trees serving the purpose admirably.

If the space is at disposal it is a good plan to plant a few here and there as accommodation will permit. In commencement beds of rich soil should be prepared in which has been incorporated some good manure. In the autumn, as soon as the foliage dies off naturally, the clumps should be divided into small tufts, with, say,

two or three crowns to each, shorten the long roots with a knife, and plant them about 9 inches apart, in rows in the prepared beds and the same distance between the rows, taking care that the crowns are left just exposed above the ground. It is extremely necessary that the soil be made firm by trampling round each one, and it is a good plan to make each bed about 4 feet wide, leaving a path of about 15 inches between.

In the following and subsequent autumns after planting they will require top-dressing with well decayed manure, and the sooner this operation is performed after the foliage is off the better. Provided all conditions are favourable, in three years after planting, the beds, whether large or small, will be thickly covered with crowns, when some of them then may be taken up and replanted, following out the same process as before, but if placed again in the same position the ground should be well manured previously. As in the case of all other plants, however, change of ground is in every way desirable.

Though home-grown Lilies subject to the above treatment are not equal to Berlin crowns for forcing, still they are very satisfactory, and if clumps are cut out with a spade and placed on a gentle hotbed to come in flower in March or April, they produce fine blooms, together with abundance of bright green foliage, which is very acceptable. It is also an advantage to let some of the crowns grow quite thickly together, as in a hot, dry season, the foliage forms a means of protection to the flowers, but, on the other hand, should the weather be wet, the blooms often decay from the same cause.

By paying attention to the points recorded above, it is surprising what a large number of fine, substantial flowers may be obtained from a small space of ground, by which it may be seen how they repay for a little care and attention in cultivation.—G. H. H.

[We have recently received a box of Lilies grown as described, which gave ample evidence of good culture, many of the spikes, clothed with large bells, being 7 inches in length.]

### ATMOSPHERIC MOISTURE.

PARCHED ground, drying winds, and a dry hot atmosphere—conditions which at the time of writing prevail throughout the greater part of our country—seem to indicate that the heading of this note is a delusion. Indeed it is, so far as the bulk of vegetation in the open air is concerned, but if the stamp of high culture is to be apparent among plants and crops grown under glass, it is absolutely necessary during the prevalence of tropical weather that special attention be given to the maintenance of a certain amount of atmospheric moisture. Experience teaches practical cultivators that unless these matters are attended to satisfactory results cannot be obtained. Why this is so is a matter which has led to much discussion, and a certain school of theorists has maintained, with all the energy and emphasis they could command, that the leaves of plants are capable of absorbing moisture from the atmosphere, while on the other hand the majority of plant physiologists deny that this is possible. Be that as it may, we know we are on safe ground in assuming that if leaves do not absorb moisture from the atmosphere they are very much benefited by being surrounded with atmospheric moisture, because it prevents the too rapid escape of moisture through the pores of the leaves.

Here, then, we have a safe basis to start on, and the next point to be considered is best practical methods of maintaining the requisite degree of atmospheric moisture. The syringe is, in many instances, the most useful of all appliances for this purpose. In very hot weather it is, however, necessary to use water in greater quantities than could be conveniently done with a syringe; here the watering can, with a coarse rose attached, may with advantage be brought into use for damping the floors and walks of plant or forcing houses, vineries or pits.

In addition to this damping of walks, stages, and other available spaces several times daily, we have to consider the matter of damping the foliage of various kinds of vegetation, and in this direction a good deal of discretion is necessary, because many plants which delight in a moderately moist atmosphere (providing it is accompanied by strong light or sunshine) are more satisfactory when syringing is not regularly practised. Pelargoniums of various sections bear out this statement, at least those that are grown for the beauty of their flowers rather than for the varied markings of their leaves.

Experience, and that alone, will teach the cultivator exactly which plants may with advantage be copiously syringed, and which produce the most satisfactory results when damping between them only is practised. A good rule to follow in the matter, under the guidance of common sense and observation, is to syringe freely all plants that are grown especially for the beauty of their foliage

or their graceful habit, as well as those that are subject to the attacks of red spider and thrips.

Both the damping of houses and the syringing of plants—practice of the greatest utility when carried out under the right conditions—have by many been greatly abused; but I for one fail to see why this led to a wholesale condemnation of the practice such as some writers indulge in, because it is well nigh impossible to mention any gardening operation which, if conducted without the exercise of intelligent judgment, will not lead to disastrous results.

In this matter of atmospheric moisture our course is so clearly defined that nothing but downright thoughtlessness or indifference can lead to failure. We know perfectly well that with a dry, hot atmosphere in the open air regular damping of plant houses must be resorted to, so that the extremes between aridity and a continual state of dampness be avoided. When under the influence of bright sunshine and high temperatures moisture dries up quickly, the time for the free use of water is apparent, and just as clearly ought it to be understood that with a lowering temperature and less rapid evaporation the distribution of moisture ought to be proportionately lessened.

Through the summer months many of the occupants of green-houses are placed in the open air, and other plants intended for flowering under glass during the autumn and winter are also grown with only the canopy of heaven above them. Syringing once or twice daily is quite necessary in such instances to keep them in a healthy condition; indeed a free use of the syringe in hot weather with many of them makes all the difference which is apparent between vigorous, healthy plants and "starvelings," while the present hot weather continues. Young gardeners cannot have too strongly impressed on their minds the necessity of applying abundance of water to the roots of plants, and of using every effort also to surround the leaves with atmospheric moisture.—H. D.

#### VIOLAS IN THE MIDLANDS.

FOR the present purpose Pansies are included in the above heading, for the sufficient reason that all Pansies are Violas, though all Violas are not Pansies. Last year a very successful show of Violas, large and small, was held in Birmingham, and in conjunction therewith a conference of gardeners. The proceedings of this conference were printed in the form of a neat pamphlet, illustrated with several portraits, and as a few copies are left persons who are interested in the flowers would find 6d. well spent in obtaining a copy from the President, Mr. W. Cuthbertson, of Rothesay, for it contains much information and selections of the best Violas in cultivation. There has been another show and conference—namely, on Thursday last, the 29th ult., and in the same place, the Botanical Gardens, Edgbaston, Birmingham, and both are eminently worthy of notice.

#### THE GARDENS.

Edgbaston is a western suburb of the great city—the Viola city we had almost said—of the Midlands, and a beautiful suburb it is, the main roads passing as it were through avenues of trees which shield many mansions and villas. The gardens are not extensive—about 12 acres—but so undulated, disposed and diversified as to appear much larger. They were formed and planted by Loudon, are supported by subscriptions mainly, and have been managed (culturally) by Mr. W. B. Latham for the last twenty-seven years, and the managers are also fortunate in having as Hon. Secretary the genial and accomplished Professor Hillhouse. The glass ranges are substantial, well arranged and excellently furnished, and the grounds, as just indicated, picturesque. In one of the houses a number of Schizanthuses in 6-inch pots displayed myriads of daintily pencilled flowers; such plants would add a charm to private gardens, and might be had in hundreds, as they are simply raised from seeds sown in September. In other structures decorative Pelargoniums, Calceolarias, Liliun Harrisii, Gloxinias (very fine), and Streptocarpuses were admirably represented, besides Orchids and various fine-foliaged plants in excellent condition. In the grounds beds of Violas were masses of beauty, notably those occupied by that effective bedder Dean's True Blue; and a new Alpine garden, opened on Thursday by G. Kenrick, Esq., will prove a valuable acquisition. It has been formed, and is in the course of being planted by Messrs. Backhouse & Sons, under the superintendence of Mr. R. Potter. A commemorative tablet informs us that it is to be known as the "Hugh Nettlefold Alpine Garden" in recognition of the worth of a gentleman who was chairman of the Gardens Committee, and in all respects an estimable man. Rocks, dells, bogs, and water are represented, and the entire work is of considerable magnitude.

#### THE SHOW.

The Pansy and Viola show was displayed in the "Exhibition House," a glass-covered structure, which was fully too hot for the blooms on the brilliant sunny day. It was mainly a competitive display, and

famous growers entered the lists. Fancy Pansies were extensively and finely represented, and Violas delightfully imposing, but Show Pansies not equal to exhibitions of them a quarter of a century ago, and it would almost seem as if the flowers were on the down grade. A great, and indeed a glaring fault, in the competitive stands of Pansies was the general absence of names of the varieties, and this in spite of one of the printed regulations, that "all Pansies and Violas must be legibly and correctly named;" not should be, but "must." Yet not one bloom in a hundred had a name attached when the Judges made their awards. The ignoring of the rule is inexcusable, and it ought to either be enforced, expunged, or modified in future, but by all means enforced, as the absence of names deprives the show of half its interest, completeness, and instructiveness. That naming can be done was evident by the large collections of Violas from Messrs. Dobbie & Co. and Mr. Pye, as well as competitive stands by Mr. Rowberry; and further, when Professor Hillhouse made it known that medals would be given to some competitive stands of Violas if names were attached, these were added forthwith, as they might have been, and ought to have been, in every stand competing for a prize. Here endeth the merited grumble, and perhaps some of the exhibitors may add "not before time."

Referring to the competition, we found in class 1, for forty-eight Fancy Pansies, dissimilar, six exhibits, forming, as may be imagined, a brilliant display, and the more so since all the stands were good, and some so close in merit that the Judges were compelled to examine the blooms with extreme care, and they were an hour in arriving at a decision. The first prize (which carried the silver medal) was won by Mr. John Smellie, Busby, N.B., with not the largest blooms, but those characterised by substance and clearness in colouration. Mr. Alexander Lister, Meadowbank Nursery, Rothesay, was second, and as he was only defeated by one point, was worthily awarded a bronze medal in addition to the prize. Mr. Alexander Bailey, jun., Silkworth Lane, Sunderland, was placed third, with perhaps the largest blooms of all, some of them 3 inches in diameter, but the colours of several were not clearly defined. Mr. John Sutherland, Victoria Nursery, Lenzie, Glasgow, was adjudged the remaining prize for stands of richly coloured blooms of moderate size, yet distinctly meritorious. In class 2, for twenty-four blooms, there were also six exhibitors. Mr. John Sutherland was the premier, followed by Messrs. Bailey, Lister, and Messrs. W. Paul & Co., Bridge of Weir, N.B., in the order named. All the stands were good, and there could have been few points of merit between any of them.

In class 3, for twenty-four Show Pansies, there were five exhibitors. The blooms were naturally smaller than in the preceding classes, yet most of them clean, many very charming, though several too small. Messrs. W. Paul & Co. well won the first position, followed rather closely, however, by Messrs. Alexander Lister and John Smellie, to whom the remaining prizes were adjudged in the order named. In class 4 there were also five exhibitors, but in a class like this for six Fancy Pansies of one variety it is, in the absence of the names of the flowers, hardly worth recording the names of the exhibitors, yet we give them—Messrs. Lister, Smellie, and Paul, though it shows the absurdity of staging unnamed flowers. It was subsequently found that the winning blooms were those of a fine new variety, Colonel M. R. G. Buchanan. In class 5, for twelve seedlings of Fancy Pansies, the prizes went to Messrs. Smellie and Lister, but the blooms were not named. In class 6, for twenty-four sprays of Violas, dissimilar, six blooms in a spray, two very attractive collections were staged by the exhibitors just mentioned, who were placed first and second respectively. Varieties not named. The classes referred to were open to all, and we now turn to the amateurs' section.

In the class for twenty-four Fancy Pansies, dissimilar, there were seven exhibitors. Mr. John McFarlane, 68, Gordon Street, Glasgow, secured the leading position with very fine blooms, but without names. Mr. Thomas Naden, 6, High Street, Elvaston, Derby, was a good second with properly named flowers, of which John Coutts, J. Allen, J. Downie, Mrs. R. Thompson, Mrs. E. L. Carnegie, and Maggie Watson were very good indeed. Mr. A. C. Christie, Shifnal, Salop, third. Five exhibitors competed with eighteen blooms. First, Mr. T. Naden with named blooms similar to those in his twenty-four stand. Second, Mr. Christie; third, Mr. W. Whitehead, Churchgate, Leicester; fourth, Mr. T. M. Eglinton, Trinity Road, Birchlands, Birmingham. Seven stands of six blooms were staged. First, Mr. T. Naden with Tamworth Yellow; second, Mr. A. C. Christie with D. Rennie; third, Mr. Eglinton with Tom Travis. In the class for twelve blooms there were nine exhibitors. First, Mr. J. McFarlane; second, Mr. T. Naden; third, Mr. A. J. Rowberry, The Crescent, South Woodford, Essex; fourth, Mr. Christie. Mr. Rowberry named his blooms, and his W. H. Clarke was one of the best in the show. Very good also were Mrs. Grossart, Rev. Gresley, Tamworth Hero, and Ceres. With six seedling Pansies, Mr. McKee, 18, Dougall Street, Belfast, was first, and Mrs. R. Lovatt, Chetwynd, Newport, Shropshire, second.

In the class for twelve sprays of Violas, six in a spray, first Mr. A. J. Rowberry, with delightful sprays, with foliage, of Cottage Maid, Craigie, Lemon Queen, Blue Gown, Christiana, Countess of Hopetoun, Blush Queen, Princess Beatrice, William Neil, Sweet Lavender, Duchess of Fife, and Amazon Queen—a new variety of the Peter Barr type, colour golden chestnut. Second, Mrs. Lovatt.

Certificates were awarded for the following:—*Viola A. J. Rowberry*.—A clear, smooth, soft canary yellow, without spot or streak; a medium-sized flower. Exhibited by Mr. G. McLeod. *Viola Prince of Wales*.—A larger flower than the preceding and of a deeper yellow, but with the faintest of faint ray lines. Shown by Mr. Andrew Irvine, Tighnabruich. *Fancy Pansy Col. M. R. G. Buchanan*.—A large bloom of good substance and excellent symmetry; body colour dense maroon,

upper petals shading to violet; edging bright yellow. Exhibited by Mr. Alexander Lister, who won the first prize also for six blooms of it in class 4.

Messrs. Dobbie & Co. exhibited in their best style a hundred varieties of Violas in sprays, consisting of nine blooms of each. They included the leading varieties in commerce, as well as upwards of thirty of their own raising. It may be said that all the varied hues in which the Viola is robed were represented in this fine collection (silver medal). Mr. Septimus Pye, Catterall, Garstang, had also a large collection. In this case twelve blooms being arranged in a spray, and being large and well displayed had an imposing effect (silver medal).

An award of merit was granted to Mr. Wm. Sydenham, Tamworth, for beautiful table decorations of Violas, the flowers being arranged in rustic-fashioned zinc tubes, a similar award being granted to Mr. Robert Sydenham for various designs of the same character, furnished with Poppies, Cornflowers, and Sweet Peas, all very beautiful; a bronze medal was also granted to the first-named exhibitor for his entire exhibit, including many fine Pansies and choice Violas.

The exhibits were arranged on tables covered with maroon serge chosen by Professor Hillhouse; it had a much better effect than the orthodox green baize, and showed the flowers to advantage.

#### CONFERENCE.

A Conference of Viola growers was held in the Library of the Gardens on Wednesday afternoon under the chairmanship of the President, Mr. W. Cuthbertson. Among those present were Professor Hillhouse, with Messrs. A. J. Rowberry, A. C. Christie, A. Ireland, R. Sutherland, Wm. Sydenham, James Sinkins, R. Potter, E. Bliss, W. Gardiner, G. Wilson, W. H. Gabb, and R. Dean. After reading letters of apology for inability to attend from Dr. Stuart, Mr. Needs, and Mr. McLeod, the President alluded in sympathetic terms to the lamented death of Mr. William Dean, who had made all the arrangements for the present show, Mr. Cuthbertson concluding by proposing the following resolution:—"That this meeting expresses its deepest sympathy with the widow and family of the late Mr. William Dean, and deplores the loss sustained by horticulture through his death."

The PRESIDENT referred to the great devotedness of Mr. Dean, his disinterestedness, his willingness to help others, and above all his greatest virtue modesty, in which he resembled the flower he loved so well. The resolution was seconded by Professor Hillhouse, supported by Mr. Rowberry, and passed unanimously. After some allusions to the extension of Viola culture, the Chairman stated that as nothing could advance the flower so much as placing before the public reliable information, he would ask some of the gentlemen present to read short papers.

Professor HILLHOUSE entitled his paper "Some Notes on the Genus Viola." It was really a valuable, historical, and scientific disquisition, in great part oral, and was listened to with the close attention it undoubtedly merited. The Professor first dwelt on the wide geographical distribution of the species, and then with the aid of diagrams made clear the structural character of the flower and the innate obstacles provided within itself to self-fertilisation. Several coloured plates were also shown of the species which in more or less degree had exerted influence in the production of the present race of Pansies and Violas. He said the Pansy was cultivated by Evelyn in 1687, and remarked that Gaspard Bauhin recorded in 1620 that beautiful varieties were cultivated in gardens by the curious. The Professor described the Pansy as a protean plant, and hence the issue of many forms which for want of a better expression he would call "natural hybrids," and therefore material is provided for further advances, which should be effected on systematic and scientific lines.

Mr. R. DEAN read a paper on "Old Violas." He traced the popularity of the Viola as a garden flower to the practice and writings of the late Mr. John Fleming of Cliveden about 1854. He raised Cliveden Yellow, Cliveden Purple, and Cliveden Blue, which were for a long time famous. He obtained Cliveden Blue, it is said, from Russia, but now probably lost to cultivation. He also grew the Great Eastern, raised by Mr. Hooper of Bath, as well as the quaint and distinct Magpie, probably the oldest variety now grown, and said to have been found in a cornfield in France. Mr. John Wills' experience with Viola cornuta about 1863 was referred to, also the work of Mr. Grieve, Mr. Baxter, and others. Mr. Dean further stated that his Blue Bell, which is found the best dry weather Viola at Syon, came as a chance seedling in his garden at Ealing, in which no Violas were grown. He brought under notice the origin of several other once popular varieties, concluding with a reference to the True Blue as raised by his late brother, and which might be left to commemorate him for many years to come. This no doubt it will do, as though it partakes somewhat of the Pansy character, its colour and floriferousness render it effective in masses, as beautiful beds in the Birmingham Botanical Gardens afforded good evidence.

"Violas in Surrey," a paper contributed by Mr. E. Burrell of Claremont, embodied his experience, which was altogether satisfactory. His method of culture was to enrich the ground and plant in October, and then, with mulching in April, he finds the plants grow freely and flower continuously. He mentioned as excellent varieties Archie Grant, Crimson King, Favourite, White Swan, Lilies, Annie King, Mrs. Bellamy, Violetta, and Ardwell Gem. He evidently did not favour the fanciful name of "Tufted Pansies," an opinion that met with unanimous approval.

WINTER CULTURE OF VIOLAS.—Mr. Rowberry read a short but very useful paper on this subject, in which he strongly advocated inserting cuttings in July or August, then when rooted disposing the

plants 3 or 4 inches asunder in nursery beds in an open yet somewhat sheltered position, finally transferring the plants to their flowering quarters as early in the spring as possible. In that way he lost few plants even during the severest frost, and had most satisfactory displays of flowers throughout the summer. Mr. Rowberry also read a paper from Dr. Stuart, giving the history and description of the many charming varieties with which the great amateur's name is identified. Considerable discussion ensued on the reading of most of the papers, and the Conference, which was very successful, closed by the election of Mr. Rowberry as President, Messrs. G. McLeod and W. Sydenham Vice-Presidents, Mr. Cuthbertson as Hon. Treasurer, and Mr. R. Dean as Hon. Secretary for the ensuing year.

#### TAMWORTH SHOW.

FOLLOWING the Birmingham display a Pansy and Viola show was held on Saturday, June 1st, in the Town Hall of the ancient capital of Mercia. The hall was built nearly 200 years ago by Thomas Guy, the founder of Guy's hospital in London, who represented Tamworth in Parliament. A portrait of the great benefactor adorns the room, as does one of another renowned man of more modern date, the great Sir Robert Peel, who also represented the borough in the House of Commons, and whose statue is conspicuous in the market place adjoining the Town Hall. Tamworth is not a picturesque, but, what is better, a prosperous town of some 7000 inhabitants, and of late years has become a Pansy and Viola centre through the enterprise of Mr. William Sydenham. It was through his efforts, in conjunction with the late Mr. W. Dean, that a show was held last year, and again this season. The present show was not large, nor intended to be, as Mr. Dean desired that competitive classes for the northern growers should be confined to Birmingham, and the Tamworth schedule was drafted to incite local interest more particularly. Especial provision appears to have been made to display the decorative effect of Pansies and Violas in the form of bouquets, wreaths, table decorations, and floral designs generally, tempting prizes being provided for that purpose. It would seem, however, as if a watching and waiting policy had been adopted, and now that ideas have been afforded on which action can be based brisker competition may be expected another year.

Messrs. Perkins of Coventry showed the way in these decorative classes, and took all the chief prizes with beautiful exhibits. Their shower bouquet was a study in yellow and crimson, the Viola and Pansy blooms being relieved by Ferns, Smilax, a few Croton leaves and Caladium argyrites. The basket of Pansies was of a similar character, and this with the double triangle of yellow and purple Pansies, also a splendid wreath of the flowers arranged in Fern and Asparagus plumosus nanus, not only made a show in themselves, but demonstrated the charming adaptability of the flowers for such purposes. Mr. Johnstone, Hunts Hall, showed a flowing bouquet, also beautiful sprays of Violas on velvet stands; and Mr. R. Hannah, Atherstone, had a pleasing arrangement of Pansies on a large shield tastefully associated with Ferns and Selaginella caesia. This was the gentleman who won the silver medal for the essay which we published last week. This medal was on view, and elicited high approval; it was really a novel and chaste design in silver and gold—one of the most beautiful medals we have seen, and Mr. Hannah has reason to be proud of its possession.

Mr. Sydenham, though he did not compete for any prizes, contributed most effectively to the general display. His six stands of table decorations, some of them umbrella-shaped, others pyramidal about 2 feet high, as furnished with white and purple Violas, white and lilac, purple and gold, and pure white flowers respectively, each stand comprising some hundreds of blooms charmingly associated with Ferns and Smilax, were worthy of a position on any dinner table or drawing room in the kingdom. They were disposed down the centre of the table, the sides being occupied by sixteen trays of Fancy Pansies, twelve blooms in each, with between seventy and eighty triplets of choice Violas across the ends—altogether a splendid exhibit, for which a silver medal was adjudged, and it was worthy of a gold one.

A similar award was worthily granted to Messrs. Dobbie & Sons for a beautiful and extensive display of Violas—nearly a thousand blooms, these embracing the best varieties in cultivation; but more space was needed for showing them to the best advantage.

Mr. R. H. Bath, Wisbech, offered prizes for fifty plants of Violas grown in pots or boxes. Mr. Sydenham was the only exhibitor, his first prize group of plants forming a pleasing change from the surrounding exhibits. If prizes were offered for say six plants, and these raised in July and established in 6-inch pots early in the autumn, plunged over their rims and grown in the open, they ought to "lift" and exhibit sheets of bloom, thus showing the adaptability of the varieties for effect in masses. Few growers could show fifty pots, but half a dozen would be no great demand. Prizes were offered for the best plant of Fancy Pansy and best Viola grown in pots, these being won by Messrs. Hannah and Pemberton, and they indicated what may be done, but done better, with Violas at any rate, in the future. It ought also to be possible to show Violas in bunches, say twelve stems, with flowers and foliage as grown, to form a bunch. Three, six, or twelve bunches in a class would afford scope for exhibitors, and bring out varieties suitable for garden decoration.

In the orthodox classes for Pansy blooms in stands there was a most creditable display. With twenty-four blooms, Fancy, Mr. T. Nadin, Derby, secured the first position, staging, among others, fine examples of Mrs. D. Johnson, W. H. Ashford, J. Coutts, Miss Hudson, Mrs. Lister, Mrs. Thompson, and Tom Travis. Mr. R. Bolton, jun., Carnforth,

was an excellent second. Mr. Nadin was also first with eighteen blooms, followed by Messrs. Bolton and Hannah. Mr. W. B. Fowler was first with both twelve and six blooms, the latter comprising Tamworth Yellow, Maggie Watson, J. H. Thornley, Miss Pattinson, E. H. Gabb, and Jas. Stafford. Messrs. Whitehead, Nadin, and Bolton were also successful in those well-contested classes. With six blooms of any variety Mr. Nadin was easily first with the grand Pansy, Tamworth Yellow. Other prizetakers in the different classes were Mrs. Lovatt, Rev. H. Watson, and Mr. G. F. Meers; but on the whole the finest Pansies in the hall, in the amateurs' competitive classes, were shown by Mr. Nadin, and the best Violas by Mr. Pemberton. No pretence is made to give the awards throughout the exhibition.

Mr. McKee, Belfast, was awarded a first-class certificate for a new *Fancy Pansy Mrs. Gamp*, an effective symmetrical flower of good substance, dense purple in colour, edged with creamy white. A certificate of merit was also adjudged to Mr. Allison Green, Richmond Park Road, Kingston, Surrey, for various appliances for exhibiting flowers, his method of wiring without piercing the calyx being very simple and good. Numbers of visitors inspected Mr. Sydenham's garden, and enjoyed the floral feast. There, after all, was to be found the great show, of which a little remains to be said another day.

Relative to certificates, the plan adopted at Birmingham is a good one. Professor Hillhouse is of opinion that first-class certificates should only be awarded for new varieties of plants, flowers, fruit, or vegetables, and that other awards should be made for meritorious exhibits of a different nature. Thus "special awards of merit" are granted, or "special cultural awards," according to the nature of the objects that merit recognition. The distinction is appropriate as well as intelligible, and it would be well if it could be generally adopted at horticultural exhibitions.

### EXPRESS GRAPE GROWING.

I HAVE no intention of continuing the discussion of this subject further, but I would just like to remark that it is difficult to see where Mr. Innes (page 478) got the "abundance of fine, healthy, fibrous roots" out of 3-inch pots! I have again to repeat that, all things considered, the performance of these straw-like Vines, planted in the middle of August out of 3-inch pots, is really remarkable. The crops they bore the next season were wonderful, and would have been splendid had the Vines been planted in the best possible condition and at the most suitable time.

However, as there seems no doubt but that things happened as described by Mr. Innes, we must regard these wonderful little Vines with the greatest respect, as being able to rise superior to all difficulties, and to reward their owner with abundance of fruit in short space of time. Long may they continue to flourish, and no doubt their grateful owner will always be extra good to them, seeing that they rewarded him so soon for the little attention they received before being planted. I hope Mr. Innes will continue to grow the best quality of Grapes possible. At the same time I would caution all who are about to go in for Grape growing not to depend on producing the same results so soon from straw-like Vines planted late in the season, even if the borders and situation be all right and the autumn bright and warm.

Such good luck does not always attend the culture of the Vine, and many people will, no doubt, be content if they get a crop half way up their houses off their permanent Vines the first year after planting, especially if they have had to plant small canes out of small pots, and late in the season.

Mr. Innes takes exception to my remarking on the "poor little starved Vines" that he planted. I have only to remark that they must have been very little not to have been starved by being kept in 3-inch pots till the middle of August. It is impossible that a Vine could be otherwise than both starved and little by such treatment.—JOHN THOMSON, *Clovenfords*.

THE articles under the above heading that have recently appeared in the *Journal of Horticulture* must have proved interesting to many readers, as showing what the Vine is capable of producing in a commercial line under sound management.

The success of Mr. Innes is the greatest stride in this direction. When we consider that the border in which his Vines were planted consisted simply of a strong clayey loam, with the moderate addition of about 20 lbs. of manure per cubic yard, the success of these small Vines in the time stated is remarkable. I could understand the success of these Vines better if they had been planted in a compost in which a large amount of manures had been mixed, to get all possible fruit from them for a few years irrespective of their constitution for the future.

I note, however, Mr. Taylor in his practical treatise, "Modern Grape Growing," now running through the pages of the *Journal of Horticulture*, recommends a proportion of bones and bone dust. That is another starting point. Given a good soil for producing Grapes, and strong canes only, moderately cropped the season after planting and well looked after, I see nothing to hinder heavy crops of Grapes of good average quality being produced for an indefinite length of time. The articles lately written on this subject will probably cause growers in private gardens where heavy crops are required to think if they cannot advance a little.

But if high-class Grapes are in request it would be safest to work on a steadier footing, for after all it is the exquisite finish that is so puzzling to obtain—that unflinching test of quality. Of course growers for sale work on entirely different lines to those in private gardens. The former

have to put Grapes on the market that they can grow profitably, and which come within the range of the means of the buyer. The latter are often expected to produce them of superlative quality without regard to profit.

Mr. John Thomson does not seem in love with Black Alicante. Probably from his point of view he is right, it not being large enough to satisfy the British public. This Grape I look on as a gardener's friend; always to be relied on, and when well grown a most excellent winter Grape. Gros Colman is a Grape that does not usually finish kindly, although it is very imposing, and most refreshing when quite ripe. To persons who do not care for the more sugary Grapes it is very agreeable.—J. J. CRAVEN, *Allerton, Liverpool*.

A VERY interesting controversy has been going on for some time in your *Journal* under the above heading, prompted in the first instance by your notice of Mr. Colebrook's great success in Grape growing, but this instance of speedy cultivation seems to have been eclipsed by Mr. Innes so far as regards the short time in which the young Vines were brought into bearing, and I have no doubt the list of growers who have departed from the orthodox system so practically written of by Mr. J. Thomson might be much augmented.

I have long ago convinced myself that it is quite unnecessary to follow in the footsteps of our forefathers in the matter of growing and cropping young Vines, and if I were compelled to treat Vines with a view of profit, I doubt not but that I should go even farther from my early teaching than I have yet trespassed, for to quote Mr. Innes, I have found the Vine to be a most accommodating subject, and capable of producing first quality Grapes, under apparently very adverse conditions, when there has been a cultivator at the helm.

In gardening how frequently we hear of really splendid results when just the opposite is anticipated by the anxious custodian. Only the other day at the Manchester show I inquired of a noted gardener how his *Mascévallias* were looking. He replied, "Never better, notwithstanding that large icicles hung from the roof to the pots for weeks in January." Is not this a state of things directly opposed to the desire of any orchidist, but which could not be avoided? Yet such unlooked for hits seem to teach us not to follow too closely in the old groove.

When reading Mr. Thomson's last letter, I fancied that I could detect a suspicion that Mr. Innes' productions were not of the best quality. Mr. Innes takes a strong position by leaving his successes to speak for themselves. Mr. Thomson will admit that nothing but really first-class Grapes come to the front at such exhibitions as Manchester, Derby, and Earl's Court. Medals and prizes won at these shows are decidedly awards of which any grower for market may well be proud, for they come in direct competition with the productions from gardeners who can and do crop much lighter, and in many cases give better attention to their houses generally.

Living in the same county as Mr. Innes I have had opportunities of seeing the Vines when under his management, and was always much struck by his unvarying successes. That he thoroughly understood the Vine and its requirements is beyond a doubt, and let his poor little ones, which became famous, have what suited them.—WM. ELPHINSTONE, *Shipley*.

MR. INNES, in his remarks on "Express Grape Growing," page 478, makes a curious mistake in reference to the crop of 2700 bunches in a house of 300 feet long, referred to by "Market Grower." He states that at 2½ feet apart there must have been 240 Vines; that is, of course, an error, as really there could have been only half that number—120. Now, the difference between Mr. Innes' calculation and the correct one is that whilst he allows but eleven bunches per rod of 12 feet, there would be twenty-three; and the weight per each rod about 40 lbs., at a moderate calculation, would give a total of 4800 lbs., certainly a very heavy crop, and at 2s. per pound worth £440. That puts the matter in a very different light.—EXAMINER.

### THE VINE AS A TOWN PLANT.

THE Vine (*Vitis vinifera*) is the only fruit-bearing plant that I know of which can be cultivated with tolerable success where other fruits, such as Peaches, Nectarines, Apples, and the smaller fruits become a total failure, and to stimulate a love for the cultivation of the Vine our horticultural societies might do worse than to offer some good prizes for Grapes that are cultivated, say, within a radius of five or six miles from Westminster.

It is astonishing that the Grape Vine should flourish in the midst of smoke, which is so injurious to mostly all other members of the vegetable world. Perhaps the physical properties of the foliage have a great deal to do with the important question of such adaptability.

Many City merchants, and not a few judges in lower Courts, have found pleasure in their town gardens, and some of them have set about the pleasant enjoyment in a most practical manner, and some of them with little or no glass can behold the purple Grape fast ripening in the summer sun while sitting at their breakfast. Surely such a pleasure might be more enjoyed.

A south aspect with merely a glass roof and verandah is all that is required for the cultivation of the Black Hamburg. No fire heat whatever; only the glorious rays of the sun and the free air to play at will amongst the foliage. With a little attention to feeding (for the Vine has a feeding time), stopping, thinning, and training of shoots into vacant places might well be suitable, leisurely employment for a king.—A. M.

EVENTS OF THE WEEK.—The Committees of the Royal Horticultural Society meet at the Drill Hall on Tuesday next, and on Wednesday the Royal Botanic Society holds its special Floral Fête in Regent's Park. These are the only events of interest to London horticulturists.

— THE WEATHER IN LONDON.—The weather in London during the past week has been changeable, but, on the whole, fine. On Friday and Saturday it was very warm, with occasional light showers, Sunday being practically the same. Monday opened somewhat dull, but cleared later in the morning, and the sun shone gloriously until towards evening, when a few drops of rain fell. A drizzly rain fell during the early hours of Tuesday and Wednesday mornings, but though continuing dull, rain ceased to fall about nine o'clock.

— ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Royal Horticultural Society will be held in the Drill Hall, James Street, Westminster, on Tuesday, June 11th. At 3 P.M. a lecture on "Rose Culture under Glass" will be given by Mr. Frank Cant. The President of the Society will also present the Veitchian Memorial medals to James Bateman, Esq., F. W. Moore, Esq., and Mons. V. Lemoine of Nancy.

— STRAWBERRY LEADER.—Like Royal Sovereign, I look on Leader Strawberry as an acquisition to varieties ripening after the early forced kinds, and, like its compeer, coming in to fill the gap just prior to the earliest out of doors. It may be good for forcing varieties for aught I know, but for ripening in May its success is assured. In point of flavour it is an improvement on either of its parents, and much in advance of Noble. I shall look forward to Leader taking a high position amongst Strawberry growers when the stock is further increased.—E. MOLYNEUX.

— HARDINESS OF SCARLET RUNNER SEEDS.—I can quite confirm all that "A Gardener" said on page 451 respecting the hardiness of Scarlet Runner seeds, and can go a little farther. I have for more than fifteen years always left my seeds on the poles as grown till planting time, in the middle of May. I have known them to be frozen for weeks together. All the seeds will grow. I am convinced that any amount of frost and the changes of the weather, wet and dry, have not the slightest effect on the seed. The poles have been standing in the same place quite twenty years, and are never taken down. This past winter ought to be a fair test, and I see they are just germinating as usual.—H. FOSTER, Watchmaker, Ashford, Kent.

— BOTHIANA.—Now that the excellent articles which have appeared in the *Journal* for the past few weeks under the above heading have come to a termination, allow me, through your columns, to express, on behalf of the young gardeners in this district, our heartfelt thanks to your correspondent, "An Old Boy," for the kind advice tendered to us therein. Those who intend to follow out as far as possible the only road to success, as pointed out by your correspondent, will I am sure in future years, when their wisdom and perseverance shall have earned for them honourable positions in the horticultural world, look back with feelings of gratitude to the time when they read and profited by the writings of "An Old Boy" in the *Journal of Horticulture*.—P. J. G., Warwickshire.

— WAKEFIELD PAXTON SOCIETY.—At the meeting of the members of the above Society, held 25th ult., Mr. B. Whiteley presided, and Mr. J. G. Brown was in the vice-chair. Mr. T. Gartery of Rotherham read an interesting and practical paper on "The Primula." He clearly and fully described how he has successfully raised these charming and useful winter blooming plants for many years past, and in detailing his mode of treatment he impressed upon professional and amateur gardeners to do everything they could to produce strong and sturdy plants. A discussion ensued on the paper having reference mainly to "the nettling effect" which the handling of a certain species of Primula had on "thin-skinned gardeners," some of whom asserted that it caused them an unpleasant sensation somewhat resembling "itch." A vote of thanks was accorded to Mr. Gartery for his essay.

— LONDON OPEN SPACES.—The trustees of the London Parochial Charities have subscribed out of their surplus income for the year 1895 £1000 to the funds of the Metropolitan Public Gardens Association for the purpose of promoting the purchase or laying-out of minor open spaces.

— DEATH OF MRS. PHILIP CROWLEY.—We learn with extreme regret of the death of Mrs. Crowley, which occurred at Waddon House, Croydon, on Sunday last, 2nd inst. Not only was Mrs. Crowley a most kind, gentle, and estimable lady, but was a devoted helper of her husband in his horticultural work, and the many friends of Mr. Crowley will deeply sympathise with him on the grievous loss of one who may be described, as far as is humanly possible, as a perfect wife. Mrs. Crowley was fifty-eight years of age.

— MR. G. M'DOUGALL, Gardener, Ravenna Cottage, Stirling, writes:—"Enclosed is a crimson Hawthorn sport for your inspection. I intend sending it to the next meeting at the Drill Hall, where it will be exhibited by Messrs. Wm. Paul & Son; but I am afraid that the excessive heat will have extracted all the colour. This is the fourth consecutive day that the shade temperature has been above 70°." [The variety is evidently the well-known *Cratægus oxyacantha punicea*.]

— PARIS HORTICULTURAL CONGRESS.—At the International Horticultural Congress, opened at Paris on Saturday, resolutions were unanimously adopted to the effect:—" (1) That the French Government should associate itself with the request addressed by the Italian Government to the Swiss Confederation, with a view of obtaining the revision of the Berne International Convention, and the free circulation between all countries signatory to the convention, of all vegetables and Vines, accompanied by a certificate of origin; and (2) that the postal administration should return to the old reduced tariff, of which periodical publications on horticulture have hitherto had the advantage."

— DIONÆA MUSCIPULA.—This little plant, popularly known as Venus's Fly Trap, well deserves a place in the greenhouse. The ordinary observer may look on it only as a curiosity, but to the plant lover it has, says a writer in a transatlantic contemporary, a beauty all its own. The upper portion of the leaf, which constitutes the trap, is dilated into a two-lobed irritable limb, furnished at the margin with a row of long stiff bristle-like teeth. When a fly or other insect alights on the inner side of this portion it immediately folds up and holds the insect while it makes the least motion, but gradually assumes its normal position again after the insect is killed and ceases to struggle. It is of easy cultivation, and does well in a greenhouse temperature, and should be placed in a position where it will be shaded from direct sunlight, but at the same time have abundance of light and air. First place the plants in small pots half filled with crocks, using live sphagnum moss as potting material, then place the pots, about six, in a 10-inch pan, and pack them firmly around with sphagnum, place the pan in a saucer, and keep this all the time filled with water.

— "THE BOTANICAL MAGAZINE."—The June number of this publication contains the following subjects:—*Crinum Schimperii* (Amaryllideæ).—The bulbs of this plant, which were sent to Kew from the Berlin Botanical Garden, came originally from the mountains of Abyssinia, where they were found by Herr Schimper some twenty years ago. The peduncles and tube are strongly marked with brown; the limb about 4 inches long, is recurved, and ends in a yellow point. *Trichocladus grandiflorus* (Hamamelideæ) is a native of the Transvaal, South Africa. The ovate leaves, when young, are a bronze brown and stellately pubescent. The flowers are white, arranged in racemes of six, each having a rose-coloured centre. *Ribes bracteosum* (Saxifrageæ).—This plant has its habitat on the north-west coast of America, from California to Alaska. The racemes are from 3 to 6 inches in length, and derive their colour from the calyx of each flower, which is a golden yellow touched with green at the tip, and red at the base. *Peraphyllum ramosissimum* (Rosaceæ).—This, which is like the former, a native of North-western America, forms the sole species of the genus. It is a shrub from 2 to 6 feet in height, with rose-coloured flowers arranged in corymbs, and so closely related to the Amelanchier as to have been confounded with it. *Rosa Lucia* (Rosaceæ).—Comes from China and Japan. It is closely connected with *R. multiflora* on the one hand, and *R. microphylla* on the other, so as to be considered by some as a hybrid between the two. The blossom is white, and its foliage lustrous, and on account of its hardiness, and appearing when other shrubs are out of bloom, has been much used for decorative purposes about the city of Boston.

— **BATTLE OF FLOWERS AT HASTINGS.**—At a meeting of the Committee held recently at the Town Hall it was announced that the Corporation had decided to assist in carrying out the project, and that upwards of £300 had been promised to the fund for defraying the necessary expenses.

— **IRIS STATELLÆ.**—This is a Sicilian variety of *Iris lutescens*, and is one of the most attractive Irises, of medium height, which flowers at this time. It has large prominent standards, tongue-shaped, and smaller reflexing falls. The flowers are of a pearly white colour, of very fine form, and most distinct. It is a fine garden variety and excellent for decoration.

— **MAY WEATHER AT DRIFFIELD.**—Mean temperature at 9 A.M., 55.41°. Wet bulb, 51.0°. Mean maximum, 61.46°. Mean minimum, 40.97°. Highest, 72.8° on the 27th; lowest, 33.8° on the 5th. Mean of maxima and minima, 51.21°. Mean range, 20.49°. Mean radiation temperature on grass, 36.58°. Lowest, 26.4° on the 5th. Rainfall, 0.60 inch. Number of rainy days, seven. Greatest amount on one day, 0.19 inch, on the 1st.—W. E. LOVEL, *Observer, York Road, Driffield.*

— **MAY WEATHER IN SOUTH WALES.**—The following is a summary of the weather here for the past month. Sunshine, 234 hours; one sunless day. Rain fell on four days. Total amount, 0.96. Maximum, 0.48 on the 25th; minimum, 0.01 on the 12th. The wind was in the E. and N.E. till the 22nd, after which it was S. and S.W. It was bitterly cold the beginning of the month, and very strong. We had a fall of snow on the 17th, since which time it has been much milder.—W. MABBOTT, *Dowlais, Glamorgan.*

— **SUSSEX WEATHER.**—The total rainfall at Abbot's Leigh, Hayward's Heath, Sussex, for May was 12 inches, being 1.83 inch below the average; the driest May in the past fifteen years, with the exception of 1893, when the amount was 0.05 inch. The heaviest fall was 0.04 on the 17th and 30th. Rain fell on four days. The highest shade temperature was 83° on the 30th; the lowest, 33° on the 2nd, 3rd, and 4th. Mean of maximum, 67.18°; mean of minimum, 43°; mean temperature, 55.09°, which is 0.58° above the average. June came in rather unsettled, and we had some slight showers, but Sunday was hot and dry, with a rising barometer. Rain much wanted.—R. I.

— **PAPAVER BRACTEATUM.**—I consider this Poppy is an improvement on the better known *Papaver orientale*, the original type of perennial Poppies. The habit of growth of *bracteatum* is more compact than in the case of *orientale*, less space being occupied by the leaves, and the flower stems are stouter, standing quite erect. In point of colour *bracteatum* is more intense in the crimson scarlet of its petals, while the plum-coloured hue of the anthers adds very much to the lustre of the whole. At the present time I have over a hundred plants in two rows by the side of a path, each carrying on an average ten fully developed blossoms. The effect produced by such an array of colour is easily imagined. In point of hardiness *bracteatum* is quite equal to *orientale*. A stock of plants can quickly be raised by sowing seeds on a well prepared bed any time during June, putting out the plants directly they are large enough to handle where they are to flower, and giving them some slight mulching material for the first year.—E. M.

— **THE EDINBURGH SCHOOL OF RURAL ECONOMY.**—We have received the prospectus of this school for the session 1895-96, and observe that it comprises courses of lectures on botany, agricultural chemistry, forestry, and numerous other subjects. In the prefatory note it says that "those who enter these classes ought to have previously completed a good general school training, and further that the complete course aims at fitting a young man to enter with intelligence into his work as a farmer, a gardener, or a forester. It should enable him to understand the greater part of the work that he will see in practice, and to study for himself any special subject that he may afterwards find to be of importance to him." The lectures commence on the second Monday of October, and end on the last day of March. The range covered by the whole course is very broad, and should be of very material assistance to those students who studied closely. The fees, which are moderate, may be paid for any particular course or for the whole of the subjects, and for these and detailed particulars those desirous of taking advantage of the classes should write to the Rev. Professor M. C. Taylor, the University, Edinburgh, who is the Secretary.

— **DEATH OF MR. E. RUSH.**—The death is announced of Mr. Edward Rush, a well known and much-respected seedsman of Chester, who expired on Tuesday, 4th inst., after suffering from heart disease for some time.

— **AN ANCIENT TREE.**—Perhaps the oldest tree of which there is any record is the Cypress of Soma or Somma in Lombardy. This celebrated tree is generally supposed to have been planted the year of the birth of Jesus Christ, and on this account is treated with great reverence by the inhabitants of that part of Lombardy where it grows; but there is an ancient chronicle extant at Milan which proves it was a tree in the time of Julius Cæsar, B.C. 42.

— **BOLTON CHRYSANTHEMUM SHOW.**—The ninth annual show of the Bolton Horticultural and Chrysanthemum Society will be held in Albert Hall of that town on Friday and Saturday, November 15th and 16th. By the schedule before us we find that though the classes are not very numerous the prizes are very good, and should bring many handsome exhibits. The Secretary is Mr. James Hicks, Markland Hill Lane, Heaton, Bolton, from whom full particulars may be had.

— **EARLY STRAWBERRIES IN CORNWALL.**—With a continuance of favourable weather the Strawberry crop in the Tamar Valley will be early and plentiful this season. Several ripe fruits were picked by Mr. Joseph Start of Kelly Gardens, Calstock, on 20th May. Children attending Geoffrey's Endowed School, Landrake, says a contemporary, gathered several bunches of fine wild Strawberries from the hedges around the village last week, and on Sunday wild fruit quite ripe were picked on the railway between Probus and Truro.

— **TASMANIAN APPLES.**—According to a contemporary the export of Tasmanian Apples to England this season will amount to about 150,000 cases. The Tasmanian Government will guarantee freight on 30,000 cases, which will be collected from the growers, but shippers of the remainder will make their own arrangements with regard to freight. All fruit sent per contract ships will be subject to inspection, and any that is not up to the mark will be rejected. Cleopatras, Adam's Pearmain, and Scarlet Nonpareils are to be not less than 2½ in diameter; and Sturmer Pippins, French Crabs, and Ribston Pippins 2½ in diameter.

— **FRUIT CULTURE IN THE HIMALAYAS.**—Is there a future for fruit culture in the Himalayas? Mr. Caley Smith of the Yalumba Vineyards, Angoston, South Australia, is of opinion, from observations at Darjeeling and Mussoorie, that very much more might be done in this direction than has yet been attempted. He further suggests that the Government of India should expend £1500 or so a year for the purpose of keeping up an experimental orchard, where experiments in hybridisation of various fruits might be made, and their results made known to horticulturists by publication in a Government journal of agriculture. This plan has, he says, been adopted with success in Australia, Canada, and the United States.—("Madras Mail.")

— **A GIGANTIC ORCHARD.**—The largest orchard in the world is said to be that of Elwood Cooper, Barbara, California. It is a tract of 1700 acres, and contains 10,000 Olive trees, 8100 in bearing, the remainder being young trees, set out during the past year and a half. Besides the Olive trees there are 3000 English Walnuts, 4500 Japanese Persimmon trees, 10,000 Almonds, and about 4000 other fruit and nut trees. The 10,000 Olives yielded 40,000 quart bottles of olive oil last year, which found a ready market at 4s. per bottle. The nut trees bore thousands of bushels of nuts, to say nothing of the Japanese Persimmons. Taken in all, it has been estimated that Mr. Cooper's orchard brings him in an income of not less than 750 dollars per acre every year.

— **LINNEAN SOCIETY.**—The gold medal of the Linnean Society has this year been awarded to Prof. Ferdinand Cohn of Breslau, whose name is well known in connection with the "Botanic Journal," which he has conducted, largely adorned with his own contributions, from 1870 to the present time. The work of Dr. Cohn extends over half a century. He was one of the earliest to investigate the life-history of the lower Algæ, and to demonstrate that they are not asexual. His important paper on "Protococcus pluvialis," published so long ago as 1850, was translated by Busk for the Ray Society. Subsequent papers by him, on the mode of reproduction of *Sphæroplea annulina*, and on the development of *Volvox*, mark a distinct advancement in botanical science. The medal referred to was awarded to him at the anniversary meeting of the 24th ult., and has been forwarded to Breslau, for his acceptance, through the German Embassy.—("Nature.")

— IS BAMBOO "WOOD?"—A judge of one of the United States Courts has been called on to decide whether a Bamboo handle for an umbrella-stick was "wood" or not. The legal luminary decided that the umbrella stick in dispute was "grass," and not wood. As a Bamboo stick is as woody as most other sticks of the same age, if not more so, it is difficult to see the grounds for the judge's decision. It is fortunate for the judge that he is not likely to present himself before any court of botanical examiners!—"Mechan's Monthly.")

— NATAL BOTANIC GARDENS.—The report of the curator (Mr. J. M. Wood) for February is as follows:—I am pleased to say that the seeds of *Cola acuminata*, received from Kew, have so far grown well, and we shall, I hope, have a few plants in the spring for trial in other parts of the Colony. The nuts of this plant are now being largely used, and are in demand. The seeds of "Cocoa" plant (*Theobroma cacao*) kindly brought for us by Mr. A. Whyte of Nyassaland, had perished on the voyage, and I regret that not a single one has germinated. We have supplied to the Government Police Station at Sydenham, in accordance with the vote passed at last meeting of committee, fifty plants to the value of £3 10s., and to Mr. Whyte, in exchange, a case of economic plants value £6.—("Tropical Agriculturist.")

— APPLE STOCKS.—What is with Mr. Molyneux a recommendation, so far as stocks raised from mixed Apple pips are concerned, is to the nurseryman a condemnation. They come so irregular or varied in habit and constitution, especially after being worked, some having a dwarfing and even a cramping habit, others have all the grossness of the Crab stock. For any home or amateur purposes it may be all very well to raise stocks in this way, because after some three or four years, as their characters show, they can be planted accordingly, some making fine standards, others dwarfed standards or bush trees. That, of course, would not do for the trade. Has anyone ever tried sowing pips, say from Manx Codlin in one case and from Blenheim Pippin in another, to name two sorts of opposite natures, and sowing and raising them separately to note results?—A. D.

— INSECTS ON FRUIT TREES.—I think it would be instructive and interesting if those of your correspondents who have tried any of the remedies for the destruction of insects on fruit trees, as recommended in the leaflet issued by the Board of Agriculture, would state their experience. I have given our Apple, Plum, and Pear trees two dressings of the mixture No. 2—viz., 5 lbs. quassia chips, 5 lbs. softsoap, 5 pints paraffin oil, with 100 gallons of water. The mixture was applied under favourable conditions by a syringe and small garden engine, a week between the applications, and I regret to say that the mixture seemed to have very little effect on the caterpillars. I have come to the conclusion that a bad attack of caterpillars can only be warded off and destroyed by using some of the arsenical compounds, as used in the United States and Canada; but I find that the mixture No. 2, as given above and prepared according to instructions, is a capital remedy for black fly on Morello Cherries.—R. M., *Newbury*.

— AGRICULTURAL EXPERIMENTS.—The extent to which many of the American agricultural experiment stations are devoting attention to the culture of small fruits and other minor crops is perhaps significant of an impending change in the economic bearings of the management of the soil, and of the partial displacement of the *grande culture* which has hitherto almost monopolised the field of experimental inquiry. Bulletin No. 55 of the Purdue University Station, Lafayette, Indiana, opens with a description of experiments with small fruits. Strawberries, Raspberries, Blackberries, Currants, Gooseberries, and Grapes form the subject of this section of the report. The bulletin concludes with a notice of experiments with Sugar Beet; but in view of the desperate condition to which the Beet growers of France are at present reduced—despite the artificial support which the sugar industry there receives under the bounty system—we cannot, says "Nature," see any immediate hope for the American Beet-sugar industry. This, indeed, is practically admitted in the bulletin, for it is said, "The condition of the sugar business throughout all sugar-producing countries is such that there seems to be little probability of capital being invested in Beet-sugar plants in this country at present." The points which are reported on include comparison of varieties, time of harvest, the respective effects of bacterial disease and Beet scab on the sugar content of Beets, the effect of loosening Beets some time before lifting them from the ground, special thinning, tests of foreign and American seed, and yield and cost of crop per acre. It is concluded that, under more favourable economic conditions, Beet factories might advantageously be established in the State of Indiana.

— CLEMATIS MONTANA.—The brief allusion to this charming Clematis, page 687, reminds me of how I saw it flourishing in Dulwich Park a week ago. There it was planted amongst the shrubs, and allowed to ramble at will over supports, such as stout boughs and tree roots. In many cases the clumps were 6 feet high and 4 feet through, and one mass of flower. Associated as these floral clumps were amongst evergreen shrubs, the effect of the snowy white blossoms was much enhanced. I thought I had never seen this Clematis so effectively employed, not even against a south wall.—E. M.

— ROYAL BOTANIC GARDENS.—The Royal Botanic Society of London was incorporated by charter in the year 1839, and for the first time in its history of fifty-six years its beautiful gardens were on Whit-Monday thrown open to the general public at a "popular" charge of 6d. each person. Nothing in the way of entertainment, not even a band of music, was provided. Up to about five o'clock in the afternoon the entries at the turnstiles had been a little under 5000. Nothing seemed required but a good band out on the lawn to make this new departure of the Botanists an unqualified success, and if it were repeated occasionally through the summer it ought to bring an important accession to the funds.

— COREOPSIS GRANDIFLORA.—For cut-flower purposes or for a border plant there is nothing which bears yellow flowers to equal *Coreopsis lanceolata* and *C. grandiflora*. I was never aware of its value as a pot plant until this year. We wintered a few plants in a cold frame in 5-inch pots and brought them indoors about the middle of January, and a shift was given them to 8-inch pots about the middle of April, when the flower-stems were well advanced. Since the last week in April our plants have been loaded with flowers some 3 inches in diameter, borne on fine stems 18 to 24 inches long. For cutting this *Coreopsis* is much superior to any other variety, and its easy cultivation should ensure its wider use as a pot plant. We sow our seed in the open ground the last week in July, and those required for indoor use should be potted about the end of October.—W. N. CRAIG (in "Garden and Forest.")

— LETTUCE.—Great complaint is made in a number of gardens of the scarcity of spring Lettuce, the severe winter killing not only those in frames for late winter use but young plants for spring planting as well, although they may have been protected by frames. This has not been the case here, all my Lettuce having come through the winter without any loss. The last sowing, to provide plants for spring planting, was made on September 1st. When severe frost sets in a frame is set over them, and as a rule there are numbers of good plants in the spring. Not having the frames to spare last winter, the plants had no protection whatever, notwithstanding they appeared no worse for the exposure. A large bed planted on the same border, for the purpose of putting into frames for winter use, as well as some Endive of both the broad-leaved and green curled varieties, also stood through the winter without loss. Perhaps it is only fair to add that for the greater part of the winter they were covered with snow; this no doubt preserved them. These plants were covered with "cloches" in early spring; cutting commenced on the 25th of April, since that time there has been a constant supply. The varieties were Brown Cos and All the Year Round. The latter I consider one of the best of the Cabbage Lettuces.—J. S. UPEX.

— PROFUSION OF CATERPILLARS.—In some of our Kentish woods or copses, where the precautionary measures against caterpillars taken in gardens and orchards are neglected, hordes of these insects are holding high revel during the month of May. The expansion of the leaves on trees and shrubs has been checked by the lateness of the season, also by the continuance of easterly winds, and the attacks of the caterpillars on the foliage at the present time will leave effects from which young trees will not recover this season. The fact is important, as being one of those showing that a very cold winter may not be any check upon caterpillar life in the following spring. The majority of them belonged, I found, to the genus *Hybernea*. The too familiar caterpillars of the winter moth were well represented, and the stout, many-coloured caterpillars of the spring usher; both these species partially escape birds by their habit of drawing the leaves together. There were also caterpillars of the early moth and the mottled umber, the latter being remarkable for their habit of swinging themselves from a silken cord occasionally, as an amusement it would seem, and not merely, like some species, when the wind has given them a shake. If we had had the heavy rains we get in some springs, a good number of these would have died at an early stage, as it is they are fat and flourishing. Some trees were almost defoliated by them, the Hornbeam and Hazel suffering much, also the Sloe.—C.

## MARANTAS.

THOUGH in all gardens, both large and small, flowering plants are usually accorded the most prominent position, space should be, and generally is, found for a few foliage plants, comprising those more especially that are useful for the embellishment of rooms. Fortunately plants adapted for this purpose are numerous, so that though Marantas may not be so used it should be no drawback to their cultivation, for they are certainly among the most beautiful foliage plants we have. There is, however, one reason why they cannot be universally grown, and that is, a hothouse temperature being essential to insure perfection. In large establishments such a difficulty is not likely to arise, but with small amateurs the case is materially different, as only one structure is usually at command to heat which to a stove temperature would be an error, as

or that their culture is but imperfectly understood, and in the opinion of the writer the latter is the reason of their unwarranted neglect.

To endeavour to remove the ban that is apparently placed on them a few details of what has proved a successful method of treatment will be given, and will perhaps induce some of the excellent and practical writers of the Journal to give their opinions about them, and also to give suggestions as to cultivation that are likely to be of assistance as well to the writer as to the very large numbers of other readers of what may justly be termed the "gardeners'" paper. Let me, then, describe a mode of procedure that may be taken as a safe basis on which to work, though it is by no means put forward as the best method, as it is probable that many growers attain to success by means differing in several of the essential points.

The propagation of Marantas, as is well known, is effected by

FIG. 90.—MARANTA MASSANGEANA VAR. FLORENTINA.

it would preclude the cultivation of many plants even more useful than Marantas. Certainly one or two varieties stand fairly well in rooms, but, speaking generally, they cannot be strongly recommended for this purpose, but simply for the adornment of houses in which the requisite heat can be insured. For such a purpose as the latter they are of value, because they provide a handsome leafage not found in any other class of plants.

Notwithstanding the undoubted merits of Marantas it is seldom that one sees an article on their cultivation in the pages of the *Journal of Horticulture*, or indeed in any of the gardening papers. True, from time to time notes appear in the "Work for the Week" column giving hints as to the treatment requisite at the moment. That these plants are not always grown well is proved on a visit of inspection to many establishments, where they may be seen represented by miserable specimens that are by no means a recommendation to their extended culture. On the other hand they may frequently be seen in the best of good health, with stout leafage, splendidly coloured, and strong, sturdy growth. These two facts either tell us they are very difficult to grow well,

division. Apparently opinions differ as to the best time for this breaking up of established plants, but there can be little doubt that during March is as good a time as any. The extent to which this division is to be carried must of course be governed by the number of plants that is desired. These offsets must be potted and then placed in a moist atmosphere, where they will be shaded from the direct rays of the sun, in a temperature of from 60° to 70°, which may be raised as the plants gain size and the summer advances. Though shade is desirable it must not be such as to shroud the plants in darkness or the growth will be tender and weak, with foliage destitute of the richest colouration. Another point conducive of dwarf growth is a modicum of fresh air, but this must be afforded with the greatest care, or instead of producing good effects it will cause an immediate and total collapse. As the plants attain size they can be transferred to larger pots, and at all times must have most careful attention with regard to watering.

During the winter months the temperature should not be allowed to fall much below 60°, and the atmosphere must always be moist but

never to the point of stagnation. At frequent intervals it is advantageous to carefully sponge the leaves, as well to keep open the pores as to insure the plants against the incursions of insect enemies to which, with the majority of stove plants, they are very liable. With regard to soil there is an abundance of latitude, as Marantas thrive well in either peat or loam, growing somewhat faster in the former than the latter, but usually with much softer stems and more flimsy leaf texture. So far as my experience teaches me, success depends, not so much on the soil, as on the atmospherical conditions under which the plant is growing, a dry atmosphere being inimical to success, while pleasantly warm, moist temperature conduces greatly towards perfection. It will be observed that no particular sizes of pots have been mentioned, and it is for the reason that this must depend entirely on the sort that is being grown, some having large leaves and attaining to considerable dimensions, whereas others have much smaller leafage and never become very large plants. This gives the general outlines of the culture necessary for these plants, and it is now left for more fluent pens to provide any details that will prove of value in rendering Marantas more easily grown, and more generally seen in good condition than is the case at present.

It would be superfluous for details to be given of the many species and varieties now in cultivation, but mention of three handsome varieties shown at the Temple show in 1894 may not be out of place. Each of these is a variety of *Maranta Massangeana*, and of the trio perhaps the best was named *Florentina* (see woodcut, fig. 90). The leaves are beautifully marked, the colours being very clear and striking. The ground colour is a lightish green, blotched with whitish green and brown, and having clearly defined rosy coloured ribs. It is singularly beautiful. *M. m. atrata* is also handsome, with dark green leafage. The ribs are pale green, and each leaf has a margin of rich velvety green. The last to be named is *M. m. metallica*, a fine variety with deep green leaves, having white ribs. The centre of the leaf near the midrib is paler green, shading to chocolate brown. These splendid Marantas were shown by Messrs. Linden & Co., each receiving a first-class certificate.—F. Row.

### LINCOLN'S INN FIELDS.

THIS fine open space of 12 acres, remarkable for being the largest near central London, and important on account of the ventilation it gives in the midst of crowded streets, has at last been thrown open to the public, after being many years reserved entirely for members of the legal profession and their friends. It is noticeable also as being one of those squares that is well timbered, so much indeed that the grass and various border plants exhibit, during summer, some ill effects from being overshadowed.

Still does the locality retain its rural designation, and, what is curious, we have not far from it a little-known bye-way which long bore the name of Whetstone Park, a relic of some plot of ground on which the people of Holborn exercised their horses, and the old Fields were probably used for the same purpose. Strolling there now one recalls the story that Inigo Jones designed the outline when it was first built on, and that the central space is just the dimensions of the base of an Egyptian pyramid. But for this tale we can find no good foundation; it is only true that he built some houses on the west, called Arch Row, about 1618.

In the seventeenth century the site was really fields, a place resorted to by idlers, beggars, and bad characters, so that at night it was exceedingly dangerous for solitary persons, and, according to Gay, the spot continued to be perilous even after the square was partly enclosed. The people we see enjoying this newly acquired public garden at any hour of the day are certainly a contrast to those said to have haunted the old Fields, and who had the name given them of Lincoln's Inn Mumpers. We can picture them, mostly ragged and dirty, playing at games, but stopping to make a rush should a coach pass in the hope of getting some money by a clamorous appeal.

Here Joseph Jekyll, who had brought in a Bill to restrict the sale of gin, was seized by the infuriated populace, and almost trampled to death. It was also sometimes the scene of executions. The residents took steps to "rail, clean, and adorn" the Fields in the autumn of 1735. There is no doubt some trees and shrubs were then planted, but I query whether any of the trees now growing date back as far. The London atmosphere does not favour their longevity, and some, the Elm for instance, are great sufferers from insects. Elms, we perceive, for this has always been a favourite in London squares, possibly a centenarian exists amongst them, but the most noticeable and numerous trees are Oriental Planes (*Platanus acerifolia*), which seem to be flourishing. There are some Limes and a few Robinias. This species is now scarce about London, most of these planted in last century have died off and have not been replaced.

Solitary Hawthorns that have reached the size of trees in this enclosure are somewhat gnarled and twisted, as if they had suffered from their conflict with the elements during many years. Elders, of course, are to be looked for in any London garden with a history, though why this tree should have been such a favourite formerly we cannot quite see; it seldom fruits about the metropolis. The presence of the Hornbeam here might imply the tree was planted by someone familiar with Epping Forest, where it grows so freely, or did till the number was reduced by extensive felling of the trees; this is not a species often selected for planting about London. An occasional Blackthorn and Guelder Rose greets us, also another shrub familiar in hedge-

rows, the Wayfaring Tree (*Viburnum lantana*), which is opening its flowers. But no shrub is so abundant as the common Lilac, which really fares well in the smoke, if the caterpillars would leave it alone.—J. R. S. C.

### THE R.H.S. EXAMINATION PAPERS.

"E. D. S." (page 470) is courageous in attempting to furnish answers to the series of questions set by the examiners for the R.H. Society, and recently published in the Journal. Still, he is to be commended if in furnishing his answers he is doing his level best, and does not mind correction or criticism. As to how far his replies would satisfy the examiners is another thing. Generally they are fairly correct, although some are rather too brief, and should have had fuller elucidation.

"E. D. S." does not tell us whether he was a candidate at the recent examination. If not, perhaps he is like very many other gardeners who now wish they had faced the ordeal, as that does not seem to have been so severe a one as was anticipated. The assumption that roots absorb compounds "E. D. S." does not say whether in solid or liquid form, through their surfaces do not accord with scientific teaching, or that they do so through what he terms "spongioles" at the extremities, meaning thereby, of course, the root cap, or borer, which is presumably of a somewhat hard impervious nature.

So far as science has made clear it seems that root hairs are the only mediums by which food is absorbed, and that, too, in an essentially liquid form. Plants are often starved to death in the midst of plenty of food, simply because moisture is absent and the food cannot be rendered soluble for utilisation. Answers 2 and 3 are very good. With respect to the formation of "callus" at the base of cuttings, the essential precursor of roots, it is indeterminate how far that may have power to attract moisture from the soil for the sustenance of the cutting before roots are formed. We do not know whether that matter, apparently hard or leathery like to the texture of roots, may not have exceedingly minute hairs on its surface through which moisture may be absorbed. Unless something of the kind is so it seems difficult to understand how cuttings can remain fresh and plump, retaining leafage so long before roots are really formed.

Answer 4 is as good as it is brief, and one would have liked to see it more fully elucidated, especially in relation to the placing of that portion of the soil which by previous exposure on the surface has become thoroughly sweetened and aerated down below, where it furnishes good plant food, and bringing the less aerated soil to the surface.

In answer 5 the description given of the growth and structure of the Pea plant, an admirable subject, is excellent, but "E. D. S." is rather out in his reference to the ordinary method of flower fertilisation. In most forms of Leguminosæ, but especially in the Pea flower, fertilisation takes place before the blooms are open, and quite outside of external agency. Cross-breeders of Peas find that it is needful to open the flower petals very early in the florescent stage, and remove the pollen anthers, so that no self-fertilisation takes place. The foreign pollen has to be conveyed to the pistil of the flowers to be operated on a little later. Were Peas so easily affected by external influences, as wind or insects, we should rarely find them come true from seed when grown close to each other.

I do not think it is correct to class an Onion as an underground stem. Practically it grows on the surface of the soil. A Potato is correctly described. Something as to the ordinary methods of Mushroom culture might have been added to the brief description of the operation of the mycelium in fungus production.—A READER.

REFERRING to this examination, I should like to ask through the medium of the *Journal of Horticulture* what those who sat think of the time allowed to answer the questions. I sat at the examination the last two years, and both times I experienced the same difficulty—*i.e.*, not being able to answer the questions in the time allowed. I thought the first time it was my inability to answer them, but this year at least two-thirds of those who sat at the same centre complained of there not being sufficient time allowed.

If this were a general opinion it would be advisable to ask the Society to extend the time to the three hours, the same as allowed at the science examinations. I notice on page 470, "E. D. S." has answered the first eight questions set, but I doubt if these answers would be full enough to satisfy the examiner; if they were, the difficulty I complain of could soon be remedied, for such answers would not take the majority long to write.—W. D., *Turnford, Herts.*

[This is not by any means the only intimation we have had of the too limited time allowed for answering the questions satisfactorily.]

### CHISWICK GARDENS.

NATURALLY very much out of sight is the work constantly in progress at these gardens. The shows held in London from time to time attract the notice of Fellows of the Royal Horticultural Society and the public, because they come more into the foreground. Chiswick, though very near to London, is not so much in evidence; it is not at all showy or demonstrative, and for these reasons doubtless it fails to attract that notice which it so much deserved. Even to the bulk of the Fellows of the Society the gardens constitute almost undiscovered territory. Their visits (when made) are few and far between, and then only when a show, conference, or some special function invites

their presence. Even on those far too rare occasions when the Committees are convened there the attendance is usually small, yet from a purely horticultural aspect probably there is no work done by the members of more real interest than is put before them at Chiswick.

To some extent the Council is to blame for this neglect of their delightful gardens. They do nothing to entice attendance, not even on show days. What would it cost the Society to hold just one fête day or reception of all the members of the Committees during the summer? making it a special gathering, as much of a social as of a professional character, the morning devoted to work, which is both pleasant and useful; the afternoon and evening to friendly association, discussion, and enjoyment. To how great an extent would such a gathering help to popularise Chiswick in the estimation of its more practical supporters.

Realising my own personal responsibility as a Fellow, I went to the gardens a few days since, just to see how they were looking and what could be learnt in them. A special need, I trust, amply satisfied ere this appears in print, was rain—a universal want. The Chiswick ground is very porous, and soon parts with its moisture. Still everything was looking exceedingly well, and every effort had been made to utilise the dry weather to clear the ground and keep down weeds. Mr. Barron's assistance is none too great, and in some cases heads count for more than backs; yet it is pleasant to see old servants, men who have in earlier days worked hard in the Society's interests, still employed and doing their best. A couple of more stont backs could, however, find ample occupation, especially where, as at Chiswick, what is done needs to be done with special care, as the work is generally of greater importance than is what usually is found in ordinary gardens.

There is good promise at present of a fruit crop there. Strawberries blooming and fruiting profusely in several parts of the gardens, and including apparently almost every known variety, should present this year a splendid opportunity for the Fruit Committee to sample them. This chance has not offered for two years—in 1893, because of the exceeding drought, and last year because of the late spring frost. Even now there is a fly in our pot of ointment, for a heavy rain is badly needed to set up the plants, as it is now with the crop a critical time. Given a heavy rain, then a fine lot of fruit should be assured. Were the Council less anxious to market the fruit, and more desirous of entertaining the Committees, no doubt an invitation to a Strawberry feast at Chiswick a few weeks hence would be freely responded to. Apples on nearly all trees are a great set, the fruits now swelling. How Nature, when there is such a big bloom, does her own thinning, may be exemplified here, where two blooms perfect themselves and ten fail.

The small bush or half-standard trees in the northern side of the gardens that seem to crop so well every year, are again full of fruit, some rather large trees transplanted last autumn excepted. Those will, however, fruit next year, no doubt. It is worthy of observation, and perhaps accounts for these small trees fruiting so freely when so many others fail as last year, that Mr. Barron does not hard prune or really shorten back the shoots. He thins out somewhat, Black Currant fashion, cutting out old branches hard down as needed, keeping the heads thin, but the branches hanging free. That promotes a somewhat drooping habit of growth, and perhaps because the bloom is not so much exposed to frost as is the case with flowers on stiff hard-pruned trees, it escapes injury. In any case it is not possible to have better average results than these trees on the Paradise stock give at Chiswick.

Pears are generally plentiful on the wall cordons; a very fine stock indeed of trees thus trained. They seem to be thin on the upright cordons, and a moderate crop on the fine pyramids in the gardens. There seems to be plenty of this fruit in any case. The old Plum quarter has been grubbed out, and a quarter formerly utilised for Potatoes and Peas has been planted with young trees in rows of three on each side of a centre path. There is abundance of room yet. All these are doing very well, and they seem to include every known useful variety. These trees are of both bush and semi-standard form, and in a few years should present a fine fruitful plantation. There is a very fair set of Peaches and Nectarines on the trees outside.

Under glass the large span-house just within the gardens is now becoming an interesting feature. The Vines trained to uprights some 10 feet in height inside have nearly covered the under side of the roof, the rods running across overhead and partially down towards the eaves. They are fruiting very well. I noticed very little fruit set on the upright stems, however, and should have thought planting quite at the sides, running the rods right to the ridge, would have been best. Still, the method of planting seen may have its objects and lessons. There is a grand lot of Tomato plants standing along the sides of the house. These are in full fruit, and should give a capital trial early. There are of Tomatoes two other later sowings, one in a span house, the plants 3 feet in height, and one in a lean-to 1 foot in height.

The Fig house is a most interesting feature. The collection is of the most complete nature, trees of all sizes; though the bulk are in very large pots, all in the most perfect health, are fruiting abundantly. It is very doubtful whether a finer collection or better grown trees in pots are to be found anywhere in the kingdom. A trial of some 100 varieties of bedding Violas cannot fail to attract attention. They are planted out in rows of six across the line of beds that border the path leading to the old Council room. No doubt later after they have become strong they will make a very attractive feature. To me they offered cause to ask why so much sheer rubbish should be indulged with names, but tastes over Violas seem just now to have rather run wild. However, favoured with rain, these Violas promise to do very well. Elsewhere Sweet Peas in great variety, herbaceous Phloxes in abundance—far

too many, in fact; perennial Asters, and Pæonies present plenty of attractive material.

Vegetables seem in grave danger of getting crowded out. I notice in the quarter devoted to Peas on one side, and runner and dwarf Beans on the other, that each variety has perforce to be restricted to rows 10 feet long. Perhaps it is enough, but it is rather bare stint all the same. Peas need sticks badly, and have all been well earthed. They have, like Peas everywhere, come up in some places thinly, but perhaps that may be all the better for the trials in the end. Beans seem to be largely represented. In another quarter there are some sixty-eight varieties of Potatoes planted, nearly all being well through the ground. Any harm from frost is now improbable. Raisers seem driven to their wit's ends to find new or distinctive appellations, and some are amusing. Some others seem to be boldly stolen from well-known varieties in cultivation. That is a method of nomenclature which should be severely repressed, and I hope the Fruit Committee will notice it.

These things I have mentioned do not comprise everything of interest that may be seen at Chiswick, but they suffice to show how the gardens are being utilised. Some day, perhaps, all the garden space may be utilised for fruits and flowers, the Council finding a couple of acres of ground somewhere else in the neighbourhood where vegetables can have wider representation and more justice rendered to their economical importance than is now shown. A very light, elegant span-roof curvilinear house, 50 feet by 14 feet, erected in the gardens by Messrs. Skinner, Board & Co. of Bristol, will, no doubt, attract much attention and ample criticism later. Its construction is novel, as also is its glazing. It is wonderfully light, but how far it may be serviceable or enduring has to be shown.—A. D.

## QUESTIONS AND ANSWERS.

### DIVISION B.—HORTICULTURAL PRACTICE.

#### QUESTIONS.

9, NAME six of the best species of hothouse flowering plants, and give some of the general details of culture. Name some of the insect pests that infest such plants, and state the best method to be adopted for their destruction.

10, Give general details for growing Peas, and the method of culture, time of sowing, &c., to give a supply for as long a period as possible. What is the use of the nodules on the roots?

11, What is an Alpine plant, as the name is generally understood in gardens? Describe the cultural requirements of such plants, and the best way to propagate them.

12, What is the original parentage of Cauliflower and Broccoli? Give the method of culture, and the best varieties to obtain a succession all the year round.

13, Give some details of the culture of Grape Vines under glass. Describe the diseases to which they are subject, and the insect pests which attack them, and their cure.

14, What kind of fruit trees and bushes are best adapted for culture in small gardens? Briefly describe the best method of culture, and arrangement of the trees and bushes.

15, In a walled garden, what kind of fruit trees would you recommend to be planted on the four aspects—south, north, east, and west? What distance apart should the trees be? Suggest the best width of the borders, and height of the walls.

16 (a), What do you consider the best class of soil for fruit trees, and how ought it to be prepared for them?

(b), Is there any method of culture likely to prevent canker in Apple trees, or gumming in Apricots, Cherries, and Plums?

#### ANSWERS.

9, Allamandas, Clerodendrons, Eucharis, Euphorbia jacquiniæflora, Gloxinias, and Stephanotis floribunda are six of the best species of stove or hothouse-flowering plants. Allamandas, Clerodendrons, Euphorbias, and Stephanotis require to be grown in a light position near the glass in an average temperature of 65°, providing a light shade during very hot weather in the summer. They succeed best when planted out in a well-drained border of soil composed of loam, peat, leaf soil, and sand, the growths being trained on wires. The Euphorbia is excellent for the back wall of a stove, where with an average amount of light to help ripen the wood it produces bloom in midwinter if afforded a temperature of not less than 60°. During the period when the young wood of the plants named is being made a moist atmosphere is essential; at the flowering period a buoyant and airy temperature, with comparatively cool conditions for all in winter but the Euphorbia. The Eucharis succeeds in pots or beds, a temperature of 70°, and a moist atmosphere with frequent syringing to promote free, strong growth. On the completion of this a more airy temperature must be maintained, finally subjecting the plants to cool conditions with little water to assist the completion of the ripening process. When placed in heat again the flower spikes are thrown up almost immediately. Gloxinias enjoy a moist temperature of 60° to 65° during active growth. When at rest the plants are leafless, and the tubers should be kept dry in a temperature seldom falling below 50°. As growth commences in the spring the tubers must have attention to repotting in a compost of loam, peat, leaf soil, and sand. A little bottom heat at this stage promotes growth. Water sufficiently, but not excessively at any stage. Give weak liquid manure when the pots are full of roots. Continue liberal treatment after flowering and until the foliage shows signs of decaying,

when withhold water gradually, ceasing completely as the plants go to rest.

Mealy bug and scale insects attack most of these plants, while a mite prevails among the roots of Eucharis. The latter can only be cleared by washing the roots and using fresh untainted soil. The first and second named are best destroyed by careful sponging, though an insecticide composed of softsoap solution, 2 ozs. to the gallon of water, adding a wineglassful of petroleum, working the whole into an emulsion, keeping it thoroughly mixed by constant agitation, is good when syringed over infested plants, serving to destroy many if not all the pests that assail them. Gloxinias should not be syringed either with insecticides or clear water. They are not, as a rule, subject to insect pests.

10, In the cultivation of Peas the ground ought to be deeply dug and liberally manured in the winter, leaving the surface rough to be acted on by frost, rain, snow, and wind. For the early crops select a warm, sunny border, sowing the earliest dwarf varieties of acknowledged merit. In favourable situations a few rows may be sown in February, following at fortnightly intervals until the middle or end of March, when second early varieties may be sown. From this date onwards to the end of May sow maincrop varieties, and in June sow again early Peas for producing the latest crops in the autumn. The method of culture with the early crops is to sow in drills 3 feet apart for the dwarf varieties, placing the seed rather more thickly than for succeeding crops. Taller varieties should be 5 and 6 feet apart, and for the main crop widely arranged rows are best, intercropping the vacancies with other vegetables. Where the soil is light and dry and for main crops generally an excellent plan of culture is to dig a trench a spade deep and wide, place in 4 inches of manure, then 4 inches of soil, on which sow the Peas, filling up, but not quite level with the surface, the remaining soil. Peas are benefited by keeping the soil loose about the rows when the plants are young, slightly drawing the earth to them when a few inches high, and sticking early. In dry weather mulch each side of rows with short manure or grass mowings and afford copious supplies of water varied with liquid manure, when such will be of assistance in swelling and perfecting the crops.

The nodules on the roots of Peas serve the purpose of converting free nitrogen gathered by the plants into assimilable matter, which can be appropriated by them. The conversion in question is effected through the agency of micro-organisms of the bacterial class.

11, An alpine plant is generally known in gardens as a hardy perennial of low growth, cultivated chiefly on specially prepared elevated sites or rockeries, the stones forming the latter providing shelter and protection for the plants from heat, drought, and cold. Their cultural requirements consist of a moderately rich and deep root run, so that they can become firmly established by rooting deeply, the soil also being kept moist to enable surface rooting. Each plant should be kept distinct from the intrusion of others. Those that need such help may be lightly top-dressed with leaf soil each spring. The propagation of these plants is effected by seeds, cuttings, offsets, and division.

12, The original parentage of Cauliflower and Broccoli is the Brassica or Cabbage. Cauliflowers for summer and autumn use require sowing in heat, transplanted into beds of good soil where shelter, if required, can be afforded by frames, finally planting in rich soil in April and May.

Broccoli may be sown in the open ground early in May, transplanted 4 inches apart when large enough, and planted on good but very firm ground in an open situation in July.

Early Snowball, Walcheren, and Veitch's Autumn Giant Cauliflowers; Snow's Winter White, Cattell's Eclipse, Leamington, and Late Queen Broccoli will afford a succession.

13, Grape Vines under glass may be started into growth at a temperature of 50° to 55°, gradually rising to 60° and 65° as the leaves expand; 10° to 15° higher may be allowed with sun heat, and a moist atmosphere maintained to encourage healthy growth. Ventilate early before the sun heat raises the temperature, and close early in the afternoons before the sun leaves the house, damping floors, walls, and staging. Moisten the inside borders if dry at starting, affording further supplies after fruit has set, and at frequent intervals up to the berries colouring, when copious waterings will not be needed so frequently. Liquid manure may also be given when the fruit is swelling, or top-dressings of some approved artificial stimulant, washing it in lightly.

Stopping and tying-in the shoots must be practised as soon as they have extended far enough, previously disbudding some of the surplus growths, leaving no more than two at most—one to bear fruit, the other to develop for the following season. Keep the atmosphere rather drier when the Vines are in flower, and assist the fertilisation of shy setting varieties by shaking the bunches of bloom at midday, or conveying pollen to them from free-setting kinds. Thin the bunches of small and crowded berries early, deferring those of Muscat Vines until the fertilised berries can be seen swelling freely. As soon as berries commence to colour give air freely and constantly, a little at night being beneficial given at the top. Front air is not necessary until the berries are swelling, air being admitted wholly from the top ventilators. Afford fire heat to maintain a buoyant atmosphere, and prevent damping as the fruit ripens. Fire heat also assists the wood to ripen if at all backward in the autumn.

The diseases which attack Vines are shrivelling of the berries owing to a lack of root power, dryness of the soil, and deficient nutriment. Rust on the berries appears from similar causes and from injury to the outward skin of the berries. Mildew arises from a damp, low temperature, insufficient air, and draughts.

Shanking originates from poverty and a lessened supply of sap and

overcropping. Young active rootlets are not numerous enough to continue the forces required from the Vines for finishing the crop well.

The insect pests attacking Vines are thrips, red spider, and mealy bug. Thrips may be destroyed by sponging the leaves when first attacked with soapy water, maintaining a moister atmosphere, which is not favourable to their spreading. Fumigation with tobacco will also destroy them, and is best where they are numerous. Red spider will not thrive in a moist atmosphere, and dusting affected leaves with sulphur destroys the pest. Special attention must be given to cleansing the Vines in winter, and in carrying out all details of culture so as to avoid fresh attacks another season. Mealy bug requires strong efforts put forth for its eradication. The best method is thorough winter cleansing of the canes with soap, water, and insecticides, painting the woodwork, whitewashing walls, and clearing out every scrap of rubbish. Even the top of inside borders should be removed, renewing with fresh material.

14, Apples, Pears, Plums, Cherries, Gooseberries, Currants, and Raspberries are best adapted for small gardens. Apples may be cultivated as half-standards and bush trees, arranged 4 to 6 feet from the walks round the central portion of garden, planting them 8 or 10 feet apart; or bush and pyramid Pears and half-standard Plums might be planted alternately with the Apples. If desired the whole may be arranged across the piece of land 10 feet apart, Gooseberries and Currants being planted among them 5 feet distance between each other in the rows. Cordon Apples and Pears are best for low walls. Raspberries should have a space of ground to themselves in which they can be planted in lines or clumps.

15, Fruit trees for a south aspect may comprise, in favourable situations, Peaches, Nectarines, Apricots, Figs and Vines. Less favoured places may grow Pears, Apples, Plums, and sweet Cherries. For north aspect, Morello Cherries, Gooseberries, and Currants. East, Pears, Plums, Cherries. West, Apples, Pears, Plums, and Cherries.

Fan-trained trees ought not to be less than 15 feet apart. Horizontally trained trees not less than 12 feet asunder grown on restricted stocks, on free stocks 15 to 20 feet. Upright and diagonal cordons may be planted 18 inches to 2 feet apart. The best height for the walls is 9 to 12 feet, the border being the same in width as the walls are in height.

16 (a), The most suitable class of soil for fruit trees is a firm loam of medium texture, neither too light on the one hand nor too heavy on the other, well drained, and not too deep, 2 feet being ample. Its preparation is best effected by deep digging, loosening the subsoil, but allowing it to remain where it is to facilitate the escape of superfluous moisture.

(b), The best method of culture to prevent canker and gumming consists first in the thorough preparation of the soil, then in planting healthy, vigorous trees, maintaining the roots active in the soil, and encouraging their production of active fibres near the surface. Avoid pruning excessively at any time, especially with stone fruit trees, as the removal of large quantities of wood at one time induces gumming. The general healthy condition of fruit trees depends largely on the state of the roots and judicious intelligent management.—E. D. S.

[We do not know whether or not our correspondent was a candidate for the R.H.S. examination. We think he has answered the questions at least creditably, if in some cases briefly, and his M.S. was admirably written, requiring practically no editorial corrections, while he has obviously imparted useful information.]

## HARROW WEALD HOUSE.

THOUGH situated within about twelve miles of the City of London, Harrow-on-the-Hill is distinctly rural in its streets, its shops, its people, but not by any means in its railway. A few days ago a bright May morning found us making our way to Euston, whence we departed for Harrow, reaching our destination in a very short space of time. From the station we had before us a walk of nearly two miles by a very dusty road. How we were repaid and what we saw shall receive attention in the forthcoming paragraphs.

For those who have not diligently studied the "Horticultural Directory" and discovered the fact for themselves, it may be as well at the outset to say that Harrow Weald House is the residence of H. Grinling, Esq., who employs Mr. Rapley as his gardener. "Not Rapley, the Calceolaria grower, who was at Bedford Hill House?" said a friend, to whom mention was made of the visit. "The very same," we said. "Then you certainly saw something good," was the instantaneous rejoinder. This was a compliment indeed to this genial gardener, who takes the keenest and most intelligent interest in all things pertaining to his calling, hence, doubtless, his success as a cultivator. Celebrated as he is for the magnificence of his Calceolarias, he is by no means behind with fruits, vegetables, Orchids, and general flowers, for his spirit prompts and forces him to do all things to the best of his ability, which means in almost, if not all cases, well.

The drive to the mansion is broad, and under grand old trees such as give an air of dignity to a place that cannot be otherwise provided. At the end is a bed of *Myosotis alpestris*, amongst which are mingled a number of bulbs of the brightly coloured *Tulipa Gesneriana*, which looks so charming as to augur well for future prospects. Passing the house we enter the garden, or at least that portion of it which is devoted to the glass structures, comprising Orchid houses, Peach houses, vineries, and various plant houses, with large numbers of frames.

After a walk through the charming grounds, a pause was made to

look over the Calceolarias, which are growing as they should be, with foliage stout, deep green, and destitute of insects; stems stiff, strong, and requiring no stakes to keep them upright; and large trusses of handsome, shapely, and heavy flowers. The colours are exceptional—here for their softness, there for their intensity, and yonder, again for their translucency. For several years this able gardener has been working on Calceolarias with the object of improving them in texture, habit, and range of colouration, and well he has succeeded. An inquiry as to when the seeds were sown elicited the reply of "July last, and the plants have never once been allowed to stand still since that time." Constantly progressing is, in this grower's opinion, the way to make the most of these plants, for says he, "Once allow them to receive a check, and all hopes of attaining to perfection may be promptly relinquished. On placing the rule to one plant growing in a 4½-inch pot we found it to measure 2 feet across, and a count showed fourteen trusses of bloom.

Leaving with reluctance the Calceolarias, we pass to the next house, that contains some grand Palms arranged in the centre with a general collection of flowering and foliage plants on the side stages, and all evidencing the best cultivation. Amongst these *Justicia carnea* with its peculiarly shaped flowers was very attractive, while on the roof was growing a splendid *Stephanotis floribunda* that was carrying great numbers of its deliciously fragrant flowers. Another point worthy of remark about this plant was its absolute cleanliness in regard to insect enemies. In another structure red and white *Lapagerias* were making splendid headway. These were a few of the many plants seen. Before leaving the flowers, however, mention must be made of the *Gloxinias* that are grown so well. The plants are from seeds secured from a crossing of two of the finest strains in commerce, and as the best of culture has been accorded, the plants are now carrying large numbers of delicately hued blooms.

Fruits under glass are well grown, the Peaches and Nectarines being especially worthy of note. All the trees are producing good crops of fruit, and of course in various stages. The growth and cleanliness of the trees were alike excellent features, creditable both to the treatment and to the grower. Strawberries in pots are a feature indeed, for they are to be seen everywhere, large numbers being cultivated. They are principally kept on shelves in the various houses, and the quantity of fruit, with its perfect colouration, is proof that here again an excellent system of culture is followed. Melons look remarkably well, as also do the Cucumbers (if we can be excused for bringing them under the category of fruits) each of which is carrying very satisfactory crops. The Vines are somewhat too limited in numbers, and consequently have to do a great deal of hard work in the form of heavy crops year after year, despite which they are in fairly good condition, and are now showing some really good bunches.

From the fruits we quickly made our way to the Orchid houses, which, if limited in number, are stocked with a finely diversified collection of plants in the best of health. As a criterion of quality, readers might refer back to the splendid *Cattleya citrina*, figured in the *Journal of Horticulture* for May 9th, and which emanated from this collection. Numerous plants of *Cattleya Mossiæ* are grown, and on some the flowers are of distinct merit. In the same house were noticed *Phalænopsis grandiflorus*, *Lycaste aromatica*, L. Deppei; a very fine form of *Cypripedium Wallisi*, with its long petals; *Brassia verrucosa*, *Oncidium concolor*, and many others. In a small house of recent erection *Odontoglossums* of various kinds find a congenial home. Several charming forms of *O. crispum* were particularly noticeable, as also were *O. cirrhosum*, *O. cordatum*, and *O. Pescatorei* in variety. Brightening the display were plants of *Epidendrum vitellinum majus* and *Masdevallia Harryana*, while interest was added with a plant of *Masdevallia nycterina*, growing in a 6-inch pot, and on which were upwards of four dozens of flowers. To do justice to the Orchids much more should be said, but time forbids, and it is necessary that we go on, or we shall not see all in the allotted time.

Out of doors neatness is the prevailing feature, and it extends over the kitchen and fruit as well as the flower garden. Vegetable crops are all looking remarkably well, Peas being especially fine. Asparagus is, and has been for some time, providing good dishes, while all other crops in season are well represented. Potatoes and Lettuces in frames have been very fine, but are now rapidly getting past. Weeds are at a minimum, as the gardener believes in allowing useful vegetable and fruit crops to derive all possible advantage from the soil, instead of being robbed, as is often the case, by useless and untidy weeds. Fruit trees, young and old, are to be seen in numbers, some carrying fruits that are readily perceptible, others, of course, being very much later. Bush fruits also find a place, and with those previously named receive the best possible attention in every way, as, in fact, is the case with everything on the place. The flower and pleasure gardens, where Roses revel, are all admirably kept, and the same may well be said of the soft, springy lawns. But time forbids more lengthy mention, so with pleasant thoughts we return to the station and London.—NOMAD.

#### GROS COLMAN GRAPE.

MR. THOMSON'S eulogium (page 476) of this fine Grape is well deserved. So far as the need for good heat to develop flavour is concerned doubtless he is right so far as Clovenfords is in question, but I have tasted from Fordingbridge the best flavour this Grape can give, as grown by Mr. S. Castle when there, and his treatment was comparatively [c. o.]. There are some Grapes, and this is one, in

which really capital flavour is found apart from deepest colour. Still, Gros Colman generally coloured very well. It would be very interesting were Mr. Castle to give a short outline of his Hampshire treatment of Gros Colman. Whether he may find it suitable at Nottingham has to be shown. If not the best flavoured Grape in cultivation it is one of the pleasantest to eat, because its flavour, unlike that of the Muscat, does not soon kill the palate, and a more refreshing Grape for ordinary use or for invalids does not exist.—D.

#### CELMISIA SPECTABILIS.

THIS is the name of the flower of which "A. B." sends us a fine specimen. It is a very rare plant, and is comparatively new, having been exhibited for the first time only about five years ago. The

FIG. 91.—CELMISIA SPECTABILIS.

woodcut (fig. 91) will convey to those readers an idea of what this little composite is like. This plant usually grows to a height of about 6 inches, and has narrow lanceolate leaves, white and woolly on the under surface. The flower heads are 2 inches in diameter, with closely set, narrow, pure white ray florets and a golden disk. Being very compact, it is well adapted for culture in pots in a cool house, or it may be found useful out of doors when more plentiful.

#### THE PLANTING OF WELSH CROWN LANDS.

ANY reflective traveller, whose business leads him over a large extent of the United Kingdom, must be surprised as the train whirls him over mile after mile of hill and dale, to see the large extent of hillsides, too bleak or too short of soil to be profitable to the farmer, lying idle and unproductive. When he considers that our foreign timber bill amounts to nearly £20,000,000 per annum, and that we have thousands of acres of land quite as capable of producing this timber as those abroad from which our supplies are drawn, our reflective traveller will probably consider that the nation's immense expenditure abroad, for what it could in great part produce at home, is a fact adverse to the practical spirit that it is sometimes credited with. If he seeks after causes he will conclude they must either be indifference, ignorance, or want of capital.

Probably the part of the United Kingdom which affords the greatest scope for improvement in this matter of planting trees or afforesting is Wales, and we are very pleased to know that Mr. E. Stafford Howard, Her Majesty's Commissioner of Woods and Forests, has determined to try some experiment on the Crown lands in this direction by having an experimental plantation made at a high altitude, and in a very exposed situation. If this experiment results favourably we hope not only the Commissioners, but landowners generally, will carry out from year to year improvements and extensions in a similar way. That plantations are wanted, and that they would pay ultimately good interest on capital invested, should be obvious to all acquainted with the climate of Wales, which equals that of the Channel Islands and parts of the Continent from whence large portions of our supplies of timber, and of lesser articles, such as eggs, poultry, fruit, flowers, and dairy produce are drawn.

The connection between these articles of our import trade and plantations may not at first be seen, but if we could persuade Agriculture to learn lessons from her young sister Horticulture, she would see the importance of shelter from winds as shown in the garden and the tree nursery. In both, this is provided for by planting either hedges that are allowed to attain a good height and width, or by borders of the hardier trees on the outer boundaries of a garden. Inside these shelters tender plants and shrubs flourish vigorously, which would die outright if planted in the full exposure. In a similar way about the farm more trees should be planted in order to give shelter from the strong winds and sea blasts. If this was done early vegetables, fruits, such as Strawberries, poultry, and cattle, all would benefit thereby. Wales has the climate for early and profitable production of all these articles, and with industry, skill, and outlay of capital on the part of her children, with a little fostering care and leading the way by the "powers that be," she might ultimately supply the great markets of Liverpool, Manchester, and the North with many thousands of pounds of produce that the foreigner supplies. It is considerations like these that make us welcome the experiment now being made as a step in the right direction.

We understand that Mr. W. H. More, crown agent for Wales and Co. Monmouth, of Harlech, has the supervision of the work, and that the Commissioner has, on his recommendation, appointed Mr. T. Lewis, jun., Arthog, Dolgelly, to carry out the planting. Messrs. Clibran & Son have supplied specially selected trees from their Llandudno nurseries, so that all that skill and care can do to make the experiment a success will be done. The public generally will owe a debt of gratitude to the Commissioner and Crown Agent for their efforts in the direction of promoting tree planting in Wales, and we trust that success will attend the experiments now in hand.—FRUITMAN.

## HORTICULTURAL SHOWS.

MANCHESTER.—MAY 31ST.

ON Friday last the annual Whitsuntide exhibition was opened at the Botanical Gardens, and the opinion, formed by competent judges who have attended almost annually since the formation of these grand shows, was that for beauty of effect and brightness there has been no previous show to compare with this one. This applies more especially to the grand display of Orchids, which completely filled the grand exhibition house from end to end: The central stage was a gorgeous bank, relieved from stiffness by stately Tree Ferns and Palms towering up to the roof, whilst similar banks arranged on each side had handsome backgrounds of Palms and draped pillars, the end being filled to the extent of some 300 feet with a fine group of Orchids exhibited by F. Hardy, Esq., Tyntesfield, Ashton-on-Mersey.

Coming to the annexe, and taking a view from the steps, the effect was even more pleasing. Below were the handsome first, second, and third prize groups put up with admirable effect by Mr. Wilkes, gardener to Miss Lord, Oakleigh, Ashton-on-Mersey, whose first prize was most worthily won. To attempt a description would only be to court failure; but it stood as an object lesson to all visitors, and shows Mr. Wilkes a true exponent of the beautiful in Nature. The second prize, exhibited by Mr. Elkin, gardener to Mrs. Agnew, Fairhope, was admirably done, whilst the third, by Mrs. Blair, was lacking in lightness of material.

Stretching beyond for a distance of 112 yards on each side were irregular banks of Rhododendrons gorgeous in colour, the tall standards inserted prominently adding much to their beauty. These came from Messrs. Jno. Waterer & Co., Ltd., Bagshot, Surrey. The centre space was devoted to nurserymen's exhibits, and here the same regard to effect had been carried out. In some cases tables had been absolutely necessary, but any formality was relieved by groups in between. The first to come under notice was the Reading firm of Sutton & Sons, and after the note on the Temple show in our issue of a fortnight ago little remains to be added. The unique Peas and Tomatoes, the handsome Gloxinias, herbaceous Calceolarias, and Begonias which stamp the firm Al in quality in every respect. A gold medal was accorded to Messrs. Sutton and Sons for this exhibit. If the Temple show was robbed of Mr. Jno. Laing's support not so here, for his group of Caladiums, which was deservedly awarded the gold medal, was arranged in the best possible form. Another noted firm who has been absent for many years we hail with pleasure—viz., Messrs. T. Rivers & Son of Sawbridgeworth, their thirty pots of Nectarines forming a pleasing feature, in addition to giving visitors some idea of the splendid culture carried out. The gold medal was unanimously awarded. The sorts exhibited were Early Rivers and Cardinal.

Hardy cut flowers were superb, everything good and noteworthy being brought together. Messrs. Cutbush & Sons' table was most tastefully arranged, the flowers being in miniature groups, with an edging of moss. Peonies, Pyrethrums, Crimson Giant Mignonette, Leschenaultia biloba major, Turner's Crimson Rambler Rose, the beautiful new border Carnations The Countess and Mrs. H. Cutbush, Calla Elliottiana being a few of the many good plants staged. Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, had a handsome arrangement, conspicuous for the beautiful Irises, Eremurus himalaicus, Lychnis, and Improved Pink Carnation. Dickson's, Ltd., Chester, showed a charming collection, comprising Irises, Pyrethrums, Poppies, Eremurus himalaicus, Cypripedium macranthum, Amorphophallus campanulatus, and Senecillis carpatica. An interesting exhibit of some 150 pots of Violas, comprising many new varieties not yet in commerce, and about 100 cut Pansy blooms was much admired. Miss Hopkins, Mere Cottage, Knutsford, exhibited a useful collection of herbaceous cut flowers and Violas. Arranged in this part was the first prize collection of hardy herbaceous and alpine plants, arranged by Mr. Plant, gardener to R. P. Gill, Esq., Ashton-on-Mersey, a most interesting feature of the exhibition.

Coming to the Orchids, a prize of £20 was offered, Edwd. Ashworth, Esq., Harefield Hall, Wilmslow, gaining first honours with a remarkably fine stand set in a bank of Ferns. To enumerate all the choice varieties would take up too much space, but it may safely be said that the quality and quantity were everything to be desired. Fred Hardy, Esq., as previously mentioned, had fine examples, particularly *Lælia purpurata*, but there was rather a lack of finish to the group. Mr. Cypher of Cheltenham came in a capital first in the collection for nurserymen, and it is questionable if he has ever exhibited anything better. *Lælia purpurata* in variety, *Odontoglossums*, and *Masdevallias* were all superb. Messrs. Heath & Son, Cheltenham, were a very fair second, and Mr. Jno. Robson, The Dawns, Bowdon, third.

For the best collection of Cattleyas and *Lælias*, Thos. Statter, Esq., Stand Hall, Whitefield, had vigorous and beautifully flowered specimens of *Lælias purpurata* and *grandis*, the Cattleyas represented being *Mossia*, *Mendeli*, and *gigas gigantea*; E. Ashworth, Esq., being second. Beautiful in this stand were Cattleyas *Mossia*, *Reineckiana*, var. *Jno. Ashworth* and *Beatrice Ashworth*, the former being—with the exception of a tinge of violet with orange marking in throat—almost pure white. For ten specimen Orchids in bloom Mr. Ashworth was again in splendid form, grand being *Cattleya Mossia*, *Dendrobium Dalhousianum*, and *Gramatophyllum Mearesianum*. Messrs. Heath & Son were an excellent second, *Dendrobium Dalhousianum*, *Phalænopsis grandiflora*, and *Cypripedium Lawrenceanum* being very good. The third went to Mrs. Hodgkinson, Bowdon. Mr. Cypher won the silver cup for *Dendrobiums* in bloom, *Falconeri* and *Beensonia* being fine. Mr. Ashworth was a smart second. For the best collection of *Cypripediums* in bloom four competed, Mr. Billington, gardener to W. R. Lee, Esq., Beech Lawn, Audenshaw, having *Winifred Hollington*, *superbiens*, and *Goweri* as his best. F. Hardy, Esq., was a capital second; Thos. Statter, Esq., third.

Thos. Statter, Esq., won in the class for *Cypripediums* in bloom, the best amongst them being T. B. Haywood; Ed. Ashworth, Esq., being a fair second. *Odontoglossums* are always a great feature here, Mr. Stevens, gardener to W. Thompson, Esq., Stone, having a collection which, for merit in arrangement, good culture, and high quality, would be difficult to excel. F. Hardy, Esq., for second place, had some superb forms, the effect, to both flowers and artistic taste, being lost by the absence of greenery to furnish. S. Hinchcliffe, Esq., was a fair third. W. R. Lee, Esq., was awarded honours for new hybrid Orchid with *Lælio-Cattleya Aphrodite*; E. Ashworth, Esq., with *Cypripedium Lawrenceanum* × *Curtisi*, partaking much of the former parent; F. Hardy, Esq., third with *Oenanthem superbum*.

Amongst the trade exhibits not for competition the place of honour must certainly be accorded Messrs. Sander & Co., St. Albans, who, to quote an expression of one of the Judges, staged the finest collection which has ever been seen in Europe, the large gold medal, which is the highest award granted, being worthily bestowed. Messrs. B. S. Williams and Son and Hugh Low & Co. vied with each other with stands of the highest possible merit. Messrs. Charlesworth & Co. had a pleasing stand. Messrs. J. Cowan & Co. (Limited), Garston, Liverpool, had a most superior collection, the best of which were *Brassia verrucosa major* with over a score of handsome spikes, a grand variety of *Cypripedium caudatum* (very dark), *Lælia purpurata Boissieriana*, and *Brassia Keilliana trista*, with a small collection of *Amaryllis*. Messrs. W. L. Lewis & Co., Southgate, had a small but choice display.

A most meritorious collection of fruit, consisting of two bunches of Black Hamburgs and one Foster's Seedling Grapes, Tomatoes, and seeds of *Cycas revoluta*, was staged by James Watts, Esq., Abney Hall, Cheadle, and a dish of Brown Turkey Figs and a new Melon May Queen, a handsome, well flavoured, scarlet flesh variety by Mr. E. Gilman, Ingestre Gardens, Stafford.

Most deserving was the first-class certificate for the beautiful plant of *Cattleya Mendeli* Her Majesty, which was exhibited by Mr. Turner, gardener to F. Jacomb, Esq., Cheam Park, Surrey; also to Edward Ashworth, Esq., for *Cattleya superba Ashworthi*, a charming variety, with white sepals and petals, the throat faintly suffused with lemon and slight violet blotch. Messrs. B. S. Williams & Son gained a first-class certificate for *Pescatorea Roezli alba*, slightly past its best; and a botanical certificate for *Brassia Keilliana trista*. Other certificates were granted, but owing to their not being placed at the time the report was taken they must be left for a short note next week. Messrs. R. Halliday & Co., Manchester, had a grand exhibit of horticultural buildings, to suit every taste. The Stott Company's trial of the new steam lawn mower

excited great interest, the unanimous opinion of competent judges being that for large establishments it cannot fail to prove of the greatest benefit. The show keeps open until the 6th of June.

The gardens indoors and out are in splendid condition, a real treat to all who toil in the busy city. It is earnestly to be hoped that Mr. Findlay and his able assistant, Mr. Paul, will meet with the success they so well deserve in catering so handsomely for the public. There is at the present time a grand specimen *Medinilla magnifica*, carrying 267 spikes, acknowledged by all who have seen it to be the greatest floral feature of the century. Messrs. Ker & Sons of Aigburth added greatly to the show by the splendid Palms which they exhibited.—R. P. R.

SOUTHAMPTON.—JUNE 3RD.

MUCH the best exhibition yet held was that on the date named by the Royal Southampton Horticultural Society in their grounds in Westwood Park.

Groups arranged for effect were the principal feature. In the largest class so close was the competition that equal first prizes were awarded to Mr. E. Wills, florist, Shirley, Southampton, and Mr. Peel, gardener to Miss Todd, Sidford Lodge, Shirley. The former had splendidly grown Palms raised on mounds, interspersed with Orchids, Gloxinias, and Crotons, the whole lightly arranged. Mr. Peel had well-grown plants of *Odontoglossum sphacelatum*, Palms, and Ferns neatly arranged.

In the smaller groups Mr. T. Hall, gardener to Sir S. Montague, South Stoneham, was an easy first with an arrangement that in every way did him credit. Mr. Kingsbury, Bevois Valley Nursery, was second with a creditable arrangement.

Mr. Carr, gardener to W. A. Gillett, Esq., Fair Oak Lodge, Bishopstoke, won premier honours with six Gloxinias, staging splendid plants. Mr. Hall was second. Mr. Carr won also with *Caladiums* and *Begonias*.

Herbaceous flowers were grandly represented in the class for twelve varieties, Mr. Ladhams winning easily, staging *Heuchera sanguinea*, *Dictamnus Fraxinella*, *Pyrethrum Sherlock* and *Mont Blanc*, *Hemerocallis Middendorfi*, *Iris Madame Chereau*, and *Erigeron aurantiacum*. Mr. West was a good second.

Roses were well represented. Dr. Seaton, Rutland Lodge, Bitterne, was the first prizewinner with a stand of even blooms. Mr. West second. Miss Kate Golding, Winchester Road, Portswood, secured the first position for the best dressed epergne, Miss Wills, Shirley, being second.

Vegetables were well staged by Mr. T. Hall in the class for six varieties, Early Milan Turnips, Duke of York Tomato, Webber's White Beauty Potato, and good Asparagus.

Non-competitive exhibits were numerous and good. Foremost was Mr. W. H. Rogers, Red Lodge Nursery, Southampton, with a magnificent bank of *Rhododendrons* and shrubs in pots. Mr. Wills staged a collection of nursery-grown plants. Mr. Ladhams a well stocked rockery, as well as a grand collection of cut blooms of hardy plants. From the Belmont Nursery, St. Denys, came a group of *Coleus*, *Lilium Harrisii*, and *Tuberoses*. Mr. Carr staged plants of *Odontoglossum vexillarium*. To Mr. Fudge and his assistant, Mr. Dallison, a word of praise is due for the admirable arrangement.

NORTHERN TULIP SOCIETIES' SHOWS.

BUTLEY.—MAY 31ST.

THE seventieth annual exhibition of this Society was held at the "Orange Tree Inn," Butley, near Macclesfield, on Friday last. Considering the tropical nature of the weather for the last ten days there was a very good exhibition, and there is no doubt that had ordinary weather prevailed for a fortnight before the show it would have been the best ever held in the old-world hamlet of Butley. Tulips, however, do not like a temperature of 82° in the shade, and have been roasted wholesale, and died in their youth. The principal prize at Butley is a silver cup for six rectified Tulips, one of each class.

The cup was given this year by the President of the Society, Mr. James W. Bentley of Stakehill. There was a good competition for it, and the Judges, Messrs. Woodhead (Staleybridge), Housley, and Booth (Stockport), awarded it to Mr. W. Kitchen of Marple, who staged Sir Joseph Paxton, flamed bizarre; Sulphur, feathered bizarre; Prince of Morocco, flamed byblœmen; Violet Aimable, feathered byblœmen; Annie McGregor, flamed rose; and Alice, feathered rose. The bloom of Sulphur was perhaps the finest example of that variety ever seen, and Prince of Morocco was superb.

A great many fine flowers were staged in the classes, and the usual standard varieties were well to the fore. Amongst the novelties that were good were Mrs. Collier, feathered rose; George Edward, feathered byblœmen; Elizabeth Pegg, breeder and feathered, and some bizarre seedlings of the late Mr. Lloyd. Following is a list of the awards:—

Silver cup for the best six rectified Tulips, Mr. W. Kitchen.

- |                                       |                                       |                                       |                                       |

| 9 Mr. Needham, with Dr. Vernon         |                                      |                                       |                                       |

The best feathered Tulip in the show was Mr. Kitchen's Sulphur, and Mr. Jones had the best flamed Tulip, Sir Joseph Paxton.

BREEDER TULIPS.

Three breeders, one of each class.—1, Mr. Bentley, with Sir Joseph Paxton, Mrs. Barlow, and Elizabeth Pegg. 2, Mr. Kitchen, with Sir Joseph Paxton, Rose Hill, and Ashmole's 114. 3, Mr. Needham, with Criterion, Mabel, and Martin's 117.

WAKEFIELD.—JUNE 3RD.

AT no time in the history of this old-established Society has the influence of the weather had such a disastrous effect on the quality and numbers of the exhibits as on the present occasion. The beds, which twelve days ago were in their full glory, entirely collapsed during the tropical spell of last week, all the classes showing, with few exceptions in individual blooms, scalded petals, the bizarre class coming on to the exhibition table in the best condition.

*Six Rectified Blooms.*—First, Mr. E. Lister with Sir J. Paxton, feathered, Sir J. Paxton, flamed, Seedling, Geo. Hardwick, Industry, and Mrs. Lee. Second, Mr. Mellor with Dr. Hardy, Masterpiece, Bessie, G. Hardwick, Annie Macgregor, and Mrs. Lee. Third, Mr. Alf. Moorhouse; fourth, Mr. J. Hardwick; fifth, Mr. W. Calvert; sixth, Mr. G. Gill; seventh, Mr. Thos. Maddock; eighth, Mr. H. Brown.

*Six Breeders.*—First prize, Mr. Alf. Moorhouse with Sir J. Paxton, G. Hardwick, Rose Hill, Hepworth, and Talisman. Second, Mr. E. Lister with Sir J. Paxton, Dr. Dalton, and others. Third, Mr. G. Gill; fourth, Mr. W. Mellor; fifth, Mr. W. Calvert; sixth, Mr. Thos. Maddock; seventh, Mr. J. Hardwick.

*Three Breeders.*—First, Mr. Wm. Mellor, with Sir J. Paxton, Beauty of Highchurch, and Isabel; second prize, Mr. E. Lester, with J. Bright and two seedlings; third, Mr. J. Hardwick; fourth, Mr. Geo. Gill; fifth, Mr. Alf. Moorhouse; sixth, Mr. W. Calvert; seventh, Mr. H. Brown; eighth, Mr. Thos. Maddock.

*For Feathered Bizarres.*—Mr. W. Calvert was first and second; Mr. Alf. Moorhouse, third and fourth; Mr. Thos. Maddock, fifth; Mr. Ed. Lester, sixth and seventh; and Mr. Wm. Mellor, eighth.

*Feathered Byblœmens.*—Mr. Geo. Gill, first and sixth; Mr. Alf. Moorhouse, second and seventh; Mr. Wm. Mellor, third; Mr. Wm. Calvert, fourth and fifth; and Mr. Freeman, eighth.

*Feathered Roses.*—Mr. E. Lister, first and sixth; Mr. Alf. Moorhouse, second and third; Mr. Geo. Gill, fourth; Mr. Wm. Mellor, fifth; Mr. Wm. Calvert, seventh; and Mr. Freeman, eighth.

*Flamed Bizarres.*—Mr. E. Lister, first and second; Mr. Thos. Maddock, third and seventh; Mr. Wm. Calvert, fourth and sixth; Mr. Alf. Moorhouse, fifth; and Mr. Wm. Mellor, eighth.

*Flamed Byblœmens.*—Mr. Alf. Moorhouse, first; Mr. E. Lister, second and sixth; Mr. Wm. Mellor, third and fourth; Mr. Freeman, fifth and eighth; and Mr. H. Brown, seventh.

*Flamed Roses.*—Mr. G. Gill, first; Mr. Alf. Moorhouse, second and fourth; Mr. Freeman, third; Mr. H. Brown, fifth and eighth; Mr. Ed. Lister, sixth; and Mr. Wm. Calvert, seventh.

*Bizarre Breeders.*—Mr. Ed. Lister, first and third; Mr. Alf. Moorhouse, second; Mr. Wm. Calvert, fourth and fifth; Mr. Geo. Gill, sixth; Mr. Jesse Hardwick, seventh; and Mr. Thos. Maddock, eighth.

*Byblœmen breeders.*—Mr. Geo. Gill, first and second; Mr. Wm. Mellor, third and fifth; Mr. Thos. Maddock, fourth; Mr. J. Hardwick, sixth and seventh; and Mr. Ed. Lister, eighth.

*Rose Breeders.*—Mr. Alf. Moorhouse, first and second; Mr. Wm. Mellor, third and eighth; Mr. Ed. Lister, fourth and fifth; and Mr. Geo. Gill, sixth and seventh.

*Premier Breeder.*—Mr. Ed. Lister with Sir J. Paxton. *Premier Flamed.*—Mr. Ed. Lister with Sir J. Paxton; a remarkably fine example. *Premier Feathered.*—Mr. W. Calvert with Masterpiece.

#### HARDY FRUIT GARDEN.

**Thinning Fruit.**—*Apricots.*—Small ill-placed fruits should be thinned from the trees without delay, so that the remaining fruits may have every facility for swelling freely. Many of the improperly fertilised fruits fall prematurely because they are not furnished with the necessary impetus for developing; others swell during the early stages, but afterwards fall, the stoning process being a test of their vigour.

Thinning the fruit is specially necessary with stone fruits because of the large amount of nutriment a large number of fruits draw from the soil simply to provide material for the development of the stones, while the flesh, the essential part for which the fruit is cultivated, suffers. Thinning operations may take place at intervals. First remove the small fruits and those swelling in awkward positions, such as the back of a branch, pressing against wall or wires, or otherwise inconveniently situated so as to be ultimately injured. The next thinning may take place when the fruit reaches the size of small nuts; the final being after the stoning, when the fruits are then apportioned at the proper distances asunder, according to the vigour of the trees, the size of the variety, or the strength of individual branches.

**Peaches and Nectarines.**—Following Apricots, Peaches and Nectarines need attention next, all small and useless fruits being removed early. Even if the crop is poor, owing to the indifferently ripened condition of the wood last season, there will still be fruits that need removing. If the fruit has set thickly thin out the weakest as soon as possible, giving a fair chance to the best to swell freely. Go lightly over the trees one after another, and return to them again in the same rotation when the fruit has swelled further. The ultimate distance at which a fair crop may be left can be kept in mind, so that this knowledge will guide the operator in determining the number to remain at each thinning. At the final thinning, after stoning, large varieties may be left 8 inches asunder, smaller 4 to 6 inches. These distances must be approached gradually by thinning at several different times.

**Plums and Cherries.**—The weather was favourable to fertilisation of the bloom, consequently there has been a good set, and there seems every prospect of good crops, notwithstanding the rough winds since prevailing. Some relief must at least be afforded to wall trees. Clip out the malformed fruits and partly reduce the size of clusters. Attention to reducing the number of fruits must promote the growth of those remaining, giving them increased and permanent vigour.

**Apples and Pears.**—There is every probability of Apples requiring free thinning, though at present the fruits are scarcely forward enough. Pears have reached the early thinning stage, and those varieties that are plentifully set with fruit may have the preliminary attention requisite, following on at intervals, because heavy crops cannot be finished well and at the same time not overtax the trees. Scantily furnished trees may remain some time longer. Trees on walls are, by their position, favourable to the development of fine fruit, so every attention ought to be given them to assist the fruit in reaching its greatest possibility of size and attaining its best flavour.

**Gooseberries.**—These are usually well thinned as soon as the berries are large enough for cooking purposes. If fine, large fruit is required for dessert, the thinning of a few trees for this purpose should be well carried out, avoiding gathering all the berries from a few branches and none from others.

**Syringing Wall Trees.**—Much benefit accrues to wall trees by washing them over occasionally with the garden engine, which removes numbers of aphides and red spider and prevents the establishment of others. Should, however, these insects increase to any extent before attempts are made to destroy them, a dose of some insecticide ought first to be applied. For aphides at the points of shoots, dipping the latter in tobacco water or a softsoap solution is a ready method. Also dusting with tobacco powder and shortly afterwards washing it off. Red spider is more difficult to deal with, as the insects are small but active, and favour the under sides of the leaves. Flowers of sulphur is an excellent remedy when it can reach the pests. The best method of applying it is to mix it with softsoap solution, 2 ozs. of each to the gallon, and then spray it over the foliage, reaching the under sides.

**Watering Wall Trees.**—Now that fruit is set and swelling, the demands of the roots and foliage must be met by adequate moisture in the soil. The ground at the foot of walls frequently becomes dry, which causes weakly sap movement and a consequent attack of insects. Dry soil also causes roots to descend in search of moisture, and this promotes strong sappy growth. It is, therefore, important not only for the current needs of trees but also for their future welfare that the

soil be maintained moist. Liquid manure can be given beneficially to moist soil but not to dry, and whenever there is any liquid to dispose of see that the ground is first soaked with clear water in order that the advantages of stimulants may be reaped by the roots of trees in bearing, to which only, and trees in a weakly condition, liquid should be applied.

**Stopping Currant Shoots.**—The side growths of Red and White Currants may now be stopped at the third joint, which will leave three or four large leaves at the base. The leading shoots should extend unchecked. Aphides often infest the points at this season, and the stopping frees the trees from their presence. If attacking the leading shoots, syringe with insecticide. These unhealthy conditions point to the necessity of assisting the roots.

#### FRUIT FORCING.

**Vines.**—*Early House.*—As soon as the Grapes are cleared from the Vines give the inside borders a thorough supply of water, followed by liquid manure, or a top-dressing of some approved fertiliser washed in. This will help to plump the buds and encourage root action, so essential to the activity of the laterals, which, if allowed moderate extension, is the best safeguard against premature ripening of the foliage. Keep the ventilators open constantly, even in cold weather. Syringe thoroughly to cleanse the foliage, especially of red spider, and repeat occasionally, or as found necessary, to keep the old or main leaves healthy. Fresh laterals will soon be produced, which should be pinched so as to maintain an even growth all over the Vines. The mulching or covering having been removed from the outside border, with just enough of the lighter part left to protect the roots, a good watering with liquid manure may be given, or a top-dressing of chemical manure applied and washed in. In watering outside borders regard must be had to the condition of the soil, only supplying water when required. Avoid heavy mulchings inside or outside; an inch or two of short stable manure, with the long strawy portion shaken out, answers admirably.

*Second Early House.*—Vines started at the new year have the Grapes ripening. Maintain a circulation of warm, rather dry, air constantly, increasing the ventilation early. Keep the floors well damped on hot days, with a view to check excessive evaporation, allowing the temperature to fall to 60° at night when cold, or 65° when warm, with sufficient warmth in the pipes to prevent the moisture condensing. If there is likely to be any want of finish, allow the Vines time by giving a long rest at night. Examine the border, and if there be any lack of moisture supply water thoroughly in the morning of a fine day, and when soaked in mulch with a little light material. This will probably be sufficient to keep the border moist until the Grapes are cut, if not, it must be repeated. Moderate moisture, even after the Grapes are ripe, is essential to the health of the foliage. The moisture will assist in keeping the Grapes plump, and prevent Hamburgs turning red and white Grapes brown, instead of retaining their jet black and rich golden amber colour respectively. A double thickness of herring or single pilchard netting drawn over the roof lights is effective and necessary where the panes of glass are large. Allow a moderate extension of the laterals to encourage root action, but keep gross laterals well in check, so as to cause an equal distribution of the sap. When ripe, a minimum temperature of 60° will be sufficient.

*Midseason Houses.*—Vines in these will be in various stages of development according to the time of starting. Those that have stoned will be swelling the berries fast, and require liberal nourishment. Top-dressings of the advertised fertilisers are excellent, supplying from 2 to 4 ozs. per square yard at intervals of about three weeks, always after watering, and then washing in moderately. Where stable or cowhouse drainings are available they should be utilised, diluting with five or six times the bulk of water. The drainage being good, the watering, whether with water or liquid manure, will need to be continued weekly if the border is limited to a small area, or fortnightly intervals if moderately large, until the Grapes are somewhat advanced in colouring, when it must be stopped, yet the border should not be allowed to become so dry as to affect the foliage injuriously.

Admit a little air constantly at the apex of the house, and ventilate freely in the early part of the day, closing early with sun heat and a genial condition of the atmosphere. Fire heat will only be necessary to secure 60° to 65° at night, and 70° to 75° by day, keeping through the day at 80° to 85°, and closing sufficiently early to run up to 90° or 95°. This will insure the berries swelling to a good size, and with a free circulation of air a good finish may be secured.

*Grapes Stoning.*—During this process the Vines should have a regular temperature of about 65° at night, and 70° to 75° by day from artificial heat, if the Grapes are wanted ripe as soon as possible. If not 65° only need be maintained on dull days, but admit air in good time on the sun appearing, always a little at 70° or before after a spell of dull weather, so that any moisture will be dissipated before the sun acts powerfully on the foliage. Allow a moderate lateral extension, but avoid overcrowding, and supply nourishing food, such as superphosphate, nitrate of potash, and gypsum, so as to provide phosphoric acid, moderate nitrogenous matter (ammonia), nitrates, and sulphate, a small amount of magnesia being of great service to Vines. Supply liquid manure occasionally, but avoid overfeeding luxuriant Vines, especially with ammoniacal manures, giving in their case superphosphate or steamed bonemeal. This will enable the Vines to maintain steady progress and finish their crops, while storing food for the coming season's bearing.

*Grapes Scalding.*—Muscats and Lady Downe's in the later stage of stoning are liable to scald; therefore air should be admitted more freely

for a fortnight or three weeks until colouring commences, when all danger will be over, provided the ventilation is free during the day and a little left on constantly. Black Hamburgs are sometimes scorched when the berries are exposed to the direct rays of the sun, which can usually be avoided by a good spread of foliage, and remedied by a bountiful supply of air by day and a little ventilation constantly at the upper part of the house, with a genial warmth in the hot-water pipes.

*Early Muscat Houses.*—The fruit ripening will need a dry condition of the atmosphere as compared with Black Hamburgs, but avoid great aridity, or the foliage will fall a prey to red spider. Muscats require a long time to ripen thoroughly, and must be given it to acquire the golden amber colour so much esteemed and characteristic of high quality. Do not allow any deficiency of moisture in the borders, for Muscats are gross feeders, but give either tepid liquid manure or top-dressings of the advertised fertilisers washed in. A mulching of short, sweet, rather lumpy manure, an inch or two thick, will supply organic matter or humus with the same nourishment, keeping the surface moist and saving watering, as well as encouraging surface rooting and giving off moisture and ammonia gradually (the latter being to some extent taken in by the foliage and utilised by the Vines). Provide a circulation of air constantly, preventing the moisture condensing on the berries by sufficient warmth in the pipes to insure a changing atmosphere. This is the best preventive of "spot," it not being possible, as we have proved by experiments, for the fungus spores to germinate in a dry atmosphere and on an exhaling surface.

Lateral extension is a good safeguard against shanking, along with a steady temperature and a not over-wet condition at the roots. Avoid sudden fluctuations and depressions. Keep the night temperature at 65° to 70°, 80° to 85° by day with a little sun, and 90° to 95° with it in full force. Ventilate early, and regulate the amount of air by the sun's increase, and so with its decline reduce early, securing as long a day of ripening from sun heat as possible. The old leaves of Muscats, also the berries directly exposed to the fierce rays of the sun, are liable to be scorched after a period of dull weather. In very bright periods draw a single thickness of tanned netting over the roof lights, which, without impeding too much light, will break the solar rays and prevent scorching.

*Late Houses.*—Any late varieties of Grapes in flower should have a circulation of dry warm air and a temperature of 70° to 75° at night, rising to 85° or 90° from sun heat, as without this the shy setting varieties do not set well. Carefully fertilise the flowers, and preferably with pollen from different varieties. Thin the berries freely as soon as they are set, but this in the case of shy setting sorts must be confined to the removal of the smallest and imperfect berries in the first instance, deferring the general thinning until the properly fertilised berries can be determined by their free swelling. There must not be any deficiency of moisture at the roots, therefore afford liquid manure copiously after the Grapes are thinned and swelling, or a top-dressing may be given of some approved chemical manure, distributing it evenly on the surface and washing in. Outside borders, if the weather be dry and the soil light, should be well watered and have the surface mulched, feeding with liquid manure or top-dressings.

*Vines in Pots and Supernumeraries for Next Year's Fruiting.*—*Young Vines.*—Potted Vines should have the leading shoot or cane stopped at 8 to 9 feet, and the laterals or sub-laterals stopped at one leaf as produced. Supernumeraries in recently planted houses may also have the leading shoots pinched at the length indicated for Vines in pots—that is, those intended to bear next season. Young Vines, after they become established, should be encouraged with judicious watering at the roots and abundant atmospheric moisture, closing the house early on fine afternoons, so as to secure a long day's work from sun heat.

*Figs.*—*Ripening.*—Perfect fruit can only be had by keeping it free from damp during the ripening process, and affording a free circulation of air. Maintain the night temperature at 60° to 65°, 70° to 75° by day, and with sun heat 80° to 90°. It is necessary to admit a little air constantly, as this prevents the deposition of moisture on the fruit and prevents "spotting." Moderate atmospheric moisture is necessary for the benefit of the foliage, but an occasional damping will be all that is necessary. If red spider become troublesome during the ripening gather the fruit closely, and then give the trees a forcible syringing, directing the water against the under side of the leaves, so as to dislodge the pests, and clear water being used and air admitted rather freely it will not interfere with the ripening of the fruit remaining, and by pursuing this course red spider may be kept from increasing very much until the fruit is gathered, when it may be destroyed by applying an insecticide.

*Second Crops of Figs.*—Liberal treatment is essential to insure the second crop of fruit swelling satisfactorily, syringing twice a day keeps red spiders in check, and affording liquid manure when watering is necessary; trees in pots require it daily, and those in borders once or twice a week, according to the vigour of the trees and extent of the rooting area. The second crop must be thinned when the Figs are of the size of small Walnuts, and in thinning reserve the larger fruits at the base of the shoots.

*Young Fig Trees for Next Season's Forcing in Pots.*—Those coming on for this purpose must not be neglected or they will disappoint the grower. Afford the trees all the light possible, keeping them as near the glass as consistent with their growth without touching, syringing well and supplying with liquid manure so as to secure a sturdy, short-jointed, well-fed growth, and when this is completed they may be placed outdoors in a sunny corner to rest, but they must not be neglected for water or syringing, and they must have the wood thoroughly ripened in the case of trees required for early forcing.

*Melons.*—Plants in flower require a little air constantly with a free circulation on fine days, fertilising the flowers as they become fully expanded, and when a sufficient number of fruits are set on a plant remove all the others and all flowers. Three or four fruits are as many as a healthy plant can bring to a good size and perfect, of fine, luscious quality. Plants swelling their fruits should have liberal supplies of water, supplying liquid manure or top-dressings and washing in, additions of fresh soil being made to the hillocks or ridges as the roots protrude.

Young plants in pits and frames with the shoots trained over the surface must be thinned to four, taking two to the front and two to the back, keeping the laterals rubbed off to 6 inches from the main stem and pinching the principal shoots when 12 to 18 inches from the sides of the frames or pits. The laterals will show fruit at the first or second joint, and the flowers being fully expanded fertilise them about noon on fine days, leaving a little air on constantly to prevent the condensation of moisture, a moist, close atmosphere being fatal to a good set. Pinch out the joints of the shoots one joint above the fruit, and after three or four fruits are set upon a plant remove all others. Keep the laterals closely pinched and thin them if likely to crowd the principal leaves.

Afford weak liquid manure, but keep it from the foliage, and sprinkle the plants in the afternoon of fine days, but not over the stems, closing about 3.30 P.M. to 4 P.M., or so early as to raise the temperature to 90° or 95°, and ventilate early in the day, or from 7.30 to 8 A.M., keeping through the day at 80° to 85° or 90°, and reduce the ventilation gradually. Keep a sharp look out for aphides and fumigate on two or three consecutive evenings moderately, an overdose doing great injury. If canker appears rub quicklime into the affected parts. Shade from bright sun, but only to prevent flagging.

## APIARIAN NOTES.

### SWARMING.

IN some places swarming has been taking place during the last week. These early swarms are, as usual, near wooded and watered places, hives situated within bee flight but outside the shelter usually being about three weeks later. Early swarms are not always the most profitable, as between the swarming and the honey season proper bees very often require to be fed.

The queens of early swarms become exhausted at the time those of later hives are at their best, which is the time likely to be profitable to the bee-keeper, continuing throughout the honey season. Keeping all the swarms will give the largest yield of honey in a lengthened honey season. But swarms coming just about the time or a week or so before the Clover will give the best results.

So very liable are early swarms to repeat the swarming, owing to the exhaustion of the queen, which in some seasons render the profit nil, that the bee-keeper should endeavour to prevent it, which is easily done by introducing young fertile queens. The best time for doing this is about ten days or so after the issue of the swarm. In the event of young fertilised queens not being at hand, on the eighth day after swarming divide the old stock into nuclei, and the weather being favourable the queens will soon be fertile. When this is so strengthen the nucleus by adding gradually the combs from the prime swarm. When that is accomplished depose the old queen; the bees having now neither queen nor combs, and the former nucleus standing on the site of the swarm or contiguous to it, the bees of the latter will fraternise at once without any trouble.

The profit from the apiary depends almost, if not wholly, on attending to the simple rule of having youthful queens to every hive, while the toil and trouble by incessant swarming is reduced to a minimum.

The honey season usually begins with us about the 21st of June, and bees have frequently to be fed till that date. Failing that, many stocks would die, while others would become unprofitable.

With the long dry weather and a falling barometer, a continuance of rain may be expected, but whether it rains or continues dry, honey will not flow, so bees must be fed till rain comes, and then, with a summer temperature, honey will flow to the delight of bees, and profit to bee-masters.—A LANARKSHIRE BEE-KEEPER.

### SEASONABLE NOTES.

THE bright days experienced during the past week have been perfect bee weather, although the nights have been rather cold, on one occasion the thermometer going as low as 36°; but the maximum temperature was reached on the 30th ult., when a thermometer placed on a stand in the shade registered 84°. Bees are increasing rapidly. A note should now be made of the best stocks, with a view of raising queens from the best workers. By taking this simple precaution much benefit will result in the future,

and the bee-keeper will be rewarded with a race of good hardy workers, without going to the expense of procuring those that have often nothing but their bright markings to recommend them.

Bees are now working freely on field Beans. These are not very plentiful, owing to the severe winter. The honey procured from these flowers is of good flavour, and many people prefer it to that obtained from White Clover, but being a pale brown in colour it does not sell so readily. The Horse Chestnuts and the May are now in full bloom, the latter not so good as usual, owing probably to the late severe winter. The bees, however, work freely on them, and during bright days when the temperature is high collect honey of a not very high quality. They also obtain a plentiful supply of pollen, which is so necessary for the well-being of the thousands of young bees that are now hatching out daily.

Stocks should now be examined, and those that are well crowded with bees should be supered either with sections or shallow frames for extracting purposes. Bees are more backward than usual this season, and I have heard of no swarms in this locality. Every day will now make a great difference in the strength of the various stocks, and as I manage my bees on the non-swarmer system I have for some years past found no difficulty in preventing the swarming mania, which is so annoying to bee-keepers when honey production is the chief aim.

I have already supered several of my strongest stocks. The bees commenced working in the supers at once, a proof that they are in the right condition for the purpose; others that are not so forward will be assisted with frames of brood and bees from other stocks. Bees unite readily at this time of the year without sprinkling with syrup, flour, or anything else. It is worse than useless supering stocks that are not of sufficient strength. The aim should be to have all stocks intended for honey production crowded with bees, and with fine weather success will follow.

#### PREVENTION OF SWARMING.

On May 10th I secured a swarm of bees and placed them in a straw hive, and being a novice in bee-keeping I should like to know how to prevent them from swarming again this season. Would a bell-glass fixed on the top for them to work in prevent it? or could I put them in a bar-frame hive? and how?—F. G.

This is the earliest swarm I have heard of this season, and if fed with thin syrup during the spell of cold weather experienced a fortnight ago the hive should now be nearly full of comb, and if the weather is favourable will soon be ready for supering, either with a crate of sections, or, if preferred, a bell-glass. But this should not be done until the hive is full of comb. Either would, in all probability, prevent them swarming again this season. A well-filled bell-glass has a very good appearance, but is not so serviceable as sections.

The crate to hold the sections should be made different to those in use for frame hives, the bottom of the crate being boarded over, only leaving a hole in the centre to fit over the hole on top of the hive. This will allow ample space for the admittance of the bees. Space must be allowed under the bottom of sections to allow the bees to pass from one to the other; cover the whole up warm, so that there is no escape of heat. Some of the best sections I have seen, and which took first prize in a strong competition, were worked on the top of straw skeps and treated as above.

This would be a better plan than to transfer them to a frame hive now, as the combs would be too tender to handle satisfactorily. They may be transferred to the hive as soon as the honey flow is over, or may be allowed to remain in the straw skep till next spring. The first swarm could then be put into a frame hive; three weeks afterwards the bees remaining in the old stock may be driven and placed in another frame hive, as there would then be a young queen, and all the brood would be hatched out.

Procure a bar-frame hive holding not less than ten frames standard size from one of our good makers who make a speciality of these goods, such as Messrs. Neighbour & Sons, High Holborn, London. A hive of this size will hold a crate of twenty-one sections, and is also useful for placing shallow frames on the top for extracting purposes. Afterwards the hives may be home-made, but whatever hive or frame is used, have them all made the same size, as they are very useful for interchanging and other purposes.—AN ENGLISH BEE-KEEPER.

#### GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—*Secretary*, Mr. G. J. Ingram, 50, Parliament Street, London, W.C.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—*Secretary*, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

## TO CORRESPONDENTS

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Dwarfing Sweet Peas (C. R. P.).**—We suspect that topping the plants now would not have the effect you desire, but you might try a few experimentally. We have seen beautiful beds of Sweet Peas by slanting light, twiggy pea sticks over them, somewhat in the form of an inverted saucer. These arrested the vertical growth of the plants, and with a little guidance and gentle handling the flowering parts were evenly distributed about 18 inches from the ground. Rough handling causes rupturing of the tissues, and is very injurious. There is not sufficient time for answering your other question this week.

**Odontoglossum cirrhosum Developing Its Spikes (The Boy).**—This depends on the season; at this time of year the flowers would take about three to four weeks from the time the buds are seen. This *Odontoglossum*, however, has a bad habit of occasionally remaining stationary for a long time, and we have known spikes to be over six months opening. This usually, however, indicates a check, and is sometimes caused by an unduly low temperature during winter. Should this happen, it is a very bad practice to place the plants in a strong heat with a view of remedying matters, as this only serves to weaken the plants.

**Chrysanthemums (The Boy).**—Cutting down the plants is not the best way to produce the finest blooms, especially of the incurved section. Plants so treated produce excellent results for grouping or decoration where dwarfness is imperative. However, as they are cut down you must make the best of them. By all means "take" the first buds that form after cutting down if they do not show before the middle of August. If they do this remove the bud, and run the shoots on to the next break. Should there happen to be any naturally late-flowering varieties amongst them the buds showing on these before the middle of August had better be retained. Pinch off all side or surplus shoots as fast as they grow, so that the energy of the plants will be confined to the selected stems.

**Treatment of Freesias (Novice).**—In all probability the bulbs were not ripened last year. This may have resulted largely from the cold wet summer. A strong foliage growth, under the full influence of sun and air, is essential after flowering, and after the leaves die down, as they must do gradually and not prematurely. The pots containing them should be stood in a very sunny position, the soil kept quite dry. When the plants are forced early the leaves are often of necessity then drawn up tall and thin, when it is almost impossible for large bulbs to form and ripen. Your non-flowering plants will be best in a frame, with the sashes drawn off on fine days, and nights too; then, if stout foliage is developed, large bulbs will be produced; but if the plants are already drawn, through being grown in a house, they cannot produce bulbs equal to those sold by dealers for producing early flowering plants.

**Cucumber Plants Stationary (S. G. Randall).**—The Cucumber plants had abundance of healthy roots, the soil being a mass of quite clean fibres, not any trace of eelworm, and plants with such roots usually grow and bear well under suitable cultural conditions. The soil is also an excellent medium, plenty of mineral matter in it, so that feeding may be practised to almost any extent. The stem of the plant was sturdy, short jointed, and the growths corresponded, being perfectly free from any parasite, but a solitary green fly. There was no trace of fungus on the leaves, which had good substance, the hairs being quite normal, even in the yellowish parts, they not being in the least disturbed, as usually is the case when the mycelial hyphæ of fungus plants pervade the tissues. We failed to discover any threads in these, the cells containing active protoplasm and nuclei—that is, they were growing. Indeed, we cannot make out anything wrong except the yellow colour of the leaves, this being confined to the older ones, and is a sort of scorching, which might have been prevented by timely shading, for there is no deficiency of chlorophyll in the leaves. We advise shading—lightly coating the lights with a wash formed of whiting and skim milk, and applying when the glass is dry with a whitewash brush, putting on as lightly as possible, so as to diffuse rather than obstruct

## GRAZING.

JUNE, the month of rapid growth, when the herbage of our pastures is most abundant, succulent, and nutritious; the month when store cattle especially are "fed to profit," and grazing land—literally pasture—is turned to full account. This surely is the best time—the best month of the whole twelve which fill the cycle of each year—for a lesson in pasture management. Results of timely and thorough cultivation are before us—the benefit of an annual spring dressing of manure, of winter sheep folding, of all that goes to sustain fertility of soil, to promote a full and early growth of pasture herbage is now apparent, and we do well to endeavour to grasp its full significance.

What head of stock will it carry? is very naturally the test of practical men. Shall we ever be able to answer "a bullock to the acre" of pasture generally? Certainly we ought to do so of all pasture under correct systematic cultivation, because experience wide and long has shown how entirely possible it is to bring pasture up to such a standard of excellence. It may be thought that anything like precision in this matter is impossible; but we are bound to say that with the exception of severe drought, there is nothing in our climate to prevent the free growth of herbage in all good pasture.

Under the present conditions of pasture mismanagement and negligence the growth is very much the sport of weather, growth generally being so much dependent upon rainfall that stock-placing with precision is impossible. This fact had much weight with us in buying cattle recently for some pasture in hand, which we well knew has not had a full dressing of manure for many years—perhaps never since it was laid down to pasture. Looking squarely at the situation, we decided to buy only a limited number of such store cattle as in size, age, and condition might fairly be expected to go off the pasture in autumn—some sooner, some later, ripe for the butcher.

We also resolved that the area reserved for haymaking should be indefinite, depending entirely on the weather during May and the first fortnight in June, our aim being to finish the bullocks well, and to turn what grass could be spared into hay. A dressing of chemical manure, given as soon as possible after the pasture came in hand, should help the grazing, the hay crop, and also the aftermath.

Anything but an easy matter has it been to obtain the class of animal we required at a price on which some profit seemed possible in the end. The first herd we regarded as being rather a bargain, as we got them for £14 10s. apiece. For the second and larger number we gave £17 15s. apiece, the price asked being £18 10s. These were large-framed beasts in their third year in fairly fleshy condition, quite calculated to be off our hands early next autumn, especially as we intend giving them a moderate quantity of Waterloo round feeding cake at once. This is a compound cake to which we give preference for two reasons, the first being its rapid fattening quality, and the second that it cannot well be used wastefully owing to its being so easily digested. In contrast to this, it is well known that cattle can only assimilate a very moderate quantity of pure linseed cake.

It will be understood that the whole thing is to be regarded in the light of an emergency, apart from ordinary practice, just a farm in hand to be made the best of for awhile, and then handed over in good condition to as able a tenant as can be had for it. Should a similar thing happen next year we shall be prepared with a good store of Oats to be crushed and used for

the beasts instead of the cake. This is not a small matter, as now, at the best, our cake bill must prove a heavy item for the thirty-two large steers we have. It is true enough there were plenty of younger ones to be had, but they, too, were high in price, proportionately much higher than older ones, and then the condition of most of them was so deplorable.

It is undoubtedly the purchase of such starveling store cattle that does so much harm to already impoverished farmers. How frequently do we hear of purchased cattle being kept for a year and then sold at a positive loss. Buy cattle on which a profit is possible, or do not have any at all. It is not enough to say there is so much grass that we must have stock; not a single head of stock should be taken to a farm for a result so speculative that a loss on the transaction is practically a certainty.

## WORK ON THE HOME FARM.

Rye Grass and mixed seeds are being mown for hay. Both are a heavy crop, and if the hay is well saved, as there is reason to expect it will be, it will afford some excellent horse fodder. There is plenty of green food now, such as Lucerne, Sainfoin, and Trifolium incarnatum, for all kinds of stock. Lambs are now folded on Sainfoin, as we regret to say winter Tares are rather scarce, but fond as we are of Tares, we desire no sounder or more nourishing green food for the lambs than Sainfoin. The advantage of most of these crops, both for green food and fodder, is so great that we regard most of them as indispensable even on a dairy farm. In bulk of crop, in high nutrition, and in general utility, they are alike excellent.

Green Maize is another fodder crop that is now being sown, either on very rich land or with a liberal dressing of chemical manure. Do not forget the absolute necessity for watching the Maize field during every hour of daylight till the plant is up and growing freely. When ready for use it is so really invaluable, coming in as it does in August, when pastures are bare and brown, and continuing useful till the first sharp frost. The fact that a crop of 30 tons an acre of it is quite possible shows that we should not mind a little extra expense in watching and cultivating it at the outset.

It is quite probable that the scarcity of chickens and ducklings now will lead to a much more general use of incubators and foster mothers next season. With this we advise greater attention to an adequate provision of snug winter quarters for the whole of the fowls to insure plenty of eggs both in winter and early spring. As old hens cease laying a bit later on destroy all at all unhealthy, and either send to the stock pot or sell all others. See that ducklings have a dry floor, with clean dry straw at night, or there may be serious losses from cramp.

Look over the pigeon stock, and make any changes or additions now in view of a plentiful supply for household requirements; also have two or three broods of guinea fowls, as they come in for the table at a time when little game can be had; they are then much in request.

## REMARKS.

26th.—Sunny throughout, but a little hazy at times.

27th.—White mist early, sunny from 9 A.M.

28th.—Bright sunshine throughout.

29th.—Misty early; bright sunny day.

30th.—Hot, rather close, and generally sunny, but cloudy about noon; distant lightning from 9 P.M. to 11 P.M.

31st.—Rain between 2 A.M. and 4 A.M., overcast early; frequent sunshine after 9.30 A.M., and brilliant afternoon; lunar halo in evening.

1st.—Overcast, gloomy, and showery till 10 A.M., occasional sunshine later; slight shower between 4 and 5 P.M.

The heat of Thursday the 30th was quite exceptional, and has only once been exceeded in May for half a century—viz., on May 19th, 1868, when the maximum was 87.6°, or 1.4° higher.—G. J. SYMONS

# LAXTON'S STRAWBERRIES

Messrs. LAXTON will distribute the coming season  
**TWO GRAND NEW STRAWBERRIES,**  
**LAXTONS' LEADER,**  
Large, rich flavoured, early; F.O.C., R.H.S.  
**LAXTONS' MONARCH**  
Enormous wedge-shaped, richly flavoured, main crop,  
brilliant scarlet colour.

Full particulars & prices of ROYAL SOVEREIGN  
And all other varieties on application.  
**LAXTON BROS., BEDFORD**

## PEED'S CALADIUMS.

Awarded a Silver-Gilt Flora Medal at the  
R.H.S. Temple Show, May, 1895.

Reports from the Horticultural Press, May 25, 1895.  
*Gardeners' Chronicle*:—"Messrs. John Peed & Sons staged a collection remarkable for the perfect colour of many of the varieties included. . . . The collection was extremely praiseworthy."  
*The Garden*:—"The best group of Caladiums was that from Messrs. J. Peed & Sons, the plants being noteworthy for their bright colours, and many most charming varieties were shown."  
*The Gardeners' Magazine*:—"Messrs. J. Peed & Sons surpassed themselves with Caladiums; the specimens were of good size, splendidly coloured, and nicely set up."

CALADIUM CATALOGUE free on application.

**JOHN PEED & SONS,**  
Roupell Park Nurseries, LONDON, S.E.

## THE NEW EARLY STRAWBERRY OF 1895, STEVENS' WONDER.

The earliest variety in cultivation and very prolific; solid fruit, good flavour, high perfume.

Awarded First-class Certificates, Royal Horticultural Society, and Royal Botanic Society, 1895. See *Gardeners' Chronicle*, March 2; *Journal of Horticulture*, March 14; and *The Garden*, March 16.

Having purchased the whole of the stock of this grand new early Strawberry from the raiser, we have pleasure in offering it as follows:—

STRONG PLANTS, in Pots, £5 per 100, 15/- per doz.  
" RUNNERS .. .. £3 " " 9/- " "

Ready for delivery early in July. Early Orders requested as stock is limited. Further particulars upon application.

**WM. CUTBUSH & SON,**  
HIGHGATE NURSERIES, LONDON, N., AND BARNET, HERTS.

## PRIMULAS! PRIMULAS! PRIMULAS!

27th YEAR OF DISTRIBUTION.  
WILLIAMS' SUPERB STRAIN, 1/6 per dozen; 10/- per 100.  
CINERARIAS same price; also DOUBLE WHITE PRIMULAS, 6d. each. Package and Carriage free for cash with order.  
**JOHN STEVENS, The Nurseries, COVENTRY.**

## FOWLER'S LAWN SAND.

Established 20 Years.

UNEQUALLED AS A FERTILIZER FOR LAWNS AND FOR THE CERTAIN DESTRUCTION OF DAISIES, PLANTAINS AND OTHER WEEDS.  
A Trial Tin will prove its efficacy.

PRICES: In Tins, 1/-, 2/6, 5/-; and in Casks, 28lbs. 8/6; 56lbs., 16/-; 112lbs. 30/- each.

To be had of the Seed and Nursery Trade generally.  
Manufacturers: **CORRY & CO., Ltd., LONDON**

THURSDAY, JUNE 13, 1895.

## THE ART OF KEEPING THE SOIL MOIST.

IT is not so much how to make dry soil wet as to consider how best to counteract excessive heat and drought that is the purpose in view. The weather is dry now. If rain falls before these notes are printed so much the better; it will do more good than all the papers, still the art of keeping the soil moist should be learned by all cultivators.

In hot seasons heavy land suffers least from drought, but unless the soil of such is very thoroughly pulverised it is certain to crack deeply and shrink into compact blocks, which first prevent tender rootlets travelling, and secondly become parched lumps. When well pulverised, however, and when the subsoil is damp, heat and drought only make the plants thrive the faster. As clay soils which are dug in autumn and early winter are in most districts pretty solid by spring, unless thorough forking is done, drought soon proves disastrous. Dug in spring and broken up then drought tells but lightly.

It is exactly the opposite with light sandy or gravelly soils. It is working much mischief to fork or dig these up lightly in spring or early summer, for they are thus prevented from exercising that capillary attraction which draws water from below and maintains a steady moisture when such soils have become somewhat firm by lying long or by being artificially firmed. Those who advise a liberal use of the fork will find it quite right on heavy soils which naturally become compact; but those who on gravelly or sandy soil take such advice will find that "someone has blundered," for it would be found that it would be as hopeful to water the Sahara as to moisten such soil.

While the mechanical condition of the soil has much to do with its moistness or dryness, it not unfrequently happens that plants apparently suffer through want of water, when in fact it is nitrogen that is wanting. A week ago the writer met a farmer bemoaning the want of rain. His hay crop was a failure, apparently with drought. Over the fence was the finest crop ever seen, and the owner of that other field was hoping "we wadna hae rain, it wad

lay the hey." The first field was suffering from starvation, the second had been, if anything, overfed by liquid manure from the farmyard. Garden crops take up much nitrogen; usually the manure is not over-rich in that, and bad treatment makes it worse. Those who are suffering "from drought" might do worse than use a little sulphate of ammonia or nitrate of soda next time watering is done. In nine cases out of ten it will be found to almost do instead of water.

At present those who have summer beds to fill and winter vegetables in want of planting will not be in an easy frame of mind. When there is water in abundance laid on in pipes and applied with a hose matters are all right; but those who have to carry it in cans, even though it is plentiful, are to be pitied, for such work is comparable to that of Mrs. Partington's when she tried to keep back the tide with a mop. If anything we can say could induce owners to lay on plenty of water and hose for applying it we would say it earnestly, for they are mis-spending money if they are paying for carrying water, when it would a thousand times more effectually run itself.

When planting must be done in dry weather and watering appliances ineffectual it is more than half the battle to have strong plants with a mass of earth and manure adhering to their roots. Plants put in deeply, planted firm with dry soil, a little cup-shaped basin left round each to be filled with water, and after that soaks away, with soil, will not suffer for a long time, for the loose earth will be the means of preventing the water escaping into the air. On a large scale, such as the planting of Cabbages, it will be found a good plan to draw a deep furrow in which to insert the plants (from beds where they were pricked-out previously among half loam, half manure) without the loss of a fibre if possible, and then to fill each furrow with water. The evening is the best time to do this. In the morning dry soil should be made to cover the moist surface to prevent evaporation. No matter how fierce the heat, we have never found plants so treated suffer, and when in a week the roots have pushed it has been found of incalculable advantage to give each a little liquid manure.

Strawberry beds are most likely to suffer in hot weather. If so the surface should be deeply hoed, nitrate of soda sprinkled between the rows, and not a sprinkling but a flooding of water given. If the beds have been mulched with ordinary manure some time before, they are not so likely to suffer; if not, a good mulching should be given as speedily as possible. Long grass is as good as anything, short chaffy lawn grass the very worst. Tan is good, as it keeps the fruit clean, does not prevent water descending, but keeps it from ascending, and after one good washing is very clean.

In the vegetable quarters nothing will keep the soil moist equal to a good coating of partly decayed manure, and often manure so applied is much more effective than when dug-in in the usual manner. Machine grass between the rows of Cabbages is very effective, a very little thoroughly protecting the soil.

In beds and borders leaf soil is of incalculable advantage applied an inch thick over the surface. Soil moistened now and so protected will enable the plants to grow luxuriantly without further watering for a long time. After the surface is covered with vegetation and the roots have burrowed 18 inches drought is not likely to do more than to cause a denser inflorescence. Cocoa-nut fibre is even better still, though hardly so neat, but the luxuriance following its use speedily puts the fibre out of sight though not of usefulness.

Even common soil makes a good mulch. Wrong though it be to turn the body of the soil into a loose mass, it is of great benefit to have an inch or so of loose soil on the surface. For this reason the soil should be thoroughly hoed, and that repeatedly, especially after watering.

The watering-can in inexperienced hands is a source of much mischief. It looks so nice in the stilly evening to have the surface of the ground all dark with damp that the temptation to sprinkle

is too much for many. Either a soaking that will penetrate a foot at least or nothing should be given. Then the surface should be stirred as soon as dry enough, unless otherwise protected by mulching. Dribbling the surface is worse than drought. It robs the soil of heat and stops the growth of plants. It entices the roots to the surface only to be killed.

When water is applied it is of much service to have it exposed some time previously to the sun and air. Pond or river water is undoubtedly best, but many places are supplied by springs and deep wells. Such water is always cold, and when applied cold it gives roots a check. Soft water is known to be best, and exposure not only warms but softens it. When tanks cannot be provided for this purpose it would pay to pass the water through an ordinary heating boiler, under which burnt a good fire, especially when the water is to be applied to Vine or Peach borders. In the case of Melons, the cans if stood in the house or frame will enable the water to attain a suitable temperature in an hour or two.

When the soil is moist, or made so and kept so, plants use the food at their disposal rapidly, and in the sunshine turn the feeding to good purpose. In dull wet weather richness does mischief often. In hot weather it is turned to riches. In gloomy years plant food abundantly applied runs into a plenitude of shoots and leaves. When the sun is out it is turned to fruit for this year, and fruit buds for next. For this reason it is good to help flagging trees now, not only with water, but water with "a cinder in it." Stable drainage, sewage, guano water, nitrate of soda or ammonia salts applied to fruit trees and bushes now will well repay in due season.

In applying water to fruit trees it is well to remove an inch or so of soil and to form a basin rim with it; then fork another inch, and flood with liquid manure the trees needing assistance. Afterwards return the removed soil, it will act as a mulch; or, better, mulch thickly with manure.

Under the hot sun and drying winds fruit trees under glass evaporate with extreme rapidity. It is well to remember that the harder the pump-handle is plied the sooner the well goes dry; and it may be worth mention that soils which furnish food in abundance are not so much "drawn on" as others. Feed a man on rice or Potatoes and he must consume large quantities. Feed plants on water with hardly traces of the food they want, and they will try to make up for it by passing greater quantities through their system. This fact accounts for the chronic drought from which starved fields suffer.

In battling with heat and drought, then, we should aim at securing that texture of soil which best favours retention of water and maintains the greatest capillary power. To soak thoroughly and avoid dribbling; to have as strong plants to put out as possible, to injure none of their roots in the process, and to apply the water under the surface; to mulch whenever practicable, and with the best material at command, be it only loose earth; to seize such opportunities for administering food when possible, and to remember that often enough it is not so much water as nitrogen that is wanted, as well as, perhaps, other food; and last, not least, that under a bright sun plants work rapidly, maturing the present crop and storing matter, if properly fed, for the crops of the future.—A. H.

PHAIUS COOKSONIÆ.

SEVERAL Orchids were shown at the Drill Hall in competition for a special prize that was offered for the best seedling, and Phaius Cooksoniæ (see fig. 92) was adjudged the coveted honour

The sepals and petals are of a peculiar buff shade, with flushings of rose. The lip is superb, being purplish rose at the outer portion, and yellow mottled with brown in the throat. It is a hybrid obtained from *P. Humbloti* and *P. grandifolius*, and was staged by Mr. W. Murray, gardener to Norman Cookson, Esq., Wylam-on-Tyne.

ODONTOGLOSSUM HALLI XANTHOGLOSSUM.

This is a very fine and beautiful *Odontoglossum*, differing principally from *O. Halli* in having a bright yellow in place of a

FIG. 92.—PHAIUS COOKSONIÆ.

white lip. The sepals and petals are massive in the best forms, and their clear bright yellow colouring contrasts well with the chestnut and purple blotches and markings. *O. Halli* thrives under the coolest treatment, and is a very restless Orchid, frequently pushing new growth in the middle of the winter. It is also a free-rooting species, and thrives well in rather larger pots than *O. crispum*. The compost may be similar, and the drainage must be perfect, as, like all in this section, it must have adequate supplies of water at the roots.

During the present bright weather, and with the drying winds prevailing, it is very difficult to keep the atmosphere of the cool house as moist as is necessary, heavy shadings and constant dampings being the order of the day. Light sprinklings too are now of great service, especially in the afternoons. A little air left on top of the house is also advisable, the atmosphere feeling fresher, and not so stuffy in the mornings as when the ventilators are kept closed all night.—H. R. R.

ORCHIDS IN "MY GARDEN."

At all times of the year Orchids in greater or lesser numbers may be found in bloom in this garden, and, as will readily be understood, an abundance of bloom is now to be seen. Later on a novelty will be found in the collection of Orchids placed under the trees over a narrow stream that winds through the garden. Here they flower profusely and look singularly beautiful, and Orchid lovers would do well to make a journey to Hackbridge to see them. Mr. A. H. Smee and his gardener, Mr. G. W. Cummins, are ever ready to unloose their stores of information for the callers who are lovers of flowers. Of course at the time of my visit the plants had not yet been transferred to their summer quarters, but were growing well indoors.

Cattleyas, of which the collection is a very fine one, were making the most varied display about three weeks ago, a very large number being then in flower. Varieties of *Mossia* were conspicuous by their handsome flowers of various shades of colour, and also by the splendid health of the plants. *Lælias*, too, made a glorious display, and are not so far past their very best to prevent one seeing what some of the flowers have been, both as regards size and colour. *Cypripediums* are also grown somewhat extensively, but only a few were in bloom at the time of this visit, and of these the best was probably *Chamberlainianum*.

In the *Odontoglossum* house several superb spikes of bloom

were noticeable, especially in the *crispum* section. The flowers portrayed elegance of form with delicacy of colouration such as is so greatly admired in these beautiful Orchids. Here again, as with the Cattleyas, the best of health was plainly perceptible in the strong growth of the many plants. Lending brightness to this house were several plants of *Epidendrum vitellinum majus* carrying numbers of flowers of good size and very rich shade. *Masdevallias* in another house lent diversity and beauty, while *Aërides Fieldingi*, the Fox Brush Orchid, tended materially to the same end.—H.

MEN AND MANNERS.

SOME reasons—good ones obviously—should be given for approaching a subject which may not inaptly be termed delicate; else an apology is due, and that is no reason at all. True, we may have to go a little beyond the practical routine of horticulture, even into the philosophy of life, to find them. Various impressions are afforded by viewing a subject from different angles or from different altitudes, and though one may be sufficiently elevated in position to look down on the little things of life, they may not be looked over or despised. Some, at least, will acknowledge the helpfulness such have been to them in attaining that position, and maintaining it with a dignity which adorns their station in life.

Probably there are many gardeners (head gardeners) who have felt the necessity of impressing on their young men the need of observing those outward and visible forms of respect due to the family they serve, or, in fact, due to all, for good manners of the best type are not put on and off to serve occasion. Possibly there are some who have at times felt some anxiety on this account. One illustration may be given of a young foreman, who was deputed with a caution to show round an expected visitor of rank, in the absence of the "head," and who expended all his courtesy on the gentleman's gentleman (the valet), finding too late that the less imposing personage coming in unobtrusively afterwards was the rightful recipient.

Observations of a quiet life solely devoted to that art beloved of readers of these pages leads to the inference that a little moral teaching of this kind is not out of place, although it does little here beyond showing its importance to those who have yet the world before them. True courtesy can hardly in fact be taught, springing, as it appears to do, from a nobler source; but there are

FIG. 93.—CYPRIPEDIUM BELLATULUM ALBUM. (See page 525.)

so many checks and hindrances to its proper development that it may be very effectually disguised. It needs cultivation by constant exercise, or it is choked by neglect, and manners good or bad are essentially contagious. Consciously or unconsciously, the cue which has been given to us by actors now passed from the drama of life is appropriated by those passing their novitiate in our company. This may be borne in mind by all. That the more plastic

material of younger minds is very susceptible of impressions must be admitted. A little reflection will show that we elders have brought forward into our lives some of the manners of our teachers, to be again carried on by others into theirs, and this imitation, if of the right kind, is the sincerest form of flattery. Further reflection will throw out the stronger light of responsibility it carries with it.

From personal experience instances might be quoted of places where an unwritten (not unexpressed) law prevailed that the young men should be of good manners and good appearance. The latter part of the stipulation is not here to the point, only so far as may be allowed that courteous behaviour is an important accessory to appearance whatever that appearance may be. Probably this experience can be endorsed by others, who have found in some shortcomings of their subordinates the cause of a reproof from headquarters, with the unpleasant duty of passing it on to those whom it directly concerned. One worthy old gardener did, who framed an apology for a lad by saying, "Well, my lady, his manners are no' verra guid, but he has plenty o' them." In this case excess of zeal had prevented that nice discrimination between servility and courtesy, resulting in manners which were offensive. But quantity will not atone for quality; hence I would point the moral to a rising generation and say, Cultivate good manners as assiduously as you would cultivate your plants for judicial inspection at a flower show—nay, more so, for gardeners of all men are always under judgment by experts in judging of men and manners.

Passing on to another phase of the subject hardly secondary in importance we may note how pupils not only grasp the letter of the teaching, but catch the spirit of the teacher. We see how energy, perseverance, and kindred virtues, which may be summed up under the head of smartness, are by some form of animal magnetism conveyed and made to permeate the staff. Wellington remarked, "Had Buonaparte been with the army in Spain the moral force of his name would have been equal to 40,000 men." It may not be easy to apply this moral of war to the art of peace; yet it is not difficult to recognise the attributes which insure victory in our field of work.

The power of will is a mighty lever, and there are but few obstacles barring the road to success that it is not able to remove. We need it, for the go-easy manner of gardening is now ancient history. We think, act, work, and live in an atmosphere heavily charged with the electric conditions of a new manner of living. All this means wear and tear to the human engine, and never was there more need of that valuable lubricant a cheerful manner to keep all running smoothly. Without it this rapid rolling of the wheels of life brings the danger of friction. Fortunately there is a refining influence in gardening which is a potent factor in character formation, but unfortunately there are elements in it playing at cross purposes, producing with some conditions of men examples which may be termed touchy. This touchiness is productive of much discomfort to all concerned, especially to the touchy one. Good and capable man he is goes without saying, for it is from the vantage ground of skill he overlooks a graciousness of manner. No advocacy of weakness is to be deduced from this, for firmness and courtesy may go hand in hand.

Truly there are crops of uncomfortable things perpetually springing up, only waiting for a little nursing to develop into noxious growth. A rough manner oft covers a kindly heart; in some cases so completely that it is a matter of surprise to find such exists, and it seems a matter for regret that an ever kindly heart should be thus cloaked, for all its beams are wanted to cheer on our young travellers in the arduous path. In all the varying conditions of life (our life), and to all men diversely gifted, there are times when the wisdom of the following quotation is at least worthy of trial, viz., "If thou art a master be sometimes blind, if a servant sometimes deaf."—OBSERVER.

## LILIES IN ABUNDANCE.

In the heart of most people lurks a love of flowers. Of course, in some the flame of love burns ardently, in others, well, there is just a living spark, and that is all. If it were left to "the masses," and possibly to the "classes," too, to decide on the favourite English flowers, the votes would go for "the Rose and the Lily and the Daffydowndilly." During the summer season there are few who fail to become possessors of at least one bunch of Roses, so many flowers come under that head, and so few, alas! come up to the perfect type. Far be it from me to deprecate humble efforts, but even the smallest and weakest grower might do a little to improve the culture of this queen of flowers. A little pruning at least, a little attention to situation, and a little manure do work

such wonders. Even in large gardens, presided over by "Mr. Prunewell," somehow or other he or his satellites pass by on the other side, and leave the standards with heads like pollard Willows, and the dwarfs with too crowded a growth of small shoots, and occasionally something suspiciously like Manetti. But this is not Lilies. In the winter months town folk see in the best florists' windows pots of magnificent forced Lilies, which go to adorn the mansions of the great; later appear buttonholes, whose modest price brings them within reach of those who can afford a few pence for the gratification of eye and nose. Between Easter and Whitsuntide, but like them a moveable feast, appear bunched up masses of partially opened flowers surrounded with a fringe of green leaves, about as unnatural in appearance as can possibly be made, and the flowers bearing as much resemblance to their forced sisters as the Crab of the hedgerow to a good ripe Blenheim Orange. Now this is about what thousands of our countrymen ever see of Lilies, and even under these depressing conditions their loyalty to the flower continues strong.

Will you see and hear of better things, such things as I saw only the other day? You shall see woodland Lilies to perfection. Our ticket, by the courtesy of a noble lord, admits four between the hours of twelve and seven. The walk is almost too wearying, and there is stabling at the head-keeper's. The entrance lodge, with its fantastic gables and black beams, takes you in memory to the western counties. Two magnificent Copper Beeches flank the gate; a broad drive, beautifully kept, with wide grassy borders, and beyond them for some distance runs a line of Yews that have braved many a severe storm of heavy snow and sharp frost. Here and there are Scotch Firs, Beeches, and in the open parts a graceful Deodara, but the main part of the wood is Oak. There are at intervals broad open spaces where the young trees are planted, in various stages of growth, of course. In the youngest plantations abound flowers of every hue and shape, for this bit of country is rich in its flora. In the heart of the wood we will put up. There we find the head-keeper's lodge and his pheasantry; they mean to rear 3000 young birds this year. What we want to see and do next is best done on foot. The rides are broad, undulating and charming. You do not go far before the eye is attracted by a close growth that comes up almost to your feet. The leaf is suspiciously like a Lily; but yet, can that be! Turn which way you will, walk till your legs are weary and your back will bend no more, or rather perhaps will no more straighten, still the same sight; acres on acres, up to a thousand, and still the dense green foliage, and among it the sweet bell-like flower.

The fantastic twigs of the Oak with its young leaves make a network of glory against the blue sky. Here and there the tall Columbine, purple, blue, or white, gently tosses its plumed head. A stately cock pheasant struts past unmoved; the air is full of the song of birds, the hum of bees, and the scent of flowers. You may sit down and gather a large bunch of Lilies just where you are, but you cannot do that; you move on and on, human nature is so strong, and you think there may be even better beyond. Now is the time to remember absent friends, and bunch after bunch is carefully laid aside in the basket your provident guide supplied—a basket of whose dimensions you were inclined to jeer on leaving home. You ask if this earthly paradise is public? Practically so, as tickets are given to every respectable applicant, and the pleasure given cannot be counted by the tickets issued. You may and possibly have seen glorious gardens which are the pride and glory of the stately homes of England; but did you ever see anything that gave you such pure pleasure as this garden of God's own planting, where Nature has her way untrammelled and Nature's children play around her knee?

I write a plain unvarnished tale, but it is simply a true picture of what I have seen so often that I would fain have others see as it were through my eyes, though language is inadequate, and the pen of the readiest quails before describing the haunt of the Lily in the great woods of N. Lincolnshire during a visit at Whitsuntide.—H. G. F.

## HARDY FLOWER NOTES.

So far as weather went the month of May well deserved the appellation of the "merry month." Cloudless skies and brilliant sunshine prevailed almost every day, and were we not inveterate grumblers those of us who are growers of hardy flowers might join cordially in singing the praises of the past month. Yet we cannot but think of the flowers which seem to enjoy alternations of cloudy and sunny days, and which have this year displayed their blossoms for a shorter period than usual, unable to stand longer the power of that orb which, after all, seems to call them into being. Some of these opened to delight us with their frail and fleeting yet beautiful blooms, and soon shrivelled under the heat

and drought which accompanied their flowering days. Still, with all, we have had a royal time among the flowers, and though tempted at times to look ruefully at the work of watering some of our alpine plants, we can look back with pleasure on the depth and fulness of the enjoyment of the garden's treasures.

As the month drew to an end and June was ushered in, fair was the scene still presented to view. Crowning a rockery, protected from the north and east by a thick hedge, the Golden Drop (*Onosma taurica*) was very attractive with its prettily shaped tubular flowers exhaling their perfume of almonds. At the base one of the best of the Alpine Bugles, *Ajuga genevensis* Brockbanki, showed its spikes of deep blue flowers. Near by the first of the Eastern Poppies, a seedling of *P. orientale*, had opened its great scarlet blooms. Clumps of *Alyssum gemonense* strove to supply the place once filled by its earlier sister *A. saxatile*, with its "gold-dust" flowers. The "Columbine commendable," as the old poet Skelton called it, was very pretty in its varied colours, and still more varied shades. The pleasing little *Geranium lancastriense* had opened its pretty flowers; *Dodecatheons* were still in bloom, with their quaint-looking and beautiful flowers; and *Iris*es, *Saxifrag*es, *Pyrethrums*, *Calochorti*, *Hutchinsia*, *Scillas*, *Cornflowers*, and many others combined their beauty to wed us to the garden in which they dwell. There is thus no lack of texts from which to discourse, and as we pass along the walks we may select a few flowers for remark.

The "Golden State" of California has yielded us many very beautiful flowers of both perennial and annual habits. Some of these, unfortunately, fail to accommodate themselves to our climate, and too often we have to mourn their loss. In the genus *Brodiaea*, named in honour of a fellow Scotsman (J. J. Brodie) who was devoted to other forms of vegetation, we have some pretty bulbs, some of which are hardy in most localities in this kingdom. Among these is *B. Howelli*, the typical variety of which has purplish blue flowers, produced in umbels on long slender stems. It was introduced from California in 1880, but is not yet much seen in gardens, even where bulbous plants are largely grown. It is, however, of a new variety of this species that I wish to speak, this being known as *B. Howelli lilacina*. It came to me by way of Holland, its history being that it was received by a bulb merchant there among collected bulbs of the type, and on flowering was named *lilacina* as a distinctive title. Very pretty is it, and well worthy of being grown in good collections. Its colour here is of the palest lilac, approaching white. It might possibly be deeper in colour if grown in full sun, but it has been planted in a place where it is partly shaded by the branches of a Lilac tree, so that it is screened from the rays of the sun. It is about 18 inches high, and has withstood the past winter without any covering in a border of sandy soil.

As I write Poppies are very fine, and before long they will be still more largely represented. Growers of hardy flowers are naturally desirous of increasing the variety of form and colour at present at command. There are several of the colour which seems to be pretty generally accepted as "salmon" colour, such as *Papavers pilosum* and *rupifragum*. This year I have flowered for the first time the variety of *rupifragum* known as *atlanticum*, and should it retain its present habit am inclined to think it is an acquisition of considerable worth. Some time ago I read the description of this Poppy in the "Journal of the Linnean Society, Botany xvi.," page 313, but could not succeed in hearing where it could be obtained until Mr. J. N. Gerard of New Jersey very kindly sent me some seeds from which my plants were raised. It is a neater and dwarfer plant than *P. rupifragum*, and with better formed flowers of much the same shade. It was found on the sub-alpine regions of the Greater Atlas, in Morocco. What would be very desirable would be some white and crimson forms of these Poppies.

These notes would fail to do justice to one of the best of the hardy flowers in bloom at this season did they not make mention of a very beautiful *Anemone* which has been much admired this year in the border. This is *A. narcissiflora*, introduced more than 120 years ago, but still all too rare even in good gardens. It is strange that so many charming plants, which were introduced more than a hundred years ago, are yet seldom seen. *A. narcissiflora* grows about a foot high, and has numerous pretty white flowers of upright habit. These individual flowers remind one somewhat of those of some of the *Narcissi*, so that its specific name seems appropriate enough. It is a useful plant for the border or rockery, and will be found rather variable, which adds to the interest of several plants. Its beauty will commend it, and it is besides one of the flowers which, from having been grown in our gardens so long, help to link us, in thought at least, to the many who in days past loved their flowers, and whom we can think of as we gaze on plants they cared for ere they passed from this mortal life.—S. ARNOTT.

## IN THE MIDLANDS.

THOUGH *Violas* and *Pansies* formed the object of the pilgrimage to the Midlands last week (page 493), a glance may perhaps be taken at one or two "side issues," though there are certain people in the world so constituted as to more than smile at what they might possibly regard as the derogatory comparison. Fancy *Pansies* and *Violas* standing before gold and diamonds! before a forest of *Orchids*! and before a great speech by Mr. Chamberlain! Is it not too absurd? There, something has slipped out and may now as well fall in with the rest in the record of experiences.

MR. CHAMBERLAIN.

Let no one of tender susceptibilities be alarmed of any intention to raise "cheers and counter cheers" by the mention of a name. For this particular occasion the right hon. gentleman shall not be regarded in the least as a politician, but as an interesting personage and an ardent amateur horticulturist. "But that speech; did you really hear it?" That is the way of the world—give a hint and it wants to know the rest; and it is a happy circumstance that we can enjoy an intellectual exposition as such, whether adherence be given or not to the sentiments uttered. Well, then the writer did hear "that speech," and laughed with the rest at the smart points of the great—orchidist.

But it was all accidental. The grand Town Hall was lighted, curiosity being thereby evoked, and the facts elicited. "London Press; pass me in quick, please," and I was in front of the platform forthwith, face to face with the lover of flowers. It was a sight not to have missed—a quiet, cool, pale-faced man, holding a packed audience of thousands in the hollow of his hand, drawing the cheers and laughter alternately as easily—well, as drawing corks; then, while the multitude settled down, quietly arranging mentally the terms of another rhetorical shot. The coolness, the deliberateness, the consummate ease, the seeming nonchalance is indescribable. There is no rapid rush of eloquence, like wave dashing on wave interminably, but every sentence, and often every word, stands alone—clear, distinct, and telling. It must be a treat to the reporters. Mr. Chamberlain could have kept his cigar going all the time, as he did during his after dinner speech in celebration of a great show in the Aston Park Grounds some years ago, and that is more than some of our lecturers on horticulture could do—if they had the cigar.

## JEWELS AND FLOWERS.

The Town Hall gathering was the night before the Pansy show. On the day after it inquiries were made for Tenby Street. "Snow Hill by cable tram to Hall Street, then ask again," was the line of guidance. Birmingham is ahead of London with trams. In London and its suburbs horses are, with few exceptions, relied on. In Birmingham they are superseded by steam trams, electric trams, and cable trams; the City, in fact, seems to be up to date. It has noble buildings with handsome streets, and all so clean, the chief wood-paved thoroughfares being washed every night, and in the morning all seems fresh and sweet. Tenby Street is not in a palatial part of the City, but in the "jewellery quarter," in which everything, from the cheapest to the most costly articles, belonging to the order of pomps and vanities are provided for the civilised and uncivilised world. It is hardly necessary to say that the street named is the business centre of the Messrs. Sydenham—a name as well known in the floral as the jewellery world, and brought into prominence in both by genuine business enterprise.

## THE DIAMOND EYE.

There are three Sydenham Brothers, and all appear to be "gone" on flowers; but one of them, the elder (Mr. George Sydenham), has to restrain his tastes in that direction through fear. Of what? Few would guess, at least correctly, if they tried for a year. It is lest he should lose his "diamond eye." It must not be thought he is like the fabled toad, and carries a jewel in his head, or wears it as an eye substitute or anything of that sort. The jewels are much less prominent as a rule. This elder brother of the trio says, if he were to watch bulbs and seeds "like Robert," and peer into rayless *Pansies*, searching for hair-like streaks, "like William," his eye would get out of joint for diamonds. He did not use the exact words, but meant them. That was clear enough, as he took out a handful of paper packets to show as might be expected samples of flower seeds, but really hundreds of glittering diamonds—some the size of Larkspur seed, some larger, some smaller. To the ordinary eye there seemed no difference between them, except in size, yet they differ in value widely; but the true value of each can only be determined by the finely trained and highly educated "diamond eye." These gems are set in pins, brooches, rings, sprays, chains, bracelets, necklets, coronets, and stored in trays in strong rooms, preparatory to their dispatch to retail tradesmen all over the kingdom. It would almost seem as if the diamond Sydenham looked after their production, the bulb and Pansy Sydenhams their distribution, keeping at the same time an "eye" on other things, and a pretty sharp one too. These other things are no doubt regarded as jewels in their way, for the bulbs and seeds yield floral gems, and *Pansies* and *Violas* glitter in the sunlight.

It must not be imagined we have been gossiping about a jeweller's shop having windows curtained with chains and bedecked with all kinds of "vanities" on velvet stands. No, the Tenby Street building is more like a bank, with mahogany counters and rows of clerks and

packers, with stacks of small boxes handy, for it is a huge postal business, and the cost of registered packages must be a very large item indeed. A square tower, thick and strong, proof against fire and burglars, is separately built within, and through the building from foundation to roof. Out of this the strong rooms open on every floor and into every room; but after all such provision for security the rooms are never left, while the chief caretaker is expected to be a man who knows no fear and can shoot. This "touch" of Birmingham life may not be wholly uninteresting; it is at least a change from the garden life with which the thousands who read these lines are familiar, and it can only be wished that it were a pleasurable or profitable life to them all, though it may not be beset with diamonds. Yet all the same, gardening adds a charm to life, and makes it better worth living.

#### THE GENESIS AND GROWTH OF A TRADE.

The Sydenhams, amidst all their costly mineral gems, could not live happily without their gardens; and it was in making purchases for them which led their friends and neighbours to desire to "join in," and in this way avail themselves of the judgment of the then amateur experts. The circle widened yearly in increasing proportion till the commissions became formidable. Thus were the caterers forced into business—not very reluctantly, perhaps, but forced all the same; and when a Birmingham man reckons to do "business" he does not do it in a sleepy way. With untiring perseverance one brother set himself to master one branch, another a different one, thus adding to capital, knowledge, the third all the time keeping his diamond eye. No one could see the great warehouse provision and adaptability to the purpose of bulbs and seeds, with the completeness of all working details, without being surprised that so much could have been accomplished in such comparatively little time. A wonderful trade has, so to say, "sprung up," and surprised even its originators. Nor does it follow at all that they have "taken the trade" from others. They have made hundreds and thousands of persons ardent flower lovers and growers who but for them would never have become fascinated with the pursuit. Their trade organisation enabled them to reach a constituency practically otherwise unreachable. The few bulbs set a rolling and seeds scattered created a demand for more. The love of flowers and gardens extending, brisk legitimate business methods were adopted to foster still farther extension, trade expanding as a consequence, and that may be said to be the long and the short of it. So now we pass on.

#### MR. ROBERT SYDENHAM'S GARDEN.

In order to reach this, and it was worth reaching, we had to drive across the city—from the "jewellery quarter," where money is made and diamonds sorted, to the suburbs, where the results are enjoyed. The Bristol Road is a long, straight, avenue-like thoroughfare, as far as the eye can reach, with attractive villas and mansions all the way, having trey frontages, and gardens in the rear. A pleasant part to live in surely, with nothing suggestive of the proximity of a smoky town. The mere size of a garden is no measure of its capacity for affording interest and pleasure to its owner and friends. Mr. Sydenham's domain is perhaps not more than an acre all told, and a third of this tennis lawn. He employs three men and a boy to keep it in order. There are no fruit houses, nor any vegetables grown beyond salads. "Then it ought to be in order," many a too hardly worked gardener will be ready to exclaim. It is indeed in such order as is seldom seen—a very paradise of a suburban garden.

There is the little undulating lawn with its rockery and alpine plants, with curving side borders of shrubs and hardy flowers, with its front line of *Violas* backed by bright bedding plants, then a hedge and another section, a good part devoted to a trial of the choicest Sweet Peas planted from pots, each group of four or five plants to be grown as a "specimen." Square blue Staffordshire tiles are laid in exact line, and at exact distances for stepping on and passing among the Peas to avoid trampling on the soil, and bringing some of it on the smooth, clean, gravelled paths. Another "quarter" is mainly devoted to narrow span-roofed houses now occupied with the best varieties of florists' *Carnations* in pots. The collection is extensive, and the plants, of which three or four are grown in a 10-inch pot, are in admirable condition. The side and roof lights are removed, but placed in position later, the houses being thus admirably adapted for *Cyclamens* and other plants, as adequate provision is made for heating. A span-roofed greenhouse and stove contain a well chosen assortment of plants in the best cultural condition, including all Mr. Davis's (of Yeovil) best double *Begonias*, the blooms of which attract so much attention at provincial exhibitions.

The side borders of the little enclosure are made interestingly gay by plants raised from the best procurable stocks of tender annuals, while those on two sides of the tennis lawn are occupied with shrubs and hardy flowers arranged by the late Mr. William Dean, the opposite side being devoted mainly to an extensive collection of *Dahlias* with a marginal line of Mr. Herbert's new *Margaret Carnations*—not *Pinks* in this case, but a strain between them and true *Carnations*, the flowers having smooth, not serrated petals. On one side of his charming enclosure Mr. Sydenham has a pretty summer-house in which the Scottish contingent of *Pansy* growers were having tea, or something else, and exclaiming in much more than Chamberlainian excitement on the perfection of all they saw around them, not forgetting the leafy cave of the "Forty Thieves" behind the greenhouse opposite. This is the commissariat department, where various kinds of soils, manures, and other requisites are stored in a row of barrels; not second-handed, dingy-looking affairs, but properly painted and varnished, in order that they may "adorn" the position they occupy in a garden without a weed, borders without a

footmark, lawns without a daisy, paths and edges without a fault, and in which nothing can be seen that "wants doing," yet all the men seeming busy, as if they had enough to do, as no doubt they have, to keep everything in such superb condition. There is no wonder that visitors to such a garden should be tempted to add beauty to their homes in a similar way, as many have done; and it is certain that the "Sydenhams" have, in one way and another, enlisted an army of recruits in the service of floriculture.

#### MR. CHAMBERLAIN'S GARDEN.

Highbury is not far from King's Heath Station, but on the sultry day a drive of a couple of miles or so from the small garden to the great one was preferable to the railway. There is no intention to write a description of this garden and its contents. An Orchid specialist with a long day before him would be needed for that, instead of an evening call of an hour's duration, when not half the houses were entered; it was not an inspection, but a mere "march past." At the particular hour in question Mr. Burbery, the skilled Orchid grower, was absent, but the still new, very courteous, and admittedly able head gardener, Mr. Deacon, gave every attention to his visitor. So far as could be gathered there is a time for work mainly, and a time for enjoyment, more particularly, in the Highbury gardens. The London parliamentary session is the working or preparing time, and if Mr. Chamberlain return for a week, such as on the occasion of a Whitsuntide holiday, this is not supposed to interfere with the ordinary routine, but when the session is over and the family established at home, then the gardens are kept in the best dress and most attractive condition.

As they would say on the Continent, Mr. Chamberlain is a "great amateur." He is no sportsman, neither indulging in hunting, shooting, racing, golfing, nor popular exercises of any such nature. The garden is his delight—his haven of rest after the turmoil of political combat. It can be safely said it has not made him effeminate, for if ever there was a fighting general we find him in the master of Highbury. A good master, too, to his men, all of whom are well recompensed for their labour, those who are responsible being afforded everything that is necessary for the satisfactory discharge of their duties. When ten tons of coke were consumed weekly during the severe weather early in the year there was not a murmur; it was simply necessary provision under the circumstances, and as such passed without comment. It is pleasant for gardeners to work for proprietors who are not only appreciative but practical.

Mr. Chamberlain may be very correctly described as a practical amateur. Some persons possess gardens, but know little about what is in them, and next to nothing of what is required in culture and maintenance. This is not so at Highbury. It must add greatly to the enjoyment of a garden by its owner to know all the trees and plants that are grown in it, as well as their needs, and greatly to the peace of mind of a gardener too, but he must be a good one or would soon be found out. Mr. Deacon has not been kindly treated by the weather, as a beginning, for he was closely followed by the ten weeks' frost, and then had to clear away the wreckage from the shrubberies—or winter work thrown into spring and early summer; but he will soon bring up arrears and have things to his liking; moreover, when extra work really presses there is no difficulty about extra men, so that a gardener has a fair chance to succeed at Highbury.

The pleasure grounds are extensive, and much planting has been done from time to time. Hardy border flowers are grown in great colonies, not dotted here and there in the orthodox mixture, but rather fifty or a hundred or more in a group. Of *Irises* there seem to be thousands; indeed, whatever is most liked is grown in profusion. The grounds are beautifully undulated, and the banks of *Rhododendrons* would have been grand but for the burning sun and prolonged drought. However, water is laid on, and Mr. Chamberlain was giving instructions for its use where most wanted, for, as he observed, everything cannot be watered over such an extent of ground. He knows all the trees and shrubs, and those which succeed best in the district, and was noting with satisfaction how well *Retinosporas* had passed the wintry ordeal.

The Highbury gardens are, however, the most famed for the glass department, or the portion devoted to plants. Adjoining the mansion is a large and lofty conservatory containing magnificent *Palms*. At one end a large bed of *Lilium Harrisii* was a prominent feature, and at the other a similar bed of *Hedychium Gardnerianum* not long since filled the house with fragrance. Then comes the fernery with its rugged rocks and wealth of "cool greenery." Here a plant of *Anthurium Chamberlainianum* is bound to arrest attention by its gigantic proportions, its leaves being large enough to shelter a man from a tropical shower if circumstances favoured. A spathe had been cut and sent to Sir Trevor Lawrence for the use of the pollen. Next comes the corridor, some 9 or 10 feet wide, the wall on the left covered with plants appropriate for the purpose and extending over the roof; on the right a series of span-roofed houses, perhaps twenty, parallel with each other; at the end of the corridor *Rose* houses. On passing the ends of the span-roofs the majority were seen to be filled to repletion with *Orchids*, *Cattleyas* making a gorgeous display. Surely thousands of blooms could have been cut of quite the first quality. A cursory examination showed how healthy and clean the plants were under the careful treatment of Mr. Burbery and the diligence of his assistants. Perhaps the most famous plant of the season was *Dendrobium thyrsiflorum*, and it must have been grand when its upwards of seventy handsome racemes of flowers were in beauty.

On the left of the corridor, which runs east and west, is the *Odontoglossum* house; there is also a north house for *Masdevallias*,

and still Orchids are packed in older lean-to houses, and there are further Orchids in frames. Their number is bewildering, their condition excellent, and value great. Some of the span-roof houses alluded to are filled with stove and greenhouse plants; one was a floriferous mass of decorative Pelargoniums, and another filled with Malmaison Carnations; soon there will be a blaze of Begonias, then in due time sheets of Primulas, Cyclamens, and others in due season, and all in imposing numbers. When the electric light is turned on through the corridor and houses the promenade, which from the mansion to the Rose houses can be little short of 200 yards, must be very delightful, not to say entrancing; still there are thousands of persons who would not travel half so far to see it as they would to hear one of its talented owner's fascinating speeches.

There are other houses—lean-to's of an ancient date—which no doubt Mr. Chamberlain "found there," with excellent crops of Peaches in some and Vines in evident process of rejuvenation in others; also numerous frames for raising plants, and all full. Every inch of space seems occupied everywhere, and there is something to tell us at every turn that we are in a cherished garden. May it afford pleasure and satisfaction to the right honourable gentleman as a patron of horticulture for many years to come, and afford him healthful repose in such intervals of leisure as he may find from the responsible public duties which are incident to his commanding position. He is cordially thanked for the facilities afforded for a glance over his garden, and for the urbanity extended to a—CASUAL CALLER.

**EVENTS OF THE WEEK.**—The great horticultural event of the week is the Floral Fête at York that opens on Wednesday, June 19th. This promises to be as great a success as ever. On Thursday, 20th inst., the Colchester Society will hold its annual show. These are apparently the only two shows of particular interest, but with the end of the month the Roses will be in full force, and growers and exhibitors will be at their busiest.

— **WEATHER IN LONDON.**—Glorious weather has prevailed in London during the past week, but the continued absence of rain or even atmospheric moisture is commencing to be felt seriously. On Tuesday evening a shower fell, but was not enough to penetrate the ground. In at least one of the London parks the grass is as brown, or more so, than it was in 1893 at about the same date. Twenty-four hours' good, steady rain would materially benefit both London and country gardeners and farmers.

— **WEATHER IN THE NORTH.**—For the last two weeks preceding the 11th a great drought has prevailed. Many of the days have been intensely warm, and a high parching wind has continued since the close of last week. Rain is very much wanted.—B. D., *S. Perthshire*.

— **OROBUS VERNUS.**—Plants with pea-shaped flowers are rare at this season, and this fact alone, says an American contemporary, would give a value to this Orobus. It is an excellent hardy perennial, and would deserve attention at any season. The plant grows about a foot high, and nearly as soon as the growths are out of the ground the flowers begin to appear. At first they are a mixture of green, red, purple, and blue, but when they get a little older they turn almost blue. This is a good border plant when it has rich soil.

— **INSECTS ON FRUIT TREES—THE POULTRY REMEDY.**—After years of careful experiments with insecticides for the destruction of the larvæ of the winter moth and Apple-blossom weevil, I have yet to see a really effective remedy for the two pests named. The difficulty about all these insecticides is bringing them into direct contact with the enemy, as the caterpillar quickly surrounds itself with a cover of foliage, and the Apple-blossom weevil is practically safe in the unopened flower buds. There can be no question as to the value of the arsenical compounds mentioned by "R. M." (page 493), as immense numbers of caterpillars can be killed thereby; but our experience at Glewston Court is that poultry are the best insect destroyers. I think no one can justly estimate the enormous quantity they devour. Up to a recent date we have had all our dwarf fruit trees shaken daily, and the fowls have followed the shaker, eagerly feeding on the caterpillars and Psylla weevils that fell down. When the great service rendered by fowls to the fruit grower becomes more recognised, I feel sure that they will be looked on as a necessary part of the business.—S. T. WRIGHT.

— **UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.**—The usual monthly meeting of the Committee of this Society was held at the Caledonian Hotel on Monday evening last. Mr. Nathan Cole presided. Four new members were elected. It has been decided by the Committee that the increase of sick pay from 10s. 6d. to 12s., and from 16s. to 18s. per week in the two classes respectively, shall commence from the half year (July 8th). The Treasurer reported that he had invested £200 in West Bromwich Three Per Cent. Stock.

— **SAXIFRAGA PELTATA.**—At the edge of a small pond this largest of the Saxifrages is throwing up its vigorous flower stems. These stems, which rise from a stout, fleshy, creeping root-stock, are from 18 inches to 2 feet high and three-fourths of an inch thick at the base. The flowers are in large clusters and rose-coloured. At this time, when the plant is in bloom, the leaves are about 10 inches high and 6 inches across. Later on the umbrella-shaped leaves increase in every way until they are about a yard high and as much across, and are very bold and handsome. It is a moisture-loving plant, and requires to be planted near a pond or running stream; in such a place it very soon increases.—R. C.

— **A CENTURY OF PROGRESS IN FLORICULTURE.**—This subject was discussed by Professor Henslow in his lecture to the Fellows of the Royal Botanic Society and visitors at the Gardens, Regent's Park, on the 31st. ult. The lecturer showed specimens of the original wild plants from which some of our most admirable garden flowers have arisen, and illustrated with numerous diagrams the various stages in the way of cultivation and hybridisation they have passed before reaching the perfection of to-day. While the changes from the, in many cases, insignificant wild flower had been little short of marvellous, there was a limit beyond which they could not go; and he was afraid that, with some few of our florists' flowers, that limit had already been reached.

— **SPRING LETTUCE.**—At page 493 mention is made of the scarcity of spring Lettuce. This is not my experience, as from a sowing made on a south border on the 14th of August last of Hicks' Hardy White Cos, Brown Cos, and All the Year Round Cabbage Lettuce, the two former wintered well, but quite half the crop of the latter succumbed. Hicks' Hardy White Cos has been in perfection during the past three weeks. The heads of this variety averaged over 2 lbs. each and being perfectly blanched, fetched top price in the market. This variety should be extensively grown for the purpose. I consider the Brown Cos when well blanched is equally good in flavour, but it does not sell so well as the former, a fact that should be made a note of when preparing for the supply another year.—S., *Yorks*.

— **STRAWBERRY ROYAL SOVEREIGN.**—Another season's experience with this Strawberry has proved it to be an excellent variety. Under ordinary treatment in a cool Peach house I had excellent fruits from pot plants at the latter end of May. For continuing the succession from the second early sorts until fruit ripens out of doors this Strawberry should take a high position. Not only does it set freely, but the fruit swells to a large size, puts on a fine colour, while the flavour is very good indeed. On plants growing in ordinary 32-sized pots I gathered many fruit weighing 1½ oz., as many as half a dozen such as these coming from one plant. Under some of the pots I placed a newly cut turf, grass side downwards, first well soaking the turf in liquid made from dissolved bones. Into the turf the roots quickly found their way, thus lessening the necessity for supplying water. The promise of fruit from plants growing in the open of this Strawberry is all that could be desired.—E. M.

— **WAKEFIELD PAXTON SOCIETY.**—The programme of meetings for the second quarter—Session 1895—of this Society is as follows:—June 15th, "A Journey to Holland," Mr. H. Chapman. June 22nd, "Preparation for, and Bedding Out in Yorkshire Compared with the South," Mr. L. Twigge. June 29th, "The Strawberry," Mr. John Hepworth, Batley. July 6th, The Rose exhibition; essay by Mr. G. Bott. July 13th, Life Boat Demonstration; (no meeting). July 20th, Visit to Cannon Hall by permission; (arrangements will be announced). July 27th, Wild Flower exhibition. August 3rd, The Pelargonium exhibition; essay by Mr. W. Hudson. August 10th, "A Chat on Alpine Flowers," Mr. J. Wood, Kirkstall. August 17th, "The Pea and Kidney Bean" (exhibition of specimens), Mr. J. G. Brown. August 24th, (subject to be announced), Mr. J. Campbell. Friday, 30th, "The Carnation and Picotee as Florists' Flowers," Rev. F. D. Horner, Kirkby Lonsdale. Each meeting will commence at eight o'clock for business, and the lecture at 8.15 prompt.

— VERBASCUMS.—These are glorious this year. A mass of *Verbascum phoeniceum* of many colours is very telling. But the charm lies with *Verbascum pannosum*, two superb spikes far excelling *V. olympicum*.—G. B.

— VERBASCUM OLYMPICUM.—Although not quite so robust in growth as *V. Chaixi*, this is far more handsome, the woolly, silvery-looking foliage, pale and yellow rosette-like blooms forming quite a pyramid. Given abundance of space it is a charming hardy plant.—E.

— QUEEN WASPS.—These have been more plentiful than usual this spring. We have already destroyed upwards of 300, and many have escaped. As the young brood will soon be hatching, a sharp look out will be kept for their nests, and if the weather is favourable they will doubtless be very numerous this summer. It would be interesting to know if they are as numerous in other parts of the country.—YORKSHIRE.

— ROYAL METEOROLOGICAL SOCIETY.—At the ordinary meeting of the Society, to be held by kind permission of the Council of the Surveyors' Institution, at 12, Great George Street, Westminster, on Wednesday, the 19th instant, at 7.30 P.M., the following papers will be read:—"Hourly Variation of Sunshine at Seven Stations in the British Isles," by Mr. R. H. Curtis, F.R.Met.Soc. "The Frequency, Size, and Distribution of Hail at Sea," by Mr. H. Harries, F.R.Met.Soc.

— CHOISYA TERNATA.—Growing at the foot of a south wall—this was on May 16th—smothered with its white Orange-like blossoms, two plants growing closely together for the last eight years now cover a space 15 feet long by 5 feet high, and annually give an exceptionally heavy crop of bloom, which proves the desirability of maturation of the previous year's growth. Plants growing in the open do not, as a rule, flower so freely as those on a wall. Abundance of water at the roots while growth is being made after flowering is an advantage.—E. M.

— THE WEATHER LAST MONTH.—May was warm, dry, and bright, with the exception of the five days 16th–20th, which were much cooler. We had no frost after the 5th. The wind was in a northerly direction nineteen days. Total rainfall, equal to 0.74 inch, which fell on ten days, the greatest daily fall being 0.32 inch on the 17th. Barometer's highest reading 30.380 on the 2nd at 1 P.M.; lowest, 29.398 on the 17th at 9 P.M. Thermometer, highest in the shade 84° on the 30th; lowest, 33° on the 5th. Mean of daily maxima, 64.64°; mean of daily minima, 43.38°. Mean temperature of the month, 54.01°; lowest on the grass, 30° on the 5th; highest in the sun, 144° on the 30th. Mean temperature of the earth at 3 feet below the surface, 50.35°. Total sunshine, 235 hours 5 minutes. There were four sunless days.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham*.

— MAY WEATHER AT HODSOCK PRIORY, WORKSOP, NOTTS.—Mean temperature of month, 53.6°. Maximum on the 30th, 80.8°; minimum on the 2nd, 32.2°. Maximum in the sun on the 30th, 129°; minimum on the grass on the 2nd, 25.4°. Mean temperature of the air at 9 A.M., 56.3°. Mean temperature of the soil 1 foot deep, 53.7°. Nights below 32°, in the shade 0, on the grass 7. Total duration of sunshine, 217 hours, or 45 per cent. of possible duration. Two sunless days. Total rainfall, 1.89 inch. Rain fell on seven days. Average velocity of the wind, 7.1 miles per hour. Velocity exceeded 400 miles on one day, and fell short of 100 miles on fifteen days. Approximate averages for May.—Mean temperature, 51.1; sunshine, 175 hours; rainfall, 2.11 inches. Except for a very cold week, from the 16th to the 21st, this has been a very bright warm month. The temperature is a record for May, and we shall have to go back to 1882 for more sunshine.—J. MALLENDER.

— MANCHESTER SHOW.—First-class certificates were awarded to Messrs. F. Sander & Co., St. Albans, for *Miltonia vexillaria* G. D. Owen, *Dendrobium Johnsoniæ*, *Sobralias Veitchi rosea* and hybridum *Amesiae* *Wilsonia* × *xantholeuca*; to Messrs. Hugh Low & Co. for *Cypripedium Gertrude* Hollington; to Mr. James Cypher for *Laelias purpurata* *Princess May* and *alba*, also *Miltonia vexillaria splendens*; to Messrs. B. S. Williams for *Pescatorea klabochorum*; and to E. Ashworth, Esq., for *Cattleya Mossiæ* John Ashworth. In addition to the certificates gold medals were awarded to Messrs. H. Low & Co. for *Cattleyas*; to Messrs. Jones and Sons, Shrewsbury, for bouquets and other floral decorations. Mr. Findlay's many friends will be pleased to hear that he is enjoying better health than was the case twelve months ago. He is trying to place the Society on a sound basis, a good start being made by the Earl of Derby contributing £100, an anonymous donor £100, and other gentlemen various sums.—R. P. R.

— SOUTHAMPTON SHOW.—Mr. Fudge writes:—"At this show a certificate of merit was awarded respectively to A. Henderson, Esq., of Buscot Park (gardener, Mr. W. Meads), for a collection of Melons *Hero of Lockinge* and *Sutton's Scarlet*; and to Mr. C. Dymott, Freemantle Nursery, Southampton, for a seedling *Pelargonium Harry Dymott*."

— EARLY PEAS.—Mr. J. Russell, The Gardens, Berrington Hall, Leominster, states that he sowed 200 pots (3-inch) with *Lightning Peas* on February 5th, started them in a vinery, transferred them to a frame on 28th of the same month, planted them on a south border March 16th; flowering commenced March 20th, and a good dish of Peas was gathered May 30th, crop full. The same variety, sown on the same border March 6th, will not be ready till the middle of the present month.

— DICKSON'S RINGLEADER POTATO.—The same gardener describes this variety as a good forcer. He began digging on May 26th from some that were planted in cold frames without bottom heat on March 3rd, having been previously set up in a vinery. Mr. Russell also says Dickson's *Golden Gem Lettuce* for early work is a perfect model.

— HARDINESS OF SCARLET RUNNER SEEDS.—There is no doubt whatever that seeds of this Runner Bean are not in any way affected by frost or rain. In a garden in this neighbourhood the bine was left on the stakes last autumn and remained there until April of this year, undergoing 28° frost, the seeds apparently none the worse for their exposure. Seven seeds were put into a Cucumber bed ten days ago; five of them have germinated, the plants making strong growth.—E. M.

— SCARCITY OF SLUGS.—Your correspondent, Mr. J. Murphy (page 475) mentions the absence of slugs, and attributes the cause to the severe winter and the heavy snowfall. But there must be some other cause for their scarcity, as during the past winter we had our share of severe frost and snow, and still slugs are quite as plentiful as usual, being probably somewhat protected by the Box edging with which the kitchen gardens are edged. In case your correspondent is afraid the slugs are like the snakes, banished from Ireland, a plentiful supply may be obtained from—A YORKSHIREMAN.

— CARAGANA ARBORESCENS.—This Siberian Pea-tree is now in full bloom in the parks of New York, and its bright yellow flowers appearing among the light green downy leaves make it really attractive. These flowers are often said to resemble those of the Laburnum; but really the flowers of the Laburnum, as they appear in long graceful racemes in England and other places where the climate suits the tree, are much handsomer. The Laburnum, however, does not thrive in this country except in a few favoured locations, while the Caragana, by its perfect hardiness and its adaptability to all sorts of soils, is a plant that we can always depend on. It sometimes reaches the height of 20 feet, and assumes a genuine tree shape. It will bloom when it is only 3 or 4 feet high, and it has a special value in that it produces flowers of a colour which is comparatively rare at this season. These Pea-trees, for there are a number of species and varieties in cultivation, belong to the Leguminosæ, and with the exception of the Red Buds, they are the earliest of the family to flower.—("Garden and Forest.")

— VIOLAS FROM HAWICK.—Mr. John Forbes, a well-known florist and advertiser, sends us a box of Violas. Amongst them we note as yellows *Lord Elcho* and *Mary Gilbert*, both very bright; *George Corbett*, paler, of the *Ardwell Gem* type. Purple margined yellows—*Duchess of Fife*, fine; *Goldfinch*, richer; *Border Maid*, paler. *Jackanapes* is also yellow with glowing crimson top petals. Whites are represented by *King of Whites* and *Sylvia*, both undoubtedly good, while the delicately tinted *Marchioness of Tweeddale* is pleasing. The *Peter Barr* varieties, with their Pansy-like centres, are represented by *Hamlet* and *Exquisite*, also a painted sport and a purple seedling, very rich. Among the purples and lilacs we find *J. B. Riding*, dark; *Fascination*, *Rosemary*, *Ariel*, *Sweet Lavender*, and *William Neil*, lighter. *Hugh Ainslie* is a pretty form of the *Countess of Kintore* ilk, and *H. M. Stanley* much darker than his adventurous prototype. Then there is the charming little *Violetta*, and some other dainties, such as *Blush Queen*, *Lyric*, and *Charming*—in different shades of peach. *Mrs. Primrose* is appropriately named, and is smooth and clear; while of lavenders we have *Bridegroom* and a particularly clear and attractive seedling, No. 27, but good as it is we scarcely think it twenty-seven times better than some of the others. The assortment shows what infinite variety there is in these sweet and pleasant flowers, which add to their value hardiness, and thus bring their culture within the means of all. Mr. J. Forbes had a magnificent collection of these flowers at the Manchester Show.

— **LINUM MONOGYNUM.**—This pure, white-flowered, New Zealand Flax is deserving of a place in any collection of herbaceous plants as a companion to the blue and yellow varieties. Linums prefer a rather dry soil, therefore they are convenient plants. From the middle of May until early in the autumn they continue to give an abundant crop of blossoms, so useful for mixing with other flowers in vases.—E.

— **MESSRS. SUTTON & SONS' ANNUAL EXCURSION.**—This pleasant excursion was held on Thursday, when for the first time Folkestone and Dover were visited by special train. The party, which numbered just over 600, was accompanied by Mr. and Mrs. Herbert Sutton, Mr. Arthur Warwick Sutton, Mr. Leonard G. Sutton, and the Misses Sutton. As usual, each married man received an invitation for his wife, and with the liberality which marks the firm on all occasions, not only was the train provided, but every person was presented with a sum of money sufficient to fully defray the expenses of the day.

— **NEW GARDENS FOR WOOLWICH.**—The ceremony of throwing open the new public gardens at Woolwich, into which St. Mary's Churchyard have been turned, was performed on Friday last, May 31st, by the Duchess of Fife. From first to last the work has cost about £1200. The soil of the churchyard is naturally composed of sand, necessitating the importation of considerable quantities of fresh material to mix with it, likewise to fill up the numerous holes which also abounded. Although the Metropolitan Public Gardens Association has only been in existence for about twelve years it has already accomplished much useful work, of which the services so lately rendered by it to the people of Woolwich are but an example.

— **CALADIUMS AT CHELSEA.**—Amongst the many plants that are grown at Messrs. J. Veitch & Sons, Chelsea Nursery, these must be accorded a very prominent position. When visiting there a few days ago I was struck with the splendid health of the plants and the richness of the leafage. Both the small and large foliaged varieties were in perfect condition, and proves that Mr. Tivey, the well known grower, thoroughly understands their cultivation. They are singularly beautiful plants, providing a leafage that is entirely distinct from any other, and of such peculiar blendings of colour as to render them practically indescribable. Particularly charming were Raymond Lemoinier, Ibis Rose, Madame Leon Say, Henry Irving, Excellent, and Lord Derby. These only make half a dozen out of very large numbers, all of which are worth growing by the lover of handsome foliage plants.—VISITOR.

— **THE SEEDS OF WEEDS.**—Some interesting investigations have been made at the South Dakota Experiment Station on the distribution of weed-seeds by winter winds. For example, says the "Garden and Forest," the contents of snow-drift on ploughed land 2 feet square, 3 inches deep, and 10 rods from any standing weeds, were melted, and thirty-two weed-seeds belonging to nine species were found in it. Other tests confirm the fact that seeds are carried great distances on the snow. Another test was made by pouring half-bushel piles of Oats and Millet on the snow-crust when the wind was fifteen miles an hour. Both Millet and Oats passed a point 20 rods from where they had been placed in forty seconds. A twenty-five-mile wind was found to drift Wheat-grains 30 rods in a minute. Of course, when winds on the plains keep blowing in one direction for days, seeds will travel many miles. The moral of these investigations seems to be that in the great western plains, at least, bare summer fallowing and matured weeds in waste ground may help to scatter seeds during the winter over great areas and they will be buried in the soil when the snow melts.

— **CHESHUNT, WORMLEY, AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.**—The above Society held the last meeting of their spring session at the school, Wormley, on June 6th 1895, when a most practical paper was read by Mr. W. Easlea, Waltham Cross, on "Roses." The following lectures have been read during the spring session:—February 5th, "Leaves, and Their Functions," Mr. W. Dyke; February 12th, "The Influence of Light on Plants," Mr. J. Godber; February 19th, "Plant Food," Mr. W. Dyke; February 26th, "Carnations," Mr. A. E. George; March 5th, "Pelargoniums for Market: Description and Culture," Mr. W. L. Yates; March 14th, "Nitrogenous Manures, and their Effect," Mr. J. Guy; March 29th, "Strawberries," Mr. A. Faulkner; April 11th, "Mushrooms," Mr. A. Hayes; April 25th, "Heating Apparatus as Applied to Horticultural Purposes," Mr. W. Harrison; May 9th, "Manures and their Application," Mr. W. Dyke; June 6th, "Roses," Mr. W. Easlea. This speaks well for the Society's welfare, for it was only started last February, and now possesses eighty-five members.

— **"BOTHIANA."**—Allow "An Old Boy" to express his gratification at the kindly note from "P. J. G., Warwickshire" (page 496), with the earnest hope that he and his compatriots may derive all the benefit they anticipate from the advice given, and more also.

— **IRIS KOCHI.**—Among the large early-flowering bearded Irises this stands distinct among the many purple kinds now in bloom. The large flowers are of a peculiarly rich dark vinous-purple colour, which is very effective and striking. Besides the typical *I. germanica* there are a number of hybrids in the same section with various shades of purple, but none more effective than this Istrian species.

— **ABUTILON VITIFOLIUM.**—Mr. Baylor Hartland, Cork, sends us beautiful flowering sprays of this handsome Abutilon, which has been figured in the *Journal of Horticulture*, when it was referred to as follows—"It is only in favoured climates like the west of England or some districts in Ireland where this tree attains to very large proportions. In most cases where it is found in gardens it is an inmate of the greenhouse, and very seldom can an adequate idea be then formed of the beauty of the shrub when fully developed. The flowers are large, of a delicate purplish or bluish mauve, not unlike the stately *Meconopsis Wallichii* in tint and form. They are produced in great abundance, and in contrast with the large dark green lobed leaves they have a fine appearance."

— **CLEMATIS MONTANA.**—One of the most charming cottage garden pictures I have ever seen was a magnificent old plant of this pretty Clematis, on an empty cottage in a Suffolk village last week. It had apparently been planted on a porch, but this had long since fallen to decay, and the long pendent shoots of the Clematis were abundant, and wreathed with the beautiful white flowers. It had also mounted to the thatch and covered the roof, hanging in festoons from the chimneys and gable. Few hardy climbers can compare with this well-known and handsome Clematis. It is not only one of the easiest of all to grow, flourishing in any ordinary soil, but beyond cutting away a few shoots that may be encroaching on anything else, no pruning, nailing, or any cultural operation is needed. The more natural the growth the more graceful is its appearance when in flower, and if closely nailed or tied this is sadly marred.—H. R. R.

— **ADVANTAGES OF GREEN MANURING.**—Dr. Webb gives the following as the typical advantages of green manuring:—There is a direct addition of plant food to the soil, as during the growth of the plant it absorbs food from the air, and the upper layers of the soil are enriched by matter brought up from the subsoil, and which, when the plants are ploughed in, becomes almost immediately available for the succeeding crop. With certain crops this gain in plant food is much more marked, as it consists in an increase of the nitrogen in the soil at the expense of that of the air. The plants which possess this power of abstracting nitrogen direct from the air are those belonging to the natural order Leguminosæ, to which order belong Peas, Beans, Vetches, Clover, Sainfoin, and Lucerne. On the rootlets of the plants of this order are a large number of small nodules or tubercles. These are the home of micro-organisms capable of abstracting free nitrogen from the air and forming nitrogenous compounds. The greater portion of this nitrogen ultimately finds its way into the plant and is there made use of. The benefit is not confined to the Leguminous crop alone, but where that crop is ploughed in, or even if only the roots are left, the soil becomes so enriched by the accumulated nitrogen that greatly increased crops result. Dr. Wagner of Darmstadt conducted experiments to test the effect of the above. Two equal plots were taken, and on one White Mustard, and on the other Vetches, were ploughed in, and Oats sown. Each received an equal dressing of chemical manure, but the yield on that where Vetches had been ploughed in was twice that on the one where White Mustard had been ploughed in. Similar experiments were conducted by Heiden, Rye being taken (1) after Lupines ploughed in, and (2) after bare fallow. The relative yields of the plots were:—Plot 1, 96 of grain and 205 chaff and straw; plot 2, 56 of grain and 114 chaff and straw. The importance of this fixation of free nitrogen cannot be over-estimated, as it provides a large quantity of the dearest manurial constituent without cost. 2, The food added to the soil by green manuring cannot readily be lost by drainage. This explains the advantage which light land derives from it, that class of land not usually being retentive of plant food. 3, A large quantity of humus is added to the soil, the benefit of which has already been noticed. 4, During decomposition of the vegetable matter mineral matters are rendered available for plant food, owing to the effects of the products of decomposition.

— TRINIDAD BOTANIC GARDENS.—The annual report of the Royal Botanic Gardens, Trinidad, for the year 1894, compiled by the Superintendent, Mr. J. H. Hart, furnishes evidence of the practical value of these colonial botanic gardens, and of their relation with the central institution at Kew. Under the Economic Section, information is given of the growth in the island of the Sugar-cane, Cacao, Coffee, Yam, Gambier, Vanilla, the Brazil Nut, and Cola, and of the principal enemies of these crops, and the best mode of combating them.

— R.H.S. EXAMINATION.—As one who sat at the above examination on May 1st, I fully agree with "W. D." (page 500), that the time allowed was much too short. One question alone (No. 13), on the culture of Grape Vines, would take from three-quarters of an hour to an hour to answer fully and well. I think "E. D. S." has given very fair answers, but it is a different thing sitting down quietly at home and writing at leisure, from sitting in an examination room, with only so much time to do the work in. In the "Science" Exam., 1895, subject "Geology," the time allowed is three hours, with only five questions to attempt to answer in the first or second stage, and only four in the honours stage. I sat for the first stage, and although the questions were not nearly so stiff as those of the R.H.S., the time allowed was not too much.—J. E.

### JOTTINGS IN HYDE PARK.

MANY of the flower beds in Hyde Park are now specially attractive. Some of them have been a blaze of bloom for a considerable time. The beds of Pansies, for instance, are exceptionally good, and merit the close attention of any visitor who delights in seeing these flowers at their best. The beds containing the plants are large, and accommodate some hundreds, all of which are in a healthy vigorous condition, and flowering profusely. Numbers of them bear blooms of remarkable size and substance, which, intermixed with those of lesser sized flowers, form a very pleasing combination.

One of these beds was edged with London Pride (*Saxifraga umbrosa*), another had a band of Lord Beaconsfield Pansy, and a third of Aubrietia Leitchlini. At Whitsuntide the latter was nearly out of bloom, but the London Pride was peculiarly attractive in its simple array of tall pretty spikes fringing the Pansies of varied hues. One bed of Pansies had clumps of Solomon's Seal rising from among them, and very pretty the drooping flowers looked on the graceful arching stems.

Dark Pansies intermixed with Aquilegias of bronzy hues formed a good combination. Pansies and Violas were largely employed as edgings. Brown and dark Pansies of various shades provided an attractive band round one bed filled with dwarf white Stocks, extraordinarily floriferous and regular in size. The plants were not only furnished with a fine central spike but with side shoots correspondingly good. A bed of red Stocks was equally effective. This was edged with white *Arabis alpina*, of course long since out of bloom; but the effect can be imagined if the Stocks were in bloom, too, when the *Arabis* was at its best. Violas Blue Bell and Lilacina respectively edged beds of dark-foliaged Sweet Williams, throwing up bloom spikes which will shortly prove to be *en masse* a gorgeous spectacle. The pale yellow *Viola Ardwell Gem* was employed as an edging to beds of herbaceous Phlox, which had every appearance of being the white variety.

Owing to the variety of plants employed, every week throughout the summer will bring forward something prominent. Beds of Carnations and Pinks are advancing fast. An edging of *Lysimachia nummularia aurea* is used for circular beds of Carnations Raby Castle and Germania, both varieties having remarkably sturdy flower spikes. Similar beds of Queen of Bedders and Danger Carnations are edged with *Antennaria*, always an attractive, compact edging, and quite hardy. Another bed of Carnations, oblong in shape, is filled with Alice Ayres, and bordered with the succulent *Sempervivum californicum*.

*Antennaria* is also employed as an edging to a large oblong bed planted thinly with *Campanula Meadum*, the spaces between being filled with Pansies. *Herniaria glabra* forms an edging to a bed of *Mimulus*.

Numerous other beds were prepared ready for planting, while Auriculas, bulbs, Primroses, Dielytras, and other things had still to be removed at the beginning of the month to be filled attractively for summer and autumn. Mention ought to be made of the single red Pyrethrums, which surpassed the double forms in attractiveness. Then there were beds completely occupied with Fuchsias, which will eventually prove most interesting. One had a groundwork of Ten-week Stock just planted. Beds which promise to be most attractive are those with scented-leaved Pelargoniums, interspersed with fine plants of *Anthericum variegatum*, having a groundwork of *Mimulus* and edged with blue *Lobelia*.

Another bed has white, yellow, and lilac Violas with clumps of Zonal Pelargonium Titiens and *Anthericum variegatum*. A very pretty bed is composed of red Stocks, Mignonette in bloom, and Earl of Beaconsfield Pansy. Good bushy plants of Ivy-leaved Pelargoniums are also employed, one bed having a groundwork of Violas, lilac and blue, edged with white *Lobelia*.

Other effective and tasteful combinations will be found by the visitor to this attractive metropolitan park, which is frequented by all classes, few of whom do not admire the banquet of floral beauty constantly displayed before them through the efforts of the Superintendent and his assistants.—E. D. S.

### NATIONAL CHRYSANTHEMUM SOCIETY.

WE are requested to state that the annual outing of the members of the above Society will take place on Monday, July 22nd, and will take the form of a visit to the gardens and grounds of Burford Lodge, Boxhill, the residence of Sir Trevor Lawrence, Bart., one of the Vice-Presidents of the Society.

### DISTRIBUTION OF NEW CHRYSANTHEMUMS.

EARLY in February I wrote to a grower of new seedlings for a set of his novelties for 1895 in the hope of getting them for a friend who wanted to grow them and show them in the coming season. The first week in June has now passed and the plants have not arrived, and when they do they will probably be merely rooted cuttings 2 or 3 inches long. By that time the whole of my friend's collection will be established in their flowering pots, and under our method of culture well advanced for the purposes required. I merely draw attention to the matter to show how little cause of complaint such people have at their novelties not receiving due recognition at our hands. It is perhaps unnecessary to add that the grower in question is not an English one.

### NEW CHRYSANTHEMUMS FROM JAPAN.

I have just returned from the interesting little exhibition of water-colour drawings by Miss Hill Burton at the Clifford Galleries, Haymarket. Pleasing as it is as a whole, I was disappointed to find that, although she deals with the Pæony, Iris, Water Lily, Cherry blossom, Wistaria, and Azalea, as they are grown in Japan, the claims of the Queen of Autumn have been entirely overlooked, for there is not a single picture of the Chrysanthemum in the whole collection.

By way of compensation, however, I find on my table an illustrated nursery catalogue from Japan, which contains a list of new and old varieties, with a large folded sheet of new seedling Chrysanthemums for 1895 that are positively gaudy and painful to the eye after gazing at the soft and delicate tones of colour employed by Miss Burton in her drawings.

These native Japanese illustrations seem to have been produced by a mechanical method of chromo-lithography, such as would be found in any of our trade catalogues, and are not to be compared with some of the work I have seen on rice paper and on silk. The flowers are not remarkable for their size, but there are one or two forms that appear to be of a striking character if reliance can be placed upon the pictures. One variety called Diamond is a Japanese with outer florets tubulated, the inner ones cupped and slightly incurving, notched at the tips, the colour deep chrome yellow, the centre suffused with green after the manner of Florence Davis. Royal Banner is a loosely incurved Japanese of the Mrs. Wheeler type, with inside of florets bright crimson lake, and reverse golden buff. Torchlight, a Japanese, a rich shade of crimson orange and golden reverse. Frost of Battlefield, a white incurved Japanese, curiously tipped with pink, reminding one of the old variety Aimée Ferrière.

It is a sign of the times that the Japanese nurserymen are naming their newest acquisitions in English instead of in their own tongue, although the older varieties retain their native names. From a cultural point of view, it may be interesting to give the measurements of some of those quoted in this catalogue. The majority are from 7 to 8 inches in diameter, but the gems of the collection from the big bloom standpoint are Tora-asobi, 8 to 9 inches across; Usu-sakura, the same; Kudsu-rio, also 8 to 9 inches; Coten-sakura is 8 to 10 inches in diameter; Kano-ko-jima, 8 to 9 inches; but the palm seems to be given to one named Hotei-maru, 10 to 12 inches. We should, of course, have been grateful to our Japanese friends if they had favoured us with translations of these curious looking names.—C. H. P.

### BEGONIA SAMUEL POPE.

OF late years there has been a really extraordinary improvement in the tuberous-rooted Begonias, both amongst the single and double varieties. This was readily perceptible at the Temple show, where some superb forms were staged. In Mr. T. S. Ware's arrangement one of the most conspicuous was a double variety named Samuel Pope (see illustration, fig. 94), to which the Floral Committee rightly adjudged an award of merit. As will be seen, the shape of the flower is perfect, and it is also quite double; in colour it is distinct, being cream edged in Picotee fashion with bright rose.

### APPLES AND STOCKS.

TIME was when I read much, swallowed much, and probably digested little of the varied literature connected with horticulture, but as time goes on one is apt to form conclusions of one's own, and to say to one's self, "I do not agree with this or that." It is quite safe to do so in

one's easy chair, but before doing so in print it is as well to examine the signature of the writer lest one should haply "catch a Tartar." Well, having read the remarks of Mr. Molyneux on page 475 I said to myself, I cannot let this pass without notice. Here is Mr. Molyneux, a man known by repute to all the horticultural world, telling the public through the medium of your well-known Journal that, practically speaking, it matters not what kind of stock is used for the Apple, as the cultivator can get equally good results from Paradise, free stocks, or Crab. I have not quoted his words, but I take this to be the sense of his remarks. If I have rightly understood him I must say that he takes a view which is diametrically opposed to all the experience which I have had and that of most cultivators, and at the risk of "catching a Tartar" I must beg leave to differ with him.

That Mr. Molyneux personally is able to obtain equally good results from Apples on all the three stocks mentioned I do not for a moment

that had the trees been carefully root-pruned at the time they were closely head-pruned, things would have been different. But then the general public does not know all this. Root-pruning is to many an unknown science, and I maintain very properly so, as it is a surgical operation to be taken in hand advisedly by the skilled gardener when his trees are worked on unsuitable stocks, but otherwise seldom needed, and far best left alone.

Now theory is one thing, practice is another; and again there are various kinds of practice. Mr. Molyneux is a skilled cultivator, mixes with other skilled cultivators, and has possibly instructed some of his less gifted neighbours. I, on the other hand, come in contact in the course of business with a very large number of less skilful gardeners, working men, allotment holders, and amateurs, and during the planting season it is a matter of daily occurrence for people to come and say "I want some pyramid Apples on your Paradise stock to plant in place of

FIG. 94.—BEGONIA SAMUEL POPE.

doubt, but because he is able to do so it by no means follows that everyone else can do the same.

Speaking of "garden trees," let us begin with the pyramid, which is the most ordinary form of culture for a garden. I admit that on poor gravel or sand, which is hardly fit for fruit culture at all, and which demands a genius to obtain anything like a satisfactory result, the Crab and free stocks have their advantages, but for anything like good soil there is not the least comparison between these and the Paradise. The ordinary cultivator of pyramid trees in a garden has only one failing, but it is a serious one. He prunes his trees too closely, with the result that they are filled with wood; thickets into which one could not thrust one's hand to take a blackbird's nest; and fruit is unknown, at any rate for some years, and then only on the outside of the tree where the wood has been able to ripen. The reason that he feels bound to adopt this rigorous method of pruning is that his trees, grafted on the Crab or free stock, will make so much growth, whereas had they been on the Paradise they would have made far less growth and far more fruit spurs. Of course I well know that the luxuriant growth was probably helped by over-kindness on the part of the cultivator, who manured his young trees as freely as though they had been in full bearing; and I also know

my pyramids on Crab stocks, which seldom or never fruit, and which I am going to dig up." So true is this that, setting aside orders received from market growers, I should say fully half the retail orders we have are for this purpose. Again, it is not only amateurs that have made the discovery that Apples fruit more freely on the Paradise than on the free stock, or why are market growers planting trees on the Paradise by the thousand

Of course I do not say that early and continuous bearing are the only merits of Apple trees worked on the Paradise. One must also bear in mind the fact that the fruit they bear ripens at least a week or ten days earlier, at any rate in the Midlands, which in a cold climate is no small advantage; and further, it is much more brilliant in colour, and far superior in point of flavour. To reduce this to hard fact a market grower in Lincolnshire told me last autumn that he had planted a field of pyramid Apples, part on the Crab stock and part on the Paradise, and that not only did the latter bear much more fruit, but that it made 30 per cent. more money in the market, and he was seriously contemplating the advisability of digging up his 12 acres of trees on the Crab (just coming into bearing) and replanting with trees on the Paradise.

One more note and I have done. Every gardener remembers with

morning the disastrous frost we had in May, 1894. We had in our nurseries a flat of espalier-trained Apples, part on the Paradise and part on Crab, the flat was rather over quarter of an acre. The greater number was on the Paradise. The trees were four years old, spurred, and well set with bloom, the varieties comprising quite a collection. After the frost only two varieties carried fruit on the Crab stock, whilst those on the Paradise stock carried a full crop. I am aware that "One swallow does not make a summer," nor does one observation prove a fact, but I may say that last August I had the pleasure of spending a day or two in Mr. Bunvard's nurseries, and I found there the same tale. His quarters of Apples on the Paradise were loaded with fruit, which he was selling at 12s. a bushel. Why? because his neighbour's trees on the free stock had failed to carry fruit.

We know that certain kinds of Apples—for instance, Lord Suffield, Cellini Pippin, or Potts' Seedling—will crop on anything on which they will exist; but for any restricted form of cultivation, be it as cordon, espalier, pyramid, or what not, it is, in my opinion, a fallacy to tell the general public that the choice of stock matters little, as I maintain that "on this the whole secret of success hinges."—A. H. PEARSON, *Chilwell, Notts.*

### WATER WANTED.

IF the cultivated plants and pastures we are everywhere growing could speak as we read in the fable the birds and beasts once could, no doubt they would tell us of great suffering endured from want of moisture. We who are sentient creatures know but too well that whilst hunger may be hard to endure, the pangs of thirst are far greater and more painful. Thus it is when we see under the hot sunshine and in parching wind the plants in gardens and fields hanging their heads and leaves because of thirst, we can imagine hearing them to moan in pain and to cry for water, water! Unless that imperative need for water, and plenty of it, is speedily supplied great harm will be done, crops of all descriptions will greatly suffer, and our labours in cultivation and in cropping in field and garden will be sadly discounted. It does seem as though we were ever anticipating blessing, but were never destined to secure it.

Our seasons are in no sense ideal ones. To go no further back than 1893, drought, long intense drought, so universally ruled that great loss resulted nearly all over the kingdom; crops that under ordinary conditions might have been heavy were reduced one-half, two-thirds—indeed, in some cases, as grass for instance, were practically non-existent. We had some compensations in the autumn, but not such as could repay for the summer shortcomings. 1894 was as wet as the previous year was dry, and it was in many ways a year of disaster with little compensation. The present year coming directly after two such opposite seasons might naturally have been expected to be of a normal type, not hot or cold, not wet nor dry, but partaking of each moderately. That is, however, not our experience so far, and one-half of the year is nearly gone. Nature seems resolved to adhere to extreme moods, hence we have had up to the present for the half year a remarkable minimum of rain, whilst early there was excessive cold and lately almost as excessive heat.

The most critical time for all our crops has now been reached, and if no rain falls before the month closes then the injury done may prove to be great and irreparable. I am writing on the 8th inst. Last night the clouds, though light, bore an aspect of change. There was evidence of thunder in the air and accompanying rain. This morning the sky is hard and clear, and the sun shines out a hot blazer. There is not a shadow of cause for hope that change is imminent, though it does seem as if the heat must soon generate thunderstorms. But it is less such terrible downpours as often accompany electrical storms that we need just now, than a gentle steady rain lasting for twenty-four hours, and fertilising the soil without beating it, or splashing and injuring crops. Alas! we may have long to wait before we get either. What a pity it is that such splendid weather, a meteorological aspect tending to show that sometimes England can wear a very warm smile indeed, should yet do harm. For all who care only for pleasure, and for some occupations, such as building, the weather is magnificent; but for all who work on the soil, and are dependent on its produce for a livelihood, the weather is deplorable.

Now again crops up the old subject for discussion—a water supply for gardens; but it is a very difficult one, seeing that there are myriads of gardens dependent for water on pumps and wells, whilst only in the comparatively few is there a constant supply. But even with these there is limitation of use, as no artificial supply can in any way compensate for the absence of rain when spread over several weeks. It is often urged that water which at certain times of the year falls too abundantly should be stored. That is easily enough advised, and even carried out where the expense of providing a huge underground reservoir is readily met. But huge must be the storage that would enable any gardener to satisfy the demands of all his crops during such a spell of drought as that is we are now experiencing. None the less, it is so obvious as to be incontrovertible that the greater the water supply during a drought the better for the garden in every sense.

Any effort to utilise natural water sources for general irrigation would at once drain our rivers and streams dry, and still leave the uplands as parched as ever. Everywhere, even where the soil is naturally retentive, we see the best crops now wheresoever the practice of deep working has been adopted. It is just such seasons as the present which show the exceeding value of trenching. There lies below, as it were, a reservoir of moisture, that is accessible to crops only when the soil is

deeply worked, and from which crops on shallow worked ground are debarred. Only yesterday, looking over some allotments, I remarked to one holder that one portion of his crops were so much stronger and fresher than they were on another part. His reply was, "Yes, I trenched that part; but this last I had only time to dig over, and that is the cause of the difference." The same results may be seen in all directions, but especially so on allotments, where the working of the soil varies so much.

In good gardens it is impossible to conceive of soil that is not always regularly trenched. If it be not, then the gardener has less reason to complain of the drought, hard as it is to withstand, than of his own neglect to give his crops every chance to withstand it. There seems to be no element in garden culture less artificial, and yet productive of more permanent benefit, than is found in the practice of deeply working the soil.—A. D.

### EXPRESS GRAPE GROWING.

I AM obliged to Mr. Innes for his reply to my query as to what his Grapes averaged per pound, given on page 478, and congratulate him in bringing so much out of so heavy a crop.

As to the difference in opinion regarding finish in market Grapes, which your correspondent thinks so simple a matter and so universally understood, all I can say is that it is a pity it is so seldom practised. I, perhaps, may have too high and particular notions as to finish in Grapes, but the great bulk of the fruit I see placed on the market has very little finish, and certainly lacks that which gives the Grape its noble and luscious appearance.

Mr. Innes has erred in his calculation regarding the heavy crop I mentioned. It is my fault, as in the hurry-burry of Grape-thinning I wrote a hasty note, and omitted to mention that the 300 feet long house had only fruit on one side. This would give only 120 rods, at 2 feet 6 inches apart, in place of 240, as your correspondent had it, and consequently will work out exactly double the crop, or twenty-two bunches on each Vine, and 21 lbs. 12 ozs. per foot run of rod. But even this weight I am aware is not anything very extraordinary, and I must have underrated the particulars, as I only saw the crop once, and wrote from memory, not having taken any notes. We have one side of a house planted with Gros Colman, 300 feet long. The Vines are from 8 to 9 feet long, and are carrying seventeen bunches each; many of them should weigh 3 and 4 lbs., and though scarcely half swelled, yet will not look nearly so heavy as the crop I saw and referred to.

It is gratifying to see so many "Growers" taking part in this discussion, and I trust that others will enter and give all your readers the benefit of their knowledge, as there is no doubt that in the matter of Grape growing market growers are far in advance of the mass of private gardeners. Like Mr. Innes, I am a firm believer in the wonders that are, and still can be, done with the Grape Vine under proper treatment, and look forward with interest to more details of other successes in the pages of the Journal soon, and hope myself to add my own share when reverting again to this subject later in the season, which I intend to do with the Editor's permission.

In connection with Gros Colman Grape, it was interesting to read Mr. John Thomson's remarks on page 476. His late father was, I believe, the first to introduce and push this variety into prominence as a market Grape, and we all know how well the same Vines have been grown at Clovenfords for over twenty years. Like Mr. Thomson, I too was at one time under the belief that shading the glass would prevent the foliage cupping and browning to such an alarming extent as it very often does. However, after testing this plan on two occasions I found it did little or no good. The principal cause of injury to Gros Colman foliage, in my opinion, is injudicious airing. We have been very fortunate in preserving the foliage of our Gros Colman up to the last; indeed, we make this a special point in our Grape growing, for we do an extensive business with autumn-tinted Vine leaves, and as every practical Grape grower knows, unless the leaves are clean and healthy they are of no use for decorative purposes. Our soil is light, and outside borders are all raised above the level of the surrounding ground, and in a dry locality. These three things are all against the preserving of the foliage of Gros Colman, and we attribute our success to never at any time using side ventilation, and if the house is large as little as possible on the top on windy drying days, giving instead additional dampings and keeping down fire heat. Another important point is abundant moisture at the roots, and the liberal use of fertilisers. This latter point is of great importance if heavy crops are borne and the leaves kept healthy. We believe in dressing the borders often, giving smaller doses, and continuing the practice on till late in autumn, as good feeding in the autumn tells with marked effect on the succeeding year's health and vigour of the Vines.—MARKET GROWER.

P.S.—Since sending my communication I have been favoured with a photograph from Mr. Innes of the house of Gros Colman he mentioned, and from which was taken the very interesting figures as to crops and prices for the last eight years. The photograph shows a very fine crop of good even-sized bunches, and is creditable to both grower and photographer.—MARKET GROWER.

I FEEL highly honoured by the compliment conferred on me by your correspondent on page 495 last week. Mr. Thomson still lingers over my little Vines, and asks where I got the abundance of fine healthy fibrous roots. Well, I found them in the pots attached to the little Vines.

I would remind Mr. Thomson that no amount of incredulity can possibly alter facts, and facts speak for themselves.

So far the greater portion of this discussion has been conducted on purely theoretical lines, as there appear but few of your correspondents who have ventured out of the old track. If my little Vines were not grown in the best possible way before planting, they gave ample proof of their appreciation of the treatment they received after planting. I gave them my best attention and fed them on the best of food, and I was highly gratified by the result.

I can from experience recommend those about to embark in Grape growing to try the newer method, which I have found so successful. I fancy there are but few market growers in the present day who would care to wait two years after planting before getting a crop of Grapes. The little Vines under discussion are not the first or the last I have planted out of 3-inch pots with equal success, and which I hope to give some account at a future time. I may add that I have found that the successful cultivation of the Vine depends more on unwearying labour and close attention to detail than to luck.

I ought to feel deeply grateful to "Examiner" (p. 495) for the trouble he has taken in correcting my errors in reference to the crop of 2700 bunches of Grapes in a house 300 feet in length, referred to by "Market Grower," page 425. I do not know where "Examiner" obtained his information, perhaps he may be in possession of facts which I do not possess. "Market Grower" makes no reference to the number of Vines, or the class of house in which the Grapes were grown. Assuming the house to be a lean-to, "Examiner" would be quite correct by stating that the number of Vines at 2 feet 6 inches apart would be 120, but with respect to his other calculations he appears to be slightly out; 120 Vines carrying the above number of bunches would average twenty-two and half bunches per rod, not twenty-three. The weight per rod at 1½ lb. per bunch would be 33¾ lbs., and not 40 lbs., as stated by "Examiner." I assume that the house is span-roofed from the fact that it was devoted to Gros Colman Grapes, and grown for market, and if so I think my figures are not very far out. "Examiner" estimates the crop at 2s. per pound, whereas "Market Grower" distinctly states the price at 1s. 1d. per pound, while he is not sure if all the crop was fit to sell, and that puts the matter in a very different light.—WM. INNES, *Derby*.

FROM Mr. J. Thomson's note (page 495) on the straw-like Vines grown by Mr. Innes I conclude he cannot have visited the Sunny Hill Vineries or he would not continue harping on the one string (though I have heard the fine air of "Auld Robin Gray" played on one string, causing a thrill never to be forgotten). Thirty years back I about committed to memory the late Mr. William Thomson's book on the Vine. It gave me ideas then that you could do almost anything with the Vine, and when I look over thirty years' notes on the cultivation of Grapes, seen and carried out by myself and others, I find that Mr. Innes' cultivation is beaten in several instances—one in Derbyshire (the able gardener now gone to rest), though this was only a small house of Alicantes.

But Mr. Innes' Grape growing was carried out on an extensive scale—fine lofty houses, well heated and well ventilated; rods as straight and regular as rods could be, with bunches hanging from the border to the full length of the rods, principally Muscats and Gros Colman, perfectly finished in colour, equally sized large berries, all the shoulders taken from the Gros Colman bunches, and they generally hung in pairs. My first visit to see these Grapes was through purchasing a basket after Christmas. They came in such splendid condition, and were of such fine flavour, that my employer said by all means go and see them, and many visits I made afterwards to take a wrinkle. Muscats and Gros Colman every year I found improved, and generally some little addition in engineering skill for raising and warming water and heating the houses.

I will quote the history of one remarkable Vine growing at one end of a lean-to house, raised from a straw-like plant, as Mr. Innes, generally from what I saw, planted these small things. The Vine in question was a Barbarossa (Gros Guillaume), and the third year (1892), carried thirteen bunches of jet black Grapes weighing 108 lbs. In 1893 it carried ten bunches, weighing 83 lbs., the berries being very much larger than the previous year, the largest bunch weighing 12½ lbs., the smallest 5½ lbs. The most noteworthy features, however, relating to these crops of Grapes were the fine quality and flavour. Some of the houses I noted a few years back, I think in the Journal. I may add another fact—namely, the character of the wood. It was nothing gross, but the thickness of an ordinary lead pencil gives the general idea of the laterals that carried these good Grapes.—GEORGE BOLAS.

## ROYAL HORTICULTURAL SOCIETY.

JUNE 11TH.

THE exhibition at the Drill Hall on Tuesday was a very fine one in every way. Hardy flowers were seen in great numbers and diversity, and the quality was excellent throughout. The display of Pæonies was the finest ever seen, and Roses were also conspicuous. Orchids were shown in the best of form, but were not so numerous as we have seen them at this season of the year. The Fruit Committee had not many exhibits before them, and they were as usual variable in quality.

FRUIT COMMITTEE.—Present: T. Francis Rivers, Esq. (in the chair); and Rev. W. Wilks, with Messrs. J. Cheal, A. H. Pearson, F. Q. Lane, H. Balderson, G. Wythes, G. H. Sage, W. Farr, R. Fyfe, A. Dean, J. Hudson, J. Wright, and Dr. Hogg.

Before the commencement of business Mr. A. H. Pearson referred in appropriate terms to the great loss of the Chairman by the death of Mrs. Crowley, and it was proposed by him, and seconded by Mr. J. Wright, "That the members of the Fruit Committee wish to express their deepest sympathy with their Chairman in the great loss and sorrow which has recently befallen him." Carried unanimously.

The Committee then proceeded to examine Melons, Strawberries, Tomatoes, and vegetables that were sent for examination. Mr. T. Spencer, The Gardens, Goodrich Court, Herefordshire, sent a very large scarlet-flesh Melon, Goodrich Seedling. The flesh was the reverse of thick for the size of the fruit, which was not fortunate in receiving any award. Mr. Owen Thomas sent from the Royal Gardens, Windsor, two new Melons. One named *The Lady* is a medium sized white Melon, without netting, and of splendid quality. The rind was thin, and flesh a mixture of green and red. A member proposed an award of merit, with an intimation that a finer fruit might be forthcoming to justify a first-class certificate. This was carried unanimously: A jocular remark passing across the table that some of the critics required another tasting treat. The other fruit sent was named Pine Apple, a boldly netted pale green flesh Melon, but the flavour was considered too strong and musky.

A grand dish of the Leader Strawberry was placed on the table, also a dish of Laxton's Monarch, a good-sized fruit of splendid quality, and the exhibitors, Messrs. Laxton Brothers, were requested to send a plant in order that its character could be appreciated pending the possible award of a certificate. Mr. J. Collis, Rollo Lane, Chiswick, sent a dish of Collis's May Queen Strawberry, a medium sized pleasant fruit. The variety has previously had an award of merit.

Mr. J. Hudson sent from Gunnersbury House Gardens a box of splendid Lord Napier Nectarines gathered from a tree bearing 400 fruits, and which last year had 600. A cultural commendation was promptly awarded. Mr. J. Corbett, gardener to the Rev. the Marquis of Normanby, Mulgrave Castle, sent a dish of his Tomato *Excelsior*, small to medium sized fruits of excellent quality, firm, and of enjoyable flavour. It has been proved a free bearer at Chiswick, and an award of merit was granted.

Mr. R. Filkins, Oakhurst Gardens, Chislehurst, sent a basket of Potato Queen of the Earlies, clean and excellent tubers, resembling Early Laxton. The tubers were planted outside on March 13th, and digging commenced last Saturday. Referred to Chiswick for trial. Samples of Spinach were sent from Chiswick, one variety named "The Carter" was remarkable for its large thick leaves, and as it is evidently the last to run to seed, was granted an award of merit under what was considered undoubtedly its proper name, *Longstander*. The seed, an excellent stock, was supplied by Messrs. Carter & Co., and the variety is worth growing everywhere. T. H. Stables, Esq., Belmont, Salisbury, sent a bundle of large blanched Asparagus, for which a cultural commendation was awarded.

Mr. H. W. Ward sent three dishes of Peas—Lightning, William Hurst, and Telegraph, transplanted from pots. Good gatherings were made on 20th May; samples excellent, and a cultural commendation was granted unanimously. Mr. J. Crook, Forde Abbey, Chard, sent bearing plants of Chelsea Gem Pea, grown without protection, and was accorded a vote of thanks.

A silver medal was recommended for twenty-four beautiful dishes of Tomatoes and boxes of The Marvel Cucumber, exhibited by Mr. Mortimer, Rowledge; also bronze medals to Mr. G. Wythes and Mr. A. Pentney, The Gardens, Worton Hall, Isleworth, for collections of vegetables, a similar award being granted to Messrs. Laxton Brothers for Strawberries.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); and the Rev. H. H. D'Ombra, with Messrs. H. B. May, J. Fraser, O. Thomas, J. Laing, C. T. Druery, H. Herbst, R. Dean, R. Owen, W. Bain, C. Blick, E. Beckett, H. Cannell, J. D. Pawle, J. E. Shea, J. Walker, G. H. Engleheart, G. Paul, J. T. Bennett-Poë, H. Turner, H. Selve Leonard, H. J. Jones, E. Mawley, and G. Gordon.

Messrs. John Laing & Sons, Forest Hill, exhibited a large and varied collection of hardy flowers, all of which were fine and in an excellent condition of freshness. Amongst numbers of others were noticed Pæonies in good variety, Phlox ovata, Geum chiliense, Centaureas montana alba and montana rubra, Gaillardia grandiflora, Campanulas persicifolia alba and persicifolia grandiflora, Erigerons glaucum and philadelphicum, Achillea macrophylla, Epilobium angustifolium, Betonica grandiflora, Veronica carnea, Doronicum austriacum, Stenactis speciosa, Anchusa italica, Polygonum affine, Heuchera sanguinea, Papaver nudicaule, together with Lupins and Irises in variety (silver Banksian medal).

A bright collection of old-fashioned and garden Roses was staged by Messrs. Geo. Cooling & Sons, Bath. The exhibit included numerous varieties of these charming flowers, and amongst many others were noticed Persian Yellow, Charles Lawson, Polyantha grandiflora, Rosa polyantha, Rosa Mundi, Sweet Briar, Janet's Pride, Copper Austrian Briar, Miniature, Yellow Austrian Briar, Harrisoni, W. A. Richardson, White Scotch Briar, Rosa viridiflora, Moss Rose Little Gem, Rosa rugosa alba, Laurette, and Sweet Briar Lord Penzance. The firm also staged a stand of the beautiful new Hybrid Perpetual Lawrence Allen (silver Banksian medal). Messrs. Kelway & Son, Langport, staged a huge collection of Pæonies, Delphiniums, and Pyrethrums. The exhibit occupied a large expanse of staging, and produced a very showy effect. Conspicuous amongst the former were Pansies Torquemada, Donald Grant, Langport Queen, Olivia, Tory Leader, Lady Beresford, Duke of Devonshire, Peach Blossom, Duke of Cambridge,

Sir Visto, and Rev. W. Wilks. Amongst the Delphiniums Beauty of Langport, King Olaf, Miles Standish, Cambridge, Election, Miss McIntyre, Susan, Geneva, and Prince Henry were exceedingly fine. Pyrethrums were well represented in varieties, Wega, Ernest, Carl Voget, Melton, Figaro, Princess Maria, James Kelway, Ruth, Pericles, and others (silver Flora medal).

A group of well-flowered plants in pots of Carnation Yellow Queen came from Mr. T. Bones, Heaton Gardens, Cheshunt. Mr. Frank Cant, Colchester, staged a small collection of Roses, which included two fine new varieties, Medea and Sappho, together with blooms of Austrian Yellow, Rainbow, Mignonette, Janet's Pride, L'Idéal, Rugosa alba, Braiswick Beauty, Dundee Rambler, Perle d'Or, Austrian Copper, and Blanche Moreau. Messrs. Paul & Son, Cheshunt, sent a fine collection of hardy flowers, in which Pæonies in variety were very effective, as also were flowers of *Campanulas muralis* and *mollis*, *Phloxes pilosa* and *Andre*, *Pyrethrums* Captain Nares and *Le Dante*, *Inula glandulosa*, *Dianthus cruentus*, *Irises spuria* and *orientalis*, *Weigela rosea*, *W. alba*, and *W. candida*; *Roses*, Sweet Briar Janet's Pride, Paul's Carmine Pillar, Austrian Copper, *Rosa rugosa alba*, and *Rosa rugosa fimbriata* (silver Banksian medal).

A fine group of Cannas and Gloxinias came from Messrs. H. Cannell and Sons, Swanley, Kent. Amongst the former were Madame Crozy, Queen Charlotte, Golden Queen, Aurore, and others; and conspicuous in the latter were Miss D. Dean, Beacon, Princess of Wales, Spotted Gem, Miss M. Pearson, Mrs. Lovelace, Miss Tudor, Purity, Mr. E. Cannell, Model, and Prince of Wales (silver Banksian medal). Mr. J. Douglas, Great Bookham, Surrey, sent fine Carnation blooms, namely, Duke of Orleans, Miss Audrey Campbell, Corunna, Phyllis, and forcing Pink Snowflake.

Messrs. James Veitch & Sons, Chelsea, staged a magnificent collection of hardy flowers, comprised chiefly of *Eremurus robustus*; *Pæonies* Reine Hortense, Emile Lemoine, *Purpurea superba*, Constance Devret, Whitleyi, Aurora, and *Humea carnea*; *Campanula glomerata dahurica*, *Phlox ovata*, *Heuchera sanguinea*, *Inula glandulosa*, *Lychnis viscaria splendens plena*, *Veronica teucrium* and *Erigeron aurantiacus*. The same firm also sent well flowered plants of *Lilium Alkeyuri*, and *Robinia hispida*, together with a good collection of hybrid *Streptocarpus*, and a few brilliant Gloxinias, namely, Elvira, Columbus, Olivette, Cicely and La Belle (silver Flora medal).

Messrs. R. Wallace & Co., Colchester, sent hardy flowers, amongst which Irises were conspicuous. Amongst others were noticed *Irises Asiatica*, Mrs. H. Darwin, *Variegata chelles*, *Siberica compacta*, *Siberica* George Wallace, and many others. Included in the group were flowers of *Calochortus Lyoni*, *C. pulchellus*, *C. albus*, and *C. amœnus*, *Lilium longiflorum giganteum*, *L. japonicum colchesteriana*, and others (silver Banksian medal).

Mr. Thos. S. Ware, Tottenham, was represented by an exceedingly large and varied exhibit. Carnations in pots claimed attention, amongst which were Lady Wantage, Orange Beauty, and The Shahzada. Conspicuous amongst the hardy flowers were *Senecio Doronicum*, *Campanula turbinata*, *Lilium colchicum*, *Lilium Martagon album*, *Inula glandulosa*, *Armeria cephalotes alba*, *Spirea filipendula plena*, *Campanula persicifolia Backhousei*, *Papaver Prince of Orange*, and *Saxifraga pyramidalis* (silver-gilt Banksian medal).

Mr. Charles Turner, Slough, sent blooms of the fine Carnation Mrs. W. H. Grenfell. M. Louis de Smet, Ghent, staged specimens of variegated *Abutilon Sawitzi*. Mr. H. B. May, Upper Edmonton, sent plants of yellow *Tropeolum Coolgardie*. Messrs. Wm. Paul & Son, Waltham Cross, staged a small, though good, collection of Rose blooms, comprised of Sylph, Mungo Park, and Zephyr. A good group of hardy flowers came from Mr. M. Pritchard, Christchurch, Hants. Amongst numerous others were noted *Linaria dalmatica*, *Veronica buxifolia*, *Dianthus sylvestris*, *Inula glandulosa*, *Gaillardia maxima*, *Heuchera sanguinea*, *Betonia grandiflora*, *Geum miniatum*, *Delphinium Gaiety*, together with *Pæonies* in variety, Iceland Poppies, and many others (bronze Banksian medal).

Mr. Blick, gardener to Martin R. Smith, Esq., The Warren, Hayes, Kent, sent well-grown plants of Malmaison Carnation Lady Grimston. The blooms were exceedingly fine, while the scent of this charming variety leaves little to be desired. Messrs. Barr & Son, Covent Garden, staged an excellent collection of Pæonies of great variety in colour. The flowers were good, and consisted chiefly of Victor Hugo, Lady Dartmouth, Grandiflora, Superba, Grace Darling, Helen Leslie, Madame Vilmorin, Monsieur Andre, Curiosa, Solfaterre, Rose Dawn, Agnes Barr, W. Marshall, Fairy Queen, Lady Somerset, Sir Walter Scott, Festiva, Maxima, Queen of May, Alexandre Dumas, Figaro. Dr. Bois Duval, Surprise, Duke of Wellington, Amabilis, Madame Henri, and others. Other hardy flowers were included in the group, and the whole produced an imposing effect (silver Flora medal).

Mr. B. R. Davies, Yeovil Nurseries, Yeovil, Somerset, staged a small but excellent collection of double Begonias, composed of varieties Mont Blanc, B. R. Davies, Britannia, Lucerne, Sir Visto, Mrs. Bennett, Miss Falconer, and several others. Mr. Anthony Waterer, Woking, staged a group of cut *Rhododendron* blooms, and flowers of *Weigela Eva Rathke*. Mr. Thomas Whillans, Blenheim, Woodstock, sent plants of seedling Carnation Blenheim Beauty, the flowers are very large, but entirely devoid of scent. Mr. B. Campbell, The Willows, Windsor, sent a splendidly bloomed plant of *Bougainvillea glabra* trained in balloon shape.

Mr. Bain, gardener to Sir Trevor Lawrence, Burford Lodge, Dorking, showed a well flowered plant of *Blandfordia aurea*, and fine blooms of Stock Mammoth White. Mr. Downes, gardener to J. T. Bennett Poë,

Esq., Cheshunt, staged a large specimen plant of *Carpenteria californica*, thickly covered with its snowy white blossoms (silver Banksian medal).

Mr. George Mount, Canterbury, and Mr. George Prince, Oxford, staged good collections of Rose blooms, for which medals were awarded. Messrs. Hugh Low & Co., Clapton, sent a small collection of *Caladiums*.

Three Veitchian Memorial medals for services rendered to horticulture were presented to James Bateman, Esq., F. W. Moore, Esq., and Mons. V. Lemoine, by Sir Trevor Lawrence, Bart. The President of the Society, in making the presentation, spoke in highly eulogistic terms of the services rendered to the horticultural fraternity by the above gentlemen. The two former recipients thanked the Chairman in a few well chosen words, and in the absence of the latter the medal was received and suitably acknowledged on his behalf by H. J. Veitch, Esq.

ORCHID COMMITTEE.—H. J. Veitch, Esq. (in the chair); and Dr. Masters, with Messrs. J. O'Brien, J. Douglas, S. Courtauld, Major Mason, W. Cobb, E. Hill, T. Statter, W. H. Protheroe, H. J. Chapman, W. H. White, H. Williams, J. T. Gabriel, F. W. Moore, H. M. Pollett, H. Ballantine, T. B. Haywood, and De Barri Crawshay.

The Orchid section of the show was not very extensive in point of numbers, but the quality throughout was exceptionally high. Messrs. W. L. Lewis & Co., Southgate, staged a very charming exhibit, comprising *Odontoglossum crispum* in variety, *Cattleyas gigas*, *Mossiaë*, *Mendeli*, *Dendrobium Falconeri*, *Cypripediums* in variety, and *Odontoglossum citrosum*. All these plants were well grown, and the flowers produced a very bright display (silver Banksian medal). Mr. Downes, gardener to J. T. Bennett Poë, Esq., Cheshunt, staged a magnificently flowered plant of *Cypripedium caudatum Wallisi*.

From Messrs. Hugh Low & Co., Clapton, came a grand show of Orchids, in which *Cattleya Mossiaë* in variety were very conspicuous. In addition to these *Cypripedium Curtisi viride*, *C. bellatulum*, *Odontoglossum vexillarium*, a superb *Lælio-Cattleya* called Ingrams, and several others were noticed (silver Flora medal). Mr. W. H. Young, gardener to Sir F. Wigan, Clare Lawn, East Sheen, staged half a dozen Orchids of excellent quality. Perhaps the best of these was *Cypripedium bellatulum album*, but *C. Aylingi*, *C. Stonei candidum*, and *C. Phædra* were all superb. A flower spike of *Lælia grandis*, Wigan's variety, and another of *L. purpurata*, Richmond Gem, also attracted a great amount of attention. The plants shown by this exhibitor were in the best of health.

Masdevallias were arranged by Mr. H. J. Chapman, gardener to R. I. Measures, Esq., Camberwell. Amongst them were observed *Wagneri*, *muscosa*, *Ellisiana*, *falcata*, *Stella*, *Schlimi*, *campyloglossa*, *calura*, and *Harryana*, The Comet. The same exhibitor showed a plant of *Cypripedium leucobihum aureum* (silver Flora medal).

A very showy and interesting group was staged by Messrs. J. Veitch and Sons, Royal Exotic Nursery, Chelsea. The flowers in this stand were exceptionally rich in colour and of fine size. Numerous kinds were represented, including *Cattleya Warscewiczii*, *C. Mossiaë*, *Lælio-Cattleya Canhamiana*, *L.-C. Arnoldiana*, *Lælia purpurata*, *L. tenebrosa*, *Cypripedium superciliare*, *C. superbiens*, *C. selligerum majus*, *C. Stonei*, *C. orphanum*, *C. Curtisi*, *Odontoglossum crispum*, *O. cordatum*, *O. Pescatorei*, *Cirrhopetalum robustum*, *Disa langleyensis*, *D. Veitchi*, *Oncidium macranthum*, *Angræcum falcatum*, and many others (silver-gilt Flora medal).

Messrs. B. S. Williams & Son's exhibit of Orchids, interspersed with foliage and flowering plants, was small, but very attractive. *Dendrobium*s, *Cypripedium*s, *Cattleyas*, *Epidendrum vitellinum majus*, and others were admirably represented (silver Banksian medal). Mr. W. White, grower to Sir Trevor Lawrence, Dorking, sent a few plants of the best quality. The exhibit was composed of *Thunia Bensoniæ*, *Cypripedium Eleanor*, *Odontoglossum cordatum aureum*, *Bulbophyllum callosum*, *Masdevallias Stella*, *Gairiana*, *Gargantua*, a superb *Odontoglossum crispum*, *Dendrobium suavissimum*, *D. Schröderæ*, *Amesiana*, and others.

The largest exhibit of Orchids came from Messrs. F. Sander & Co., St. Albans. The most conspicuous were *Odontoglossum vexillarium*, *F. W. Moore*, and others; *Lælia tenebrosa*, *Epidendrum vitellinum majus*, *Dendrobium Johnstoni*, *Lælio-Cattleya Aylingi*, *Sobralia Veitchi rosea*, *S. Keinastiana*, *Angræcum Fournierianum*, *Cypripedium Mons. A. de Laïresse*, a hybrid between *Curtisi* and *Rothschildianum*; *C. Frau Ida Brandt*, a cross between *Io grande* and *Youngianum*; *Phaius Owenianus*, *Lælia Lucasi*, and several others (silver-gilt Flora medal).

A group of Orchids was shown by Mr. Masterton, gardener to Welbore S. Ellis, Esq., Dorking, composed chiefly of varieties of *Odontoglossum crispum*, besides several others. Messrs. Charlesworth & Co. sent a few Orchids, including *Lælia tenebrosa*, *Oncidium macranthum*, and others (silver Banksian medal). E. H. Woodall, Esq., Scarborough, received an award of merit for *Renanthera Imschootiana*. Mr. R. Johnson, gardener to T. Statter, Esq., Manchester, receiving a first-class certificate for *Cattleya superba alba*. De Barri Crawshay, Esq., Sevenoaks, showed a few very fine Orchids, amongst which were *Cattleyas*, *Odontoglossums*, and *Lælias* in grand form (silver Banksian medal).

Very bright and beautiful were the Orchids exhibited by J. Gurney Fowler, Esq., South Woodford, and which included some splendidly grown plants and large, substantial flowers (silver Flora medal). H. T. Pitt, Esq., Stamford Hill, also showed a most praiseworthy group of Orchids of various kinds (silver Banksian medal). Mr. J. Hamilton, gardener to H. Bass, Esq., Burton-on-Trent, staged plants of *Cattleya gigas Sanderæ*, a grand form of the type (silver Banksian medal).

## CERTIFICATES AND AWARDS OF MERIT.

*Begonia B. R. Davis* (B. R. Davis).—This is a deep crimson coloured, double form of fine quality (award of merit).

*Begonia Lucerne* (B. R. Davis)—This variety has curiously coloured blooms, there being a mixture of orange, rose, white, and pink. It is a double variety (award of merit).

*Begonia Mont Blanc* (B. R. Davis).—A handsome, perfectly double white variety (award of merit).

*Bentinckia nicobarica* (F. Sander & Co.).—This is a new Palm from Central Asia, with broad pale green leaves. The habit is that of a *Kentia* (first-class certificate).

*Blandfordia aurea* (W. Bain).—The plant of this *Blandfordia* was very finely grown, and carrying large numbers of yellow flowers (first-class certificate).

*Calochortus Lyoni* (R. Wallace & Co.).—This is a charming variety, with large white flowers, slightly tinged with lilac (award of merit).

*Carnation Corunna* (J. Douglas)—This is a fine yellow self variety with well-shaped flowers, which have no appearance of splitting in the calyx (award of merit).

*Cattleya gigas Sanderæ* (J. Hamilton).—This is a superb variety, with bright rose sepals and petals and a broad lip of the richest maroon. The throat is yellow, veined brown. It was one of the finest Orchids staged (first-class certificate).

*Cattleya superba alba* (R. Johnson).—This is a pure white form of the type. The lip has a charming yellow blotch in the centre (first-class certificate).

*Cirrhopetalum robustum* (J. Veitch & Sons).—This is an uncommon Orchid, with greenish yellow flowers (first-class certificate).

*Cypripedium bellatulum album* (W. H. Young).—This is an exceptionally handsome Orchid of splendid shape. As the name infers, the flowers are pure white. The woodcut (fig. 93, page 513), sketched at the Drill Hall, portrays the form of the flower (first-class certificate).

*Cypripedium Frau Ida Brandt* (F. Sander & Co.).—This is a very handsome hybrid obtained from a cross between *Io grande* and *Youngianum*, the former being the seed-bearing parent. The flower is very large, and the dorsal sepal of fine size, the ground colour being white flushed rosy purple and green. The petals are rosy purple with chocolate spots. The pouch is pale reddish brown (award of merit).

*Cypripedium Eleanor* (W. H. White).—The dorsal sepal of this hybrid is white flushed rose, the pouch dull chocolate brown, and the petals rosy purple heavily blotched with brown (award of merit).

*Cyrtanthus obliquus* (F. Sander & Co.).—This bulbous plant has flowers of the *Blandfordia* style. The colour is orange red shading to yellow, with green tips (first-class certificate).

*Delphinium Beauty of Langport* (Kelway & Son).—This is a fine variety with a medium sized spike, and flowers creamy white with petals tinged with sulphur (award of merit).

*Inula Hookeri* (Paul & Son).—The flowers of this *Inula* are not very large, but the colour is a very rich yellow (award of merit).

*Iris asiatica* (R. Wallace & Co.).—This is a fine *Iris*, of free and robust habit. The flowers are large and borne in great profusion, with blue standards and violet blue falls (award of merit).

*Lælia grandis, Wigan's variety* (W. H. Young).—The type of this is well known, and the variety noted has sepals and petals of the same colour. The lip is dull white with deep red marking (award of merit).

*Lælia purpurata Richmond Gem* (W. H. Young).—This is a very handsome variety with white sepals and petals. The lip is, however, the best feature. The outer portion is rich velvety crimson with a paler patch at the edge, and a pale yellow throat with crimson veins (award of merit).

*Pæony Duke of Devonshire* (Kelway & Son).—A large double variety of deep rose colour, with outer guard petals and dense centre (award of merit).

*Pæony Lady Beresford* (Kelway & Son).—An immense semi-double flower of blush pink colour (award of merit).

*Pæony Solfaterre* (Barr & Son).—A large flower, creamy white in colour, the outside guard petals being pure white (award of merit).

*Renanthera Inschootiana* (E. H. Woodall).—This is a fine Orchid with dull red coloured flowers (award of merit).

*Rose Lawrence Allen* (George Cooling & Co.).—A good Hybrid Perpetual, having fine well formed flowers of colour rosy pink and sweet scented (award of merit).

*Rosa rugosa, Blanche Double de Coubert* (Paul & Son).—This is a splendid double white form of *R. rugosa* (award of merit).

*Streptocarpus Distinction* (J. Laing & Sons).—The flowers of this *Streptocarpus* are large in size and of a bright blue colour, the lower portions of the bloom being blotched with deep violet (award of merit).

*Thunia Veitchi grandiflora* (F. Sander & Co.).—This form of the well-known type is large, but the colour of the lip is much brighter and more intense (award of merit).

## SKIMMIA FRAGRANS.

THE *Skimmias* (fig. 95) are better known and more valued for their brightly coloured berries than for their flowers, yet though these are unattractive they possess one property—fragrance—that renders the plant a favourite in some establishments. The rich green foliage of the *Skimmias* is always an attraction; then we have their flowering period, and later on a rich display of fruits, so that they can be fairly considered as useful in a more than ordinary degree.

## HALE FARM NURSERIES.

LOVERS of hardy flowers will always find abundance to interest them at these nurseries, and despite their proximity to the smoke of London, the display just now is very brilliant. Not so much so, perhaps, as has been the case in many former years, and will be again in future seasons, as two enemies have had to be contended against, not coming concurrently, but following each other in immediate succession. The former of these was the terrible frost, and the latter the persistent dry weather, accompanied by bright sunshine and parching winds. The effects of these combined are plainly apparent on some plants, but the ill effects have not been sufficient to destroy all the beauty, all the colour, and all the diversity. Considering, however, that upwards of 40 acres are here devoted to hardy flowers, one would be surprised indeed was there not always a number of handsome hardy plants to be seen in bloom from the early spring months onwards through the year.

During the past few years there has been a kind of revival in favour

FIG. 95.—SKIMMIA FRAGRANS.

of this class of plants, and to create, meet, and increase this demand Mr. T. S. Ware has always been in earnest. Nothing can be said against this growing popularity, as hardy plants not only provide an extraordinary diversity of colouration, an extremely varied range of form, but are also adapted for culture in all gardens from the smallest to the largest, and indeed in almost all they are found represented in some form or another. The amateur in London, or any other large manufacturing town, may find amongst hardy perennials plants that will grow and flower year after year, apparently little, if any, the worse for their smoky environs. For cutting purposes many of them are unequalled, lending themselves as they do so admirably to tasteful arrangement, and lasting so well when placed in water. Other attributes in their favour could be mentioned, but sufficient have been put forward to render permissible the title of Flowers for the Million. Not that everyone can have such a display as is provided at Tottenham. This of course is not possible, but by a judicious selection flowers can be had over a very long period of time that will afford a never failing source of pleasure to the owner, whether the number is limited to a dozen or runs into the hundreds.

One could, with ease, form a collection to comprise scores or hundreds of kinds and varieties, but when to be limited to a dozen or so the task would be nothing short of formidable. The reason of this has not to be sought for, as it simply consists in the plethora of beauty. One sees a plant that must be had here, another there, and so on until the dozen is passed, and rapidly extending to or exceeding the score. In the formation of a garden of perennials several things have to be

considered as important, such, for example, as the shape of the garden, the situation, the manner in which it is laid out, the principal object for which the plants are to be grown—whether for cutting or otherwise—and last, but not least, the amount of money at disposal. In this latter respect, at any rate, hardy perennials are certainly unrivalled, as they can be had to suit all purses; indeed, they can readily be adapted for each of the purposes enumerated. With the idea of seeing what is now in flower a journey was made to these nurseries, and notes of a few out of the many attractive flowers are subjoined. The selection made is good from the writer's point of view, but not necessarily the best. Individual taste must play an important part in looking at hardy flowers, and it would be little short of arrogance for one to say, "These are absolutely the best that can be procured," as it is practically certain that the next person would make a different choice, and would have an equal right to use the same expression if he felt so disposed.

The stately beauty of the Eremuri must be the excuse, if such be needed, for placing these in the foremost position in the notes. To extol their beauties and their merits requires the pen of an expert, and readers who desire more information will do well to read the admirable article dealing with them that appeared in the *Journal of Horticulture* for February 26th, over the well-known signature of "S. Arnott." There they were dealt with fully, as they deserve to be; here they can only be accorded a brief paragraph. They are amongst the most handsome of the hardy perennials, but their beauty is not such as would appeal to everyone, and perhaps this is as well, for they are scarcely the sort of plant one would recommend for the garden of very limited extent. The enormous spikes rise to a height of several feet, the flowering portion of such sorts as *robustus*, which was "held up" by Mr. Page Roberts in the *Journal* for September 20th, 1894, and *himalaicus* being upwards of 3 feet in length. Quite as good as the two already named is *Aitchinsoni*, which has yellow flowers shaded with buff, while others worthy of mention are *Elwesi* and *Bungayi*. It is unfortunate that these plants are not more extensively grown, as when seen in good condition their ornate beauty commands admiration from everyone.

Passing naturally from the long to the short we have the charming *Veronica rupestris*, which in large clumps is a perfect sheet of blue. This is a well-known and highly appreciated little plant, but it is worthy of mention here, and of more extended culture in small gardens. Equally attractive, and as general a favourite, is *Heuchera sanguinea*, which seen at a distance of a few yards, with the sun glistening on it, is at once a striking and a singularly beautiful sight. It is an exceedingly useful plant for cutting, providing red flowers of a distinct shade and form. *Achillea millefolium* is a plant too seldom grown, and as seen at Tottenham one of the most beautiful on the place. A large bed was noticed, in which the plants were smothered with their pearly white blossoms, that are valuable for cutting purposes. This is a plant that almost anyone would place in a prominent situation, despite which it is seldom seen. Perhaps some reader can suggest the reason for this. A dwarf *Aster* next attracts attention by its mauve-coloured flowers, produced on a plant only a few inches high. It is called *A. alpinus*, of which there is a very beautiful variety named *speciosus*, with larger and more richly coloured flowers. Both of these plants possess several good points that will insure them a goodly number of admirers.

For brilliancy the Poppies are unrivalled, and many sorts are well worth growing. Foremost amongst them must be placed *Papaver bracteatum*, probably the finest of the oriental varieties. Everyone knows the massive, richly hued flowers with the dark blotch at the base of each petal, and there are not many people who do not admire them. Other handsome varieties are *Silver Queen*, *Royal Scarlet*, and *Little Prince*, each of which possesses undoubted merits. In addition to these there were the dwarf growing *P. miniatum* and the Iceland Poppies, both very charming and useful for cutting. *Aquilegias* have not made the growth that is usually one of their characteristics here, doubtless owing to the very dry weather, but the plants are smothered with flowers. Hybrids are numerous, while the well-known *Skinneri*, *californica*, and *chrysantha* are seen in profusion. Beyond these are *Inulas glandulosa* and *grandiflora*, each distinct from the other. Of the two perhaps the latter is preferable. Two other plants not seen so frequently as their merits deserve are *Lathyrus Sibthorpi* and *Orobis lathyroides*, both, of course, belonging to the pod-bearers. Boldly conspicuous was a clump of *Spiraea aruncus*, about 8 feet high and as far through.

The collection of *Nymphæas* is very extensive, though at the present time there are not many kinds in flower. Amongst those noticed *N. Laydekeri rosea*, *N. candida*, and *N. odorata rosea* were perhaps the best. These plants are grown in tubs plunged into the ground close to the large rockery, and greatly enhance the appearance thereof. In a frame adjacent to this rockery there is a number of *Brodiaëas* thriving in a most satisfactory manner. It is curious that these plants are not more extensively grown, but possibly they are not sufficiently showy for the generality of plant growers, though they cannot fail to add interest to the garden. *Brodiaëas coccinea* and *congesta* are perhaps the best known, but *Howelli* ought to be grown, as it is quite distinct, and possessed of many good points. The climbing *B. volubilis* was also seen, but is not apparently of any particular merit. In the same frame large numbers of *Sparaxis* are growing and flowering, besides numerous other plants not at present in bloom. Irises are almost over, there still remaining, however, a few to bloom. The collection of these is very large, and the display when hundreds were in flower must have been very fine indeed. *Phlox ovata*, *Veratrum album*, *Dictamnus Fraxinella* (the Burning Bush), *Geranium ibericum*, and *Hemerocallis Dumorteri*, all add beauty and diversity to this floral feast.

Justice cannot be done in such brief notes as these, but they must not be concluded without a reference to the thousands of *Liliums* that are cultivated, and which are not yet of course in their full beauty. Comprised in this collection are probably all the best kinds in commerce, and it cannot be doubted that in a short time when the plants are in full flower the sight will be a truly glorious one. Of those now in bloom *Szovitzianum* and *canadense* are the most prominent, and indeed look very charming. Every day fresh beauties will be apparent in the newly opening blossoms, and visits at frequent intervals could not fail to be of interest and also prove very instructive. Deserving of congratulation are the firm and its grower, Mr. Johnson, for the efforts they have made and are making to popularise these plants, and for the good health of the stock, that prevails over the establishment.—NOMAD.

#### ROSE SHOW FIXTURES FOR 1895.

- June 19th (Wednesday).—York.\*  
 " 20th (Thursday).—Colchester and Ryde.  
 " 25th (Tuesday).—Isle of Wight (Cowes).  
 " 26th (Wednesday).—Richmond (Surrey).  
 " 27th (Thursday).—Gloucester (N.R.S.) and Canterbury.  
 " 28th (Friday).—Exeter.  
 " 29th (Saturday).—Windsor.  
 July 2nd (Tuesday).—Diss, Maidstone, and Sutton.  
 " 3rd (Wednesday).—Brockham, Croydon, Ealing, Farningham, Lee,† and Sittingbourne  
 " 4th (Thursday).—Eltham and Norwich.  
 " 6th (Saturday).—Crystal Palace (N.R.S.).  
 " 9th (Tuesday).—Ipswich, Westminster (R.H.S.), and Wolverhampton.\*  
 " 10th (Wednesday).—Chelmsford, Farnham, Hitchin, and Redhill (Reigate).  
 " 11th (Thursday).—Bath, Great Malvern (Hereford Rose Society), Helensburgh, Woodbridge, and Worksop.  
 " 17th (Wednesday).—Derby (N.R.S.).  
 " 18th (Thursday).—Canterbury (Kent Hospital Fête) and Halifax.  
 " 20th (Saturday).—Manchester.  
 " 23rd (Tuesday).—Tibshelf.  
 " 24th (Wednesday).—Chesterfield and Newcastle-on-Tyne.\*  
 " 25th (Thursday).—Trentham.  
 Aug. 3rd (Saturday) and 5th.—Liverpool.†

\* A show lasting three days. † A show lasting two days.

I shall be glad to receive the dates of other Rose shows than those named above for publication in future lists.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

#### WINDSOR SHOW.

THE Committee of the Windsor Rose Society are anxious to make the fact known that the show on the 29th inst. is to be held in the private grounds of Windsor Castle, by special permission of Her Majesty. The Court will be at Windsor at the time, so the show may possibly be visited by Royalty.

#### ROSE MARÉCHAL NIEL UNDER GLASS.

HAD I questioned the soundness of "W. R. Raillem's" system of growing this Rose there may have been some reason for Mr. Divers' oracular statement in last week's issue; as I did not it calls for no comment, and I can only condole with Mr. Divers on his want of success with grafted plants. I have not infrequently had growths 20 feet from the grafts in one season, so that the objection on the score of weakly growth can hardly be maintained.—H. R. R.

#### ROSES UNDER GLASS.

AT a meeting of the Royal Horticultural Society held at the Drill Hall, Westminster, on Tuesday last, an exhaustive and instructive paper on "Rose Culture Under Glass" was read by Mr. Frank Cant, the well-known grower of Colchester. The essayist in his opening remarks said that several books had been published on the cultivation of Roses, but he considered the Rev. A. Foster-Melliars' "Book of the Rose" was one of the best, and one he could safely recommend to all who contemplated growing these charming flowers. Considering the popularity of Roses, and the ease with which they may be grown under glass, their culture under these conditions was not carried on so extensively as might be expected.

He commenced by describing the kind of house required for them, and stated that though Roses can be and are grown in all kinds of structures, a light span-roofed house, with ends facing north and south, is the one most suitable, with side and top ventilators fitted to open the entire length. The house should be of sufficient width to allow for a bed in the centre, with a path round it, and a border on each side. The Roses may either be grown in pots or planted out, but in case of the latter the roof of the house should be so formed that it can be lifted off, this

being done about the middle of June. The beds may be planted with standard and half-standard Teas and Hybrid Perpetuals, while on the roof and supporting pillars should be trained climbers, but these must not be allowed to become so dense as to obstruct the light.

Though ample ventilation is essential it can be overdone, therefore great care is necessary on this point. If it is thought desirable to plant the Roses out, this should be effected in November, allowing ample ventilation for two or three weeks, only closing to exclude frost. The plants should be pruned in January, and a warm, humid atmosphere maintained until flowering commences. For growing in pots plants dug from the open ground are not satisfactory the first year; it is therefore necessary that they should be subject to pot culture at least twelve months before they are required for forcing. Presuming a stock has been raised, the plants should be overhauled and the roots examined thoroughly in September. If these are in good condition potting will not be necessary, a good top-dressing sufficing. In either case the compost should consist of good fibrous loam from an old pasture which has been stacked for at least six months, this to be chopped fine and a little coarse sand added.

Water must not be given too liberally directly after potting, and if the plants be protected out of doors till the middle of December, they may then be removed to the house. Pruning should be done about a fortnight after this, and if the flowers are not required before April no artificial heat will yet be necessary. After January the plants commence growing, when each morning the pots, paths, and walls should be well syringed. Soon the flower buds will appear, and the grower's efforts be amply rewarded by abundance of flowers.

No hard and fast rules can be laid down with regard to watering, but great care is necessary, as oversupplies produce mildew, which is one of the worst pests to which Roses are subject. It may be avoided by judicious watering, but in case of its appearance the best means of eradication is to make the water-pipes hot and then paint them with a mixture of flowers of sulphur and milk. During the months of March, April, and May the syringe should be freely used, as red spider will appear if the atmosphere be kept too dry. Green fly is sure to present itself, and may be kept in check by frequent use of the syringe; if, however, it makes headway, the best means of extermination is fumigating, which should be done on a still evening after sunset, syringing the plants thoroughly next morning.

With regard to stimulants, liquid manure from the cowyard is doubtless the best, and may be applied in a diluted state twice a week, failing that clear soot water is a good substitute, liquid from the horse stable being dangerous. If evaporating pans are provided on the water pipes it is a good plan to fill these with some ammoniacal liquid manure, as this strengthens the foliage. Roses when in bloom are benefited by being shaded with roller blinds, which ought to be green, and not too thick or heavy. After the flowering season is over the plants should be plunged in ashes outdoors, the surface of the pots be covered with some rough hotbed material, and all flower buds kept removed until September.

In conclusion Mr. Cant said that many people were of the opinion that Tea and Hybrid Perpetual Roses could not be grown satisfactorily in the same house, but he had experienced no such difficulties, both being perfectly at home. Rose-growing under glass, he said, is a most interesting occupation, as they are there free from the atmospheric drawbacks which often affect them out of doors. At the close of the lecture a hearty vote of thanks was accorded to Mr. Cant for his interesting paper.

### RED SPIDER ON VINES.

THIS pest on Vines is, I think, the worst of all, and when once established on the green leaves nothing will move them except the sponge. I have experienced bad cases of the red spider, and have sponged whole houses of Vines, but even after that the Vines have appeared checked, caused, I believe, by the rubbing of the leaves, closing many of the pores, and interrupting the leaves breathing or feeding on the atmosphere.

Some growers recommend the use of soft water from the syringe. That I have tried, but at the expense of getting marked berries, and without the rich bloom we like to see on the exhibition table. I do not attribute much value to the spider harbouring under the bark of Vines, as I conclude that if the state of the Vines and the condition of vineries are suitable for the pest it will reach there, notwithstanding the extreme means that have been taken in cleansing house and Vines. In my opinion, spider travels in the air, and lodges in any suitable place. Take for instance Beans. Fill a house, and have in no other plants. Place some near the hot-water pipes, fairly well heated, and the atmosphere rather dry; spider will appear on them in a very short time. Another instance which came under my notice last season. In my early Hamburgh house I forced Strawberries, and when just ripening I was surprised to find them covered with spider, and the Vine leaves nearly touching them. I quickly removed the Strawberries to other quarters, and on examination I found none on the Vines, but for prevention I dusted the shelf with flowers of sulphur.

I do not think the flowers of sulphur had all to do in keeping them clear. I believe over-cropping, which means stagnation to growth; borders allowed to become too dry, damping down not regularly done, over-heating of hot-water pipes all breed red spider. I use liquid manure from the farmyard, putting a little in the vapouring troughs as a preventive of red spider.—W. COATES, *Darnhall Hall*.

### ROYAL NATIONAL TULIP SOCIETY.

THE annual northern exhibition of this Society was held on Tuesday, June 4th, in the Free Library, Middleton, near Manchester. The library, which was kindly lent free of charge by the Corporation, with its good accommodation and interesting surroundings, made an ideal exhibition place; and the growers, who came in good numbers from far and near, were delighted with their visit to the town. The people of Middleton, from the Mayor and the Rector downward, did their best to make the visit a pleasant one to the members of the Tulip Society, and it is most likely that the show will next year again be held at Middleton.

The month of May this year has been a trying one to the Tulip grower. During the early portion Tulips were later than usual, and cold rough east winds prevailed; then came a milder period, and the blooms began to develop quickly, but on the 14th strong rough north to north-west winds prevailed for a week, and progress was all but stopped. On the 21st it appeared as if the date chosen for the show would be just right; but blazing tropical weather set in, with the result that the flowers had but a short life of it, and were literally roasted on the beds. From this cause scarcely a grower could show his full strength, and those from early districts had not a single flower to bring. Notwithstanding these adverse circumstances there was a very good display of Tulips both in numbers and quality, the show of feathered flowers being far above the average. Breeders were not in good order, having suffered severely from the hot weather.

The Judges, Messrs. Housley and Booth (Stockport), Woodhead (Staleybridge), and Keyzey (Gorton), commenced their labours at eleven o'clock, and it was shortly afterwards known that the silver cup for the best stand of twelve rectified flowers, which is the "blue ribbon" of the exhibition, had been won by Mr. James W. Bentley of Stake Hill House, near Middleton, whose success was locally very popular, and that Mr. Charles W. Needham was second. As the judging proceeded it became apparent that the local growers were getting the principal prizes, their flowers being, generally speaking, in the better condition. The Rev. F. D. Horner, President of the Society, who had managed to save about half a dozen blooms, took the first prize for "pairs" with two fine flowers, which gave the growers an idea of what he could have done had he been able to come in strength. Messrs. Moorhouse, Jones, Dymock, Kitchen, Mellor, and Gill all exhibited some excellent flowers, and all had sad stories to tell of grand flowers ruined by the intense heat.

The usual varieties, such as Sir Joseph Paxton feathered and flamed, Masterpiece, Dr. Hardy, Mabel, Annie McGregor, and Talisman, were shown in good style, although some of the earlier ones, such as Bessie and Chancellor, were almost practically over, and never was the importance of growing some late varieties, such as Queen of the May, Charlemagne, Beauty of Litchurch, Typo, and Nimbus better exemplified. Among little known varieties the following were very good—Albert, feathered bizarre; George Edward, feathered bybloemen; Mrs. Collier, feathered rose; Mrs. Longbottom, flamed bybloemen, shown by Mr. Bentley; and Sarah Ann, feathered rose; Lewis W. Morris, feathered bizarre; and Collier's Seedling, rose breeder, shown by the veteran grower, Mr. John Morris, whose re-appearance as an exhibitor was heartily welcomed. The Rev. F. D. Horner showed some seedling bybloemen breeders of great promise, and the seedling bizarre breeders of the late Mr. Lloyd, shown by Messrs. Bentley and Needham, were very good. After the judging was finished the public were admitted, and the Mayor, Mr. Alderman Thorpe, in an admirable little speech, welcomed the Tulip Society to the town and declared the show open. The growers and friends then adjourned to the old Elizabethan inn, the Boar's Head, for luncheon. The Mayor presided, supported by the members and friends, among whom we saw Messrs. Bennett Poë and Barr of London, Dr. Pegge of Beeston, Notts, and Messrs. Cliff (Leeds), and Barratt (Stockport).

The show was largely patronised by the public, and local horticulturists were interested in competing for extra prizes offered for groups of plants, Pansies, Ferns, and cut blooms, the presence of which among the Tulips greatly improved the show from the ordinary spectator's point of view. The following is a list of the awards.

#### RECTIFIED TULIPS.

Class 1. *Twelve rectified Tulips, two feathered and two flamed in each class.*—First, Mr. James W. Bentley, Stakehill, Middleton, with Mrs. Atkin and Mrs. Collier, feathered roses; Mabel and Triomphe Royale, flamed roses; George Edward and King of the Universe, feathered bybloemens; Talisman and Queen of the May, flamed bybloemens; Albert and Sir Joseph Paxton, feathered bizarres; Sir Joseph Paxton and Dr. Hardy, flamed bizarres. Second, Mr. Charles W. Needham, Royley, Royton, with Vicar of Radford and Mabel, feathered roses; Mabel and Madame St. Arnaud, flamed roses; Elizabeth Pegg and Nellie Hughes, feathered bybloemens; Charlemagne and Talisman, flamed bybloemens; Masterpiece and Magnum Bonum, feathered bizarres; Sir Joseph Paxton and Dr. Hardy, flamed bizarres. Third, Mr. A. Moorhouse, Wakefield, with Mrs. Lea and Thomas Parker, feathered roses; Madame St. Arnaud and Mabel, flamed roses; George Hardwick and Queen of the May, feathered bybloemens; Queen of the May and Hepworth's Seedling, flamed bybloemens; Sir Joseph Paxton and Masterpiece, feathered bizarres; Sir Joseph Paxton and Dr. Hardy, flamed bizarres. Fourth, Mr. W. Kitchen, Marple, with Heroine and Alice, feathered roses; Heroine and Annie McGregor, flamed roses; Violet Aimable and Violet Lillard, feathered bybloemens; Talisman and King of the Universe, flamed bybloemens; Typo and Sir Joseph Paxton, feathered bizarres; Dr. Hardy and Polyphemus, flamed bizarres. Fifth,

Mr. J. H. Wood, Middleton, with Modesty and Heroine, feathered roses; Mabel and Triomphe Royale, flamed roses; Bessie and Hepworth's Seedling, feathered byblœmens; Talisman and Chancellor, flamed byblœmens; Sir Joseph Paxton and Masterpiece, feathered bizarres; Sir Joseph Paxton and Richard Yates, flamed bizarres.

Class 2. *Six rectified Tulips, one of each class.*—First, Mr. Bentley with Heroine, feathered rose; Annie M'Gregor, flamed rose; Guido, feathered byblœmen; Mrs. Longbottom, flamed byblœmen; Sir Joseph Paxton, feathered bizarre; and Sir Joseph Paxton, flamed bizarre. Second, Mr. Needham with Modesty, feathered rose; Annie M'Gregor, flamed rose; Adonis, feathered byblœmen; Talisman, flamed byblœmen; Sir Joseph Paxton, feathered bizarre; and Sir Joseph Paxton, flamed bizarre. Third, Mr. Moorhouse with Mrs. Lea, feathered rose; Aglaia, flamed rose; George Hardwick, feathered byblœmen; Queen of the May, flamed byblœmen; Hardwick's Seedling, feathered bizarre; and Sir Joseph Paxton, flamed bizarre. Fourth, Mr. Kitchen with Modesty, feathered rose; Madame St. Arnaud, flamed rose; Violet Aimable, feathered byblœmen; John Hart, flamed byblœmen; Sir Joseph Paxton, feathered bizarre; and Dr. Hardy, flamed bizarre. Fifth, Mr. Wood with Modesty, feathered rose; Heroine, flamed rose; Talisman, feathered byblœmen; Nimbus, flamed byblœmen; Sir Joseph Paxton, feathered bizarre; and Sir Joseph Paxton, flamed bizarre. Sixth, Mr. W. Dymock, Stockport, with Julia Farnese, feathered rose, and Seedling, flamed rose; Seedling, feathered byblœmen; Seedling, flamed byblœmen; Lord Lilford, feathered bizarre; and Sir Joseph Paxton, flamed bizarre. Seventh, Mr. W. Mellor, Wakefield, with Mrs. Lea, feathered rose; Annie M'Gregor, flamed rose; George Hardwick, feathered byblœmen; Bessie, flamed byblœmen; Sir Joseph Paxton, feathered bizarre; and Sir Joseph Paxton, flamed bizarre.

Class 3. *Six dissimilar rectified Tulips, one of each class, for small growers only.*—First, Mr. H. Gill, Wakefield, with Mabel, feathered rose; Mabel, flamed rose; George Hardwick, feathered byblœmen, and Queen of the May, flamed byblœmen; Masterpiece, feathered bizarre, and Sir Joseph Paxton, flamed bizarre. Second, Mr. John Morris, Middleton, with Sarah Ann, feathered rose; Mabel, flamed rose; John Hart, feathered byblœmen; Talisman, flamed byblœmen; Catafalque, feathered bizarre; and Sir Joseph Paxton, flamed bizarre.

Class 4. *Three feathered Tulips, one of each class.*—First, Mr. Bentley with Owl, rose; Wm. Bentley, byblœmen; Wm. Wilson, bizarre. Second, Mr. Mellor with Mrs. Lea, rose; Violet Aimable, byblœmen; Masterpiece, bizarre. Third, Mr. Moorhouse with Modesty, rose; May Queen, byblœmen; Sir J. Paxton, bizarre. Fourth, Mr. Wood with Modesty, rose; Alice Grey, byblœmen; Sir J. Paxton, bizarre. Fifth, Mr. Kitchen with Heroine, rose; Violet Aimable, byblœmen; Lord Lilford, bizarre.

Class 5. *Three flamed Tulips, one of each class.*—First, Mr. Bentley with Annie M'Gregor, rose; Talisman, byblœmen; Sir J. Paxton, bizarre. Second, Mr. Morris with Mabel, rose; Lord Denman, byblœmen; Dr. Hardy, bizarre. Third, Mr. Dymock with Seedling, rose; Seedling, byblœmen; Sir J. Paxton, bizarre. Fourth, Mr. Wood with Triomphe Royale, rose; Duchess of Sutherland, byblœmen; Sir J. Paxton, bizarre. Fifth, Mr. Kitchen with Aglaia, rose; Talisman, byblœmen; John Ratcliffe, bizarre. Sixth, Mr. Gill with Mabel, rose; Reliance, byblœmen; Sir J. Paxton, bizarre.

Class 6. *Two Tulips, one feathered and one flamed of any class. Maiden growers only.*—First, Mr. J. H. Wood, Middleton, with Heroine, feathered; and Nimbus, flamed. Second, Mr. Bashforth, Leeds, with Criterion, feathered; and Sir J. Paxton, flamed.

Class 7. *Two Tulips, one feathered and one flamed of any class.*—First, Rev. D. Horner, Burton-in-Lonsdale, with Mrs. Atkin, feathered; and Sir J. Paxton, flamed. Second, Mr. Bentley with Garibaldi, feathered; and Sir J. Paxton, flamed. Third, Mr. Needham with Wm. Annibal, feathered; and Sir J. Paxton, flamed. Fourth, Mr. Wood with Heroine, feathered; and Nimbus, flamed. Fifth, Mr. Morris with Lewis W. Morris, feathered; and Sir J. Paxton, flamed. Sixth, Mr. Kitchen with Sir J. Paxton, feathered; and Aglaia, flamed.

Class 8. *Single blooms, feathered bizarres.*—First, Mr. Bentley with Masterpiece; third, with Lord Stanley; sixth, with Sir J. Paxton; and eighth, with Sir S. Romilly. Second, Mr. Morris with Lord Lilford; seventh, with John Ratcliffe; and tenth, with Sulphur. Fourth, Mr. Jones with Unknown; and fifth, with Charlie Flather. Ninth, Mr. Mellor with Hardwick's Seedling.

*Feathered Roses.*—First, Mr. Needham with Mrs. Atkin; third, with Comte de Vergennes; and tenth, with Dr. Vernon. Second, Mr. Morris with Sarah Ann; fourth, with Heroine; and seventh, with Mrs. Collier. Fifth, Mr. Horner with Modesty. Sixth, Mr. Bentley with Owl; eighth, with Industry; and ninth, with Madame St. Arnaud.

*Feathered Byblœmens.*—First, Mr. Jones with Coningsby; and second, with Bertha. Third, Mr. Bentley with Martin's 117; fourth, with Mrs. Jackson; fifth, with Beauty of Litchurch; sixth, with William Parkinson; eighth, with Elizabeth Pegg; and tenth, with Queen of the May. Seventh, Mr. Moorhouse with Hepworth's Seedling. Ninth, Mr. Mellor with George.

*Flamed Bizarres.*—First, Mr. Bentley with Sir Joseph Paxton; third, with Dr. Hardy; fifth, with Samuel Barlow; sixth, with Orion; and ninth, with Sulphur. Second, Rev. F. D. Horner with Sir Joseph Paxton. Fourth, Mr. Kitchen with Duke of Devonshire; and eighth, with Target. Seventh, Mr. Dymock with Polyphemus. Tenth, Mr. Jones with Wm. Lea.

*Flamed Roses.*—First and third, Mr. Bentley with Annie McGregor; second, with Madame St. Arnaud; fourth, with Triomphe Royale; fifth and tenth, with Mabel; and seventh, with Martin's Seedling.

Sixth, Mr. Bashforth with Mabel. Eighth, Mr. Kitchen with Queen Anne; and ninth, with Minerva.

*Flamed Byblœmens.*—First, Mr. Bentley with Mrs. Longbottom; second, with Talisman; third, with Elizabeth Pegg; fourth and ninth, with General Barnaveldt; fifth, with Adonis; sixth, with Chancellor; and eighth, with Hepworth's 68/62. Seventh, Mr. Gill with Mrs. Gill; and tenth, with Reliance.

Class 9. *The best feathered Tulip in the whole exhibition.*—King of the Universe, exhibited by Mr. Bentley in his stand of twelve Tulips. *The best flamed Tulip in the whole exhibition.*—Sir Joseph Paxton, exhibited by Mr. Bentley in Class 8.

#### BREEDER TULIPS.

Class 10. *Six dissimilar Tulips, two of each class.*—First, Mr. Bentley with Annie McGregor and Lady Grosvenor roses, Beauty of Litchurch and Elizabeth Pegg byblœmens, Sir Joseph Paxton and Lloyd's 47 bizarres. Second, Mr. Needham with Annie McGregor and Madame St. Arnaud roses, Talisman and Martin's 117 byblœmens, Sir J. Paxton and Lloyd's Seedling bizarres. Third, Mr. Moorhouse with Mabel and Hepworth's Seedling roses, Queen of the May and Talisman byblœmens, Sir Joseph Paxton and Hardwick's Seedling bizarres. Fourth, Mr. Wood with Annie McGregor and Mabel roses, Surpass le Grand and Alice Grey byblœmens, Horatio and Lea's No. 1 bizarres. Fifth, Mr. Mellor with Annie McGregor and Isabella roses, Beauty of Litchurch and an unnamed variety byblœmens, Sir Joseph Paxton and John Brook bizarres.

Class 11. *Three Breeders, one of each class.*—First, Mr. Bentley with Rose Hill, Leech's Seedling, and Sulphur. Second, Mr. Moorhouse with Mabel, George Hardwick, and Sir Joseph Paxton. Third, Mr. Mellor with Isabella, Beauty of Litchurch, and Sir Joseph Paxton. Fourth, Mr. Gill with Madame St. Arnaud, George Hardwick, and Willison's King. Fifth, Mr. Needham with Annie McGregor, Elizabeth Pegg, and Sulphur.

Class 12. *Single Blooms, Bizarre Breeders.*—First, second, third, fourth, fifth, seventh, and eighth, Mr. Bentley with Storer's Seedling, Lloyd's 239, Lloyd's 219, Lloyd's 223, Horatio, Lloyd's 119, Dr. Hardy. Sixth, Mr. Jones with Sulphur.

*Rose Breeders.*—First and third, Mr. Morris with Collier's Seedling. Second, Rev. F. D. Horner with Hepworth's 9/64. Fourth, fifth, sixth, seventh, and eighth, Mr. Bentley with Mrs. Barlow, Annie McGregor, Rose Hill, Mabel, and Queen of England.

*Byblœmen Breeders.*—First and third, Mr. Bentley with Martin's 117, second with Elizabeth Pegg, and sixth with Beauty of Litchurch. Fourth, fifth, seventh, and eighth, Rev. F. D. Horner with Seedlings.

The prize for the best breeder in the show was won by Mr. Morris with Collier's Seedling in Class 12.

#### SCOTTISH PANSY AND VIOLA ASSOCIATION.

THE first meeting of the above Society was held in the Religious Institution Rooms, Glasgow, on Wednesday, 5th June. There was a large attendance of members, and over 200 varieties of seedling Pansies and Violas were staged for the opinion of the Judges, who gave the following awards:—

Certificates of merit to Fancy Pansies Mrs. Gamp and The Baron; first-class certificates to Mr. Soots; certificate of merit to Viola Sunray, exhibited by Mr. S. M'Kee, Belfast; certificates of merit to Fancy Pansies Lady M. Hozier, Jeannie R. Karr; first-class certificate to A. Struthers, exhibited by Mr. G. Macpherson, Avondale; certificate of merit to Fancy Pansy Mary Bennett, exhibited by Mr. H. Chalmers, Beith; certificates of merit to Fancy Pansies Jessie Gillespie, Alex. Lister; first-class certificate to Col. Buchanan, exhibited by Mr. Alex. Lister, Rothesay; certificates of merit to Fancy Pansies John Mackie, James Smellie; first-class certificate to Mrs. Wm. Steele; certificate of merit to Violas Jessie Pretswell and Nellie, exhibited by Mr. John Smellie, Busby; certificate of merit to Viola Progress, exhibited by Messrs. Dobbie & Co., Rothesay.

The Judges were Mr. Wm. Cuthbertson, Rothesay, who presided; Mr. J. Baxter, Daldowie; Mr. M. Gray, Glasgow; Mr. M. Campbell, Blantyre; Mr. J. Stewart, Lennoxton; Mr. H. Hamilton, Lochwinnoch; Mr. W. Maxwell, Glasgow; and an entirely new departure was made in the method of making the awards. Each Judge was provided with a paper with columns for points for form, size, texture, colour, and distinctness, and each one put down figures according to his ideas of excellence. The maximum was twelve for each variety, and thus the highest possible total of the seven Judges was eighty-four. Sixty-three points carried a first-class certificate, and forty-two a certificate of merit.

The flowers were first handed to the Chairman, who after making his notes passed the variety on, and in this way all went before each of the seven Judges. The voting was practically by ballot, as all exhibits were placed on uniform stands, with only a number attached before going before the Judges.

#### GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—*Secretary*, Mr. G. J. Ingram, 50, Parliament Street, London, W.C.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—*Secretary*, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

ROYAL GARDENERS' ORPHAN FUND.—*Secretary*, Mr. A. F. Barron, Royal Horticultural Society's Gardens, Chiswick, London, W.

## FRUIT FORCING.

**Peaches and Nectarines.**—When the fruit is all gathered from individual trees the wood on which it has been produced should be cut away to the shoot at its base, which is to afford the bearing wood for next season, except if the fruit has been produced on wood that is necessary to retain for the extension of the trees. All growths not absolutely necessary for next season's bearing or for the extension of the trees should be cut away, as it is important the foliage have full exposure to light and air, and it is equally important that it should die naturally, not prematurely through attacks of red spider or lack of moisture at the roots. Keep the inside border well watered, and the outside one must not be neglected if the weather be dry. Admit all the air possible, and when the buds are plump and the wood thoroughly ripened the roof lights, where moveable, may be taken off. Employ the syringe freely, one forcible application being of more service in freeing the trees from red spider than many sprinklings.

**Trees Ripening the Fruit.**—Ventilate the house freely, leaving a little air on constantly, and to insure the preservation of the foliage in health sprinkle the paths, borders, and other bare surfaces with water in the morning and afternoon, not allowing the soil to become dry, but giving due supplies of water as required. A light mulching of short spent material is very useful in preventing the surface cracking and the roots going down in quest of moisture. Syringing must cease directly the fruit commences to soften for ripening, or the moisture will cause the skin to crack and leave an unpleasant musty flavour, as well as spoiling its appearance. Some netting placed beneath the trees is useful to prevent falling fruits being bruised; but let the netting be "pocketed," so as to prevent the fruit clashing against each other. In gathering the fruit great care is necessary, as slight pressure is sufficient to spoil the appearance.

**Trees Swelling-off Their Fruit.**—After the fruit has stoned and is taking the last swelling give every attention to the trees in watering with liquid manure or feeding with top-dressing of chemical manures washed in, mulching the surface lightly with short manure. The shoots should be allowed to extend where there is space, not pinching the laterals too closely, but they must be prevented shading the fruit, which should be raised with the apex to the fullest light. This can be effected by placing laths across the trellis, securing them to the wires. Continue forcible syringing morning and afternoon until the fruit begins ripening, then cease; but do not allow the border and other surfaces to become parchingly dry, as moderate moisture, provided the ventilation is liberal, will not injure the fruit, and it is absolutely essential for the benefit of the foliage.

**Succession Houses.**—Trees started in February are stoning, those brought forward gently having the fruit of good size, as is always the case when the trees are not hurried nor overcropped, and well attended to as regards nourishment and proper exposure of the foliage to light and air, with free ventilation on all favourable occasions. To continue the fruit in steady progress, and insure its stoning satisfactorily, there must not be any deficiency nor excess of moisture at the roots, and the foliage should be kept clean by daily syringings, and if necessary by the application of an insecticide. Continue the temperature at 60° to 65° artificially, allowing a free circulation of air between 70° and 75°, having it full when the latter is reached, and close at 75° with abundance of atmospheric moisture. If the temperature rises to 80° or 85° it will not do any harm, but admit a little air after nightfall, so as to allow the pent-up moisture to escape and the temperature to gradually cool through the night. Commence increasing the ventilation from 65° with the advancing sun.

**Late Houses.**—If it is desired to retard the fruit in any of these, so as to prolong the season of supply, it is best effected by free ventilation during the day and night when mild; indeed, there is only need to ventilate day and night to keep back the crop, so as to ripen about the same time, as usually occurs with trees against walls, and by judicious ventilation the fruit may be had over a lengthened period. It is necessary not to overburden the trees with more fruit in the early stages of growth than can remain for the crop, a moderate one being always better than a heavy crop; therefore thin well in the early stages, leaving a few more than will be required ultimately. Keep the trees well syringed, and mulch lightly, so as to keep the surface moist, thereby encouraging roots to the surface, giving thorough applications of water when necessary, and if the trees are weak and carrying heavy crops of fruit, afford liquid manure or top-dressings of chemical manures.

**Pines.**—*Fruit Ripening.*—When the fruits commence ripening syringing must cease, but the supply of moisture at the roots should be continued, affording water as necessary. With a view to improve the quality of the fruit, ventilate whenever circumstances permit, but do not allow the temperature to fall below 80° in the daytime, applying fire heat to maintain a night temperature of 70° to 75°, gradually reducing the moisture in the house. Queen and Providence Pines started in February will ripen this month, coming in about three weeks or a month before Charlotte Rothschild, Smooth-leaved Cayenne, and similar varieties

started at the same time and under similar conditions. They afford a successional supply which may be still further extended by removing some of the plants with the fruits to a cooler house. Although the Providence is not equal to a Queen Pine in quality, yet its size being superior, it is desirable to grow a limited number, as large fruits are useful at parties, if only for effect in table decorations. The heat at the roots should be 85° to 90°.

**Plants for Winter Fruiting.**—The strongest plants of those in the fruiting pots last September will now be showing fruit, if not means must not be further delayed to effect it for a supply of fruit for winter use. Bring the plants together and subject them to a comparative rest for the next month or six weeks, lowering the heat at the roots to 75°, maintaining a free circulation of air about the plants in favourable weather, ventilating at 75°, and allowing the heat to fall to that degree before closing the house, only employing fire heat to prevent the temperature falling below 60° at night, not withholding water altogether, but whenever a plant becomes dry afford a proper supply. The smaller suckers of last autumn that were wintered in 7 and 8-inch pots, and shifted this spring, must be kept growing until the pots are well filled with roots, at which time, if considered necessary, they may be subjected to the same treatment as advised for the larger ones, and those plants will then give a successional supply of fruit.

**Spring-potted Suckers.**—The strongest of those potted in March must be in their largest pots, if not there should be no further delay, as to allow them to become root-bound is detrimental to their after well-doing. Recently potted plants require regular bottom heat of 85° to 95°, and to be thoroughly watered, if the soil be dry, after potting, not giving any more until the soil again needs a supply. A too wet soil is not favourable to the formation of roots, moderate moisture only being needed.

**Ventilating, Watering, and Shading.**—Young stock will be making rapid progress, and must be regularly attended to in every particular, allowing such plants sufficient space for development, as nothing is so prejudicial to sturdy growth as crowding in the early stages. Ventilate early in the day at 75° to 80°, to render the foliage dry before it is affected by the sun. Examine the plants twice a week for watering, not giving any until it is needed, and then a thorough soaking with tepid liquid manure, being careful not to give it too strong. Discontinue shading succession plants; but those fruiting with the crowns in close proximity to the glass will require a slight shading from powerful sun. Syringe the plants on bright afternoons, and otherwise maintain a genial condition of the atmosphere by sprinkling the house, but avoid moisture in dull weather, as it only tends to cause soft growth. So long as water remains in the axils of the leaves syringing is not much required, therefore pour the water well up the plants, as the leaves have roots at their base that contribute to the vigour of the plants and swelling of the fruits.

**Potting Suckers.**—The early-fruited plants as they finish will afford suckers, which should be taken off and started at once in sufficient quantity to meet the demand, which will afford plants for fruiting about this time next year, forming supplementary plants to those started in the spring. The treatment then given will answer for these, only they will require more careful shading and frequent attention to damping, keeping close until rooted, as indicated by their commencing to grow.

**Cucumbers.**—In houses fire heat will only be necessary to prevent the temperature falling below 65° at night and to insure 70° to 75° by day artificially. Attend well to stopping the shoots, removing bad leaves, well thinning the old growths, and watering with weak liquid manure about twice a week. To encourage surface roots sprinkle the bed with sweetened horse droppings once or twice a week, and occasionally with a little soot or some approved fertiliser, both of which will supply nourishment to the roots and give off some ammonia.

**Utilising Empty Structures.**—Houses cleared of Vines in pots, Strawberries or bedding plants, may be usefully devoted to Cucumbers. They can be grown well in boxes of 15 inches depth and 18 to 24 inches square. A wood or other trellis may be improved at 18 inches from the glass. No fire heat will be necessary, the house being closed at 3 to 4 P.M., or earlier, according to the sun being clear or overcast, syringing then, the floors and every available surface being kept damp, so as to secure a good moisture through the day; but do not syringe in the morning, this often being the cause of great mischief to the foliage. Admit air at 75°, and allow the temperature to rise to 85° or 90° with sun, and close between 80° and 85°, and if the temperature rise to 90° or 95° all the better. Train with a single stem to the trellis, rubbing off all laterals to that height, then allow to grow; pinch the leader after it has grown two-thirds across the trellis. The laterals must be stopped one or two joints beyond the show of fruit.

**Pits and Frames.**—Water the plants about 4 P.M., closing then or earlier according to the weather, but it is not safe to close so early as to raise the temperature above 90° or 95°. Liquid manure should be given occasionally, but not over the foliage, and not applying it too often. Keep the growths fairly thin, thinning out old shoots and encouraging others in their place, so as to keep up a succession of bearing wood. Stop one or two joints beyond the show for fruit. Avoid crowding, also overcropping, and do not allow the fruit to remain on the plants a day longer than can be helped.

## THE KITCHEN GARDEN.

**Asparagus.**—Very hot weather in May hastened the growth of Asparagus. With many growers it is the rule to cease cutting on or about June 15th, and this date should certainly be the latest this year. Besides, Peas ought to be fairly plentiful by that time in most warm

gardens. Exhausted beds would be greatly benefited by a dressing of fish guano, or nitrate of soda and guano mixed, and applied at the rate of 2 ozs. per square yard of bed. If very weedy give a liberal dressing of manurial salt, enough to whiten the bed, or otherwise the weeds will not be long before they smother the Asparagus. It is not yet too late to fill gaps in the rows of young Asparagus, or even in the older beds. Select a showery time if possible, but do not wait long for this; and move young plants that have already formed some top growth. This year's seedlings move readily. If seeds are sown where the plants are to remain permanently, thin to a distance of not less than 15 inches apart, or they may be left half that distance, and half be transplanted next spring. Extra strong growths on either isolated plants or thinly planted beds should be supported with stakes, otherwise they break in wet windy weather, to the injury of the buds or crowns forming at their base.

**Artichokes.**—Seedling Globe Artichokes turned out of pots into rich soil should be supplied with water occasionally till strongly established in their fresh quarters. They may eventually be left 18 inches apart in the row, and by cutting out the inferior forms directly they are detected good room will, as a rule, be given. Some of the old clumps are now pushing abundance of growths, and these must be thinned very freely with a view to having three extra strong, branching flowering stems from each. Divisions or newly rooted growths ought to be liberally treated, more so than in the case of the naturally vigorous seedlings. All pay for having abundance of water in dry weather, liquid manure helping the older clumps. Mulch with strawy manure.

Jerusalem Artichokes, unless planted similarly to Potatoes, are almost certain to come up too thickly, and if the tops are crowded it is not possible for a good crop of tubers to form below. The simplest way out of the difficulty at this late date is to cut 3 feet spaces between the mass of plants. Draw soil up to the rows generally, and that will be all that is needed.

**Broccoli and Cauliflowers.**—Varieties of Broccoli that heart late in the autumn are of good service as forming a succession to late Cauliflowers, and for carrying on the supply well through the winter. Veitch's Self-protecting Broccoli is one of the best, and this ought to be put out to have plants, lifting and storing in pits, frames, or cool houses, where they will continue to heart during the winter. This class of Broccoli may safely be disposed between widely planted Ashleaf or other short-topped early maturing Potatoes. If the later varieties are too thick in the seed beds, and the ground is left clear for this crop, do not delay planting; but they must be grown on very firm ground, and given good room, or otherwise they will become too rank to be hardy. It is the later raised plants that usually prove the hardiest. If Autumn Giant Cauliflower is planted now these will give a serviceable supply late in the season. When early Cauliflowers commence hearting give liquid manure freely.

**Various.**—Top the more forward Broad Beans to destroy aphides and hasten the growth of pods. If in demand late in the season sow rows of Beck's Dwarf Green Gem. Brussels Sprouts should be planted early, and on firm good ground, or they may be disposed among early Potatoes, as advised in the case of early Broccoli. Treat the Green Curled Borecole similarly. It is possible to be too early with Savoys, as these are only of value after frosts have destroyed the more tender vegetables. Endive is not in great demand early in the season, but if appreciated sow seeds of Moss Curled and Green Curled thinly in drills 9 inches apart, thinning to about 6 inches asunder when large enough. Sow good forms of Cabbage and Cos varieties of Lettuce at fortnightly intervals in lines where the plants are to mature. If Radishes are in demand sow the Turnip-rooted every ten days on good ground, and dust over frequently with soot and lime.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### VENTILATING FLOOR.

PREVIOUS to the ventilating floor, ekes or "raises" (as they were frequently termed) were for a long time in use, especially with the Stewarton hive. These ekes were used for two or three purposes. In the winter for ventilation for the better preservation of the bees, and in the summer to help to prevent swarming. When the proper time came the eke was put under the hive; the bees took possession of it immediately, and combs were built on those having bars. These ekes were allowed to stand from one to three days, when they were removed and the supers put on, by which removal, and the hive becoming more crowded, the bees took to the supers at once.

The combs built in the eke were removed and used as "tooks" for supers. These white combs preserved the purity of the future combs, and produced finer honey than those made on comb foundation. During the autumn, or the time the hives were prepared to stand the winter, an eke was placed under each hive. This was intended to prevent damp and mould on the combs, and bees from dying from distension and similar diseases.

When used in my apiary I observed ekes did not prevent damp, mould, or dead bees on the floor and between combs. I also observed when bees were airing in the winter months many of them were enfeebled before they left the hive from the damp floor. Hives which had no ekes, and having their combs well down, the bees on returning were safe. In order to make all clear the strong hives were always the worst winterers. My first step with the ventilating floor was to do away with the ekes entirely, bringing the combs, or rather managing to have them, near the entrance. I had my floors covered with perforated zinc, then over it a reversible and moveable wooden floor, but later the wood was removed, for I observed that bees died when they came into contact with damp wood. They passed over zinc at lower temperatures with impunity. I tried floors of coal, turf, wax, and wood, but damp could not be entirely prevented, so contrived the perforated zinc over an empty chamber. The best plan of all is peat beneath the zinc for the winter only.

Considerably over thirty years ago, when taking my bees to Arran, they were subjected to rough treatment and overheating in the railway vans and on a steamer, with the result in a short time that one hive only was free from foul brood. To clear out the disease required prompt action. I put every hive through the "purgatorial" process, adopted the ventilating floor, and have not seen one diseased cell since. This, coupled with hives which were never taken to the moors, pointed to the fact that overheating was the prime, if not the sole, cause of foul brood. Raising the hive from the floor in very hot weather does not cool its interior to the extent we are led to believe, as it cannot by the plan be made lower than the temperature outside. The ventilating floor keeps bees in a healthy and cleanly state, the hive being always free from dust or débris.

Full instructions were given lately how to construct the whole hive, including the floor. This is simply a case the size of the hive and from 4 to 6 inches deep, having a sheet of perforated zinc on the top. This lowers a little to the back fillets for the wooden shutter to rest against, being held tight to them by a button at the back and by a fillet each side. These fillets lower at the back to permit the shutter to drop when ventilation is wanted, or when the shutter has to be cleaned of parasites and dirt. It resembles the bottom of a bird cage. To keep the stand rigid and less in depth I nail pieces of wood on the flat about 3 inches by half. These stands, as all nailed framework should be, are checked; the feet too, about 2 inches below the stand about 2 inches by  $1\frac{1}{4}$  inch, should also be half checked and fastened with brass screws.

In conclusion, I may inform your correspondent, "J. B.," that between the perforated zinc and shutter there must be a space between 1 inch and 2 or 3 inches to condense the perspiration on the shutter, and there will be no dead bees on the floor nor foul brood, unless infected from another source.—A LANARKSHIRE BEE-KEEPER.

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Gold-coloured Beetle** (*C. L. M.*).—The beetle received is popularly called the Rose Chafer (*Cetonia aurata*). It emerges from the pupa some time in June. Though associated with the Rose, it often swarms on the bloom of other plants, the Privet and Elder for instance, and also on humbler species, such as Candytuft. Most authorities agree that it bites the petals, but some entomologists have questioned if this is the fact. In the larva state it lives on decayed wood, also probably upon roots of various plants during two or three years. It occurred abundantly about the old market gardens of Brompton and Fulham.

**Zonal Pelargoniums for Winter (Wreath).**—As you particularly require an answer this week it must be short. The plants should be encouraged to make stout, short-jointed stems and thick leaves through being potted firmly in generous soil and grown in the full sun in the open air, but first where they can have protection, as in frames, from drenching rains. Top them once or twice, give weak liquid manure when the pots are filled with roots, and pick off all flower buds as they form during the summer. Your other questions did not arrive soon enough to be satisfactorily answered in the present issue.

**Tomatoes not Swelling—Preventing Mildew (Cross).**—Wednesday morning's letters can only be answered briefly in the current issue. If you top the plants you will prevent other fruits forming and swelling, though it might assist the lower fruits. It is a question of space and the value of the crop in the aggregate. We have previously stated that Mr. R. Fenn absolutely prevents mildew on his Tomato plants and Vine in the same house by the systematic use of anti-blight powder. Previous to its use both Vine and Tomatoes under glass, and Roses outdoors were, as we have seen, white as millers; since its regular use, as we have also seen, they are absolutely free from even a speck of mildew. Mr. Fenn has himself recorded his experience on the subject in our columns.

**Diseased Tomato Plants (J. Barr).**—The plants are affected with the drooping disease. It is caused by the Tomato slime fungus (*Plasmodiophora tomati*). The whole of the *Plasmodiophoras* are prevented by dressing the ground with quicklime, and avoiding manures of the sulphate class, or those formed by dissolving with sulphuric acid. Dusting quicklime (air slaked) on the affected parts arrests its progress. Your plants are also affected with the Potato fungus (*Phytophthora infestans*), and issuing from the tissue of the yellow or brownish portion of the leaves we detected the conidiophores of this fungus. The preventive, for there is no remedy, is to spray the plants with Bordeaux mixture, or dust them with one of the anti-blight powders in the market. This will prevent the spread of the disease, and you may yet have a satisfactory crop, especially as the plants are healthy at the roots.

**Rhododendrons not Flowering (Somerset).**—It is not unusual for Rhododendrons to flower very fully one year and but sparingly the next, through being more or less exhausted by the excessive production of bloom, and seriously retarded in the formation of buds by neglecting to remove the trusses as soon as the flowering is over. If this be done by taking each spent truss between the fingers and thumb, and a sharp twist given downwards on one side, the work can be done readily without damage to the pushing shoots, and seeding being prevented the growth and buds will profit correspondingly. You could not have anything better than the leaf mould and manure rubbed through a sieve, but it is desirable to add some sand, either mixing it with the compost or sprinkling on the surface. We do not advise lifting the shrubs, as it sacrifices their healthy appearance, and is not good for them generally, though it certainly has a tendency to induce the production of flower buds.

**Dividing Clumps of Asparagus (C. R. P.).**—It is not advisable to take up and divide thick clumps, as the plants or divisions do not grow at all well, the check being too great; hence the best plan is to fill up the gaps by planting one or two-year-old plants from seed in the spring, preferably when the plants are starting into growth, or early in April, setting carefully, and without injuring the roots or crowns of the old plants. Some growers make the gaps in old beds good by sowing seed early in April, inserting the seed in holes about an inch deep, and two seeds in a hole, the holes being 15 to 18 inches apart, and so made where the bare places are to fill them evenly, covering the seeds with fine soil. The young plants from the seeds will gain strength from year to year, and produce heads in the third year fit for cutting. The best varieties are Conover's Colossal and Early Giant Purple Argentueil. If you prefer saving seeds from your own plants, either keep them in the berries over winter or separate them from the pulp when thoroughly ripe.

**Diseased Potato Crops (W. C.).**—The Potato plant is affected with "curl" disease, which is caused by a fungus called *Macrosporium solani* as regards the "curl," for we found two distinct parasites, the one just mentioned being present on the part above ground, whilst on the dead portion or decaying stem below ground was the somewhat common fungus found on decaying Potatoes—namely, *Fusarium solani*. The latter is closely allied, if not synonymous, with the fungus producing the "sleeping" disease in Tomatoes, whilst the former is little different, if at all, from that causing "black stripe" in these plants and fruits. The spores in both cases are in the soil, and they seem to be capable of resting for considerable periods, and on the ground being cropped with the plants on which they are parasitic they germinate, attack and destroy the crop or such part as they infest. The diseases, however, are carried over from year to year in the seed or sets, and the only preventives are clean seed and ground subjected to a due course of crop rotation, with an occasional liming, not using less than 1 peck per rod or 40 bushels of freshly burned lime per acre, employing it during dry weather in the spring, about a month or six weeks before planting, and spreading it on the ground as soon as slacked. To prevent the spread of "curl" fungus, which causes the tops to collapse later on in plants that escape the first assaults of the malady, spray the plants with Bordeaux mixture, and repeat twice at about three weeks intervals, the first taking place when the tops are about 6 inches high. The spraying is equally effective against the Potato disease fungus (*Phytophthora infestans*).

**Nectarine Fruits Falling (Nemo).**—On examining the fruits sent we have no doubt the misfortune complained of is due to one of two causes, or it may be in part to both—namely, imperfect fertilisation or a deficiency of lime. If the border contains a good quantity of calcareous matter, then undoubtedly the blossoms did not set as they should have done. This may have arisen from a deficiency of pollen, imperfect organs of fructification, or a damp atmosphere when the tree was flowering.

**Apple Shoots Withered (R. S.).**—The shoots are dried, and have probably suffered through the trees being kept a considerable time out of the ground, or they may have been injured through freezing and handling before planting. Certainly they have had their tissue destroyed by some means, the sap not being able to penetrate the damaged parts. No damage seems to have resulted from the pruning, the tissue being entirely destroyed, and no doubt prior to the pruning, although the wood might not show the defective condition until it was subjected to the increased evaporation of the advanced season.

**Apple Chermes (Inquirer).**—The most efficacious wash for the destruction of this pest is one containing sulphuret of lime. This may be made by combining the sulphuret with water, or more conveniently by boiling together sulphur and lime in the proportion of 1 lb. of sulphur and 2 lbs. of lime to 4 gallons of water. Tobacco water also kills them, with or without the addition of Gishurst compound, but the difficulty is to reach the insects, secluded as they are in the blossoms. In fact, not much can be done during the spring, and the time for the destruction of chermes is the winter. Those which are to be the parents of the new brood lodge within cracks of the bark, angles and ridges of twigs, and the like places of shelter, where, however, they may be reached and killed by copious syringing with a hot solution of softsoap.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (W. S.).—*Kerria japonica* flor. pleno. (Y. G.).—1, *Oncidium sphacelatum*; 2, dead. (H. C.).—1, *Carex paludosa*, Marsh Sedge; 2, *Geum urbanum*. (W. T.).—1, *Dendrobium Parishii*; 2, *Cypripedium barbatum*; 3, *Maxillaria tenuifolia*. (C. F. F.).—1, *Alternanthera magnifica*; 2, *Kleinia repens*; 3, *Funkia undulata variegata*; 4, *Cupressus Lawsoniana erecta viridis*; 5, *Retinospora plumosa aurea*. (Junior).—The numbers had become detached. The small flower was *Cymbidium bicolor*; the larger one *Maxillaria Hendersoni*, and the *Cattleya* a form of *gigas*. (H. Cameron).—1, *Cytisus alpinus*, the Scotch Laburnum; 2, *C. Adami*; 3, *C. purpureus*; the second a bud sport intermediate between the other two, all growing on the same tree; 4, *Cornus sanguinea*, the Red Dogwood. (R. H.).—1, *Habenaria bitolia*; 2, *Listera ovata*. (W. H. C.).—1, *Salvia verbenacea*; 2, *Spiraea bella*; 3, *Pentstemon Cobœa*; 4, *Mertensia dahurica*; 5, *Prunella vulgaris*; 6, *Spiraea lævigata*. (Z.).—1, *Andromeda ovalifolia*; 2, *Thujaopsis dolabrata*; 3, *Abies canadensis*; 4, *Pernettya mucronata*; 5, Possibly *Pinus pinsapo*, specimen too young. (T. K.).—*Medicago orbicularis*.

COVENT GARDEN MARKET.—JUNE 12TH.

OUR market has settled down to a more regular business, supplies of Peaches, Grapes, and Strawberries being good. Large consignments of Southampton outdoor Strawberries to hand.

FRUIT.

SWINE.

“BUY when live stock is cheap, sell when it is dear,” is a trade maxim which might be applied to swine now with advantage. For a longer time than usual pigs have been so high in price that breeders have found them very profitable; but the usual reaction has come again at last, and store pigs have fallen to a nominal price. At two markets recently we have bought sturdy little “stores” at 12s. apiece. We could take almost an unlimited number of really healthy pigs at that price for our corn farms, giving them a run on grass near the homestead with just enough corn to keep them in fair growing condition till the corn stubbles are ready.

As they come off the stubbles they are pushed on for market briskly, most of them being sold as “light bacons” or “middles.” These are pigs in prime condition, with a range in weight from 130 lbs. to 190 lbs., and with a thickness of fat not exceeding 2½ inches in any part of the back. Such pigs command the highest prices from the best bacon firms if consigned to them by the truckload of twenty-five pigs. They will purchase others at special quotations up to a maximum weight of 240 lbs. and a back fat thickness of not more than 3 inches, the price falling with every 20 lbs. in weight over 190 lbs. and with a proportionately greater thickness of fat, but they will not quote for heavier pigs in quantity.

This is an aspect of the pig trade with which farmers generally are unacquainted. Our special object in mentioning it is to urge on their attention the true importance and profit of striving for a share of the big wholesale trade in the prime light and middle bacon pigs which we have described. To take full advantage of it, or, in point of fact, of the pig trade at all, the breeding, selection, and classification of swine must be more systematic and on a much larger scale. In this, as in most other farm produce on which a profit is still possible we want regular consignments by the truckload from rural districts; we should then cease to hear complaints of preferential railway rates because they would cease to exist. It is simply because most imported farm produce can be handled in bulk with such ease and so quickly that the railway rates for it are so low. But this is a matter which must be dealt with in another article.

Turning now to the question of breeding, we would have middle whites or a good cross for porkers, and Tamworths for bacons. The beneficial effect of judicious cross-breeding is simply marvellous. Berkshire or Suffolk sows crossed with a pedigree middle white boar give excellent porkers, on which a profit is always possible. Porkers of 50 or 60 lbs., and bacons of about three times that weight, are profitable pigs. Have no

sows that are unsatisfactory in any way. Begin breeding at the age of six months, and as fast as possible subsequently. After the first farrow a sow should average at least twenty pigs a year, but it should not be kept for breeding when it becomes very big and unwieldly. As to the number of sows, we should like to have seen very many more of them during the two years of high prices through which we have just gone. It is certain that in 1892 when pigs were so cheap they proved very profitable to those who had the wit to buy cheap in the autumn of that year and sell in the spring of 1893, when they became very dear. With corn so cheap we certainly do not think it advisable to reduce the number of sows now—rather would we take advantage of a cheap market to add to their number.

Always have before you the risk of swine fever, and not only keep sty and litter thoroughly clean, but pay heed to the dietary, which change occasionally. If the sow and pigs cannot have a run out on grass give them such green food or roots as the season affords, a few coal cinders occasionally, also some Thorley’s condimental food, and above all constant attention.

WORK ON THE HOME FARM.

Mangolds generally appear to be a full, strong plant, and we have seen much singling and hoeing being done among them during the past week. Continuous Mangold growing is done on the sewage farm at Luton with complete success, the crop every year being a fine one. In 1892 it was remarkably so, but then and always the narrow beds were enriched and moistened by the sewage with which the trenches between the beds are kept filled. The obvious lesson is not merely immunity from drought by such a system of irrigation, but also how, when soil fertility is as fully sustained as this is, Mangolds or any other crop may be grown in it to perfection continuously.

Wild Mustard is rampant more or less just now wherever we go. We have a small arable field lying fallow which is just a sheet of yellow with it. The flower petals are falling, and we intend having it well worked by the steam cultivator before the seed of the Mustard, Charlock, or Kedlock ripens at all. This has been an arable field for many years, and it would still be very useful for green crops or roots, but with the Charlock before we have decided to get it fairly clean this summer, and then lay it down to grass with a corn crop. To keep it in plough means a long battle with the Charlock at a considerable outlay to very little purpose. Laid down to grass the pest is beaten, and the matter settled once for all.

Dull weather has retarded the haymaking, but no harm has been done, as what thunder showers there has been were very local. Mixed seeds are a splendid crop, both Rye Grass and Cocksfoot being alike vigorous. Meadow grass comes on apace, and the haymaking in all rich pasture south of the Trent will soon be general. Growth in poor meadows lags behind sadly, growth waits on rain as usual. If rain does not come soon there will be no mowing till the first weak growth that should have been the hay crop is getting brown and sere, and what should have been the aftermath has grown up among it. This sort of semi-failure is no new thing, but happens more or less yearly.

REMARKS.

2nd.—Fine all day, but brighter in the after part.  
 3rd.—Bright, with hot sunshine till about 3 P.M.; overcast after, and drizzle in evening.  
 4th.—Overcast all day, a little sunshine in evening.  
 5th.—Drizzly early, and overcast morning; generally sunny after 2.30 P.M.  
 6th.—Generally overcast till 11 A.M.; bright sunshine all afternoon.  
 7th.—Brilliant throughout, with pleasant breeze.  
 8th.—Bright and warm throughout.  
 A uniformly fine week, but of variable temperature; the high maximum on Saturday made the mean for the week slightly above the average.—G. J. SYMONS.

# WM. PAUL & SON'S

## NEW ROSES for 1895.

**SYLPH** (Tea), White, tinted with Violet and Peach, a beautiful blending of colours; large, high-centred, with deep, stiff petals, vigorous, and constitution hardy, very free-blooming, 7/6 each.

**ZEPHYR** (Tea), Sulphur-Yellow, changing to nearly White, large and full, cupped form, very free and elegant, good habit and vigorous; a very effective Rose, and excellent for cutting, 7/6 each.

### NEW AMERICAN VARIETIES.

**MRS. PIERPONT MORGAN** (Tea), 3/6 and 5/- each.

**PINK SOUPERT** (Polyantha), 3/6 and 5/- each.

**PRINCESS BONNIE** (Tea), 3/6 and 5/- each.

### The New Continental Roses for 1895.

A selection of the best varieties, including **FIAMMETTA NABONNAND** (described as a White Papa Gontier), 3/6 each; 36/- per dozen.

### NEW ROSES OF 1894.

**CLIO** (H.P.), Flesh colour, shaded Rosy Pink; flowers large and handsome, exceedingly vigorous and free blooming. A grand Rose. 3/6 and 5/- each.

**DUKE OF YORK** (China), White to Rosy Pink, edged and tipped Ormson; exceedingly pretty and distinct. 3/6 and 5/- each.

**LORNA DOONE** (Bourbon), Magenta-Carmine shaded with Scarlet; large. A splendid Autumnal bloomer. 3/6 and 5/- each.

**LORD PENZANCE'S HYBRID SWEET BRIARS**, 5/- each; the set of nine varieties, 42/.

**OTHER ENGLISH & CONTINENTAL ROSES OF 1894**  
All the best sorts, 2/- to 3/6 each.

Full Descriptive Catalogue post free on application.

Also a large general collection of ROSES in pots for out-door planting, or for pot culture, 12/- to 30/- dozen, 75/- to £10 per 100; larger plants, 42/- per dozen and upwards.

**PAULS' NURSERIES, WALTHAM CROSS, HERTS.**

**C. COX,** Horticultural Engineer,  
**TUNBRIDGE WELLS.**

THE HERCULES.—Design Registered.

## TENANT'S FIXTURE PORTABLE SPAN-ROOF CURVILINEAR CONSERVATORY OR GREENHOUSE

No brickwork required. These houses are made of the best materials, painted four coats, and glazed with 21oz. clear sheet glass, a flat painted stage is fixed on each side and one end, and slatted path up centre.

CASH PRICE, Carriage Paid to nearest Station in England & Wales, within 100 miles of Tunbridge Wells, fixed free, £15.

SEND FOR ILLUSTRATED CATALOGUE.

## CUCUMBER & MELON FRAMES,

Painted three coats, and Glazed with 21oz. Glass.

1 Light Frame, 4 ft. by 6 ft.	.. .. .	£1 10 0
2 " " 8 ft. by 6 ft.	.. .. .	2 10 0
Violet Frame, 4 ft. by 6 ft.	.. .. .	1 7 6

Carriage Paid on Orders amounting to 40s. and upwards to any Goods Station in England and Wales.

## THE NEW EARLY STRAWBERRY FOR 1895, STEVENS' WONDER.

The earliest variety in cultivation and very prolific; solid fruit, good flavour, high perfume.

Awarded First-class Certificates, Royal Horticultural Society, and Royal Botanic Society, 1895. See *Gardeners' Chronicle*, March 2; *Journal of Horticulture*, March 14; and *The Garden*, March 16.

Having purchased the who'e of the stock of this grand new early Strawberry from the raiser, we have pleasure in offering it as follows:—

**STRONG PLANTS**, in Pots, £5 per 100, 15/- per doz.

**RUNNERS** .. .. £3 " " 9/- " "

Ready for delivery early in July. Early Orders requested as stock is limited. Further particulars upon application.

**WM. CUTBUSH & SON,**  
HIGHGATE NURSERIES, LONDON, N., AND BARNET, HERTS.

## FOR PRESENT & LATER SOWING. THE THREE WALLFLOWERS BEST

ARE  
**DICKSONS GOLDEN BEAUTY.**  
**DICKSONS SELECTED DARK RED.**  
**DICKSONS PRIMROSE DAME.**

Per Packet 6d. and 1s., Free by Post.

Choice Mixed Double Wallflower, Myosotis, Silenes, &c.  
For Prices and all other particulars see our ILLUSTRATED CATALOGUE, Free on application.

**DICKSONS, Seed Growers, NURSERYMEN, &c., CHESTER.**

## Bedding Plants.

SPECIAL CLEARANCE OFFER. ALL SPLENDID STUFF.

**ALTERNANTHERAS**, Magnifica, Aurea Nana, Yellow Gem, Versicolor Grandis, and Amœna Spectabilis. In pots, 2/- doz.; 12/6 100. In boxes, 1/3 doz.; 7/6 100.

**AGERATUMS**, best dwarf sorts, to name. In pots, 2/- doz.; 12/6 100. In boxes 1/3 doz.; 7/6 100.

**GAZANIA**, Splendens and Variegata. 2/6 doz.

**SALVIA**, Patens, 3/6 doz. **MUSK**, Harrisoni, 2,6 dozen.

**OENTAUREA**, Ragusina Compacta, 3/- doz.

**IRESSINE**, Lindenii and Brilliantissima. In pots, 2/6 doz.; 15/- 100. In boxes, 10/- and 12/- 100.

**TROPÆOLUMS**, named, from cuttings, best dwarf crimson and scarlet, 3/- doz.; 20/- 100.

**LOBELIAS**, finest blue varieties, to name, from cuttings. In pots, 2/- doz.; 12/6 100. **KLEINIA**, Repens, 3/- doz.

**VERBENAS**, best bedding sorts, to colour, 2/- doz.; 14/- 100.

**ECHEVERIAS**, Sanguinea and Peacocki, 6/- doz.; Agavoides and Rosea, 9/- doz.; Metallica, 12/- doz. CATALOGUES FREE.

**WM. CLIBRAN & SON,** OLDFIELD NURSERIES, ALTRINCHAM  
Also at MANCHESTER, LLANDUDNO JUNCTION, &c.

## PEED'S CALADIUMS.

Awarded a Silver-Gilt Flora Medal at the R.H.S. Temple Show, May, 1895.

Reports from the Horticultural Press, May 25, 1895.

*Gardeners' Chronicle*:—"Messrs. John Peed & Sons staged a collection remarkable for the perfect colour of many of the varieties included. . . . The collection was extremely praiseworthy."

*The Garden*:—"The best group of Caladiums was that from Messrs. J. Peed & Sons, the plants being noteworthy for their bright colours, and many most charming varieties were shown."

*The Gardeners' Magazine*:—"Messrs. J. Peed & Sons surpassed themselves with Caladiums; the specimens were of good size, splendidly coloured, and nicely set up."

CALADIUM CATALOGUE free on application.

**JOHN PEED & SONS,**  
Roupell Park Nurseries, LONDON, S.E.

## GATHER HONEY FROM YOUR FLOWERS.

WHY NOT COMMENCE BEE-KEEPING?

Fruit trees to which Bees have access bear the most abundant crops

For Vines, Plants, and Vegetables. Crushed Bones, and all high-class Fertilisers, for Farm or Garden. Genuine only from—

**W. H. BEESON, Carbrook Bone Mills, Sheffield.**

## Journal of Horticulture.

THURSDAY, JUNE 20, 1895.

### PRODUCE FOR PROFIT.

GREAT BRITAIN throughout all modern history has been a commercial and utilitarian nation. If this had not been so the mere geographical speck occupied by this nation on the face of the globe could not possibly have attained to the prominent position now enjoyed and admitted by the force of its enterprise and corresponding wealth. There have been ebbs and flows in its prosperity, and from time to time one or other of its great industries have been periodically inflated and depressed. Its population has been continually increasing, and, subject to temporary checks, its trade expanding. But it was not to be supposed that other nations would be content to look on and let us take the lead unchallenged in the field of production for meeting the wants of the world. The extraordinary developments in rapidity of communication and the transference of commodities forbade that, and we have now formidable rivals in many lands.

Though we inhabit a small island there is no such thing as isolation, and the days of monopolies are past. It is, so to say, as easy now to pass from nation to nation, even to the uttermost parts of the earth, as it once was to pass from county to county across our little territory from east to west, or north to south. As a result we have now, in practically everything we produce as a nation, keen competitors in other lands, distant as computed by mileage only, and for commercial purposes very near, even on speaking terms. The time has gone for ever when each civilised nation will be content to supply its own needs alone, and each is now striving to meet the wants of the other. This rivalry in production is bound to go on, and many who engage in the contest must of necessity find it "hard to live," and some in the very nature of things will "go under."

The harder the times become as affecting certain industries the greater the pressure will be on our legislators to remove obstacles and make laws for the benefit of such industries. In this reference it may be well to bear in mind that legislators are made by the community, and the fact that this is very "mixed" renders the process in any particular direction provokingly

slow to the persons interested. The great problem of the times appears to rest in the discovery of some method of helping one section without hindering the other, and whatever may be the outcome of collective effort on behalf of an over-pressed industry, one thing is clear—namely, that those persons engaged in it cannot make any possible mistake in striving with all their might to range themselves amongst its most successful representatives. This can only be done by the acquisition of the widest knowledge, the exercise of the best judgment, and the application of methods they have discovered to be sound, or which others may have found satisfactory.

The *Journal of Horticulture* and its supporters are directly interested in the successful cultivation of garden products both for home use and commercial purposes. At the moment we have in view the last named aspect of gardening, in which more and more persons are engaging every year in the hope of deriving profit from it. Some succeed, while others fail, as in all occupations. There is no disgrace in failure when efforts have been conducted on strictly honourable lines, and we have no reproach for striving and industrious men who are not favoured by fortune in their undertakings. A person may be thoroughly competent as a cultivator, yet if he does not happen to have a supply of what is most in demand at a particular time his labour will have been to a large extent wasted. If we have more inquiries of one kind than another they are from persons who either desire to know what can be grown to give profit, or how to remove difficulties which are encountered in the work of commercial gardening.

Several months ago we were inundated with letters in reply to a communication inserted from a perplexed correspondent relative to the profitable occupation of houses in the winter that were devoted to Tomatoes in the summer. Not half of what came to hand could be published, and with the view of eliciting information of a more precise nature, we offered a silver medal for the best essay, or essays, bearing directly on the "Profitable Occupation of Glass Structures in Winter." This brought a mass of information, so great and so varied, that it was most difficult to deal with. As a matter of fact no adjudicators could be found to declare any one essay to be better than all others. On that basis a decision would never have been arrived at. The essays were then divided according to the subjects treated—namely, those which dealt with plants and flowers mainly, and those which dealt with other crops. Then a further assortment had to be made which led to the setting aside of some admirably written essays containing valuable hints and cultural details, but in which the cost involved and the profits obtainable were not indicated with sufficient clearness. A few essays had been too hurriedly written and thus lost points. It should be borne in mind by writers that the value of literary productions is determined on the same principles as exhibits at shows; that is, judges are bound to note all faults as well as merits, and they cannot take into account the difficulties of exhibitors.

Ultimately the essays were reduced to four, and these divided into pairs according to the subjects treated, with the object of granting two medals. Two examiners were in favour of the essays of "Excelsior" (Nantwich) and "One of the Craft," two others voting for "Excelsior" (Leominster) and "Practice." In the dilemma a referee, with power to decide the matter in any way he thought best, was appealed to, his verdict to be final. It was as follows:—"In my opinion each essay contains something better than the other, that should not be lost, and as I cannot exclude any of them without a sense of injustice to the writers I am bound either to advise a medal for each or not one for any." Silver medals are, therefore, granted to Mr. Peter Williams, Oakfield, Nantwich; Mr. George Summers, Sandbeck Park, Rotherham; Mr. George Hart, Buckingham, Shoreham; and Mr. Robert Morrow, Leominster. These essays will be published in the hope that they will afford useful information that may be turned to account under circumstances to which it may be applicable.

Four other essays are deserving of honourable mention, but as the writers have not been communicated with we do not feel at liberty to publish their names.

## FIGHTING INSECT PESTS.

GARDENERS assuredly need to be blessed with indomitable courage and unceasing energy, for the enemies they have to fight against are innumerable, and the persistency with which their battles must be waged afford ample scope for the proverbial British determination.

Red spider and thrips are at the present time causing much trouble, and strict attention is necessary to prevent their ravages destroying many a promising crop. In the case of Peach and Nectarine trees under glass or in the open air the difficulties are not nearly so great as formerly, because we have now several splendid insecticides, which, if used in the right way, may be depended on to completely destroy red spider and thrips, without injuring the leaves they infest in the least. Calvert's carbolic soap, used at the rate of 1½ oz. to a gallon of water, will do this, but of course especial pains must be taken, when the water is being applied with a syringe, that the under side of the leaves is thoroughly wetted in every part. There is, however, one objection to the use of this preparation on Peach trees under glass—viz., that it leaves a settlement on the trees, also the glass and wood-work of the house.

The great competition which has been going on between the manufacturers of insecticides has, however, at last brought about another step in advance, for the XL All insecticide, if mixed at the rate of one part to thirty parts of water, will kill red spider and thrips in one application, and when syringed on trees or plants leaves the foliage perfectly clean and free from disfigurement. The aim of the cultivator should, however, be to try and if possible prevent insects from gaining a footing. With this end in view care should be taken that the trees do not suffer from want of water at the roots, and to prevent evaporation a mulching of short manure ought to be given for a distance of several feet around the stems of wall trees. In the case of trees growing in lightly constructed houses it is often an excellent plan to apply a thin shade when a period of tropical weather sets in.

When red spider once gains a footing in vineries it is a much more serious business to completely eradicate it than in the case of other fruits; not because insecticides are less deadly in their effect on insects feeding on Vine leaves, but rather because it is so difficult to apply them without destroying the "bloom" which high-class Grapes always carry. True, there are instances where the crops are light or the bunches large, and therefore wide apart, in which syringing may be practised on a great amount of the leaf surface without touching a berry with the moisture; but they may be taken as exceptions. Where full crops of Grapes are the rule it is a most difficult, nay, almost impossible matter to syringe either with the insecticide or even clear water without disfiguring many of the berries. The question then arises, How, then, can we keep down this dreaded red spider?

My experience teaches me there is no better plan than the old one of thoroughly sponging the leaves with soapy water or XL All insecticide. If the work is taken in hand as soon as the slightest trace of the enemy is seen it seldom gives much trouble unless other details of culture are not well carried out. It has always been my practice to keep a sponge and tin containing insecticide in each range of vineries, and as soon as a suspicious looking leaf is noticed it is thoroughly sponged. If after a few days signs are apparent of insects in several parts of the house every leaf is sponged, and further trouble is not often needed. Of course, it is necessary to continually impress on the young men performing the work the importance of taking every care not to spatter or rub the bunches during the operation, as the slightest touch, though not noticed now, will be clearly apparent when the Grapes are ripe.

The practice of painting the hot-water pipes with sulphur is one which I never like to follow, except in extreme cases, for both Grapes and leaves lose their freshness after the operation. Instances sometimes occur when the practice is, however, a necessity. This is so when Vines are known to be badly infested, and time cannot possibly be spared to sponge the whole of the leaves. When this is the case mix in a dry state three parts flowers of sulphur with half a part of newly slaked lime, then add gradually a sufficient quantity of milk to form the whole into a thick paint, stir thoroughly, and apply to the hot-water pipes with a brush. Then heat the water in the pipes to boiling point, and keep it at that temperature for an hour afterwards, allowing the water to

cool down again. Follow this procedure for two successive nights, and every red spider in the house should be destroyed.

Moist, but not sodden, Vine borders, a moist atmosphere, with early, free, yet careful, ventilation, should be the order of the day where insect pests are troublesome; then if the Vines are not starved or overcropped there ought to be no difficulty in successfully combating the foe; but half-hearted measures in any respect will only lead to failure. I ought also to mention that young growth should be encouraged as much as possible, as a free circulation of sap helps to bring back a deep green colour to the disfigured leaves.—POMONA.

### STRAWBERRIES IN POTS.

VARIOUS methods are pursued by cultivators to produce good fruits of the above in the most satisfactory and economical manner. Some growers layer runners from plants irrespective of their age, others from plantations of the previous autumn placed in rows 2 feet apart, the plants closely together in the rows. Others layer their plants from "permanent" plantations made the previous autumn, and, all points considered, the latter plan seems the best. The usual custom is to layer in small pots, afterwards transferring them into larger sizes, a plan attended with every success when properly carried out.

Our Strawberries in pots not having proved satisfactory for several seasons, led me to look well after the cause. The soil is certainly not of the best quality, being too light. In the spring, after the plants were taken inside and began to grow, they usually lost a good many of the previous season's roots, which was difficult to understand, for the plants had every attention paid them. On examination of some of them the balls of the plants as turned out of the small pots, appeared nearly entire in the centre of the compost in the fruiting pots, the roots emitted not being so numerous as desirable. At potting time the balls of the young plants were partially shaken out, but by the later indications not sufficiently so. Now I think this was our stumblingblock. Pressure of various matters probably prevented the whole of these small plants being repotted before they became matted. The consequence, as afterwards proved, was the roots not being sufficiently disentangled, and the soil firmly rammed around the young plants in the fruiting pots, prevented vigorous root action taking place in the limited time they had for growth.

When introduced into heat the following year, under more arid conditions, probably it would be difficult to keep the balls in the centre of the pots in a moist, growing state, hence the collapse of a portion of the roots. Last year we altered our plans, and went in for layering straight into the fruiting pots, a practice followed by certain good growers I believe for some time past, so it is nothing new. Practically I had hitherto no experience in the method, if I except a few plants experimented with two years ago. The compost was prepared the latter end of May, and consisted of the following mixture: six parts loam, one part wood ashes, one part cleanings from surface of Vine borders, three parts manure as prepared for Mushroom beds, three parts dried clay, half part bone-meal, with a 4-inch pot of soot per barrowload. The loam being of poor quality, a substantial compost is necessary if good results are expected. The fruiting pots, mostly 6 inches in diameter, were washed and carefully crocked, a small portion of soot being placed on the layer of rough turf over the crocks to stay the ingress of worms, and the pots were filled with the mixture firmly rammed by the time the runners were ready.

These were taken from plants of the preceding season, and some from a plantation made in March of the same year. The pots were carefully placed in position to suit the runners, but not shifting them about when once down on the ground. The runners were pegged on to compost contained in the pots, and when established the plants were detached, and from that date grew splendidly, the drainage in the pots being in no way blocked by being placed on the ground. In the autumn the pots were plunged in ashes in cold frames, exposed as much as possible, with a light covering in severe weather only. All went well, and in due course the plants were introduced into the houses, a moderate temperature maintained, raising it gradually, but not exceeding 60° at night until the fruits were set.

The plants flowered magnificently; the fruit was in due course thinned according to the variety, about a dozen being left on such as President. The fruits have been fine, as you will see by those sent for your inspection, the system adopted turning out satisfactory in every way. The varieties grown were Scarlet Queen, Duc de Malakoff, La Grosse Sucrée, and President. The fruit is mostly required the latter part of April and May; therefore the plants were not forced, so to speak, but had they been I feel sure they would have given a good account of themselves.

Considering the cold, wet autumn of 1894, with the adverse

ripening conditions, I have been surprised and much pleased at the success of the method, and shall henceforth continue to practise it. It claims as its advantages a great saving of time, no risk of plants getting root-bound ere they can be potted, and giving the crowns perched on the top of the soil every chance of thorough ripening. As the season is now at hand for preparing plants for the forthcoming year, I pen these lines with the thought that the lesson taught by these failures in the past may perhaps prove useful to some of your numerous readers in the future.—J. J. CRAVEN, *Allerton Priory*.

[The fruit sent was an excellent sample, being large and of good flavour, proving that the above system of cultivation has answered admirably.]

### LABOUR-SAVING METHODS.

IF we can hit on or adopt labour-saving methods without militating to any material extent against the productiveness of a plot of ground, then we act wisely in doing so, and if it can further be shown that it is both possible to economise labour and actually improve the value of the crops by so doing, we are most unwise if we stick to the older and more expensive methods of culture. When, however, saving labour is the primary consideration, it need not surprise those who think of nothing else if their crops are partial or complete failures in most seasons. Sometimes it happens that what appears the most economical practice in the first instance actually turns out to be the most laborious and least satisfactory. I will give an instance. In many allotment gardens rows of stakes used for supporting Runner Beans one season are left standing to serve for the next crop.

The Beans are dibbled in and start into growth healthily enough. With the help of chemical or liquid manures there is no good reason why Runner Beans should not do well on the same site for two years in succession, but when later on it becomes necessary to support the old stakes with strong new ones to save them from being blown down wholesale, the saving in labour and stakes is a doubtful one. What gardener does not take special pride in his Onion bed? In some instances the same site is selected for this important crop several years in succession, and as this is very liberally treated as regards manuring it answers well, always providing the Onion maggot does not prove troublesome. The latter is a great bugbear in many gardens, and a complete change of site is desirable in all such cases accordingly.

A good bed of spring Cabbage is frequently of even more importance than Onions. What I mean is this—it would be better to have a moderately good crop of Onions and a good bed of spring Cabbage than a first-rate breadth of the former and a scarcity of the latter. This season Cabbages have been very scarce, and only quite recently has it been possible to buy any much under 3s. per dozen. There must have been far more failures than successes, and the former were largely due to the inability of the plants to stand a severe frost. What few really good breadths I have met with were nearly all growing on ground previously occupied by Onions, and this, though by no means a new idea, affords a good instance of a labour-saving and also profitable method of culture. All that is done is merely to surface-hoe and clean ground previously occupied by Onions, draw drills, water if at all dry, and then dibble-in the Cabbage plants.

Such varieties as Ellam's Dwarf Spring and Wheeler's Imperial are among the best that can be tried; they may safely be planted thickly, say 12 inches apart, in rows 18 inches asunder. The firm root run promotes a sturdy habit of growth, the plants when fully grown appearing all heart, whereas when put out on rich, deeply dug, loose ground Cabbage are rarely hardy, and form far too many large outer leaves. Much the same remarks apply to Broccoli. When these are grown to a great size on loose rich ground it needs only a moderately severe frost to destroy them wholesale; but if planted in succession to Strawberries and early Peas, without any digging, there will be fewer losses from frosts. Broccoli thus grown may not present a very imposing appearance—the grower might feel ashamed of them in fact; but this season they were so very scarce that it appeared to be quite an achievement to cut a few small hearts. Nothing was said or thought about the appearance of the plants that produced these.

It is sometimes said of certain men that they are "fond of making themselves work," this meaning that they go the wrong way about it, adopting methods that prove to be the most laborious in the end. If we dig the ground nearly cleared of a crop in dry, hot weather the chances are we bury dry soil and bring to the surface what little moisture there is left in the ground. To make matters worse, soil of a clayey nature quickly becomes hard and tough after exposure, and before it is fit for either planting or seed-sowing it requires to be baked by sunshine, after which rainfall or

the watering-pot will cause it to crumble sufficiently. If, therefore, we wish to follow one crop closely with another during the summer months, digging may well be avoided in most instances. Some of the best Celeriac, or Turnip-rooted Celery, I have ever grown was planted in close succession to early Cauliflower without any manuring or digging. The firm, yet by no means poor, root run favoured a sturdy top growth and the formation of extra fine "knobs" at their base.

It is much the same with Turnips. Poor ground does not suit them, while the other extreme, coupled with looseness, promotes a far too leafy top growth. I have frequently grown good Parsnips on ground that had not been dug for that crop, and of the many scores of such beds I have inspected this season the roots that present the best appearance were sown on ground that had not been dug since other crops were cleared off in the autumn and early winter months. Those who have taken the most pains with the preparation of the ground, and had, perforce, to wait the longest for the surface to crumble down finely, have not as a rule promising crops of Parsnips.

Do not think I am favouring methods of the "lazy" order generally. What I am constantly urging is the avoidance of set rules for all seasons and circumstances. Latterly I have my work cut out trying to prevent men carrying out what is locally termed "flat hoeing" among their rows of late-planted Potatoes. What they call "flat hoeing" I consider reckless, and in most cases uncalled for hacking. Heavy half-mattock hoes, and which I believe are made larger and heavier, specially for certain parts of Somerset, are driven deeply into the ground between and close up to the rows of Potatoes to the extent of bringing up some roots prior to "round hoeing" or moulding up. What little moisture was in the ground this heavy hoeing either brings to the surface or else further exposes it to the drying influence of easterly winds and fierce sunshine. Either very lumpy or imperfectly worked ground would, as a rule, be benefited by this hoeing, but in most instances where such work was being carried on ground was quite loose, and a surface hoeing or cleaning would have met the case. In addition to giving themselves unnecessary labour this "flat hoeing" will undoubtedly have hastened maturation, and a light crop will be the consequence. Thickly planted rows are the first to give signs of suffering from drought, and this is another penalty for over-zealousness, or trying to get too much out of the ground. Far better have planted fewer rows and save extra expense.

Of late years seeds have become considerably cheaper through the competition going on in every locality. One consequence of this is thick sowing. On all sides are to be seen crowded rows of Carrots, Onions, Turnips, Peas, Beans, and such like, and in the case of the three former at any rate this means so much extra labour in thinning, other ills also having to be reckoned with. By all means allow for various mishaps, but at the same time avoid sowing everything Mustard and Cress fashion. Very few growers care to thin out their Peas and Beans so freely as they ought to do, while in numerous instances the other kinds named are not yet thinned. Those responsible are or were waiting for the rain that failed to come just when wanted.

About the time these notes were penned gardens in all directions were receiving their daily drenching with cold water, and the question is, Were those so busily engaged rightly advised in the matter? Plants newly transplanted had to be kept alive; but is anything gained by the frequent watering of Onions, Carrots, and such like? Where the ground was well prepared the crops still look remarkably well without any aid from the watering pot or hose, especially when the surface has been kept in a loosened state. Applying the Dutch hoe among advancing crops, not merely for the purpose of killing weeds, but with a view to keeping the surface from cracking, is rightly calculated to do more good than watering; the latter, unless persevered in, actually doing more harm than good. Moisture supplied artificially soon evaporates in strong sunshine, and leaves the ground colder and poorer than it finds it. If a crop can have a thorough soaking, preferably with pond or warm softened water, followed by surface hoeing and a mulching of some kind, this might do good, the latter saving much hard labour.—W. IGGULDEN.

### HARDY FLOWER NOTES.

LAST year I referred to some charming blooms of Calochorti kindly sent me by Dr. Wallace of Colchester. Their beauty induced me to attempt their cultivation in order to test their endurance in our more northern land. A small selection was made, and the bulbs planted in September in one of the warmest and driest places at command, this being a slightly elevated small plateau on a rockery facing south-west, and well protected from other sides. Some of them made growth rather early, and the

intense frost penetrated the covering of a few inches of litter which was placed over them when the severe weather arrived. This has caused the loss of some varieties, but the proportion which has survived is quite an encouragement to persevere with these charming Mariposa Lilies.

Planted beside them, and undergoing the same treatment, were a good many Ixias, Sparaxis, and Tritonias, which, with the same amount of protection, generally survive our ordinary winters in this locality, but all of which have succumbed to the disastrous frost of 1894-5. Thus I consider the Calochorti hardier than these fine flowers. The soil was light, and was enriched by the addition of some bone-dust, which I frequently find beneficial to bulbous plants. I think, however, that I have erred on the side of safety, and that a firmer soil would have given me larger flowers, as those sent to me from Colchester were finer than those grown in my garden. Very beautiful they are, however, and certainly add much to the interest of one's garden. Bright and cheerful has been the little *C. Benthami* (fig. 98, page 549), a dwarf species with rich yellow flowers produced several on a stem, and having the petals prettily covered with the hairs, which give so much additional beauty to the Calochorti. Less striking, but very fine also, has been *C. cœruleus elegans*, said to be synonymous with *C. Maweanus*, with white and purple petals. Taller and more effective than the latter was *C. lilacinus*, a pretty pink-coloured flower, which is said to have been figured in the "Botanical Magazine" as *C. uniflorus*, and to have the synonym of *C. umbellatus*. It is unfortunate that there is so much confusion in the nomenclature of the Calochorti. One could say something about other elegant and charming Mariposa Lilies, but it is not within the scope of these notes to deal exhaustively with them, and I must pass on with the conviction that those who have had the pleasure of seeing these flowers will not cavil at their favourable mention now.

We have Irises over so long a period that there are few months in which there is none in bloom. At this season in particular many call for mention, and amid the throng of more showy species and forms I should like to single out the white variety of the elegant *Iris sibirica*. We have many more massive flowers of the same colour, and many with greater purity of colour, but *I. sibirica alba* is so exceedingly neat in size, and so graceful with its grass-like leaves, that many who have not grown it should make its acquaintance. Its very smallness makes it desirable for cut flowers, and the colouring of the falls, which deprives it of perfect purity, adds to the pleasure felt when closely examining the flower. This colouring is a compound of white, yellow, green, and blue, the blade being veined slightly with blue only; but as with nearly all the Irises the colour is so distributed and shaded as to baffle an attempt at description. While in commerce comparatively plentiful and cheap, in gardens it is comparatively scarce. This is not due to difficulties in the way of its cultivation, as it will grow readily either in a moist or dry place. *I. sibirica* belongs to the sub-genus *Apogon*, and with its varieties seems to be found over a wide region.—S. ARNOTT.

### THE PROFITABLE EMPLOYMENT OF GLASS STRUCTURES IN WINTER.

[Silver Medal Essay by Mr. PETER WILLIAMS, Oakfield, Nantwich.]

THIS is a subject which at the present time occupies the minds of persons whose business it is to grow produce for profit. Every endeavour is made to utilise conveniences at command to the best advantage, and the keen and ever increasing competition tax the ingenuity and experience of the grower to the utmost. Though the system of producing fruits, flowers, and vegetables for market has almost arrived at perfection, there nevertheless exists a period of about five months, during the winter and spring, in which expensive structures and appliances have to be comparatively idle.

An inflexible code of what, and what not, to grow for market cannot well be laid down and applied to every locality. Some assert they find cut bloom a lucrative business. By all means let them follow it up; others assert to the contrary. It no doubt depends to a great extent on local circumstances, in which persons must be guided by discretion and observation. The greatest obstacle growers have to contend with in the cut bloom industry is the foreign competition, as were it not for this far better prices would be realised. If we take the supply despatched from the Riviera alone, according to the reports cut flowers by the ton or tons were sent over to this country, and, as is usual, disposed of by auction in central towns, and from thence despatched to all parts of the provinces in a short time. Wreath-making and kindred work, where there is a good demand, is a very profitable business, but according to the testimony of florists there is not a tithe of the demand now as was the case a few years ago.

Taking, then, a general and impartial view of opinions as expressed, the state and prices of various products in the markets, the inference is that the floral business as a lucrative one is declining, while the supply is not decreasing. What, then, is to be grown? That is the question at issue, and it is one of vast importance as affecting gardeners—market gardeners especially. We need to grow a commodity among others for which there is a good demand generally, and at the same time one which the foreigner cannot well supply in a fresh and marketable condition. In conjunction with the housing of bedding Pelargoniums, Mushroom-growing, and devoting a little spare space *pro tem.* for Rhubarb, my chief object in this article will be to advocate the growing of Mustard and Cress as being among the most remunerative products which can be grown during the winter and spring months. Those who have an abundant supply of salads after a severe winter can appreciate the value of them, especially when four consecutive crops can be sown and cut off the same space of ground. Some gardeners near large centres are engaged in Mustard and Cress growing to an enormous extent, whence it is sent to provincial towns, often a great distance, owing to a deficiency in the home supply in those places. Gardeners generally have not realised the importance of this apparently insignificant commodity; but when made a speciality of it is almost incredible how remunerative an article it is, and once it has secured local favour the demand rapidly increases. It has an advantage over other crops in being quickly grown, and it must also be quickly disposed of, and it is here the home grower can give the foreigner the “go-by.” Radishes and Lettuces meet with a ready sale, but as those can be better grown in frames that is out of our province at the present.

**STRUCTURES.**—As there are endless systems of glass structures in vogue at the present time the same rule for the culture of things here dealt with can be applied to them, as space permits, and to any number as required.

The first, and in most general use, is the span-roofed house, usually from 8 to 10 feet wide, about 8 feet high, and varying in length. The interior is divided by a path, on each side of which is a 4 feet border, usually 3 feet from the ground, and supported by brick columns. In some the flooring of the path is a grating, under which the hot-water pipes extend the length of the structure. In others the pipes extend round the house under the borders. Others are constructed, even in modern times, with the old-fashioned flue, which are preferred by some as giving a more lasting and regular heat, which is so essential to the successful cultivation of plants which require bottom heat, such as Cucumbers, and Melons.

The second style of structure which will be mentioned is, as the previous one, span-roofed, the material difference being that they are about 25 feet wide, 12 feet high, and usually about 60 feet in length. Extending round the interior is a 4 feet border, as in the other under which the hot-water pipes extend. Along the side, and parallel with the border, is a path  $1\frac{1}{2}$  foot wide, extending of course round the house. The portion in the centre is on the ground level. This is by far the most serviceable kind of house in the end, giving as it does a greater area in every direction. The primary outlay in construction is certainly a trifle more, but it is amply recompensed in a few seasons by the extra accommodation afforded. I have seen enormous crops of Tomatoes grown on the ground in these houses, which is contrary to the general theory that they must be grown close to the glass.

We take it that where growing for market is extensively practised there is a corresponding convenience for obtaining necessary materials as required for the various purposes. Before, however, dealing with the border and ground crops it will be necessary to utilise the space above. At a distance of, say, 5 feet from the top of the house, may be suspended a shelf, made of boards a foot wide and of convenient length, to allow of taking down when not needed, and fitted to rest on L brackets, which are screwed on to the supports of the roof, of which there should be one at every fifth sash. There must of course be sufficient room left between the glass and shelf for watering. On each side of the house, and between the top shelf and the border at equal distances apart, two other shelves may be fitted, each being 15 inches from the glass, and of the same width. Fitted along the sides of these shelves are zinc troughs, to carry off the surplus water.

On these shelves are placed bedding Pelargoniums, for which there is a brisk demand in the spring time. They may either be made into cuttings in August and placed into 60-sized pots, or put in boxes as cuttings, potting them off in January into 60-pots. If the former plan is adopted there is much less labour expenses attached to it as they are put into the pots, stood outdoors until rooted, and until frosty nights appear, when they can be transferred to the shelves, and there remain until brought out to harden in the spring. Given the top shelf to be 3 feet wide, and extending the whole length of the house—viz., 60 feet, the 60-sized pots being 3 inches in diameter, 2880 plants could be placed there. The other four shelves being each 15 inches in width would accommodate 4800, or a total of 7680; but making allowance for a little space between the pots, 7000 would be a safer estimate.

It is surprising how quickly a business in this direction will develop when the public becomes aware of it, and it is of immense advantage in every respect for the grower to be able to dispose of the plants retail. Thus the bronze, silver, and choice varieties sell readily at 4s. per dozen (pots of course included), and the scarlets and whites at 3s. per dozen. Placed on a wholesale market, the approximate average price for various

sorts would be about 20s. per 100. Even at that figure a good margin for profit is left, after deducting about 30 per cent. expenses. Once a stock of Pelargoniums is in possession, it should be kept up to allow of a number of cuttings being taken annually. Lobelia for edging purposes is also in good demand, and when sown about the end of July, pricked out in boxes, then potted in  $2\frac{1}{2}$ -inch pots, will be good plants by the following spring, and realise at retail price 3s. per dozen. Thus thousands of useful bedding plants could be wintered and well established by spring at little expense or trouble, but would be one important item in the “profitable employment of glass structures in winter.”

Mushroom growing in glass structures is becoming more general, and is a step in the right direction, as the manure purchased will answer a double purpose in the houses before being used on the ground outside. To this end a good supply of suitable manure should be procured by the time the houses are cleared of Tomatoes. This is generally about the end of September, and as soon as convenient the glass and sashes of the structures must undergo a thorough cleansing, washing them with hot water in which softsoap or any disinfectant has been dissolved. The spaces under the borders are usually employed for the growing of Rhubarb and Seakale, but may be more profitably

FIG. 96.—MR. PETER WILLIAMS.

employed in the growing of Mushrooms, though before making the bed it is necessary to place boards on their edge along the pipes, also along the path to keep the manure compact.

As Mushroom growing is so fully dealt with in Wright's “Mushrooms for the Million,” it would be useless for me to dilate on their culture here. I may, however, point out, in passing, that a less quantity of manure will suffice in glass structures, as artificial heat can be applied at leisure. Yet the other extreme must be guarded against—viz., that of making the beds too shallow, as the produce would not be so weighty nor of the best quality. A depth of 1 foot, soil included, may be named as being sufficient where the beds are made level. If severe weather should intervene and hard firing have to be resorted to, care must be taken that the bed next to the pipes does not become too dry, or failure may result. In the centre of the house and on the ground level the manure may be formed into ridges running parallel with the house; making them in this way will give a greater superficial area to forming one flat bed or beds.

According to the dimensions of the structure, the borders and paths occupy a space of 11 feet in width; there will then be 14 feet width left for this purpose. Making each ridge 2 feet wide at the base and of the same height would allow of six ridges being made, the remaining 2 feet being divided to allow space between the ridges for gathering the crops. The beds will need covering with hay or other material, and the same routine of attention as directed in articles on Mushroom culture. When grown in glass structures, however, they will require damping and watering oftener than when grown in unheated places.

Computing that Mushroom ridges of these dimensions will produce a clear profit of 9s. per lineal yard, we may sum up the total accrued from this source as follows:—Placing the length of the ridges in the centre at 55 feet (they could not extend the length of the house, as space for a path would be required at one or each end), the total length of the ridges would be 110 yards, giving a clear profit of £49 5s. The beds

under the borders would extend the whole length of the house; but as allowance must be made for the pipes and boards a safer estimation would be 7s. 6d. per lineal yard; the total length value £15. Thus a Mushroom crop on the foregoing principles would produce a net value of £64 5s.,—another and second substantial item in “the employment of glass structures in winter.”

(To be concluded.)

### IN THE MIDLANDS.

THE pen ran on to such an inordinate length last week that there was no space left for the reference that was intended to *Violas* and *Pansies* at Tamworth—not at the show there, which was briefly referred to on page 494, but to the extensive and diversified collection of Mr. William Sydenham. Tamworth is only eighteen miles from Birmingham, and if you happen to be there when the Midland night mail arrives someone will be sure to tell you it is one of the fastest trains in England, the distance being covered, from start to stop, in eighteen minutes, and if time is precious something less. Just before arriving at the station there is a splendid viaduct, and looking down from the train on the right large masses of colour are seen glinting between the trees. These, though the fact was not known to the narrator during his journey, are Mr. Sydenham's *Viola* beds.

To come in close contact with them the town has to be crossed, and they are found on the lawn of what may be described as an old-fashioned, comfortable, and commodious country house. The pleasure grounds are well timbered, and the lawns somewhat extensive—the larger being free from beds, the smaller full of them, and these full of flowers from early in April till nearly the end of the year. At the close of May they were simply sheets of colour—yellow, purple, mauve, cream, white, and various other hues, which only these flowers can produce in low masses. *Violas* are extremely attractive as tastefully arranged in sprays on sloping stands at exhibitions, but to appreciate their fullest charm and great decorative adaptability they must be seen growing as in this garden, which is made so beautiful and sweet by their presence.

It is not very easy to convey an impression of the numbers of *Violas* and *Pansies* grown in this Midland emporium. We first came to some thirty beds of the former, several round, and from 6 to 10 feet wide, each representing a separate variety, while larger beds are panelled. As a soft yellow for bedding *Viola Ardwell Gem* is still pre-eminent, though one named *Wonder*, which is brighter, and the flowers opening quite flat, is Mr. Robert Sydenham's favourite. Brighter still, brilliant and rich, are *Yellow Boy*, *Bullion*, *Lord Elcho*, and *Annie Hughes*; while softer and particularly charming in the mass is the newer *Luteola*, the upper petals pale, the lower of a deeper glow, and habit excellent.

For producing a mass of pale blue with a mauve tint all the season, it is doubtful if *Blue Gown* has any superior. The habit is procumbent, and the variety a persistent bloomer. William Neil, with a pink tinge, is a distinct and excellent bedder. *Bessie Clark* is of the same character as *Blue Gown*, but paler, the prevailing colour being deep lavender. Of somewhat the same colour we find *Aimée*, which produces a butterfly-like mass by its creamy white lower petals; while lighter still among the lavenders is the well named *Charm*. Though the habit of this is not so close as some others, in colour it seems to stand alone—a sort of pearly lavender and rayless. *Blush Queen* is also sweet and pleasing. Among the darker blues the well proved *Archie Grant* holds its own, while *True Blue* has many admirers, though some critical *violaists* do not consider it free from faults. *Hibernia*, purplish violet, made a rich display, and Mrs. Charles Turner is a good dark variety.

The well known and very pleasing *Countess of Kintore* has many descendants; bluish purple, more or less shaded with white. Of these Mrs. Bellamy, Mrs. Grant, *The Mearns*, and *Iona* are all effective, while the newer Mrs. W. H. Gabb, and perhaps the still prettier Mrs. Richard Hare, cannot be overlooked, the dark bars radiating from the golden eye over the pale porcelain ground having a pleasing effect.

The creamy *Sylvia* is one of the best for massing among the whites, as it is so dwarf and floriferous, but it has a formidable rival in the newer *Marchioness*, of similar colour, and very beautiful in the mass. Among the pure whites *Countess of Wharnccliffe* is particularly clean and very sweet, and the *Countess of Hopetoun* maintains its reputation. *Mary Scott*, white, with a faint blue suffusion, arrests attention by its delicacy, and is both dwarf and free; also compact and floriferous is Mrs. Scott, which is distinctly attractive by its yellow throat. For charm of flower, as regards form, the creamy rayless *Mary Stuart* has few, if any, rivals for supremacy; while for boldness of character the pure *Niphotos* commands attention.

The margined *Violas* have a beauty all their own, and of these *Duchess of Fife*, primrose, edged with bluish mauve, ranks very high. A bed of this, some 20 yards long, covered with myriads of flowers, presented a sight not to be forgotten. *Goldfinch* is of the same character, but a deeper yellow, and has a darker edge. Of the whites with blue edges of the *Skylark* type, *Blue Cloud*, *Blue Garter*, and *White Duchess* are all worth growing, as indeed are many of varied tints which cannot be named here. Nor can anything be said about those little gems, the *Violettas*, beyond the mention of *Sweet Mary*, *Ronalda*, and *Marginata* as a dainty trio, delightfully perfumed.

The thirty beds of *Violas* mentioned only represented a small part of the collection. A strip, some 10 yards wide and 80 long, has been taken off the grass field next the carriage drive. This is divided into about forty half-moon-shaped sections with double *Daisies*, each section forming a bed of *Violas*. From another side of the field a still longer strip

has also been taken and devoted to the flowers. Then there is what appears to be a trial ground of *Violas*, set out into a hundred panels of about a yard square with *Daisies*, the panels containing many more than 100 varieties of the flowers for which they were formed. *Daisies* are employed as described, because they are found to be good barriers against wireworms and other underground enemies—a hint worth noting. Still traps are also used, and excellent they are—perforated tin cylinders about 2 inches across the top, tapering to a sharp point. These are filled with pieces of Potatoes, Carrot, oilcake, or other tempting baits, and thrust into the ground; a wire cross handle being provided for drawing them out at intervals and extracting the depredators. Thrusting sticks through Potatoes and burying them is a primitive mode of “fishing” for wireworms, as compared with the handy contrivance in question.

But to see all the *Pansies* and *Violas* we must go yet further. A walled garden is filled with Fancy *Pansies*—a splendid collection of some 300 varieties, and a rich display they made. One of the finest is *Tamworth Yellow*; beautiful also, each in its own way, are the following varieties, chosen from the great collection:—*Constance Steel*, *George Stewart*, *Bernard Doulton*, *Agnes Mabel*, *A. H. Murray*, *Andrew Frater*, *Clandeboye*, *Cleopatra*, *Dr. Harrison*, *Emmie Stuart*, *John Taylor*, *Marmion*, *Mrs. Bagett*, *Mrs. D. Johnstone*, *Mrs. E. J. Martin*, *Mrs. J. D. Stuart*, *Mrs. John McConnell*, *Ralph Wardlaw*, *Rev. Gresley*, *Tamworth Gem*, *Tom Terry*, *W. H. Clarke*, *Wm. Watson*. The two dozen varieties named, if well grown, are not likely to disappoint their possessors.

Still, there are more plants, even acres of them, in the adjoining field, which also contains at least a hundred low span-roofed frames for propagating purposes. These are strong sensible frames, 6 feet by 4 feet, made of 1½-inch deal, sides about 6 inches high rising to a foot at the ridge, and the sashes moveable. They are excellent for their purpose, as such protectors would be for various purposes in gardens.

*Pansies* and *Violas* must be grown extensively in various parts of the country, or such a vast number would not be raised yearly as is found in this Midland emporium, which is after all only one of many supply establishments; but it is a large one undoubtedly, and it is apparent that nothing is spared to make it as complete and satisfactory as possible in respect to care in selection, nomenclature, and culture of these beautiful and diversified hardy flowers.

They are flowers for the million, and in all probability are destined to play a more important part in the decoration of home surroundings and public parks in the future than they have in the past, as there are few difficulties attending their successful cultivation and preservation. The short time at Tamworth was spent pleasantly, and the floral feast with the agreeable association of a happy family of flower-loving people will not soon be forgotten by—A CASUAL CALLER.

### HARDY FRUIT PROSPECTS AROUND LIVERPOOL.

As in former years, I have again taken a few short notes on hardy fruit prospects in the Liverpool district. These will, I hope, be acceptable to readers, giving, as they do, a fair idea of crops in gardens where fruit is cultivated in various positions.

#### ALLERTON PRIORY.

The late severe gale, coupled with the long spell of dry weather, has, in Mr. J. J. Craven's opinion, spoiled what promised to be a good set. Trees of moderate vigour seem to be carrying a good crop. Strawberries and Red Currants are abundant, Black Currants an average. Raspberries and sweet Cherries a fine crop; Governor Wood, May Duke, Frogmore Bigarreau, and Bedford Prolific are the best among the latter. Espalier-trained Pears are thin, Durondeau and Pitmaston Duchess the best. Jargonelle and Comte de Lamy are the best bushes, the finest on south wall cordons being *Beurré d'Amanlis*, *Doyenné d'Été*, *Glou Morceau*, *Josephine de Malines*, *Marie Louise*, and *Thompson's*. Apples.—*Bush*: *Irish Peach*, *Ribston*, and *Red Astrachan* very fair. *Pyramids*: *Keswick* and *Sturmer Pippin* good, *Warner's King* moderate, *Mère de Ménage* fair. *Standards*: *Warner's King* and *Lord Derby* missed last season, but are this year laden with fruit. *Pomeroy* of Lancashire, *Kerry Pippin*, and *King of Pippins* are all good. Plums a very fair crop. *Pond's Seedling* on standard, *Green Gage*, *Coe's*, and *Bryanston* on east wall good; *Coe's* on west wall fair; *Czar* and *Hazlewood* as bushes very fair. Whilst on the fruit topic I may remark that Mr. Craven's Grapes will again give exhibitors some difficulty, judging from present appearances.

#### CLEVELEY, ALLERTON.

Mr. Cromwell has within the last few years planted many young trees, which are now bearing freely. Apples are a good all-round crop, more especially *Lord Suffield* (which is always certain) and *Ribston Pippin*. *Standard Pears* a good average crop, and on walls they require some thinning. Plums flowered abundantly, but many fruits are turning yellow. This Mr. Cromwell attributes to cold winds when the blooms were fully developed, these interfering with proper fertilisation, and to the drought since. Cherries are a full crop, the foliage being exempt from the usual black fly. Currants are bearing well, especially *Black*; so also are Strawberries. A mulching of litter, which is placed between them, should help to mature the best crop seen for years. Gooseberries are good, and free from caterpillar. Raspberry canes suffered during the severe frost, many killed outright. Out of six varieties grown *Fastolf* has proved much the hardiest.

## KNOWSLEY HALL, PRESCOT.

Apples are a very heavy crop, Pears quite an average, those bearing well last year being fruitless this. Cherries, Nectarines, Peaches, and Plums are good, Apricots average crop; Red and White Currants good, Black nil; Gooseberries very heavy, Raspberries under average, many canes being killed by frost. Strawberries a very heavy crop; indoors there is the usual supply kept up by Mr. Doe.

## THE CALDERSTONES, AIGBURTH.

Mr. Tunnington has such a heavy crop of Apples that they have in most cases to be thinned, a practice which he carries out with various fruits, and which he fully believes pays for the trouble. Pears are on the whole a fair crop, while Peaches, Nectarines, and Damsons are a full one. Plums are better than they have been for some years past. Cherries of all kinds are literally weighed down with fruit. Currants, Gooseberries, and Strawberries are a heavy crop throughout, but the latter are suffering from drought, many fruits having failed to set perfectly are coming deformed. This is more noticeable in the case of President. Raspberries suffered during the frost, but on the whole are a fair crop.

## COURT HEY, BROAD GREEN.

To enumerate all the kinds carrying good crops would take up much space. Mr. Elsworthy always exhibits in fine form, and has this year a promise of abundance of fruit of all kinds excepting Raspberries, which suffered very much during the severe winter. The Strawberry crop may be mentioned as enormous, but like other places feeling severely the long spell of dry weather.

## BLACKLOW HOUSE, ROBY.

Apples are a very good crop throughout. Pears very fair, Marie Louise, Beurré Diel, and B. d'Amanlis being heavily cropped. Currants are excellent, Strawberries good, but would have been much better with more rain, Cherries and Plums a fair crop. Raspberries planted twelve years ago and mulched each season, but not dug between, are as usual splendid. Old and young Gooseberry bushes are a picture. I always make a practice of mulching with stable manure 3 inches deep early in April, and since working on this plan have never seen a caterpillar. This year, not having sufficient at the time, the work was delayed until the second week in May. By that time the enemy had made its appearance, many branches being completely stripped of their leaves. After removing some of the best of the horse manure for hotbed purposes, the bottom of the heap was carted out in its damp state and spread amongst the trees, also between Raspberries and Black Currants. The ammonia in the manure at the time was very powerful, and whether from smell or what not, the caterpillars soon took their departure, there not being a sign of such, whilst the fine foliage, completely free from red spider, is a treat to look on, compared with what one sees in many gardens.

I am also convinced that where time could be devoted to the work, that a good soaking of liquid manure is highly beneficial to all kinds of outdoor fruit trees, given just before the blooms expand. Many trees treated in this manner are bearing heavy crops, whilst others in close proximity which have been left to themselves are not nearly so good, the blossoms appearing as if they are all withered. There is no doubt about the effect of the drought on many crops, but on Wednesday evening we had a few smart thunder claps accompanied by a perfect deluge of rain and hailstones, the weather being much cooler. To-day, Friday, there is every appearance of rain, and a few days' steady rain will help the fruit crops materially.—R. P. R.

## HOW GARDENERS ARE MADE.

"INVICTA," on page 489, gives us a very impressive example of how gardeners are made, and in his fictional example shows clearly how they enter the garden, though many of them enter without being asked to pay a fee to unlock the door. A great deal has been written in the Journal about the gardener. I cannot quite agree with the idea that nine-tenths of the gardeners succeed in securing good places. My experience has been very much the reverse, and I do not expect the future holds out any prospect of improvement under the present system of making gardeners.

On an average the best places employ four young men, who are hoping some day to become head gardeners, and it stands to reason that only one can be employed as head in a place, so the other three have to find employment elsewhere than the garden; nor have they any right to expect head places, for reasons which I shall explain. First, they come into the garden at ages from thirteen to seventeen years of age; they as boys do what they are told, and very likely remain in their first place, say, three years. The gardener recommends them as journeymen, and here they remain one or two years, then go on to another place for a similar period, and in each of these places they have been constantly employed under glass. This journeyman wants a foreman's place, "under glass again;" he serves two or three years, and then, what do you see?—viz., "Mr. Peachgrower can with every confidence recommend his present foreman, John Growell, to any lady or gentleman wanting a first-class gardener; married when suited." This man may have been respectable, hardworking, and with a fair knowledge of indoor work, which he has performed to the satisfaction of the gardener. Has the gardener considered whether he is perfectly honest in recommending him as a first-class gardener?

What can young men brought up under glass know of practical

gardening? How can they manage a place? Certainly they cannot without a great many mistakes. Still, some manage to pull through in a way. If gardeners would unite, and agree to recommend no man, however respectable, unless he had passed through all the departments, acquired a general knowledge of all outdoor work, given some of his evenings to self-improvement, and had shown a love for his avocation, the glut in the garden market would cease.

The young man to recommend is the one who has come to the gardener at 9 P.M. with his specimens of wild flowers for naming, collected on his ramble round the hedgerows on a summer evening; who comes in on a winter evening to show some garden plans, to seek advice, or the solution of a geometric problem; who has asked to be shown the way to bud, graft, prune, nail, mow, and dig; and who has given up all other pleasures for his calling. This is the man we want. He may not appear so bright, good looking, or strong as the other; but still he is the man to be recommended. No gentleman ought to engage a gardener unless the applicant can satisfy him that he has served in a vegetable garden for not less than two years, and two in pleasure grounds and flower garden. I find after twenty years' experience that very few young men care for improvement. I have had many young men start, but few go on; some have and hold honoured places to-day, but the majority of them is wearing Her Majesty's uniform. I recommend a man only when I am sure he can manage what is required of him. It is not honest to recommend a man just because he has managed the houses well, and has kept himself respectable. I know a case where a gentleman wanted a gardener for 28s. a week and a house. A good man for the place was recommended, but the fortunate applicant never served an hour under a gardener in his life; in fact he had been employed to look after a pony, clean knives, boots, and do other odd work in a clergyman's household.

If every gardener would agree to enter each lad he starts in the garden on the understanding that he will only recommend him if at the end of his time he passes a fair examination in general gardening work, and in no case should he be called journeyman till he has done so. Then, when he enters as a journeyman, let him study for the foreman exam, and before taking a head place let him pass a final exam. Some persons may say, Who is to examine, and how is it to be done? Well, this can be done from centres. In the country head gardeners could be appointed, where young men could go, say, twice a year, and I am sure our leading nurserymen would help as far as they could. The final certificate to be given in London, Edinburgh, and Dublin, and a body of scientific men be appointed to draw up the form of examination papers.—SHIRBURN.

## APPLES AND STOCKS.

FROM the good-tempered criticism of my note (page 520), Mr. Pearson would have us believe that the Paradise is the only fit and proper stock to use for unskilled gardeners, allotment holders, amateurs, and cottagers. He evidently pins his faith to this one stock, and considers all others are not fit to employ. He tells us how good the results are from the use of the Paradise, but he does not say how long the trees will continue to be satisfactory. I have been told that trees worked on Paradise stocks are not long-lived; but my age does not warrant my saying aught about this phase of the argument.

Mr. Pearson, too, confines his remarks to "garden trees;" but how about the grand standard and half-standard trees one sees so often in country districts that are worked on the seedling and Crab stocks? Surely it would not be wisdom to advocate the growing of "garden trees" only, and these worked on the Paradise stock. What we want to aim at is the production of fruit in quantity and of the best quality only. It matters not how it is obtained so long as it is procurable. I contend, in spite of Mr. Pearson's condemnation of other stocks, that the Paradise is not the only stock to depend on. My contention is that Apples will grow on trees worked on other stocks equally well as they will on the Paradise. Surely Mr. Pearson does not advocate the entire use of Paradise stocks, with their dwarfing and free-bearing propensities, for such varieties as Stirling Castle, for instance, which crops to such an extent generally as to preclude much freedom in growth?

From Mr. Pearson's own showing good results can be obtained from the use of the three kinds of stocks named. This is a distinct confirmation of the note I penned on page 475. I cannot believe that it is necessary to adhere solely to any particular stock. I write only from experience, and have good reason to advocate other stocks than the Paradise. As to persons requiring specially educating to manage trees worked on other stocks beside Paradise, I fail to see this. To me it seems a simple matter to get crops of fruit from trees grafted, or budded, on seedling stocks. If some fail to obtain fruit owing to following wrong methods of culture, that is no argument against the use of stocks that will give satisfactory results under rational treatment. I have carefully read and re-read Mr. Pearson's article, but yet fail to find aught in it to alter my expressed opinion that "it seems idle to pin one's faith to any one of the three named."

Some persons maintain that the Paradise stock has not vigour enough in it to withstand the influence of cold, wet, heavy soil, and give satisfactory results. I am also acquainted with a nurseryman, an exceedingly large fruit tree grower, who does not make use of the Paradise stock at all in the raising of trees, but pins his faith in stocks obtained from seedlings—pips from the cider mills. I do not think any Paradise stock could give better results than this man's trees.—E. MOLYNEUX.

EVENTS OF THE WEEK.—At the Drill Hall, Westminster, on Tuesday next the Committees of the Royal Horticultural Society will meet, and on the same day the Isle of Wight Rose Show will be held at Cowes. On the Wednesday the Richmond show will be held in the Old Deer Park.

— WEATHER IN LONDON.—For another week we have had fine weather, though on Friday and Saturday last the mornings and evenings were rendered cold by the prevalence of easterly and north-easterly winds. During the early hours of Wednesday morning rain commenced to fall steadily, and at the time of going to press it had ceased.

— WEATHER IN THE NORTH.—The drought continued till late in the evening of Monday, when gentle rain began to fall and continued the greater part of the night. Tuesday morning was fair, but dull, and more rain seemed probable. On the morning of Wednesday the 12th, and again on the following Friday, Potatoes were blackened by sharp frosts. On the former morning 17° frost on the grass is reported from Blair Athole.—B. D., *S. Perthshire*.

— THE next meeting of the ROYAL HORTICULTURAL SOCIETY will be held in the Drill Hall, James Street, Westminster, on Tuesday, June 25th, when special prizes will be offered for hardy herbaceous flowers. Mr. Dyer is unable to lecture, and instead thereof a conversational lecture will be given on some of the most interesting plants in the day's exhibition by Professor Henslow.

— WATERING NEWLY PLANTED TREES.—The earlier in the season trees are transplanted the less need there is of watering them, but as the season gets late and the weather warm and dry it is unsafe to transplant trees without first wetting their roots or watering them as soon as they are planted. Deciduous trees and shrubs can be handled with tolerable certainty, the later and drier the season is when they are planted the harder we cut in their tops. But we cannot very well do this with evergreens. Instead, we sprinkle them with water twice a day for a few days after planting, then once a day till we are sure the plants have "taken to the soil."

— PROPAGATING HARDY PERENNIALS.—Many perennial herbaceous plants are propagated by taking up the roots and dividing them in the fall of the year. Others are easily propagated by sowing the seeds; but even these methods of propagation are not always rapid enough for the desired increase of any particular plant. It is not generally known, says a writer in a transatlantic contemporary, that plants can be made by cutting up flower stems. For this purpose the flower stem is allowed to grow up to a blooming point; but when that is reached the flower buds must be entirely cut away. This throws more vital energy into the flower stem, and well-developed buds form in the axils of the leaves. In a few weeks, after the flowering heads have been pinched out, the flower stalks may be separated for cuttings. Pieces with two or three buds are sufficient. In this way such plants as the hardy Phlox may be very rapidly increased. The various kinds of Lilies can be propagated in the same manner.

— "MEN AND MANNERS."—Under this heading, on page 513, "Observer" details a few remarks which I read with interest, and as I happen to be one of the craft whom his remarks directly concern, I feel constrained to ask him a question on a point on which he omitted to touch—that is, which is the proper way for a gardener to salute his employer? I see a good many gardeners raise their hat to their employer or members of his family; but I have it on the authority of a French governess that they ought not to do so, because by so doing they place themselves on the same social level as their employer himself. By merely touching their hat or cap with their finger they make the distinction between employer and employed. Is this so? I myself am a gardener, and daily meet friends and relatives of my employer, both within the precincts and on the public road, hence I am anxious to know if I commit a serious breach of etiquette by raising my hat when I meet them, or if I should simply touch it and no more. If "Observer" or any reader of the Journal will enlighten me on this point they will greatly oblige an—IGNORAMUS.

— GARDENERS' ROYAL BENEVOLENT INSTITUTION.—At the instigation of N. N. Sherwood, Esq. (Renter Warden), the Worshipful Company of Gardeners has given a donation of £5 5s. to the funds of the Gardeners' Royal Benevolent Institution.

— THE WOBURN EXPERIMENTAL FRUIT FARM.—About thirty gentlemen visited the extensive series of experiments on Tuesday last on the invitation of his Grace the Duke of Bedford and Mr. Spencer Pickering, F.R.S. They were greatly interested and hospitably entertained. The publication of a report of the work in progress must be deferred till next week.

— NEWCASTLE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.—At the last monthly meeting of this Society there was a good attendance, and Mr. Larke, North Dene, Gateshead, occupied the chair. Mr. J. Holmes, of the Fleming Memorial Hospital, Newcastle, read an instructive paper on "Hardy Herbaceous Plants," which was very much appreciated, illustrating and adding interest to his remarks by numerous specimens.

— LONDON RAINFALL.—Since the commencement of the present year the total rainfall in London has been very little over 5 inches, or only half the average quantity. Last month the rainfall in London was only 0.34 inch, or little more than one-sixth of the normal amount. From the beginning of June up to last evening the total fall in London was only two-hundredths of an inch, the average quantity for the expired portion of the month being rather over an inch.

— HAMPSHIRE STRAWBERRIES.—The Strawberry season in Hampshire is now at its height, as indicated by the fact that 2000 baskets of Strawberries were received at Waterloo Station on the 7th inst. from the Swanwick district. The Hampshire growers now send the greater portion of their fruit in neat cross-handled baskets, with the result that it reaches the market in good condition, and consequently commands a more satisfactory price than was frequently the case when a more rough and ready system of packing was adopted. Immense quantities of Strawberries are also being received from France. On one day, says a contemporary, 3000 packages from Havre and St. Malo were placed on the London market.

— SALE OF PLANTS.—The well-known collection of specimen stove and greenhouse exhibition plants grown by Mr. J. Dyer for Mrs. Marigold, Park House, Edgbaston, was disposed of under the hammer on the 12th ult. by Mr. John Pope, King's Norton Nurseries, as Mrs. Marigold contemplates leaving her present residence shortly. For several years past this collection of plants has figured prominently amongst the local shows. Mr. Dyer, who has been for about eleven years in his present situation, is about to enter business on his own account at Northfield, and has already erected two or three glass structures. It is somewhat remarkable that within the space of a few weeks two of the most prominent local exhibitors should be lost to the Birmingham and Midland Counties Horticultural Society; firstly, in the person of Mr. J. Palmer, late gardener to W. Bown, Esq., Beech Lane, Harborne, and whose fine collection of Orchids was sold a few weeks since, as notified in the *Journal of Horticulture*. It may be mentioned that amongst the several fine specimens of Palms sold at Park House a magnificent plant of *Kentia Fosteriana*, 12 feet high, passed into the hands of a well-known ducal exhibitor of plants in the Midlands.—G.

— HORTICULTURAL CLUB.—The last dinner and conversazione for the season 1894 and 1895 was held on Tuesday last at the Club Rooms, Hotel Windsor, Victoria Street, Westminster. The chair was occupied by Mr. Geo. Gordon, and amongst those present were Messrs. Geo. Paul, George Laing Paul, James Walker, A. H. Pearson, J. Edward Cockett, H. Selve Leonard, T. W. Girdlestone, the Rev. J. H. Pemberton, and the Secretary. The subject for discussion was "Single Roses for Garden Decoration," and was opened by an interesting paper by Mr. Geo. Paul, jun., who dealt with some of the most valuable Roses for this purpose, both species and hybrids. A very animated discussion followed, in which most of those present took part; and a desire was expressed that more prominence should be given to this class at our earlier Rose shows, as the Roses belonging to it are mostly over by the beginning of July, except it may be in the north of England. A cordial vote of thanks was given to Mr. Paul for his paper, which will, we believe, appear in the "Rosarians' Year Book," 1896. We believe there is in contemplation to revive the excursion, and it was proposed that it should this year embrace one or two of the market gardens in North Finchley, and a visit to Hatfield House and gardens.

— GARDENING APPOINTMENT.—Mr. W. J. Gilks has been appointed head gardener and Orchid grower to H. Smith, Esq., Summerhill, Kingswinford, Staffordshire.

— IRIS MADAME CHEREAU.—To those who are fond of the Iris family, this ought to be added. It is singularly beautiful and chaste in colour—white, margined with blue. The blooms individually are not large, but freely produced on rather tall stems.—E. M.

— VEGETATION IN FRANCE.—The hot, moist, and clammy weather in France is pushing forward vegetation by leaps and bounds. This is causing anxiety to Potato growers, who fear the appearance of the fungus; hence the very prudent cultivators have already commenced spraying with the Bordeaux mixture.

— BLENHEIM PALACE GARDENS.—By permission of the Duke of Marlborough, Blenheim Palace and Gardens were opened to the public on the 3rd inst. They will be open every Monday, Thursday, and Saturday until further notice, from noon until 4 P.M. on Saturdays, and from noon until 6 P.M. on the other two days of the week.

— SHIRLEY AND DISTRICT GARDENERS' AND AMATEURS' ASSOCIATION.—A meeting of the above Society was held at the Parish Room, Shirley, Southampton, on Monday, 17th inst., Mr. B. Ladhams, F.R.H.S., presiding over a large attendance of the members. Mr. J. E. Axford, florist, Fair Oak, gave a very interesting and instructive paper on "Rose Culture Under Glass," and a long discussion ensued, which was joined in by a number of the members.

— UPROOTED TREES IN THE TEMPLE.—On Friday morning, June 7th, the Temple gardeners were engaged, says the *Daily News*, in replanting the three Plane trees in Essex Court, which had been uprooted and laid prostrate on the previous afternoon by a sudden gust blowing through the archway leading into that square of dingy brick buildings. The trees were young, but the force of the draught was still remarkable, for they had attained to a height of some 40 feet, and the stem of the stoutest is 13 or 14 inches in circumference. On the same day another Plane in Pump Court was nearly overthrown from a like cause. The trees have now been provided with props or wire ties.

— EUROPEAN GARDENERS AND THE UNITED STATES.—The "Florists' Exchange" says that it is interesting to note the number of arrivals of gardeners in the United States from other countries. During the year ending 30th June, 1894, which is the latest period for which the statistics have been made up, there arrived from Bohemia, 2 gardeners; from Hungary, 6; from Austria, 6; from Belgium, 2; from Denmark, 19; from France, 13; from Germany, 160; from Greece, 16; from Italy, 25; from the Netherlands, 22, one a woman; from Norway, 5; from Russia, 3; from Sweden, 20; from Switzerland, 14; from Turkey, 2; from England, 146; from Scotland, 38; from Ireland, 54; from Columbia, 2; from China, 7; from Japan, 3; from Australia, 3; from the Hawaiian Islands, 1, making a total of 569, 535 of whom, including one woman, were under forty, and the remainder over forty years of age.

— DEATH OF MR. R. C. KINGSTON.—Many of our horticultural friends will hear with regret of the death of their old friend Mr. R. C. Kingston, the well-known and highly respected head gardener and estate manager of Brantingham Thorpe, who, after a short illness of only a few hours, passed peacefully away on Thursday, June 6th. Mr. Kingston was born in the East Riding of Yorkshire in 1818, and after receiving a good education he went as under gardener at Stapleton Park Gardens. From Stapleton our friend went as foreman to Chiswick, where he served for some years with great credit, and in the year 1841 he took charge of the gardens at Brantingham Thorpe, then owned by the late R. Fleetwood Shaw, Esq. In a very few years Mr. Kingston became well known as a leading horticulturist and botanist, as well as a most successful exhibitor at the leading shows in the county. At that time the collection of Orchids, stove and greenhouse plants, and British and exotic Ferns at Brantingham Thorpe was one of the best in the north of England. About thirty years ago the estate passed into the hands of Christopher Sykes, Esq., and during that time much of the estate has been remodelled and improved. To one and all he was ever kind, courteous, and sincere, and many of his gardening friends will recall with pleasure the cheery and hospitable welcome they always received at his hands. On Monday last, in the presence of his family and his late master (C. Sykes, Esq.), as well as a very large number of friends, the remains were quietly and unostentatiously laid to rest in the beautifully situated churchyard at Brantingham.

— FROST IN JUNE.—At Ridgmont 7° of frost were registered last Saturday night, and Potatoes were injured in various parts of the country.

— FROST IN HAMPSHIRE.—On the morning of Thursday, 13th, quite a sharp frost was experienced in the valleys around here. In several instances Scarlet Runner Beans, Vegetable Marrows, and in one instance Potatoes, exhibit decided effects of the visitation. Especially are the leaves of the first-named blackened, which cannot fail to give a check to direct growth. Here in the garden the thermometer did not fall below 37°, but the situation is high and comparatively dry.—E. MOLYNEUX, *Swanmore Park*.

— WEATHER IN THE VALE OF EVESHAM.—A severe frost visited this district on Saturday morning, 15th inst., doing a considerable amount of damage on the low lying lands to Vegetable Marrows, Cucumbers, Potatoes, and other things susceptible to frost. Fruit does not appear to be affected by it, but would be greatly benefited by a good rain. The crops all seem parched with drought, and it has caused the Kidney and Runner Bean crops to become almost a failure. The early Potatoes appear to be ripening, yet are too small to commence digging.—ALFRED G. GROVE.

— FROST IN CO DURHAM.—On the morning of June 13th I registered 3° of frost about 5 A.M. The sight was such as I have never seen before at midsummer, the fields being covered with white frost. Potatoes are very much blackened; tender annuals, such as Perillas, African and French Marigolds, and Dahlias are in a great many cases killed. The young growth on Rhododendrons is also damaged, and in exposed places killed outright. This is very disappointing after the fine spring we have had, and surely beats the record.—A. BENTLEY, *The Gardens, Eshwood Hall, Durham*.

— THE COTTAGER'S CALENDAR OF GARDEN OPERATIONS.—This very compact calendar, which was originally compiled by the late Sir Joseph Paxton, has been revised and adapted to the requirements of cottagers and allotment holders. The operations for the different months of the year are described, and though the form naturally leads to some repetition, the work has been thoughtfully done. There has been no padding out; but, on the contrary, the desire for compression seems to have been kept well in view. Vegetables, fruit, and flowers are included throughout, and the selections are well adapted for cottage gardens. Sensible notes are given on pruning and most other operations. Chapters are given on manuring (too compressed), vegetable and fruit cookery, and insects (illustrated). The "Calendar" is packed with information from end to end, and being cheap, is well suited for distribution amongst cottagers who desire to have the gardens attached to their houses attractive and productive. It is published at the "Gardener's Chronicle" office, 41, Wellington Street, Strand.

— "IN A GLOUCESTERSHIRE GARDEN," by the Rev. H. N. Ellacombe, M.A.—This is not only an entertaining but a useful book. The style is clear and direct, and while the poetic aspect of gardening and the beauties of Nature are not lost sight of, there is a complete absence of that vague and dreamy spirit of rumination which is only too common in works of this character. Every page bears the stamp of a versatile and widely cultured mind, which, while deeply tinctured with the old classical learning, does not dwell in misty regions of the past, but lives and breathes in the full light of modern knowledge and modern science. In this book there will be found no musings, no humorous anecdotes of university, clerical, or village life, none of the loftiness of the philosopher, and, above all, nothing of the pulpiteer. With the exception of a very short chapter at the end there is little allusion to matters ecclesiastical, and throughout the tone is that of an eclectic reader with a strong partiality for horticulture and botany. The author seems to have thoroughly assimilated all that is of general interest in the received authorities on science and horticulture in so far as they bear upon his subject, and puts it forth in the most popular and intelligible form. Inasmuch as there is no attempt at fine writing, the style being equally pleasing and instructive everywhere, no single extract could adequately represent the peculiar excellence of the book. We refrain, therefore, from quotation, and say that those who follow gardening seriously and intelligently cannot fail to obtain satisfaction from its perusal seeing that it is written with a very direct purpose by an enthusiast whose enthusiasm never betrays him into either dulness or obscurity. The form in which it appears is in the highest degree tasteful, and reflects great credit upon the publisher, Mr. Edward Arnold, of Bedford Street, Strand, London.

— It is said that Ferns which grow in rank profusion in Western America are now used largely for paper making at the Alberni Mills.

— PRESERVING THE COLOURS OF FLOWERS.—Ammonia in the air is the main cause of flowers, when cut and dried, losing their colour. This may be prevented, says Herr Nienhaus, by pressing specimens between paper which has been previously saturated with a solution of 1 per cent. of oxalic acid in water. In this way the true tints of even the most delicate Poppies may be preserved.

— LILACS AT THE ARNOLD ARBORETUM.—One of the most attractive floral displays ever made in an American garden was seen in the Arnold Arboretum when the Lilacs were in bloom. About 120 varieties of *Syringa vulgaris* were in flower. The collection occupies a wide bed, stretching for more than 900 feet up a rather steep slope, along one of the principal drives, and the colour of the flowers is well brought out by a high green slope behind and parallel with the bed. Among the most attractive of the varieties in this collection are Marie Lagrange, white; Rubra insignis, dark red purple; Trianoniana, purple; Madame Briot, red purple; Geheimath Heyder, pale reddish blue (very large compact panicle); Alba grandiflora, white; Charles X., dark red purple (an old variety, but still one of the very best); Emil Liebeg, pale blue; Bertha Dammann, white; Virginalis, white; Ambroise Verschaffelt, flesh colour; Gigantea, mauve; Carsli, dark purple red; Maxime Cornu, pale blue (double); A. Lavallée, pale blue (double); Lamarck, pale blue (double); Ludwig Späth, dark red purple (very late); Philamon, dark red purple; Alice Macguery, purple red; La Tour d'Auvergne, dark red purple (double, very large compact panicle); Félicité, pale flesh colour (semi-double); Madame Moser, white; Tournefort, dark purple in the bud, opening bright blue (double).—("Garden and Forest.")

— PEA KING WILLIAM.—Two years since Mr. C. Orchard of Bembridge, Isle of Wight, sent me a single Pea haulm on which was growing half a dozen pods of Peas, to show what was apparently a good early new Pea. Taking care of the few green pods I managed to save enough to obtain a few seeds for use this year. The result is one of the finest second early Peas in cultivation. I cannot call it a first early Pea because sown on the same day as William I. it is fully ten days later than that variety. King William, like other varieties, varies in height. Sown in pots on March 6th and planted on a sunny border the haulm has grown 5 feet high, and is now bearing fully twice as many pods as William I., several containing eight Peas of an exceptionally dark colour, and for an early Pea of a really good flavour. Sown in the open on March 11th on the same border the haulm is quite a foot shorter, and consequently a lighter crop will be the result. Sowing William I. in pots on March 6th we gathered the first dish June 7th. King William sown on same date was ready June 17th, as previously stated. As a close succession to William I. or any other early Pea I regard King William as a grand acquisition to the early Pea list.—E. MOLYNEUX.

— PÆONIES.—There was a big show of these noble hardy flowers at the Drill Hall on the 11th, but I saw nothing there so striking as was found at Mr. J. Walker's flower farm at Ham a day or two after, when the door of a huge packing shed being opened I saw the entire floor literally covered with big masses of double Pæonies, gathered and bunched in half dozens, ready for packing for market. All these flowers were standing in water, for it is a good plan to so place them in water so soon as cut, as the stems then get well charged with moisture before going to market. There were pure white, canary white, fleshy pink, rose, red, and crimson, though the colours are not so many, nor are the sorts so bewildering as were seen at the Drill Hall. It is not a matter for surprise that these grand flowers sell well, as they really are beautiful and enduring. I did not observe any of the loose, flaccid single varieties. They are beautiful enough on the plants, but do not seem so well fitted for market purposes. Of course, these Pæonies are grown at Ham in immense numbers. They seem to like the deep sandy soil found there, but it is needful to have it well fed, and not to be sparing of top-dressings after the plants begin to age. A couple of years from planting usually has to elapse ere really fine flowers are obtained, and after a period of some six or seven years then it may be needful to lift, divide and replant. That work should always be done early in the autumn, so as to enable new roots to be made before the winter sets in. Those who grow Pæonies in gardens should be content with a few, say a dozen good sorts, and nowhere do they look better than fronting a shrubbery. Still, there they cannot get the same generous culture which they so well repay.—D.

— A FINE DOUGLAS FIR.—A large tree of Douglas Fir, 36 inches square by 60 feet long, was recently loaded (says the "Western World") on two flat cars at the Brunette Mills, New Westminster, from Montreal for use by the Harbour Commissioners for the construction of a bridge. In this immense baulk, which was the prettiest ever cut at the mill, there was neither knot nor blemish. It is claimed that no larger timber was ever cut in the State, though some may have exceeded it in length.

— ENCOURAGE THE CHILDREN.—What a pleasure it is to a father or mother who is fond of flowers and gardening to have their children take an interest in Flora's treasures. How delightful it is to walk in the garden in the cool of the evening with a warm, soft little hand in yours, leading you to where the favourites grow, a pair of interested and laughing eyes flitting between yours and the blossoms, and a sweet little voice piling you with questions and comments about the Pansies, the Roses, the Poppies, and the flowers. While all children love flowers, some are more emphatic than others in their fondness for them, for the love is stronger. At Dorset many children come to us for flowers; they want a few for the church, or the school, or some particular friend, or a funeral, or not infrequently for themselves, for they love them. And they all get some. Be they rich or poor, young or old, stylish or in tatters, acquaintances or strangers, it is immaterial to us, they get some flowers. The other day we came upon a ten or eleven-year-old boy down on his hands and knees smelling the Pansies in the borders; he was all alone, and a stranger to us. On inquiry we found he lived some three miles away and came here after school hours alone and on purpose to see the flowers. Such children should be encouraged.—("American Gardening.")

— THE ROMANCE OF PLANT LIFE.—This has been the subject of special study by Dr. D. Morris, says a contemporary, and the two lectures he has arranged to give before the Fellows of the Royal Botanic Society have created much interest. At the first of the two lectures Dr. Morris discussed, with his usual ability, some of the most striking features of the vegetation of the Canary Islands. Chief among these were the singular Dragon trees, which were closely related to trees distributed over widely separated parts of Africa. They were regarded as the survivals of a very old African flora, which flourished on that continent at a time when the climate was much colder than at present. It was suggested by Balfour and others that, as the ice in the Ice Age gradually receded northward and the climate got warmer, these plants were driven to higher regions, and hence, on the high peaks of Central and South Africa, the Canary Islands, the slopes of Ruwenzori, and the mountains of Abyssinia, the remains were found at the present day of an old African flora which, by climatic changes, had been gradually driven out and replaced by more tropical plants. The study of these and similar plants afforded one of the most interesting problems in botanical science. Reference was made to the Canary native Palm which incidentally led up to a most interesting account of curiosities occurring in Palm life.

— PEACHES AT HAM.—Mr. J. Walker's very fine range of Peach houses at Ham Common are to all interested in Peach culture just now, and will for the next few weeks, well worth a visit. There are nine of these fine houses, each 24 feet wide and 180 feet long, whilst they rise to 12 feet in the ridge. The trees within are all on 4 feet stems. These, as showing the variations found in stocks, are of different dimensions, although in most cases the heads are equally large. The trees are planted as near to the sides as well can be, and at distances apart that vary, some being fully 25 feet, yet having heads that meet each other, whilst others are from 14 to 16 feet apart. Not a few very large trees were lifted and replanted last autumn, a thinning out having become necessary. These are all doing well, and carrying some fruit, but next year without doubt they will bear very fine crops. Although the soil is made very firm and not rich, yet a too luxuriant growth is in some cases developed that cannot be more effectively checked than by lifting and replanting. Alexander, the earliest Peach, has given a good crop, and is being followed by Waterloo and Hale's Early. Then will follow a dozen others of the best varieties, but colour is in marketable Peaches a matter of the first importance, as it enhances the value of the fruit from 10 to 20 per cent. Of Nectarines Lord Napier, all along one side of a house, is a superb sight. Early Rivers is, of course, the earliest, and colouring of its fine fruit superbly, but it is not yet largely planted. Several other fine varieties are grown. In almost every case the wires are filled with growth and leafage from end to end, and yet it is evident that although some trees here cover nearly 300 square feet, they could soon fill double that area if they had room. However, the house should be seen to be properly appreciated.—A. D.

## NITROGENOUS MANURES AND THEIR EFFECT.

THERE are ten elements absolutely essential for the production of plants. These are nitrogen, hydrogen, oxygen, carbon, sulphur, phosphorus, potassium, calcium, magnesium, and iron. It is to the first-named element (nitrogen) that I wish to call attention, and I will endeavour to show how important it is that we should become well acquainted with it. Nitrogen was discovered by Rutherford in 1772, and is a colourless inert gas, slightly soluble in water. It occurs free in the atmosphere, of which it constitutes 79 per cent., or 11 lbs. to every inch of the earth's surface. The nitrogen and oxygen of the atmosphere combine under the influence of electric discharges, nitrous acid being formed, which is converted into nitric acid by the action of ozone or peroxide of hydrogen. It forms several compounds useful to those engaged in horticultural and agricultural pursuits. Ammonia is a compound of nitrogen and hydrogen.

Owing to the complicated changes of nitrogen in the soil, it is of the utmost importance that we should study the natural sources of its loss and gain there if we wish to become well acquainted with the difficult question of soil fertility. How does the soil obtain nitrogen in a natural way? The presence of organic nitrogen which is found in the soil has been formed by the decay of vegetable and animal matter. It is also brought down in rain as organic nitrogen, ammonia nitrates, and nitrites. The amount obtained in this way was determined at Rothamsted to be  $4\frac{1}{2}$  lbs. per acre per annum. But this varies in different parts of the country. It is estimated that an acre of fertile soil contains from 6000 to 30,000 lbs. of nitrogen in the first 18 inches, but the larger half is in the first 9 inches, and the quantity decreases the deeper we go, 96 per cent. of it being present as organic matter.

From the above it seems that we have an inexhaustible supply of nitrogen in the soil, when our most exhaustible crops (Turnips) only remove about 150 lbs. per acre. But probably not more than 5 per cent. of the nitrogen in the soil is in the form of nitrates, and thus available as plant food. Fallow land always contains a much higher percentage of nitrates than land under crop; for instance, the first 27 inches of soil over an area of one acre of fallow contains from 33 to 60 lbs. of nitrates; land under crop only contains from 5 to 14 lbs. in the same bulk of soil. This shows how quickly the nitrates are taken up by a growing crop.

These nitrates are most abundantly formed during the late summer and early autumn months, when the soil is warm, especially after cereal and other summer crops are removed. Nitrates, it should be remembered, are very soluble in water, and if light sandy soils are allowed to remain bare during the winter a very large proportion of this valuable manure will be washed out by the heavy rains. To prevent this loss some kind of winter crops should be grown, as these take up the nitrates. If the crops are of no other use they can be dug in during the early spring, and will then form a good organic manure which is beneficial to light sandy soils, as it helps to make them more retentive.

I have stated that our most exhaustive crops remove about 150 lbs. of nitrogen per acre, and from experiments at Rothamsted it was found that from 35 to 45 lbs. of nitrates per acre were washed out of the soil into the drains per annum, making the total loss of nitrogen about 157 lbs. per acre in one year. Gardeners must bear in mind that this loss goes on the same in garden soils, and therefore to keep it in a fertile condition we must replace this loss by the application of some nitrogenous manure, such as the following.

*Ammonium Sulphate.*—This is a compound of ammonium and sulphuric acid. It contains 20 per cent. of nitrogen, equal to 25 per cent. ammonia. This is the most concentrated of all nitrogenous manures, and is very soluble in water.

*Potassium Nitrate.*—This is a compound of potash and nitric acid, and usually contains 13 per cent. of nitrogen, equal to 16 per cent. ammonia. It also contains about 45 per cent. of potash. It is a very valuable manure. Any gardener can increase the supply by the following process:—Make a compost heap of vegetable matter, such as garden refuse, and mix with it a fair proportion of wood ashes and lime. The wood ashes, which are rich in potash, can be obtained by burning all fruit tree prunings and hedge trimmings. The lime added helps to decompose the organic matter and liberate the nitrogen, which then chemically combines with the lime; but another change takes place by which the nitrogen leaves the lime and combines with the potash, thus forming potassium nitrate. The compost heap must be frequently turned so that all parts become thoroughly oxidised.

*Sodium Nitrate.*—This is a compound of soda and nitric acid, and contains about 15 per cent. of nitrogen, equal to 19 per cent. ammonia. It is very soluble in water, and contains its nitrogen in a form that can be immediately appropriated by plants.

*Peruvian Guano.*—This manure varies from 1 to 12 per cent.

of nitrogen. It is a more general manure than the preceding, as it contains nitrogen in three forms. 1, As organic nitrogen; 2, ammonia; 3, nitrates, and is, therefore, a more lasting manure.

*Dried Blood.*—Blood contains nitrogen equal to from 12 to 16 per cent. ammonia, but it is slower in action than any of the above manures, as it has to undergo decomposition before it is available as plant food.

*Fish Guano.*—This is also a slow acting manure. It contains nitrogen equal to from 8 to 10 per cent. ammonia.

*Farmyard Manure.*—This is the most general of all manures. One ton contains from 9 to 15 lbs. of nitrogen, besides other valuable manurial ingredients, such as potash and phosphoric acid.

*Animal Urine.*—One ton of this from horse stables contains 36 lbs. of nitrogen; from cows, 30 lbs.; and from sheep, 38 lbs. Most gardeners can get a good supply of stable manure, and many persons have noticed the black streams draining away from it. If the value of the fertilising ingredients of this liquid contain was better known it would not be allowed to waste as it does. This is the analysis of it in 100 parts. Water, 82 per cent., and dry substance 18 per cent. The dry substance is made up as follows:—

Ash	...	...	...	10.7	Magnesia	...	...	0.4
Nitrogen	...	...	...	1.5	Phosphoric acid	...	...	0.1
Potash	...	...	...	4.9	Sulphuric acid	...	...	0.7
Lime	...	...	...	0.3	Silica	...	...	0.2

It will be seen by this analysis that the liquid contains, in addition to nitrogen, five of the mineral ingredients that are essential for the production of a healthy growing plant; the one not mentioned is iron, but plants only require a trace of this ingredient. And it is usually present in soils. It must be borne in mind that all the manures mentioned, except the sodium nitrate, the potassium nitrate, and part of the Peruvian guano had to undergo a process, next to be dealt with, before they can become available as plant food.

*Nitrification.*—This is effected in the soil by two micro-organisms (Bacteria). The first, known as the nitrous organism, converts ammonia into nitrous acid; the second, the nitric organism, converts the nitrous acid into nitric acid.

Carbon as organic matter must be present for the existence of these micro-organisms. Air, heat, and moisture are the three things that promote nitrification. It is very feeble at a temp. of 40° F., and ceases at 32° F. It is, therefore, necessary that the soil should be well drained. If the soil is waterlogged the air is shut out, and nitrification ceases, the nitrates present becoming denitrified, with the result that the nitrogen is set free. We must understand that nitrification takes place exactly the same in the soil of the smallest pot, under the gardener's care, as it does in any prepared border, or in the open field. If the soil in pots become waterlogged nitrification ceases, and if allowed to remain long in this condition the roots will perish.

*Basic Condition of Soils.*—Sufficient lime and potash must be present as carbonates or sulphates for the nitrates when formed to combine with, nitrate of lime and nitrate of potash then being formed, and these are the two sources from which all plants obtain their nitrogen from the soil. If any soil is not in a good basic condition it cannot be fertile.

*How Plants Obtain Their Nitrogen.*—The dry substance of plants usually contain from 2 to 3 per cent. of nitrogen, and they all (except the leguminous plants) obtain it from the soil principally as nitrates. Some gardeners still favour the idea that the foliage of plants has the power of absorbing nitrogen as ammonia from the air, but the most eminent botanists in England and on the Continent have concluded that the quantity obtained by plants in this way is so small as not to be worth considering. We may deduce from this that damping down houses, when closing in the afternoon, with liquid manure, as practised by some gardeners, does not benefit the plants so much as they think. Some, however, consider that the fumes of ammonia are injurious to red spider and other insect pests.

*Leguminous Plants.*—Peas, Beans, and Clover belong to this family. These plants have some power, not yet properly understood, of absorbing the free nitrogen from the atmosphere. Dr. Paul Sorauer, in his popular treatise on the "Physiology of Plants" (1895), says, "As far as our scientific knowledge goes, the leguminous plants can subsist on the nitrogen they take from the atmosphere, while cereal crops, fruit trees, and indeed all other phanerogams, must obtain this substance in some soluble form from the soil. Nitrates seem to be the most suitable form of salt from which plants obtain their nitrogen. Ammonia, which can probably be absorbed in minute quantities even in a gaseous state, is less suitable." It is a fact that leguminous plants can be grown in a soil devoid of nitrogen. These plants do not rob the soil of this element, but act as purveyors of it to the soil.

*Why is Good Loam so Valuable?*—The first 9 inches of an old

well-drained pasture is full of nitrogen, in three forms—nitrates, ammonia, and organic matter. The first 9 inches of soil in 1 acre, if weighed when dry and all roots removed, would contain about 2,250,000 lbs. of soil. At 0.10 per cent. of nitrogen this quantity of soil would therefore contain 2250 lbs.; but the turf we use for potting has all the roots in it, and these by their decomposition yield a large supply of nitrogen. Clover being a leguminous plant, greatly increases the nitrogen in a pasture.

*How is the Nutrition of Pot Plants Effected?*—The various composts we use for potting purposes should contain sufficient food for the growth of the plants; but the food in the richest soil can only last for a short time in the limited space of a pot, and therefore we should try to make the best of the soil. It is a common practice when sifting soil to throw out the lumps of turf that will not pass through the sieve. This is a great mistake. These lumps should be rubbed through, as their decay greatly increases the supply of nitrogen to serve as plant food.

When the soil in pots is getting exhausted the plants cease to grow vigorously, the foliage becomes pale, and the plant is weak in the growing point. We must now supply it with food. Soluble artificial manures are generally used where good liquid manure cannot be obtained. Great care should be taken not to overfeed, as this encourages rank growth; young tissues are built up too fast; the plants are not well matured, and when in this condition are more liable to prevalent diseases. Dr. Sorauer says that "the majority of diseased plants he received from gardeners was the result of overfeeding."

I have used tons of chemical manure, and from practical experience I find it better to under than over-feed. If we wish to keep our plants healthy we should know the composition of the soil we have to deal with; also the composition of manures, and the ash constituents of plants. We should then be able to mix our own compounds to suit plants under our care. In conclusion I may say that of all the elements essential for plant life nitrogen is the most important. It is one of the chief elements of protoplasm, and this is the substance which gives life to plants.—(*Paper read by MR. J. GAY, at a meeting of the Wormley and District Horticultural Society.*)

CATTLEYA GIGAS SANDERÆ.

AMONGST the most conspicuous of the many handsome Orchids shown at the last meeting of the Drill Hall was *Cattleya gigas Sanderæ*, of which the woodcut (fig. 97) represents a flower. This *Cattleya* is superb in colour and of splendid shape. The sepals and petals are of the brightest rose, while the lip is of an intensely rich maroon with gold and brown veins in the throat. It was staged by Mr. J. Hamilton, gardener to Hamar Bass, Esq., Burton-on-Trent, and was awarded a first-class certificate by the Orchid Committee of the Royal Horticultural Society.

#### BROOMFIELD COLLECTION OF ORCHIDS.

THE celebrated collection of Orchids got together by Matthew Wells, Esq., Broomfield, Sale, near Manchester, is to be sold on the premises on Wednesday and Thursday, June 26th and 27th. The plants will be sold without reserve, as Mr. Wells is relinquishing their cultivation; and Messrs. Protheroe & Morris, of Cheapside, London, will effect the sale, commencing at half-past twelve o'clock each day. The collection includes many rare and beautiful species, varieties and hybrids.

#### HABENARIA BIFOLIA.

THIS, the British Butterfly Orchid, is now very beautiful in the woods hereabouts, and a dozen spikes loosely arranged in a glass before us are exquisite, and fill the room with fragrance. But it is growing naturally under the deep shade of Hazel bushes, and with the pure white flowers in contrast with the dark green of the surrounding foliage the true beauty of this is seen. Here, also, is where they luxuriate, revelling in the moist soil and shady cool atmosphere, and the strongest spikes in dry open positions cannot compare with these for size of flower or length of spike.

This Orchid is easily naturalised in suitable positions in shrubberies or underwood in the pleasure grounds, and the nearer the conditions approach those indicated above the greater will be the success with it. In localities where they are plentiful no harm can be done by lifting a few clumps just after the flowers fade, and

establishing them in the garden. This is quite different from the reckless spoliation of our native wild flowers and Ferns, which goes on and apparently increases in the vicinity of all large towns, hawkers digging up Primroses and Ferns just as they are in the middle of the season's growth, these being planted in town gardens without any regard to a suitable position or soil, and consequently dying at once. The *Habenaria* referred to thrives in an ordinary, fairly stiff loam, and after planting should be mulched with some short stiff material, as lawn grass or half-decayed leaves. Possibly, owing to the conditions under which it grows, this species is not quite so free in seeding as the *Orchis* species—e.g., *O. maculata*, *O. militaris*, or *O. pyramidalis*; but if the flowers are not cut too hard there will soon be a number of young plants, which during June and July will fill the air with the delightful perfume of their blossoms.

#### LÆLIA MAJALIS.

ALTHOUGH a dwarf-growing plant this superb species takes rank with the finest in the genus, and compared with the size of the growth the flowers are wonderfully large; in fact, if well managed there is not a more satisfactory species to grow. A small plant in a suspended pan 5 inches across has three twin-flowered spikes, and these, when fully opened, will doubtless be 7 inches across, no mean result from pseudo-bulbs barely 2 inches high. A common cause of complaint against this species is its alleged paucity of blooming, but this is chiefly the fault of the cultivator.

*L. majalis* should be grown in a light sunny position in the coolest part of the *Cattleya* house, with an abundant supply of moisture at the roots, and these, being fairly large and fleshy, delight in an open and well aerated compost. Some growers use blocks for this Orchid, and but for the almost constant attention required in watering, this system has much to recommend it, the roots having nothing to surfeit them, and the fact of their being wholly exposed to the atmosphere is conducive of their longevity—an important point. Still the fact cannot be gainsayed that blocks should only be used for those species which it is impossible to rear in any other way, and with *L. majalis* this is possible—in fact, easy.

Shallow pans, filled to within half an inch of the rims with crocks, these being kept rather high in the centre, and a thin layer of compost, are all that is needed. Good fibrous peat in lumps as large as a pigeon's egg, fresh sphagnum moss, and a little charcoal will be a suitable mixture for it. As soon as the pseudo-bulbs are quite finished, as indicated by their plump appearance, the plants must be turned out of doors and fully exposed to all changes of weather excepting very heavy rains. On the other hand, they must not by any means be dried, but need frequent attention in watering.

As the nights get colder at the end of August or beginning of September they must be taken either to a cool airy vinery or Peach house, or arranged in a pit with a south aspect, still exposed by day, but drawing the lights on at night. This thoroughly consolidates and ripens the growth, and is the principal point in the cultivation of this species. The plants may now be kept nearly dry until the new year, when they may be again introduced to the *Cattleya* house, and as soon as the buds at the base of the pseudo-bulbs commence to swell the compost must be put in order, repotting or surfacing as may be necessary. This insures the new roots a congenial medium to run in, thus increasing the vigour of the plants.

The flower spikes appear in the centre of the young growth and quickly develop, being generally in full beauty by the end of May. It is from this circumstance that the species received its native name of "Flor De May, Mayflower." The blossoms, as mentioned above, are frequently 7 inches across, the sepals are lanceolate, the petals broader, both of a pretty rose tint. The lip is large, rose, with streaks and a few spots of deep lilac purple. *L. majalis* is a native of Mexico, whence it was introduced in 1838.—H. R. R.

#### MODERN GRAPE GROWING.

##### EARLY TRAINING.

(Continued from page 470.)

It is a common practice with those even who intend to grow their Vines on the restrictive method, to commence with something which is far beyond the extension system, and can only be termed a wild or rambling system. "The more leaves, the more roots," they say. Possibly, but that depends on whether you calculate by weight or numbers.

Allow a Vine to make rampant growth and you get large fleshy roots comparatively few in number, and which, if unrestricted, will travel several yards away from the stem during the first season, desert the border altogether you have been at so much pains to prepare for them, and all your after watering and feeding of the prepared portion will be so much labour and material thrown away, for once roots get away from

the stem they do not return again of their own free will. The aim should be to induce the formation of the largest possible number of small roots, for large fleshy roots are comparatively useless. Every rootlet, however small, has near its extremity root hairs by which all the nourishment a plant obtains underground is taken in. Large roots and rampant growth mean only an excess of water; for a real solid building up you must have innumerable small roots, and hard if smaller stem growth.

I am in the habit of treating young planted out Vines exactly as I do those grown for fruiting in pots. The main stem is encouraged to grow till midsummer, and then, or at least early in July, it is stopped, the side shoots all the time being kept pinched to one leaf. Some of the upper buds will burst out again and again, but they are persistently stopped so long as there is no danger of the principal buds down the stem starting. A great deal of watching and discretion are necessary to

had a great deal to do with throwing this splendid Grape into the background, and I believe now that those Vines obtained from a western source have the better constitution, and as a rule this variety is grown better in the western counties. For ordinary practice there is no excuse for inducing late growth, which has to be ripened as well as it can be by a large amount of fuel.

In the autumn, as the lower buds on the main stem become partially ripe, the laterals may by degrees be closely cut off, beginning from the base, and sometimes in September the Vine may be shortened to the length it is intended to remain, or if there is any risk of its starting again one or two extra eyes may be left to be cut off later. It matters not whether the rod is 6, 12, or 20 feet grown and ripened in the way I have indicated. Any variety, with perhaps the exception of Lady Downe's, will, if allowed to start naturally in the spring, do so from every eye. They should never be stinted of water to induce ripening,

FIG. 97.—CATTLEYA GIGAS SANDERÆ.

see that they are not stopped too closely, and yet to take care that they are stopped as closely as circumstances will permit. According to my experience the leaf growth made after July is not worth having, and all the plants' energies should be concentrated on making plump buds, hardened wood with small cells and wire-like roots. "All this is old-fashioned," someone will say, "and we must go on quicker."

Possibly, but I am not without some experience of quicker methods, and one instance in particular would, I think, exceed anything recorded of late. The season before Mrs. Pince was distributed Mr. Meredith went to Exeter and procured a partially ripened plant from its owner. He planted it in rich soil, gave it plenty of heat and moisture, and it made such growth that six hundred plants were raised from it the following spring, the remainder of the plant carrying and ripening twenty-three bunches of Grapes, three of which were exhibited at a Netherlands exhibition, and received special notice from the Queen of the Netherlands.

Mr. Meredith certainly obtained a few guineas for his Vines and outwitted Mr. Pince, but I have always thought that the plan adopted

and never be allowed to become dust dry whether they are making visible growth or not.

Whether Vines are allowed to fruit the season after planting should depend altogether on their strength. If they are sufficiently strong it does good to fruit them moderately; but the fruiting should be quite a secondary matter, the great aim being to build up a good and regular framework for the future. There is frequently a tendency in young Vines during the second year to make irregular growth, some shoots being as large again as others, and frequently the leader is out of all proportion to the rest. All the strong shoots, including the leader, should have their points pinched out just beyond where they show fruit, and in a few days others which have overtaken them should be served in the same way, and by this means the plants will early in the season become perfectly balanced. Sometimes it is advisable to allow the leader to grow again; but never at the expense of the lower branches, and all the growth it is allowed to make should be completed before July.

It will be seen that the second season is devoted entirely to laying

the foundation of a handsome framework for the future, and I attach great importance to this. There is no difficulty and there is no loss in having our Vines objects of beauty, and as we do not all intend to throw them away in ten or even twenty years, I advise a considerable amount of attention to this now, for if the chance is allowed to slip it cannot be remedied afterwards. There will generally be considerably more growths than are wanted for permanent laterals; the superfluous ones may either be rubbed off when they commence growing or they may be cut off later on, before they have had time to harden. From 15 to 18 inches, according to the variety, should be allowed between the branches.—WM. TAYLOR.

(To be continued.)

## SEASONABLE HINTS ON FLORISTS' FLOWERS.

### AURICULAS.

THE most important point in the culture of these beautiful spring flowers is now engaging the attention of all who love their quaint and unique charms, for by this time the plants having been removed to their summer quarters, out of the influence of the hot sun and parching east winds, which we have for five or six weeks experienced, when watering has been so absolutely necessary, they will be anxious to place this into new soil where they may obtain fresh nourishment for their roots, that in which they have been growing for the last twelve months being very nearly exhausted of all its good qualities. Whatever may have been the opinions and practice of growers in times past, when each man of any celebrity was supposed to have his nostrum by which he ensured success, the treatment of the plant is now simplicity itself.

I think most growers are agreed that good fibrous loam which has been laid up for about twelve months is the chief thing to be relied on in making the new compost; in fact, three parts of this combined with one part of well-decayed manure and leaf mould, the latter not too old, with a good dash of coarse sand, is sufficient for the purpose. Of course the fibrous loam varies in quality in different places. Most of our southern growers obtain it from Epsom Downs or some of the neighbouring Downs of a similar character. I remember in my earlier days what was called the Kilmacannock loam, which was obtained from the limestone districts in the county of Wicklow, was much coveted by the Dublin growers of Auriculas. It is perhaps better where possible to have the compost mixed together for some considerable time previously, but this is not essential, and if it has been kept under cover so that the good has not been washed out of it, it will lose nothing by being mixed just at the time of potting.

Some growers prefer the use of horse and others of cow manure. The former is perhaps the stronger of the two; but although I have the choice of both I think I prefer the latter. There is less probability of fungus, which is very apt to run amongst the horse manure. In potting it is better to use too small pots than too large ones. Plausible reasons are brought forward by the advocates of both kinds. Coarse Bedfordshire sand or powdered charcoal may be added to keep the soil open. In potting it is very desirable that the soil should be well pressed down; indeed, tight potting is what should be aimed at, for some of the ingredients not being quite decayed shrink as they become more so, and make the soil (what we call in this county) "hover," so that the water will pass too freely through it unless this plan be adopted.

I need hardly say that perfect drainage is absolutely necessary, and that care should be taken before the compost is placed in the pots that worms and grubs of all kinds should be looked for and thrown away; if left in, as the worms increase in size they are very apt to disturb the drainage, and there is nothing that the Auricula resents so much as stagnation. Deep potting is, I think, to be preferred, especially as by adopting this there is a greater likelihood of obtaining offsets; and I have been very much surprised to find how few of these there are this year. This is one of the causes of the Auriculas maintaining their price. We cannot make cuttings of them, nor layer them, but just simply wait for their pushing forth the offsets, and it not unfrequently happens that the plant will not do this for two or three years. Some varieties, such as Traill's Beauty, and most of the selfs, are very prolific; while others, such as Prince of Greens and Lancashire Hero, are very shy in producing offsets.

When the plants are being potted it is well to have an empty frame in which they can be placed and shaded for a few days. All aphides should be brushed off before the plants are placed in their summer quarters—indeed, where they are grown in a pit, it is best to fumigate them before commencing potting. The frames should be opened after a few days, and for some time the outer leaves will gradually decay, and should be taken away for fear of creating damp. After this the plants will require but little attention save that of watering, weeding, and giving air upon all suitable occasions; in fact, the frames ought never to be closed during the summer, for when they cannot be left entirely open they should be tilted. Of course, if persons wish to obtain new varieties this is a good time, but they are very few in number and their price is high.

### CARNATIONS AND PICOTEEES.

From all sides I hear lamentable complaints concerning these where they are grown in the open. Those who grow them under glass are doubtless independent of the elements, but we cannot all do this, and are therefore obliged to be content to grow them in beds, and a most disastrous time it has been for us. The summer of 1894 with its deluge of rain prevented the layers from rooting well; the grass was so lishy

that it seems not to have had the power of rooting well, and consequently, although I had a goodly number of both florist and border varieties, I have hardly a sufficient number of plants to make up a bed. The only exception to this disastrous condition is that of a number of seedling plants raised from seeds kindly sent me by Mr. Martin R. Smith. These have been out and unprotected all the winter, and are now stocky plants, promising an abundance of bloom. These are, of course, from the seeds of 1893. Every seed grew, and the plants seem exceptionally strong and vigorous. As the flower stems spindle for bloom they should be tied to stakes, and the surface of the bed may be top-dressed. Weeds should be looked after and earwigs trapped, as they have a bad habit of getting into the bed and nibbling away at the base of the petals, so as to entirely destroy the bloom; in fact, they are as great a pest to the Carnation as they are to the Chrysanthemum. The compost for layering should now be prepared in a dry place; provided it is light and porous there is no need for being too particular about it.

### GLADIOLI.

So far these promise well. There can be no question but that a dry season suits them best. I feared from the fact of last autumn being so wet that one might expect many of the corms to be feeble, but as yet I see no evidence of it, but I have long ceased to put any confidence in these bulbs. They are no doubt the subjects of a destructive fungoid disease, which Dr. Cooke, the eminent microscopist, to whom I sent some bulbs, has clearly shown. Unfortunately he suggests neither preventive nor cure. I think it will be well, as the plants are advancing in height, to water if this drought continues, not giving them dribbles every day, but a good sousing now and again. Stakes should now be got ready, so that towards the end of the month, when the plants throw up their flowering stems, they may be placed to them, for it is a pity a good spike should be valueless by being crooked through want of support. Liquid manure may be applied with caution, and in light soils top-dressing with decayed manure may not be inadvisable, but the Gladiolus very much dislikes contact with fresh manure.

### RANUNCULUSES.

I have a most melancholy tale to tell concerning these. My beds last year were a sight worth looking at, but this year there is hardly a bloom to be seen, and I fear very much the greater portion of the tubers may be lost. I do not attribute this to the severe weather of the present year, but to the excessive wet of the last; the tubers were not ripened properly as there was no sun to do it, consequently I believe there was no real vigour in them; so largely did they increase last year that I gave hundreds away in all directions, and now I shall with difficulty save enough for planting again. Those who have any should carefully watch them and take them up when the foliage decays. The ground is now very dry, and should rain come they will commence growing, and this is fatal to them.

### PANSIES.

My small collection in pots has done exceedingly well, and I have had a good bloom. I cut them down and shall plunge them in pots, as in our drier climate I find they do better this way than in planting out. When it is desired to increase the stock cuttings may be made of the side shoots; larger and hollow stems are of no use whatever, they are very much gone out in the South owing, probably, to our climatic conditions, but they are a very beautiful class of plants.—D., Deal.

## STRAWBERRY ROYAL SOVEREIGN.

I SEND a sample box of outdoor grown Strawberry Royal Sovereign to show that it is a good early variety. We had some fruits ripe on the 7th inst., growing side by side with Noble, under exactly the same conditions as to soil and treatment. We gathered three or four days earlier from Royal Sovereign, which I consider the best early Strawberry that has yet come under my notice of the Paxton type. So far as I can judge, when better known it will be largely grown by market growers. The fruits seem very firm, and will no doubt travel well, and as the price this season will be reasonable I would advise all lovers of a good early Strawberry who do not possess Royal Sovereign to lose no time in securing a good stock for another season.—G. R. ALLIS.

[The specimens were very handsome and of splendid flavour.]

I WAS pleased to see Mr. Molyneux's note (page 517) in reference to this magnificent Strawberry. I have at least twenty varieties, including all of the late Mr. Laxton's raising, and in my suburban garden here, with strong calcareous addition to the ordinary soil, this is by far the best. It is a few days behind Noble, and as early as Sensation, but of better quality than either, and doubly prolific. The berries are from 1½ to 2 ozs. each, and this notwithstanding the season here has been unusually dry and warm. I am surprised, in the sunny south of England, Mr. Molyneux did not pick his under glass until the end of May. The first week in June mine in the open, and without any particular care, were fit to pick. Other varieties give a few good berries, but Royal Sovereign promises to have successive pickings equally good. Rain yesterday (June 13th) diminished many of my garden troubles, arising from the persistent and continued dry weather.—W. J. MURPHY, Clonmel.

I CAN corroborate "E. M." (page 517) as to the good quality of this variety. I have not tried it for forcing owing to the stock being

limited, but grown in the open quarter of the kitchen garden it has proved to be hardy, early, and very fruitful, weak plants carrying a heavy crop of large fruit of good colour and excellent flavour. Many of the fruits from one-year-old plants weighed over 2 ozs., the first of which were ripe on the 10th inst. As showing its earliness other varieties grown on the same quarter were President, Sir Joseph Paxton, Auguste Nicaise, Lord Suffield, Gunton Park, Vicomtesse H. de Thury, and several other varieties, but the latter is the only variety that has commenced to colour. I predict a great future for this novelty, as it has earliness, size, and quality to recommend it. The flesh being solid and firm it will travel well, and I realised 2s. per lb. for fruit of this variety in the open market, although other varieties were coming in somewhat freely from the South, and were being sold at 6d. per lb.—a fact that should be made a note of by market growers.—GEO. SUMMERS, Sandbeck Park, Yorks.

## ROSE SHOW FIXTURES FOR 1895.

- June 20th (Thursday).—Colchester and Ryde.  
 „ 25th (Tuesday).—Isle of Wight (Cowes).  
 „ 26th (Wednesday).—Richmond (Surrey).  
 „ 27th (Thursday).—Gloucester (N.R.S.) and Canterbury.  
 „ 28th (Friday).—Exeter.  
 „ 29th (Saturday).—Windsor.  
 July 2nd (Tuesday).—Diss, Maidstone, and Sutton.  
 „ 3rd (Wednesday).—Brockham, Croydon, Ealing, Farningham, Lee,† and Sittingbourne  
 „ 4th (Thursday).—Eltham and Norwich.  
 „ 6th (Saturday).—Crystal Palace (N.R.S.).  
 „ 9th (Tuesday).—Ipswich, Westminster (R.H.S.), and Wolverhampton.\*  
 „ 10th (Wednesday).—Chelmsford, Farnham, Hitchin, and Redhill (Reigate).  
 „ 11th (Thursday).—Bath, Great Malvern (Hereford Rose Society), Helensburgh, Woodbridge, and Worksop.  
 „ 17th (Wednesday).—Derby (N.R.S.).  
 „ 18th (Thursday).—Canterbury (Kent Hospital Fête) and Halifax.  
 „ 20th (Saturday).—Manchester.  
 „ 23rd (Tuesday).—Tibshelf.  
 „ 24th (Wednesday).—Chesterfield and Newcastle-on-Tyne.\*  
 „ 25th (Thursday).—Trentham.  
 Aug. 3rd (Saturday) and 5th.—Liverpool.†

\* A show lasting three days. † A show lasting two days.

—EDWARD MAWLEY, Rosebank, Berkhamsted, Herts.

## ROSE MARÉCHAL NIEL UNDER GLASS.

I DID not reply again to "H. R. R.'s" letter on this subject, though I was glad to see Mr. Divers' corroboration, because it is a generally accepted fact that grafted Roses are distinctly inferior to those which are budded for a permanence. "H. R. R." says he has not infrequently had growths of 20 feet from the grafts in one season, but has he ever got as many first-class blooms per square foot of glass from a grafted plant as I said I had from my budded one? My Maréchal Niel makes twelve shoots of 15 feet long each every year, and they would be considerably longer if they were not stopped. They are now just beginning to start.—W. R. RAILLEM.

## NEW ROSES.

WE have received from Messrs. Wm. Paul & Son, Waltham Cross, specimens of two new Roses, one representing the Tea section named Sylph, the other of the China class, called Queen Mab. The former is superb, with its stiff petals and bushy, floriferous habit. The colour is white, delicately suffused with rosy lake, and is apparently distinct from any other of the section. We shall expect to hear more of this Rose later on. Queen Mab is the Rose for buttonholes, the buds being of perfect shape for that purpose. The colour is somewhat difficult of description, but rich, pale terra-cotta with rosy purple-tipped petals will convey some idea. Each flower is of great substance, and as we suppose both to be seedlings of Messrs. Paul's raising we may safely congratulate them on their acquisition and introduction.

## ROSE MRS. W. J. GRANT.

WE have received a long letter relative to the change of name of this British-raised Rose, and two plants have been sent to us under another name. As this letter makes reference to matters and alleged statements which have never appeared in the *Journal of Horticulture* its publication would be obviously irrelevant. The writer, however, claims that the purchaser of a plant that has been named, certificated, and awarded a gold medal has the right to change the name and substitute any other that he may choose. We will not argue the matter as to what right a citizen of a foreign nation may have to do this for the sale of what he re-names in his own country; but we have a right to protest, and we do protest, against a foreign name superseding

the legitimate name of a plant in the country in which it was raised and in which it has been honoured by competent officials at public exhibitions.

The Rose Mrs. W. J. Grant was raised by Messrs. Dickson & Sons in Ireland. It was awarded the gold medal as a new variety at the National Rose Society's show at Chester in 1892, and granted a first-class certificate (which was well deserved) at Wolverhampton during the same year. Whether it had more honours we do not at the moment remember, nor does it matter, as the name of the Rose was officially recognised in the most public manner, and no other name can be found registered in either the National Rose Society's books or the public press of that year.

Mrs. W. J. Grant, then, is the true name of this Rose, and under that name the variety ought to be exhibited and grown in this country. It is a well known law in botanical nomenclature that the first name given to a plant and authoritatively accepted is its correct name, and always takes precedence if any others are given inadvertently. If it were not so nothing but confusion would ensue, and no person has any right whatsoever to alter the name of any plant, be it species or variety, that was certificated and registered, say, at the last meeting of the Royal Horticultural Society, and sell that plant under an entirely different name in this country, if anywhere else. If a person purchases an unnamed variety of a flower, or even a named variety that has not been placed before the public, then he can give it what name he chooses for the purpose of exhibiting and gaining a certificate, but after it is honoured no one is justified in changing its name because he happen to purchase the stock, and intends selling plants under another name in the country in which the variety was raised.

Investing flowers with the names of individuals is a compliment to those persons whose names are used, and we are bound to say that it is the reverse of graceful to attempt to obliterate the compliment by erasing the name. Nor, in the case of that name being a respected name, is any change likely to increase the sale of the plant at home. As a fact, we know of persons who simply will not purchase plants of Mrs. W. J. Grant Rose under any other name, and this is the name that will be used in the *Journal of Horticulture* under whatever other appellation blooms may be exhibited.

If one person has the right to alter the name of a Rose under the circumstances indicated, and to work up stocks and sell plants under another name, so has another. All the names so given, whether few or many, would be wrong. Only one could be right, and the only right name of the Rose under consideration is Mrs. W. J. Grant.

Since the foregoing was in type we have received information that a resolution was passed at the last Committee meeting of the National Rose Society to the effect "that, as Messrs. Dickson's new Rose was exhibited and awarded the gold medal of the Society under the name 'Mrs. W. J. Grant,' the Committee considers that that name only should be recognised in Great Britain." This, it is hoped, will settle the matter.

## LATE PEAS.

IN Scotland we have a decided advantage in the climate over cultivators in the south, and in that respect there is less difficulty in keeping up a long-continued supply of Peas. At the same time, in order to prolong the season, a special course of treatment must be followed. After the earliest crop out of doors has been provided for, there is no trouble with Peas until we come to the crop that has to provide for September, October, and, in favourable years, part of November.

At the best there is uncertainty as to the result, which sometimes occurs on account of the weather, occasionally from the attacks of rodents, and not infrequently because a sowing is made too early or too late. In the last mentioned case it may happen that Peas from a sowing put in towards the end of May will continue in bearing until stopped by frost; or on the other hand, the best results may follow from a sowing in the middle of June. My latest sowing last year was on June 21st, and if it had not been for the severe frost in the second week of October that would have been just right. As a rule, however, I find it best to make a big sowing in the second week of June, any time, say from about the 7th to the 13th. Quite twice the usual breadth must be put in, more if space can be spared, because as the season cools the young pods fill slowly, and when this vegetable is a daily requirement it is needful to have a sufficiently large quantity to enable one to secure a dish off a fourth or even less of the crop.

The preparation of the ground is of some importance. For my own part I think it a mistake to sow Peas of any sort in trenches enriched with manure in layers, and for a late crop this is not required at all. If the ground is deep and in good heart no manure will be required; but once the plants have reached the flowering stage, I find a dressing of soot, nitrate of soda, or sulphate of ammonia, most helpful in causing a fresh and continued growth of haulm. Deep sowing is also beneficial. The seeds may be 6 inches from the surface, though at first it need be covered only 3 or 4 inches in depth, and when the plants are staked a little more soil may be drawn to them. A good plan is to make a trench 8 or 9 inches wide, and in this to set two rows of Peas at least 6 inches apart, while the seed in the rows ought to be not closer than 3 to 4 inches. A few rows intended to yield the very latest supply should be sown even wider. Thin sowing, and the consequent free space allowed each plant, is the surest means I know for securing a late crop of fine Peas.

Late Peas are generally tall growing, and it is one of the commonest

things in the autumn to see the overgrown tops bent over, and the space between the rows filled with haulm, which rarely if ever is capable of producing fruit. The way out of this difficulty is by pinching or cutting over the tops before they have quite reached the limit of the sticks. Later in the season the side growths may be pinched with very good effect, in order to hasten the filling of the pods. It may here be remarked that rows of late Peas should be kept picked in the earlier weeks of bearing, for if once pods are allowed to ripen, or even to remain too long on the plants, growth will be seriously checked.

As to sorts I suppose most people have their favourites. The present is the first year that I have dispensed with Ne Plus Ultra. After growing Fame for three years alongside it I have come to the conclusion that the latter is the better of the two, and particularly so with respect to its continued bearing habit. I am also growing a good breadth of Juno, a comparatively dwarf sort, of which I have formed a favourable impression. Besides these I am trying a few novelties of recent years, but these of course will in no manner affect the crop, even should they fail.

—R. P. BROTHERSTON.

### EXPRESS GRAPE GROWING.

I AM obliged to "Market Grower" for the information and explanation respecting the 300-foot house of Gros Colman Grapes referred to by him. The crop was undoubtedly heavy, but unfortunately did not finish well. Yet heavy as that crop may have been, judging from "Market Grower's" statement, his own Vines are carrying a heavier crop at the present time, and he states many of the bunches look like weighing 3 and 4 lbs. It will be quite interesting to hear how these Vines finish their crops.

It is wonderful what the Vine is capable of doing under good management. As "Market Grower" remarks, abundant moisture and liberal feeding are absolutely necessary if heavy crops of first-class Grapes are to be produced annually. It is unreasonable to expect a Vine confined to a limited border to continue year by year for any great length of time to mature heavy crops of good Grapes without a supply of the necessary foods. As all the available plant food in the soil very soon becomes exhausted, and must of necessity be replaced, experience has taught me that frequent small supplies of manure are the best. I often tell my friends to feed their Vines as they feed themselves, viz., a little at a time and often, and give plenty of water, tepid if possible, which warms the soil, especially in the early part of the year, and which stimulates and encourages root action, cold water having the opposite effect.

I thank Mr. Bolas for his remarks in his letter of last week, in which he refers to a Barbarossa (Gros Guillaume) Vine grown in a lean-to Muscat house. Like all the other Vines in this house, it was planted out of a 3-inch pot in the latter part of June, 1890. It made a splendid cane, and was cut back, leaving about 8 feet of rod. The following season, 1891, a second cane was run in, and the Vine carried six bunches. The two largest were exhibited at Derby in strong competition, and were awarded a first prize in 1892, as stated by Mr. Bolas. This Vine carried thirteen bunches, weighing 108 lbs. They were a fine even crop, well formed, compact, neatly shouldered bunches, and well coloured, but the berries were not so fine as the previous year. Only two bunches were exhibited, and were awarded a third prize in 1893. It again carried ten bunches, and finer I have never seen. Some of the bunches were the largest the Vine has ever carried, and every bunch was perfect in finish and good berries. All the bunches were exhibited; the two largest were staged not for competition, and were awarded a cultural commendation and special first prize. Two were placed in open competition, and were awarded a second prize at Derby; four were exhibited at the Botanical Gardens, Manchester, and awarded first prize. The ninth bunch was included in my collection of Grapes at Earl's Court, and awarded the silver-gilt medal; and the tenth bunch was staged in my collection of Grapes at the Town Hall, Manchester, and was awarded the Society's gold medal.

As Mr. Bolas also remarks, I have never had any extraordinary results from very strong wood. I have always found that the best results are to be obtained from medium well matured wood, as large growth generally contains a large proportion of pith which never can produce fruit of first-class quality.—W. INNES, *Derby*.

### ROYAL HORTICULTURAL SOCIETY.

JUNE 11TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair); Mr. McLachlan, Professor Müller, Dr. Bonavia, Rev. W. Dod, Mr. Michael, and the Rev. G. Henslow, Hon. Sec.

*Injury by Salt*.—With reference to this subject, discussed at the last meeting, Mr. Dod observed that it was reported from Lancashire that while evergreens had been uninjured during the severe frost, yet they succumbed to a storm which conveyed much salt from the sea.

*Asparagus Fasciated*.—Mr. Arthur Sutton sent a remarkably fine specimen of this not uncommon phenomenon in Asparagus. Mr. Dod observed that it was probably the result of over-nourishment, as he had fertilised *Primula rosea* with superphosphates, and fasciation resulted from it.

*Beetles and Orchids*.—Some specimens of cockroaches were received, said to be very destructive to Orchids and Ferns. Mr. McLachlan named them as *Blatta lapponica* and *germanica*. They were doubtless

imported with the plants. Any method usually adopted for destroying cockroaches should be applied.

*Dried Orchid Flowers*.—Mr. Chapman, gardener to Mr. Measures, sent some remarkably well prepared specimens of dried and varnished Orchid blossoms, retaining their colours.

*"Barbarossa" Grape*.—Dr. Masters exhibited specimens of Grapes which had burst, and apparently showing another in the interior. This has been the usual interpretation; but an examination of the monstrosity in the young state proved that the interior "Grape" was really a seed, but coated with a succulent membrane, something like the seed of a Gooseberry. Dr. Masters observed that Robert Brown had noticed the same phenomenon to occur in *Leontice*, *Berberis*, and *Crinum*.

*Double Daisies*.—Some fine specimens of double white Daisies on very long peduncles were received from MM. Lambert, Treves. It was suggested that they may have been derived from *Bellis sylvestris*, which has very similar scapes, and not from *B. perennis*.

*Ustilago primulina Disappearing*.—Mr. Dod remarked that plants formerly badly infested with this disease gradually recovered, and were now quite free from it. He observed that the remedy so often given of total destruction by burning of plants infected by certain fungi might be sometimes too drastic a measure. Dr. Masters corroborated this observation, as he had known a similar recovery to have taken place in Lilies.

*Infected Soil from New Zealand*.—With reference to this matter the report from Kew is as follows:—"The root fungus sent to Kew for investigation from Cambridge, New Zealand, is known as *Dematophora necatrix*, *Hartig*, the cause of the much-dreaded 'root disease' in vineyards and orchards, and is widely distributed throughout France, Italy, Austria, and South-west Germany. The fungus also attacks young Maples, Oaks, Beeches, Pines, Spruces, and Laburnums; Beans and Beet are also attacked. The fungus can live in the soil as a saprophyte, and there forms at least two forms of reproductive bodies, which are dispersed by wind, birds, or small animals. When the mycelium comes in contact with the rootlets of a living tree it becomes parasitic, and spreads rapidly in the living tissues.

"All diseased plants should be burned, and the soil where infected plants have grown should be thoroughly mixed with quicklime if available; if not the soil should be burnt, so as to destroy all remnants of roots which contain the mycelium. Diseased patches of ground should be isolated by digging a trench about 1 foot deep, and left open. Wood ashes or manure containing potash, but no acid, dug into the soil among the roots is a preventive.

"The disease has probably been imported with trees from Europe. If the roots of imported trees are made very moist, and kept in a warm place for three days, the fungus, if present, will show itself under the form of snow-white strands and tufts of mycelium."

A vote of thanks was unanimously given to Mr. Massee for his important investigation.

### SAXIFRAGAS IN LONDON.

So many times have the beauties of Saxifragas been extolled in the pages of the *Journal of Horticulture* that it would appear, at first, superfluous to refer to them again now. The generality of these articles have, however, dealt with their cultivation in country gardens either as border or rockery plants, and it is to call attention to their adaptability to town gardens that these notes are penned. This then is the excuse, if any is needed, for again placing them before readers. It is true that many of the larger forms are now extensively cultivated, but it is to the smaller gems of the family that I would now refer. Between these and their larger brethren there is very little in common; in fact, on a cursory glance, it seems impossible that they belong to the same family. A garden of sufficient size should certainly contain representatives of the big and the little, but for gardens of very limited extent the latter are undoubtedly preferable. They naturally permit of an infinitely greater variety, which is synonymous with extended interest, and for this reason should be chosen.

By way of experiment I tried about a dozen sorts, and all but one grew, and are now flowering with the greatest profusion in a narrow border that gets only the afternoon sun. So well have they done that I hope by this time next year to have a much larger collection, and I have little doubt that they will afford entire satisfaction. There is a rockery in the garden, which is situated within earshot of Big Ben, but unfortunately it is used as a stepping-stone for the cats which abound, and consequently no plants will grow thereon, except perhaps the Stonecrop, which just manages to exist round the margins where the felines do not jump on it so much. It was originally purposed to plant the Saxifragas on this bit of rockwork, but after considering the matter it was decided to leave it to the cats, and place the plants in a narrow border that runs round the garden. We had some qualms about doing this for fear they should not succeed, but we need not have had, for, as previously mentioned, the plants took readily to their new home. The idea of planting was originally suggested some two or three years ago by the manner in which they were and are grown in Dulwich Park, and fostered by the notes referring to them that have appeared in the *Journal* from Mr. S. Arnott. But the circumstances were essentially different, for there they had the fresh air from an open space of upwards of 70 acres, whereas in my garden the distance between the rows of houses certainly does not exceed 60 feet. Nevertheless, we felt bound to give them a trial, and would now like other of your town readers to go

and do likewise. They will almost certainly be well satisfied with the results that will eventually be attained.

The first thing considered was the soil, and it was decided to put them in the ordinary soil, instead of making any special preparation for their reception. The mould is of a somewhat light nature, but is really very poor, as few things seem to thrive. Apparently it contains a certain per-centage of lime, as Mignonette is one of the few plants that grow well, and as it is frequently said this plant will not do well without lime in some form or another in the compost, consequently we have concluded it must be there. Perhaps it is considered a requisite for Saxifragas, and if so this, of course, will account in some measure for the welcome success. When the plants arrived the weather was so bad as to render planting an impossibility, so they had to remain in the package for upwards of a week, until the ground was in a fit condition for the work to be proceeded with. However, it was not by any means a long operation, and soon the whole were planted out and duly labelled.

As this was in the spring, and the weather turning bright with warm sun, a small flower pot was inverted over each plant every day, and removed in the evening. In addition to this, careful attention was given to the watering, a little being given whenever it was considered necessary or advisable. Despite these precautions, however, the plants flagged badly for several days, and it was thought they would not survive; but it is a long lane that has no turning, and eventually the plants commenced to grow. After this all was plain sailing, and only one plant of the dozen succumbed. This was decidedly encouraging, and insured them every possible attention. It was not very long after the plants had become thoroughly established ere they commenced flowering, and the modestly beautiful little flowers have received a goodly amount of admiration, which they thoroughly deserve. At first people do not admire them—on the contrary, regarding them as insignificant; but when once they have been induced to look closely into the flowers they have quickly discovered their beauty, and have been proportionately profuse in their expressions of approval. One lady became so far interested as to procure a magnifying glass, go down on her knees, and thoroughly examine them by its aid. It need scarcely be said to those who know and love these plants that her astonishment was very great at the discoveries she made.

It may be interesting to some readers to know the names of the sorts that are grown. All are remarkable for their lowly beauty, and not for any imposing appearance. The first little gem is *S. Huetti*, which has miniature yellow flowers, while *S. Mooreana*, apparently of the London Pride type, has small flesh-coloured blooms of great beauty. *S. glaucum* has whitish flowers, but the most exquisite of all is *S. Andrewsii*, with its star-shaped inflorescence about the size of a three-penny piece. The base of each of the petals, of which the ground colour is white, is chastely spotted with crimson, and adds a singular beauty to the plant. It is the diamond of the collection in my opinion. The remainder comprises *Kingi*, *muscoides purpurea*, *leptophylla*, *Aizoon minor*, *hypnoides*, *decipiens*, and *Haworthii*. It would be interesting if other readers who have grown Saxifragas in towns would give their experience on them as town plants. Their notes would be read with interest by many besides—A LONDON AMATEUR.

#### CALOCHORTUS BENTHAMII.

THIS is a beautiful little Californian bulb, somewhat nearly related to *C. pulchellus*, but distinguished by its bright yellow flowers, on the upper surface of the divisions of which are thickly clustered a number of short yellow hairs (see woodcut, fig. 98). It is very dwarf, seldom exceeding 8 inches in height, but is free both in flowering and growth. It is particularly well adapted for culture in pots, and with the protection of a cool frame it develops its flowers early in the year, and is much better than when grown in the open border. A pretty companion for it is *C. Maweanus*, which has bluish purple flowers about the same size as *C. Benthamii*, and similar habit. This is, however, found near the coast, and in the neighbourhood of San Francisco.

#### LILACS.

It is doubtful if amongst the whole range of hardy deciduous shrubs any can claim so many admirers as Lilacs. Not only are they enjoyed by the wealthy when grown "out of season," but when naturally flowered the plebeian may indulge in the pleasing perfume so freely emitted by the bulk of them. Now that new varieties are raised so assiduously by French nurserymen quite a large collection of varieties is obtainable.

Too often Lilac bushes are left to take care of themselves, consequently they quickly become crowded when growing amongst other plants in the shrubbery. Nothing is done to renovate exhausted bushes by the removal of weakly overcrowded branches, or the prolongation of that necessary vigour to give annually the best results by the addition of a small quantity of manure or fresh soil to the roots. It is liberal and rational treatment that produces that magnificence of flower panicles that renders Lilacs so charming as compared with the puny blossoms from half-starved bushes.

The bulk of choice varieties are grafted or budded on seedling stocks, not only to increase their numbers, but to improve their growth. Too often the sucker-like growths which spring from the base of the stock are allowed to grow away at will, much to the detriment of the real

Lilac bush. These growths make such rapid progress if at all neglected that in a very short space of time the original bush is nothing more nor less than the stock. Nothing could be more handsome than a vigorous naturally grown Lilac bush on the lawn. I know of one, *S. vulgaris*, 20 feet in diameter, growing under these conditions, which was this season a mass of blossom.

Having taken a note of deserving varieties as they appear, I will briefly allude to each with a view of assisting intending planters. The method of arranging the plants in the shrubberies is a matter for individual concern, but to obtain a lasting effect not less than three bushes should be planted together. Some persons may still cling to *S. vulgaris alba* as a white-flowered Lilac, but those who are acquainted with Marie Legraye know quite well that the original variety is now superseded. Not only are the flower panicles so much larger, but the colour is even more pure. The habit of Marie Legraye is so much more

FIG. 98.—CALOCHORTUS BENTHAMII.

compact, the older variety having such a habit of "running up," while the newer form is less tall in its growth, although vigorous enough to give excellent results.

Perhaps the most appreciated of all white Lilacs is the double flowered Madame Lemoine. The panicles and the individual blossoms are exceptionally large, and of the purest white; indeed it is a grand acquisition to the Syringa family. The Siberian and Persian forms are distinct, yet pleasing; the semi-drooping panicles are freely produced on somewhat weakly-looking stems; the latter, especially, is free and rich in colour. Charles X. is another single-flowered kind that everyone should grow. No variety that I know blossoms so freely. The buds before opening are bright red, the expanded flowers changing to a deep lilac. La Tour d'Auvergne buds are deep red, rosy lilac when fully expanded; a very fine double-flowered variety. Lemoineana flore-plena.—In colour soft lilac when fully expanded. Those who appreciate free-flowering varieties of compact growth should not miss having a plant or two of this Lilac. Leon Simon is another double-flowered, medium-sized variety, having well-formed, light pink, mauve-shaded blossoms. President Grevy.—Lilac in colour, double-flowered. La Virginite.—Light pink changing to white, a beautiful double-flowering variety. President Carnot.—Semi-double; in colour pale lilac, having a peculiar slaty appearance.

Alphonse Lavallée.—The double-flowered buds are rich rose, changing

to light mauve by expansion. One of the best of double Lilacs is Michael Buchner, rosy lilac in the bud, paler when expanded. Amongst the newer single-flowered varieties Souvenir de Louis Spath is perhaps the most showy of all, rich purple red, which colour is retained after expansion. Géant des Batailles.—The single-flowered buds are red at first, changing by expansion to deep lilac. Beranger bears enormous clusters of large lilac-purple flowers, and is quite one of the best of single varieties. Liberti has compact clusters of lilac-blue flowers with a metallic reflex.—E. M.

### PRUNINGS.

APROPOS of restoring "Rollo's Oak" by masonry (page 474), some years since I repaired by this method a venerable Beech—too grand in its decaying glory to leave to its fate. Half way up the trunk an extensive cavity—probably caused by the loss of a limb—collected the rain water, not only hastening decay, but becoming at times offensive from the smell. This cavity was scraped out, filled up with bricks and Portland cement, and the latter smoothly surfaced over the brickwork, thus by its colour being hardly distinguishable from the natural bark. Eventually the bark closed in over the mason work, and this bit of surgery gave complete satisfaction.

"Food Requirements of the Vine" (page 466) and the discussion on "Express Grape Growing" are both interesting and instructive. For renovating old Vines I pin my faith on Thomson's Vine manure. As a tonic, where the system has gone down, it works wonders. Those troubled with shanking, and unable to clear out the old stock, should try it. I never fail to fork a light dressing of it into the border at starting time, and, it must be added, never fail to grumble at the cost.

The veteran Potato grower's text "Powder" (page 479), and a promise of shot to follow, we may be sure is no flash in the pan. Presumably many a sieve will scatter Tait and Buchanan's anti-blight powder o'er many a Potato patch, so we will keep our powder dry, and use it dry. Without diving into trade secrets, one may suppose that copper in some shape or form is present in the composition, hence the thought arises whether this will have any deleterious effect on the operator.

Each number of the *Journal of Horticulture* forcibly impresses the more liberal spirit of the new order of things. An illustration to the point is "Free Growth of Peach Trees," by Mr. Iggulden (p. 490). Modestly he says, ". . . there is nothing very novel in this;" and that we may allow in noting the practical instances he quotes. Possibly there is nothing new in it—so far as theory goes—but there is an army of cautious ones loth to attack an old custom until they can see their way clearly defined by some practical leaders. Mr. Iggulden introduces the thin end of the wedge so cautiously, yet so convincingly, that many will, I wot, strike a blow for freedom—the freer training of Peach trees.

"Battle of (flowers at) Hastings," see note (p. 497). Not exactly the Norman invasion. ". . . £300 has been promised . . ." to provide the sinews of war. True flower lovers will not regard with unqualified satisfaction this continental innovation. Poor flowers! I would suggest a slight alteration in the programme, viz., flour instead of flowers. At one time when touring in the Emerald Isle, being in Dublin on a gala day, I was struck (literally and figuratively) with the manner in which the students of Trinity College used small paper bags of flour, and the excellent sport it gave (to them). I merely throw out this flour as a suggestion and a plea for the flowers we love.

*Marantas*.—These beautiful foliage plants do not readily lend themselves to utilitarian purposes. To this—in this age—we may attribute their decline. Mr. Row's paper (p. 499) clearly points to a matter of vital importance in successful culture, viz., atmospheric moisture; consequently the removal of these plants for but a short time from these satisfying conditions will show they do not like it. M. Veitchi, an old variety, but taking high rank in the family, recalls a difficulty—not in growing it for exhibition, but in getting it to stand for the few hours it was needed for such. On some occasions when reaching home it required, and had, a warm bath to get it out of the sulks. M. zebrina and M. Warscewicz, grown in cork-covered tubs, are noble objects in a tropical conservatory.

*Bees*.—The two bee-keepers ("Lanarkshire" and "English") keep us *au courant* with apiarian work. It is a matter for surprise to find that in so many fine gardens bees are not. Perhaps it is considered that the work of the modern bee expert is too intricate to be lightly engaged in. Setting aside considerations of profit, I have found one or two of Neighbour's cottage hives—which by-the-by are not cottage in price—with the bell-glass supers give agreeable results. Although honey can to-day be purchased so cheaply, a bell-glass with its virgin contents is ornamental and useful, and especially esteemed, when home produced, on the breakfast table. To a beginner the question of more stings than honey is obviated by a veil and gloves.

*Onions*.—Some time since a correspondent advocated the sowing of Onions with a dash of sulphur in the drills. This was pruned out for trial, and results are, so far, highly satisfactory. This season must be

looked upon as highly propitious for the maggot. The attack has been made, but the maggot on reaching the sulphur "gave it up." Nothing else was done as a preventive. A good sprinkling of nitrate was given in anticipation of rain (which did not come). This exultation may be premature, but present appearances when viewing the Onion plot call forth blessings on your correspondent and his sulphur remedy from—SAYNOR.

### CHRYSANTHEMUM MISS M. M. JOHNSON.

THIS American variety, a deep golden yellow incurving Japanese, raised by Messrs. E. G. Hill & Son, is reputed to be very dwarf, and an early October bloomer of some merit. It has been illustrated in the leading American gardening papers, and should be a valuable companion to Mrs. E. G. Hill, which came from the same source.

### CHRYSANTHEMUMS IN AUSTRALIA.

THESE flowers seem to be holding their own in the Colonies. A friend in Sydney has just sent me a recent number of the "Australian Agriculturist," in which appears a large illustration of Mr. Ernest Calvat's seedling, Mdle. Thérèse Rey, which is now being distributed in Australia. Chrysanthemum shows are reported to have been held at Sydney, Goulburn, Cootamundra, and Albury. The one at Sydney is said to have been a great improvement on those previously held there in many respects.

### RECENT CHRYSANTHEMUMS.

The above is the title of Bulletin No. 91 of the Horticultural Division of the Cornell University, and is edited by Mr. Michael Barker. It contains notes on varieties grown at Cornell last year, the majority of them being, of course, of American origin, although we notice among them Beauty of Exmouth, Charles Davis, *Enfant des Deux Mondes*, and William Seward. Mr. Barker, who is also the editor of the "American Chrysanthemum Annual," deals with methods of cultivation and insect friends and enemies. There are several illustrations in black and white.

### AMERICAN CHRYSANTHEMUMS.

Mr. Michael Barker, the editor of the "American Chrysanthemum Annual," gives a list of new American varieties for 1895, which numbers sixty-seven. But the total, if we include what are now known as Californian seedlings, will probably be much larger. Along the Pacific coast are raisers and importers who introduce into the States from Japan the best of the new kinds as they come out there, and many of these come to be looked upon as American varieties. If these are included it may be safely estimated that there will be no fewer than 150 new Chrysanthemums for 1895 distributed by the American growers.

### CHRYSANTHEMUM MADAME LUCIEN CHAURÉ.

There is a coloured illustration of this variety in a recent number of the "Moniteur d'Horticulture" of Paris. It was raised by M. de Reydellet last year, but like many others from this grower of late is hardly known to English cultivators. Seven or eight years ago we had a fair proportion of M. de Reydellet's seedlings on our exhibition tables, but the keen competition of the American and English varieties seems to have placed his recent seedlings at a disadvantage. As depicted Madame Lucien Chauré is a Japanese flat-petalled variety of only medium size, but the colour is warm and rich, a mingling of violet crimson buff, tipped golden yellow. It was certificated at Chambéry.—P.

### THE R.H.S. EXAMINATION PAPERS.

I AM glad that "Reader" (page 500) has offered a little criticism, encouragement, and correction to my answers on page 470. I may tell him I was not a candidate at the recent examination. With reference to the absorption of food by the roots of plants, "Reader" says that the assumption that roots absorb compounds through their surfaces does not accord with scientific teaching. I infer he does not challenge the statement that compounds do constitute the food of plants. Plants I know do not receive their food in a solid form, it must be either in a liquid or gaseous form. Certain chemical elements combine to form chemical compounds, says Mr. G. Abbey in the *Journal of Horticulture*, and as such are imbibed by the roots of plants. He also says that they receive the food by the absorbent surfaces of the roots.

I did not say that the "spongioles" were the only medium by which the food of plants was received. I am fully aware that the root's hairs are of considerable importance, but I likewise claim that the spongioles are of equal importance as absorbents of moisture, which of course is food to the plant. Thompson's "Gardeners' Assistant" says that "The function of spongioles consists in absorbing moisture and conveying it into the structure of the plant." Further, "Spongioles absorb fluids with great force." I would further ask "Reader," What causes Calceolarias to collapse suddenly when in full growth and flower? My answer

is the loss of the spongioles. How? By being bitten off by leather jacket grubs in the soil. Having an attractive bed of *Calceolarias* in full flower, I was curious to know the reason why a few plants here and there were drooping and withering beyond renovation. I pulled them up. The roots seemed healthy, but all the extremities were gone, cut clean off. I searched the soil and found specimens of this grub, which I doubt not is the cause of the destruction. This, to me, is a convincing proof of the immense assistance the spongioles are to plants as feeders and sustainers of life.

I think I have demolished "Reader" on this point, but I will concede him his correction on the fertilisation of the Pea flower, thanking him for the information.

With reference to answer 4 I should not advise, when deeply moving soil by trenching, the practice of burying all the good surface soil and bringing the barren inert material to the top. I would rather keep the layers of soil in their original position. There is, however, I consider, no harm in bringing up a little of the subsoil, even if it is poor, and mixing it with the rich surface.

"Reader" does not say what he would style an Onion. Perhaps he would term it a bud containing future growth in embryo. The question expressly states, "What organs of the plant are represented by an Onion, &c.?" Strictly speaking, then, an Onion bulb represents all the organs of the plant stored up within itself in an embryonic state. I admit that many of the questions could be amplified to a considerable extent, but this, I take it, is not the object of the framers of the questions. They need plain, brief, and condensed answers.—E. D. S.

### HOLDING SOIL.

IN the common acceptation of the term, holding or retentive soil is that which is stiff or clayey. That it is well entitled to that description in wet weather or in the winter there can be no doubt, but how often is the term a misnomer in drought such as of late has been so severely experienced. Only those familiar with stiff soils know how hard baked they become under drought, and how rapidly, because of that baking, they part with their reserve of moisture. That arises very much from the natural tendency of all soil of a stiff nature in baking to contract, and thus produce fissures or cracks all over the surface and running down several inches. It is in such cases impossible for soil to retain moisture long. Of course were the surface freely hoed or stirred these cracks would be filled or covered, but that hoeing or stirring is one of the things next to impossible once stiff soils are parbaked. Literally they are as hard as ordinary roads.

As this is the normal state of stiff soils under drought, it is not correct to term them holding, seeing that they fail to prove so at the most trying periods of the summer. Even watering of such soils so long as rain and cloud are absent, and the sun manifests great heat, only leads to making matters worse than before, unless the moistening can be deep and thorough, and then the surface being stirred, it is covered with a mulch of manure. In that way not only is baking checked, but moisture is retained. But whilst light or sandy soils are not termed holding or retentive because they do not retain moisture as clay does in the winter, yet it is found in heat or drought such soils are far more retentive of moisture than are stiff ones. This arises first from the practical incapacity of soils of sandy nature to bake or contract; and, second, because of the great ease with which a loose surface can be obtained.

We have had in the home district a period of drought of unusual duration. Practically there has been little or no rain worth mention for fully five months. We have, too, had of late great heat, accompanied by very drying winds, hence the moisture-holding nature of soils under crops has been well tested. In the spring I planted at Mitcham, in each case on soil having about equal manurings in previous seasons, ten rows of Potatoes in many sorts, and on three diverse soils; sand, lying high, and fully exposed to sun and wind; black bog, where slightly shaded; and clay, also very slightly shaded. A few days since I examined these respective plots, and found on the sand capital growth in each case, and the soil beneath the loose surface, which was of course very dry, apparently nice and moist, indeed much exceeding in that respect my expectations.

I found a similar state of things on the black or bog ground, which, too, had a light surface, whilst on the clay the growth was in all cases a week later, the soil being terribly hungry, and very dry. Now these conditions exactly reflect what is ordinarily found on similar soils of fair average depth. That being so, we should not refer to these stiff clay soils or holdings, as they seem to be the first to give out under drought. Certainly nothing tends so much to the retention of moisture in heat as being enabled to produce a loose friable surface.—A. D.

### ROYAL BOTANIC SOCIETY.

#### FLORAL FÊTE.

THE above fête was held at Regent's Park on Wednesday, June 12th, and as a large number of the exhibits came direct from the R.H.S. meeting held at the Drill Hall on the previous day the display of bloom in the large tent was an exceptionally fine one, there being magnificent collections of Roses, Orchids, and hardy flowers.

Messrs. F. Sander & Co., St. Albans, sent an excellent group of Orchids and rare stove plants. Many of the Orchids and other plants received certificates of merit, including *Odontoglossum mulus*

*Sanderianus*, *Phaius Owenianus*, *Miltonia vexillaria* F. W. Moore, *Thunia Veitchi*, *Dracaena Sanderiana*, *Begonia Rajah*, and others. Mr. B. R. Davies, Yeovil, staged an effective group of double tuberous *Begonias* arranged with Maidenhair Ferns. From Messrs. R. Wallace and Co., Colchester, came Irises in quantity and *Mariposa Lilies*. Mr. Frank Cant, Colchester, staged a fine display of cut Roses, as also did Mr. G. Mount, Canterbury. Messrs. Sutton, Reading, staged *Gloxinias*, well grown and in great variety. Messrs. J. Cheal & Son, Crawley, sent a collection of hardy flowers, which included Poppies, Violas, and others. Another effective group, comprised of *Pæonies*, Irises, *Liliums*, and other hardy flowers, came from Messrs. J. Veitch & Sons, Chelsea.

Messrs. J. Laing & Sons, Forest Hill, staged hardy flowers in great variety, and also a fine miscellaneous group, which contained *Crotons*, Palms, *Caladiums*, Ferns, *Begonias*, Orchids, *Gloxinias*, and others, all tastefully arranged. Messrs. Barr & Son, Covent Garden, were represented by a fine group of *Pæonies* and other hardy flowers, the effect of which was exceedingly bright. Mr. H. B. May, Edmonton, sent a group of *Gloxinias* tastefully arranged with Ferns. A large collection of hardy flowers came from Mr. T. S. Ware, Tottenham, conspicuous amongst which were *Lilium colchicum*, *Papaver nudicaule*, *Saxifragas*, and *Campanulas*.

A large exhibit of *Pæonies*, *Delphiniums*, and other flowers came from Messrs. Kelway & Son, Langport, the effect of which was fine and varied. From Messrs. Laxton Brothers, Bedford, came several boxes of Strawberries, containing excellent examples of *Monarch*, *Sensation*, and *Royal Sovereign*. Fine well-bloomed *Gloxinias* were staged by Messrs. J. Carter, High Holborn. Messrs. Hugh Low & Co., Clapton, exhibited a handsome group of Orchids, containing *Cattleyas*, *Odontoglossums*, and others, with Ferns, *Caladiums*, and Palms. From Mr. Chas. Turner, Slough, came a group of Fancy and Show *Pelargoniums*, thickly covered with bloom, together with a fine exhibit of Roses. Messrs. W. Paul & Son, Waltham Cross, made a fine display with Roses, both plants and cut flowers, containing many beautiful varieties. Mr. R. Scott, gardener to Miss Foster, The Holme, Regent's Park, staged a large and handsome group of plants, comprised of *Liliums*, *Caladiums*, Ferns, *Spiræas*, Palms, *Begonias*, *Coleus*, and others. Another effective group was exhibited by Mr. J. C. Clarke, gardener to Ludwig Mond, Esq., Regent's Park. A handsome group of *Caladiums* and other foliage plants—arranged with *Spiræas*, *Heliotropes*, *Hydrangeas*, and others—came from Messrs. J. Peed and Son, Norwood.

*Floral Parade*.—In spite of the threatening appearance of the weather the Children's Floral Fête was a great success. The presence of Their Royal Highnesses The Prince and Princess of Wales, the Duchess of York, and the Duke and Duchess of Teck, was sufficient to insure a large gathering of well dressed ladies and gentlemen. The prize for the best exhibition on the parade was awarded to Mrs. Bernard for a pony and carriage tastefully decorated with flowers and Grasses. Many other charming arrangements were also noticed in the shape of mail carts, pony carriages, and Sedan chairs, dressed with Daisies, Pinks, *Marguerites*, red Roses, Irises, and other flowers.

The groups of children representing different subjects, such as "The Festival of Flora," "Stolen by the Fairies," "Buttercups and Daisies," and "Lalla Rookh," were much admired, as also were other designs representing "Britannia" in Oak leaves and Roses; "Oxford and Cambridge," in the shape of a young lady on horseback, dressed with blue Cornflower trimmings; "Wild Poppy," and "Forget-me-not."

### FRUIT GROWING ON A LARGE SCALE.

THE excellent paper on this subject, contributed by Mr. Charles D. Wise to the Journal of the Royal Agricultural Society, has been published in pamphlet form by Messrs. Spottiswoode & Co., and will be acceptable to many. The author, as manager of the celebrated fruit plantations at Toddington, is well entitled to be listened to, and this is what he says:—

Owing to the great increase in the fruit-growing industry a good deal has been written during the last few years on fruit farming and the enormous profits to be made. The bulk of these reports is greatly exaggerated, although under certain conditions, which I will endeavour to set clearly before you, fruit growing yields a fair return on capital expended. Many people think that fruit trees have merely to be planted, and that profitable returns in due course are assured; and it is only by experience, and in many cases by loss of capital, that they find that fruit growing is a *business* and a *science*, and that, as is the case in other trades, the apprenticeship has to be gone through and the business thoroughly studied—I do not say *learned*, as the fruit grower learns something new every day, and his lessons will never be over.

Why do not farmers go in for fruit growing? This question is asked again and again. I think the simple answer is that, even if they felt inclined to do so, they do not know how to set about it, and not only do they not understand the business, but where is the necessary capital to come from? and even should that be forthcoming, it is not on every farm that land adapted for fruit culture is to be found.

We have also these important considerations:—

1, There are only selected areas where you can hope to succeed so far as soil, shelter, and situation are concerned.

2, Fruit growing, especially on a large scale, should be within reasonable distance of a good market or railway station.

3, The tenant must be prepared to stand out of his capital for certainly four years, or perhaps longer, before a fair return is obtained; and no tenant should plant on a large scale except under a lease of at least twenty-one years, and with compensation for improvements fully assured at the end of his tenancy.

Given suitable soil and situation, with railway accommodation at hand and security of tenure, I am of opinion that hundreds of acres of land might be planted with fruit, to the advantage of both landlord and tenant. The landlord should give every encouragement to a tenant who wishes to plant fruit, either by finding the trees or by giving him written permission to plant under the Agricultural Holdings Act, which will entitle him to obtain compensation at the termination of his tenancy. It is most certainly to the interest of the landlords to meet tenants in this way, as by the planting of fruit the value of their property is enormously increased.

That is not the teaching of the mere faddist or sensation monger, who seeks to dazzle with glowing platitudes, misleading more persons than he can usefully teach, but deduction from experience. Under favourable conditions and conducted with knowledge, Mr. Wise believes fruit culture to be to a reasonable extent profitable, and goes on to say:—

We hear a great deal of what the Royal Commission on Agriculture is going to do for the tenant farmer; but I fear, unless tenant farmers look after themselves, they will obtain very little help from that quarter; and, although I do not say that fruit growing will be the salvation of the agriculturist throughout the country, I do maintain that on very many farms, if a certain proportion of the acreage were under fruit, it would be to the advantage of both landlord and tenant. A few acres should be planted to start with, and as experience in management is gained the acreage may be steadily increased until the 5-acre plantation soon becomes 50 acres, and a good business is developed. Where agriculturists have planted fruit, and the soil and situation are favourable, we find that the plantations do increase in area, and we may therefore conclude that the tenants are not losing money. In the Evesham district, for example, the fruit-growing and market-gardening industry is extending every year, and the small allotment holders, instead of growing corn, are planting their land with Asparagus or other vegetables and bush fruit, with one or perhaps two rows of Plum trees or other standards round the outside, according to the size of their holdings.

The author treats on the cost of establishing plantations of different kinds of fruit, also of management and gathering, with the amounts realisable, concluding with a good word for jam as follows:—

Assuming that during the next twenty years the acreage under fruit in Great Britain, and the imports, increase as rapidly as during the past twenty years, the question arises as to whether or no the supply will exceed the demand. If we look at the enormous increase in the consumption of fresh fruit, and also of jam, throughout the country (the number of jam factories with their trade increasing each year), and the increase in the population, it hardly seems possible that, at all events for many years to come, fruit growing can be overdone.

Jam is now within the reach of all classes, and if only fresh fruit could be distributed as easily, there would be no fear of markets being glutted. In almost all the large towns throughout the country there are fruit markets, and there are many towns with no fruit markets in which one might be advantageously held, say once or twice a week.

It would be a great advantage to growers if they could pulp down some of their fruit in seasons of glut; this is not so difficult as some people imagine, and is quite worth consideration.

Foreign competition (with the exception of Apples) ought not to materially affect our fruit trade. Soft fruit from abroad cannot be put on the market in as good a condition as the home grown, and as the public taste becomes more educated, the more demand will there be for fresh fruit and pure jams. Jams made from imported fruit and pulp cannot compare with that made from fresh gathered fruit.

We have cited one page out of the twenty-three as a sample of the pamphlet, which may be studied with advantage by persons who are desirous of engaging in the fruit growing industry.

#### HARDY FRUIT GARDEN.

**Summer-pruning Fruit Trees.**—It is possible to render great assistance to fruit trees growing on restricted methods by the judicious practice of summer pruning. Pyramids, bushes, espaliers, and cordons all need attention in this respect from the present time in order to subdue the luxuriance of the side shoots, and concentrate the energy which unchecked would be wasted in the production of long shoots. The basal buds on these shoots, which are eventually intended for the future fruit buds, receive through the shortening an increased amount of sap, but any surplus vigour finds an outlet in the upper buds, growths from these being also stopped, and the whole cut back in winter.

**Plums and Cherries.**—Plums and sweet Cherries furnish a considerable amount of side shoots, foreright shoots, or breastwood as it is termed. The best time for shortening is when the lower leaves have assumed full size. Shorten to the third good leaf from the base, or including the small basal leaves at the fifth leaf. Owing to this restriction spurs will form at the base, and sooner or later become fruitful. Air and light is admitted to the fruit while superfluous vigour has a safety valve in the upper buds, which will probably produce laterals, these also to be pinched back to one leaf when that has attained full

size, and so on with sub-laterals if any are produced. It is not advisable to shorten every shoot on wall Plums and Cherries, because there may be available spaces where suitable young shoots may be trained in at full length, and they would after the second year be in a fruitful condition. Leading shoots should not be stopped where there is room for extension.

**Pears.**—These may be dealt with next. Where disbudding was partially or wholly neglected a quantity of weak spray may be noticeable in some old trees, which ought to be thinned out entirely, leaving the strongest shoots. A mass of weak shoots serves to crowd the trees, preventing the proper ripening of the buds on the reserved shoots, which require all the light and air possible. In commencing the summer pruning shorten the shoots on the upper parts of the trees first, gradually descending to the lower, leaving weakly shoots to gather strength, if necessary, for a short time longer. Leave four to six full-sized leaves, in this case not counting the small basal ones, which are of little assistance in manufacturing food for fruit buds. Young trees and cordons not fully covering the space available must not have the leading growths shortened.

**Apples.**—Apples require similar treatment, retaining four to six leaves; but as a rule the early part of July is soon enough to carry out the shortening. Too early stopping might result in the lower buds starting into growth, which must be avoided. Where it is seen that any weak or crowded growths can be dispensed with cut them out entirely. Abundance of light and a free circulation of air among the spurs aid their development, strengthen the foliage, improve its texture, rendering it better provided against insect enemies. Overcrowding is bad for the fruit swelling, as undue shade prevents the utilisation of the sunshine by the leaves which feed the fruit.

**Currants and Gooseberries.**—Red and White Currants may have the side shoots shortened to three or four leaves, Gooseberries also pruned on the spur system, whether in the open or against walls, being similarly treated. Summer pruning is beneficial, as it admits light to the fruit, and affords an opportunity of obtaining finer bunches of Currants and increasing the size of Gooseberries, though much help is rendered to this end by good ground, as well as assisting the bushes with stimulants and generally adopting good culture. Remove suckers entirely from the roots of Gooseberries, and thin to a few of the best with Red and White Currants if new branches are needed, otherwise they may be cut out. A good selection of sucker growths or shoots from the base of bushes may be left on Black Currants, cutting out exhausted wood after the fruit has been gathered. As the latter is borne entirely on young wood it is obvious that sufficient growth of that character must be retained for the following season and not shortened in any way.

**Mulching Fruit Trees.**—Bush and pyramid trees, cordon and espaliers in the open, or against walls, that are bearing good crops, and have had the soil moistened effectually, may receive a moderate mulching of decayed manure over the roots, which will largely prevent rapid evaporation from the moist soil, and render frequent watering less necessary. Larger trees in the open that have fibrous roots near the surface will also be benefited, and as small bush fruit trees are usually furnished well with fibrous roots, a manurial mulching will both feed and encourage their remaining near the surface.

**Strawberries.**—If not yet mulched with strawy material to keep the fruit clean, they should have it applied at once. As a rule, however, it is best to spread manure between the plants early, any fertilising constituents it contains being then washed into the soil and appropriated by the plants, the dry residue remaining affording a clean bed for the fruit to rest on. For the latter purpose only chopped straw has been found useful, while tiles, glass, or forked sticks can be employed advantageously. It is very desirable that the fruit should be supported free from the soil owing to the ravages of slugs and the probability of the ripe fruit becoming gritty from contact with the soil.

**Raspberries.**—Remove superfluous suckers, and clear the ground of weeds, pulling up the strong ones, but cutting others down with the hoe in dry weather for the sun to wither. Afterwards mulch the ground between with some rich manure, and if possible afford a few supplies of water and liquid manure to each stool, which will materially help the fruit swelling and enhance its flavour when ripe.

#### FRUIT FORCING.

**Vines.**—*In Pots for Early Forcing.*—Stop the canes when from 6 to 8 feet long, pinching the laterals and sub-laterals to one joint as produced. Supply water and liquid manure at the roots as required, but only then, keeping neither under nor over-watered, but if anything the first, and see that the foliage is kept clean by judicious syringing, admitting air rather freely in the early part of the day, as this will favour elaboration and the storing of assimilated matter.

*Vines Cleared of Grapes.*—Syringe occasionally to keep down red spider, thrips, and similar pests; afford water or liquid manure to keep the soil moist. A light mulching of short spent manure will prevent the surface cracking, and the moist surface and nourishment will attract the roots to the surface. Allow a moderate extension of the laterals, and admit air freely above 60°. There is no fear of the wood not ripening, and the difficulty is to prevent the ripening and premature fall of the foliage.

*Houses of Ripe Grapes.*—These will be the better for a slight shade from powerful sun. Some pilchard or a double thickness of herring nets drawn over the roof lights will mostly be sufficient shade, and a good spread of foliage will assist Black Hamburgs and other black

Grapes in keeping their colour. Moderate moisture will not injure the Grapes if accompanied by free ventilation. Keep laterals fairly under, but a little extension will assist in the retention of the principal leaves, and on their continuance in health depends the maturity of the buds for next year's crop.

*Grapes Ripening.*—When the berries commence changing colour admit a little air constantly, with sufficient heat in the pipes to maintain a night temperature of 65° and 70° to 75° by day, with 80° to 85° or 90° from sun heat. Avoid an arid atmosphere, damping occasionally, and do not allow the border to become dry. Vines ripening heavy crops will be assisted in perfecting them and storing food for the future by an occasional application of tepid liquid manure, or a top-dressing of some approved fertiliser washed in, operating in the morning, and choosing a fine day, so that superabundant moisture will be dispersed before evening. A light mulching of dry spent material will assist the Vines by securing uniform moisture and keeping the roots near the surface whilst avoiding excess of moisture, and thus preventing cracking. It is a confined atmosphere that does much of the mischief in Grapes spotting and cracking, therefore leave a little air on constantly and increase it early in the day.

*Scalding and Scorching.*—A gentle warmth in the pipes and a little ventilation constantly, with an increase by the time the sun begins to act on the house in the morning, and somewhat free circulation by day, makes all the difference between scalding and non-scalding, also between scorching and non-scorching. Occasionally Muscats are scalded or scorched when the berries are exposed to the direct rays of the sun in the most carefully ventilated structure, and chiefly at the higher parts of the house, furthest from the hot-water pipes, which points in the direction of atmospheric moisture condensed on the berries during the night, or before air is given, being the cause of the mischief, which is certainly not an ailment, but a cultural defect, an excess of watery vapour, and subsequent heating or scalding. In the northern parts of the kingdom the sun's rays acting through large panes of glass are so powerful that scorching sometimes takes place under the most advantageous conditions of heat and ventilation. It therefore becomes necessary when the Grapes are ripening to afford a slight shade, as that of a herring net over the roof lights, in order to subdue the fierce direct rays of the sun, which not only insures the more even swelling of the berries, but their immunity, other conditions being favourable, from scalding, and the greater regularity of the colouring. Black Hamburgs seem to colour best beneath a good spread of foliage, but all require thorough exposure of the foliage to air and light.

*Late Grapes.*—There must not be any delay in thinning the berries and bunches. Nothing is so fatal to perfect finish as over-cropping. To burden a Vine with more Grapes than it can swell well and evenly, is to cause it to ripen the fruit later, and leave doubts as to the berries colouring and having that amount of saccharine matter stored in them which secures their sound keeping. Thin well to secure large and highly finished berries, leaving those of the larger berried varieties about an inch apart, the oval-berried kinds not requiring so much room as the round ones; but all should be thinned so that they will have space for swelling to their fullest extent without wedging, and yet be so close that when dished they will retain their form. Loose bunches that show the footstalks are not pleasing, however fine the berries, as those more compact. Some twist the shoulder inwards so as to give sprawling bunches a compact form, something like an inverted sugarloaf. Shy-setting varieties are often thin of berries through the number of stoneless ones that must be removed, to guard against which no pains should be spared in getting the wood ripe and in fertilising the bunches when in flower with Black Hamburg pollen, or that of other free-setting sorts. A pound of Grapes per foot run of rod is usually as many as most Vines can finish well, therefore reduce the bunches so as to give about that weight, and if an error is made let it be on the safe side, as Vines that are overburdened never finish the fruit well, and it is inferior in keeping qualities.

*Regulate the Growths.*—Allow all foliage to remain that can have full exposure to light, but when the space is fairly covered with leaves keep the shoots closely pinched. An excess of foliage is not good, though it is often encouraged with a view to root action, but it is elaborated juices that build up the structure of the Vine, the crop of the current year and the wood and buds that give the fruit of the next. The foliage should be rather thinner in the case of white Grapes than in black; this more particularly applies to Muscats, which of all Grapes require high elaboration of the sap to insure their assuming the rich golden amber so much prized. Avoid large reductions of foliage at a time; it only tends to induce shanking through the check given the roots.

Keep the growths tied down from the glass and so prevent scorching. Vines extending must be allowed to make as much lateral growth as practicable, always bearing in mind the wood on which the fruit is to be borne next season must have full exposure for its foliage, as it is the principal leaves that elaborate the sap and transmit the assimilated matter that forms the buds at the base. The laterals from these having been stopped at the first joint, they may be allowed to extend afterwards, subject to their not interfering with the access of light to the main leaves.

*Watering and Feeding.*—Inside borders must be well supplied with water, following in the case of Vines that are carrying full crops and in good, but not too vigorous health, with liquid manure, mulching lightly with short lumpy material, which, if kept moist, will give off ammonia and attract the roots to the surface. If more aliment is wanted supply

sulphate of ammonia where the soil is strong, but not chalky or particularly calcareous; where the soil is light, also very calcareous, use nitrate of soda. From half to one ounce of either of these salts is enough, repeating at intervals of three or four weeks. If the Vines require solidity use superphosphate of lime, say 2 or 3 ozs. per square yard, and if the foliage is pale in colour add half an ounce of powdered saltpetre and one-eighth ounce sulphate of iron. These are best given after the border has been watered, following with a light watering after their application. Do not allow the border to become and remain dry at the surface. Neglect in watering borders that are well drained, and mulching, especially where the Vines are carrying heavy crops, is not only disastrous to the present crop, through inducing attacks of red spider and premature ripening of the foliage, but injuriously affecting next year's crop of fruit. Outside borders may only need a light mulch, but where rains have not fallen, or if dry, give a soaking of liquid manure, or supply water, then a top-dressing of the advertised fertilisers, and wash in lightly whenever necessary.

*Temperature and Ventilation.*—Cold nights render fires still necessary. All late Grapes thrive best in a high temperature, with abundant food at the roots and a genial atmosphere. Fires should be employed to maintain a night temperature of 65°, and 70° to 75° by day in dull weather. Admit air early, allowing a little ventilation at the top of the house constantly, increasing the ventilation with the temperature. Advance to 85° or 90° with sun heat, at which keep through the day by that means, reducing the ventilation with the declining sun. Close at 85°, damping the paths well then, and again before nightfall. It is well to close for a short time, and afterwards admit a little air, which will prevent a vitiated atmosphere, and allow of the foliage drying in the morning by the time the sun acts powerfully. Late Grapes cannot well be given the fullest advantage of the sun's heat; therefore, make the most of it by judicious ventilation, and aiding with artificial heat so as to keep them in steady progress, avoiding cold draughts or sudden depressions of temperature, as this cause rust and favours the spread of mildew and other pests.

## THE BEE-KEEPER.

### APIARIAN NOTES.

HEARING is one thing, and seeing another. We read of the glorious weather, and of bees gathering honey in galore, but ocular demonstration shows brown pastures, gardens, fields, and roadways strewn with leaves as if autumn was on us; confirmed by the thermometer sinking to 30° at night for a whole week, railway sheets covered with ice, and the leaves of Walnut trees frosted down, and occasional sleety showers, bees being fed while they remain at a standstill.

Many hives throughout the country are suffering from chloric dropsical fever, which simply means lost hives, no use for this year, and which cannot be satisfactory for another; in point of loss, foul brood cannot be compared to it.

Foul brood is easily dealt with, but as yet no cure is known for chloric dropsical fever. In 1893 at this date surplus honey was the rule. This year, unless in a few cases and fed hives, there are no swarms yet. In 1870-72 about the same date the frost was severe, cutting the Potatoes to the ground, and by the 28th August there was a repetition, being ten days more than two months for tender things to grow, and were barren years for honey.

Water is scarce in the hill districts, as well as in the lowlands, and a spring in my garden was never known to be so low. Birds are desperate for want of it, the sparrows pecking many green vegetables, and the leaves of some trees, and bees when forgotten, in vain, endeavour to sip water from dampish places. Fruit prospects are not so good as they were a month since, and as the Clover is spoiled in some places by the drought, there must be copious rain before it springs and blooms again, which will be out of season. Honey from that source will not be generally plentiful.

In hopes of writing in a better strain, I delayed this copy till the 15th, but the deplorable weather has become worse. The haulm of my Potatoes is frosted to the main stems; many flowers are shorn of their beauty, bright sunshine continues with alternate north-easterly and north-westerly winds, and clouds of dust. The thermometer at midday fluctuated between 55° and 58°, and bees are almost idle or flying about listlessly.

It has always been my practice to prepare young stocks for another year at an early date, simultaneously with supering and depriving, but at present it (unless a favourable change comes) will be my only work, and even that will be performed with some difficulty, as drones are not permitted to live. Feeding one hive more than is necessary will have to be done in order to insure fertile queens. This may be rather too much of a pessimistic view, but we have had similar experience, and cannot forget the

lessons. Bees are only a small item compared to the crops which have suffered already, and those who must suffer are many indeed, and to which sympathy will be but a poor recompense.

I cannot advise what to do with bees more than is in the foregoing—viz., prepare young queens for next year, and be in readiness for any honey flow which may occur.—A LANARKSHIRE BEE-KEEPER.

#### TRADE CATALOGUE RECEIVED.

Ant. Roozen & Son, Overveen, Haarlem, Holland.—*Dutch and Cape Bulbs.*

\* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Beetles on Ferns** (*T. V. B.*).—Your specimens reached us too late to have attention this week, and will be examined and reported on in our next issue.

**Peach Leaves Eaten** (*T. W.*).—The leaves have been perforated by some weevil, which are smaller in the holes than those usually made by the grooved or so-called Vine weevil (*Otiorynchus sulcatus*); but whatever it is you may ascertain by spreading some sheets on the soil beneath the trees before dark, and when night comes shake the trees sharply, then with a lantern see what has fallen and destroy the pests. The house must be entered cautiously, and the light not used until immediately after the shaking of the trees, then act promptly.

**Soil for Tomatoes** (*W. H.*).—Spread the soil out a foot or 15 inches thick, or place it in the bed or border and sprinkle on it a peck of quicklime per rod, then stir with a fork. This will make an end of certain parasites likely to be harbouring in the turfy loam, and if none it will be useful from a chemical point of view. Then dress the ground with a mixture of two parts kainit and one part nitrate of soda, both by weight and crushed fine, using 2 ozs. per square yard, and distributing evenly on the surface leave for about a week and then point over, mixing thoroughly. This will make an end of most parasites, and benefit the soil for the Tomatoes, which may be planted when the soil has been turned and mixed for the last time as described.

**Beetles on Rose and Apple** (*W. P., Chippenham*).—The species is that familiarly called the June bug, or bracken clock, *Phylloperla horticola*. It devours the petals of various garden flowers, also eats those of fruit blooms, and even the immature fruit, as you have noticed; the Strawberry is sometimes infested. All that can be done is to apply some solution that makes the buds bitter or distasteful to the beetles, such as tobacco water, solution of softsoap with petroleum, decoction of quassia, or Gishurst compound in the proportion of 1 oz. to a gallon of water. It is at night they chiefly feed, and after dusk quantities of them may be taken in their season of flight by searching for them with a lantern, and shaking trees or shrubs that are attractive.

**Rose Leaves Curled** (*J. L.*).—The Rose leaves have the outgrowths of a blister fungus (an *Exoascus*), and closely allied, if not identical, with Peach-leaf blister fungus (*E. deformans*), but there are no blisters, hence the presence is, perhaps, accidental as it certainly is a new host for the parasite. The outgrowths, however, are so few as to scarcely account for the downward infolding of the leaflets, and there is still fewer mycelial hyphæ (threads), which are comparatively large. There is also the fine threads of the worst pest of the Rose—a fungus nearly allied to that of the Potato disease—*Peronospora sparsa*, which we have only (as yet) found on plants under glass, but we failed to find the outgrowths so essential for identification, yet there is both the mycelial hyphæ and the corkscrew-like threads in which the resting spores are produced. If the fungus develops further—produces brown spots on the leaves—you may forward specimen, or if those to hand develop anything further we shall be pleased to report thereon. The fasciated Rose shoot is merely a freak of Nature, but such abnormalities are frequently caused by the intervention of fungi, *Exoascus* species giving rise to witch knots.

**Insects Attacking the Stems and Roots of the Brassica Tribe** (*Muntham*).—The insects in both specimens are the maggots and pupæ of the Cabbage fly (*Anthomyia brassicæ*). It is the maggots that do all the mischief, which is one of the most common infestations and malignant to which cultivated Brassicas are subject. The presence of these maggots may be easily detected by the flagging and change of colour of the leaves. The maggots are hatched from eggs deposited on the stem, and when full grown they leave the plants and turn in the earth into pupæ, from which the flies emerge in about a fortnight or three weeks. These are of an ashen grey colour, the male darker than the female, and in general appearance resemble the Onion fly, but are smaller. It is most common in its attacks on plants that are grown in rich and the same ground for a number of years, hence the best preventive is crop rotation and liming the land.

**Grapes Colouring** (*Constant Subscriber*).—When Grapes commence colouring they swell considerably up to the ripening tint pervading the skin of the berries, when they, of course, cease to enlarge. To aid the swelling moderate moisture is necessary, and at closing time more is perhaps done than at any other period of the day, as it checks evaporation, hence somewhat early closing (so-called) is advisable; but this, in the ripening stage, means reducing the ventilation, leaving a little air on constantly, which being done will prevent the sweating you allude to, and is absolutely necessary to prevent "spot," as well to allow evaporation from the berries to proceed, yet modifying the ventilation so as to get plenty of size into the berries without interfering with the colouring process—the transformation of the chlorophyll into the ripening hues. The moisture and growing conditions are thus gradually withdrawn, and this is far better than reducing the moisture all at once. When the Grapes begin to colour reduce the moisture and admit air more freely, leaving the first off by degrees and increasing the latter gradually, so that the one can be left off altogether, or nearly so, when the Grapes are evenly coloured, and the other given freely, with a little constantly.

**Azaleas and Camellias after Flowering** (*H. J. and Wreath*).—Retain the plants under glass until the growth is perfected and the buds formed, when they may be stood outdoors on a base impervious to worms. They will be all the better for a few weeks' sojourn outdoors, care being taken if they have been grown in a shaded house to afford a slight shade from bright sun until they become used to the exposure. They should be duly supplied with water, and be syringed in the evenings of hot days. From the beginning to the middle of July is about the time Azaleas are sufficiently advanced in growth and bud for placing outdoors. They should be housed in September, before the weather becomes very wet and cold. Camellias should be kept under glass and treated similarly to the Azaleas until their buds are well set, and may then be placed outdoors in a sheltered situation and shaded from midday sun, duly supplying them with water and returning under glass towards the close of September. To flower during the winter their growth required to be made somewhat early, but this habit they will acquire after a few years' culture. If your situation is cold they should not be placed outdoors, but be kept under glass constantly, taking care not to overwater, nor, on the other hand, to allow to become too dry, and giving all the air possible after the buds are set.

**Tomatoes Diseased** (*A. B.*).—The "fruits" are affected by blotch or black stripe fungus, there not being anything but the mycelial hyphæ, and these are forming "knots" along them, which indicate mature condition of *Fusarium solani* or *lycopersici*, this particular disease being carried over from year to year in the seed of the Tomato, and in the soil by the resting spores. The infection, however, of the fruits before us has not been effected from the root or stem, for the footstalks are perfectly innocent of any fungal growths; but the spores of the parasite have germinated on the decayed organs of the flower, and the germinal tubes or pro-mycelium pierced the then tender cuticle, and growing within the tissue just beneath the epidermis, have produced the blotch. This is a new phase of the subject, and a most important one, as it is clear the infection may be either from the soil—communicated by the growths from the resting spores (the *Hypomyces solani* or *lycopersici*) or by the top—by means of the first-stage spores (*Diplodadium solani* or *lycopersici*). The preventives therefore must be twofold: (1) Disinfect the soil, nothing answering better for either Potatoes or Tomatoes than quicklime; and (2) dust the plants with air-slaked lime quite dry and flowy, repeating as necessary to keep the foliage and fruit coated with lime. If you add one part per hundred of sulphate of copper, and mix thoroughly, you may defy this and other Tomato pests. The plants must not be syringed. Affected plants should be pulled up and burned, using quicklime freely where they have been, after removing as much of the roots as practicable. The white worms are injurious, but they succumb to dressing with quicklime.

**Assortment of Flowers for Winter Cutting** (*Wreath*).—For early use there is nothing better than Chrysanthemums, which you may procure in plants, such as Madame Desgrange, Lady Selborne, Mrs. G. Rundle, Empress of India, Mdle. Lacroix, Florence Davis, Beauty of Exmouth, Alba Fimbriata, Elaine, Ethel, Fair Maid of Guernsey, and Elsie. These will afford a supply up to Christmas, the plants being kept outdoors until the beginning of October. Tree Carnations may also be secured in plants; Mrs. Reynolds Hole, Miss Lizzie McCowan, Mrs. Henry Cannell, Miss Jolliffe Improved, Uriah Pike, and Germania, keeping them outdoors until October, their blooming depending on the

advanced condition of the buds, giving them the lightest position possible. *Primula sinensis alba plena*, grown well, affords a quantity of flowers for cutting, as also does the *Cyclamen persicum* vars. of the improved strains, which may be raised from seed. Roman Hyacinths procured early, potted and grown on, will flower about the new year or from December, and are amongst the finest plants for cutting. *Cinerarias*, sowing seed early and growing the plants in frames, give a quantity of useful flowers during the winter. *Eupatorium riparium* is very free flowering, plants being rooted early in the spring and grown on give a number of sprays. Christmas Roses (*Helleborus niger* and var. *maximus*) in strong clumps, lifted and potted in early autumn, flower finely under glass. There is also *Calla* (*Richardia*) *aethiopica*, grown well during the summer and potted up in late summer, flower well during the winter. These are some of the most desirable, but their winter flowering depends on the good management during the summer previous.

**Insects on Pseudo-bulb and Root Stem of *Laelia albida* (J. F.).**—The insect on the pseudo-bulb is white scale (*Aspidistis orchidarum*); that on the root, stem, and part of pseudo-bulb which has been covered by the potting material is the somewhat uncommon Orchid-root mealy bug (*Dactylopius orchidarum*), a singular insect with a dirty yellow body, surrounded by a broad white border in divisions, with ribs like a fan; long, somewhat stout antennæ, having three pairs of legs, rather thick and hairy, and an enormous beak with which to bore into the stems. It is just visible to the naked eye, and as seen through a pocket magnifier somewhat resembles a small mealy bug. It is an interesting but very destructive pest. The best means of riddance is to shake the plants out and wash them carefully with hot water, but not hotter than the hand can be borne in it half a minute, using a brush so as to dislodge the pests, then use an insecticide against the scales and mealy bugs, dislodging, and washing again in clean warm water. Methylated spirit may also be used, merely moistening a small brush with it, and then dressing the affected parts. There is danger of injuring the young roots if the methylated spirit contains a large amount of spirits of tar, but we have not found any bad consequences follow when the spirit was diluted with an equal amount of soft water. By either process both insects may be destroyed. Ants do not do any good, they feed on the secretion of the other pests, scavenging being the measure of their usefulness.

**Tomato Diseases (Southampton).**—There is no doubt your plants are attacked by two distinct kinds of fungi—a slime fungus, which is taken from the soil by the roots, the Potato fungus which is produced by spores coming in contact with the leaves under favourable conditions for germination. Many Tomato growers have found by costly experience that it is necessary to change the soil, in some places every year, in others every two years, according to its nature and other circumstances. It is also known that one form of disease is communicable by seeds in which fungus spores rest. Why one plant should be taken before another is as unexplainable as the precise reason why one person takes the influenza before another or any other contagious malady. It is a question of the fitness of the subject or plant, as the case may be, as a "host." For practical purposes it is enough to know that your houses "swarm" with fungus spores, and if the atmospheric conditions, and the state of the plants, are favourable for their germination they will germinate, otherwise they will not. This is what all experience teaches both in nature, as displayed by outdoor crops, and in cultivation under glass. With suitable houses the Potato disease fungus is practically controllable. With fungus in the soil the case is more difficult to deal with. As you have evidence satisfactory to yourself that the plants you are destroying "have been infected, not from the soil, but from other diseased plants in the house," so much the better, as we should regard it, having the future in view, as the lesser of two evils, however great, and much to be regretted, the present may be. Your houses will need to be thoroughly cleansed and disinfected when they are empty, and it would be extremely prudent to remove as much of the soil as you can and bring in fresh. If this is moderately fertile and made firm, also the ventilation is as it should be for promoting firm growth—"hard" stems and leaves, we should have small fear of the *Phytophthora* taking possession of the plants. We have just been inspecting Tomato plants in three houses at Chiswick. They are quite different in character, as containing far more woody tissue, than those you have sent. We have not the slightest fear that the Chiswick plants will be invaded by the Potato fungus. They are this year grown in pots, but these are only half filled with soil till many fruits are set. They are thus "firm," short-jointed, and fruitful, and not until good crops are swelling is more soil added. Most persons, we do not say all, whose plants are smitten with disease grow them too luxuriantly and "soft" in their early stages. One of the largest Tomato growers in England, and who has had profitable crops and no disease for twenty years, almost, as many persons think, starves his plants till a good set of fruit is swelling, then, and not till then, feeding them. Nothing would induce him to change his method, because it pays. The formula for making Bordeaux mixture has been given again and again. The full strength has been found to injure tenderly grown Tomato plants. The strength recommended by Mr. Abbey, whose formula you require, will be found on page 282, March 28th of the present year. The preparation of carbonate of copper solution is given in the same paragraph; anti-blight is also referred to, but neither one nor the other can restore plants in which the fungus is so firmly established as those which you have sent. We are thoroughly convinced that if the advice there given had been followed at the time and subsequently, in conjunction with otherwise good cultural management, that

your plants would not be in the sad condition they are now. Preventive measures can alone be effectual in combating successfully fungoid enemies that attack Tomatoes and other plants.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J. J. C.).—1, *Viburnum Lantana*; 2, specimen insufficient; 3, *Viburnum Opulus*. (A. McMillan).—*Bouvardia trifolia*. (Somerset).—Roses are florists' flowers, that can only be named by comparison in a large collection. (B. F.).—1, *Veronica buxifolia*; 2, *Dianthus sylvestris*; 3, *Heuchera sanguinea*; 4, *Geum miniatum*; 5, *Inula glandulosa*; 6, *Linaria dalmatica*. (R. O.).—1, *Cypripedium barbatum*; 2, *Cattleya gigas*; 3, *Epidendrum vitellinum majus*. (F. C.).—Specimen insufficient, send when in flower; 1, possibly a *Cotyledon*; 2, a *Crassula*.

COVENT GARDEN MARKET.—JUNE 19TH.

HEAVY supplies of Strawberries from all four counties—Hants, Essex, Middlesex, and Kent—to hand, completely glutting our market, and prices have fallen considerably. Grapes have suffered in consequence, and are with difficulty cleared. Peaches have been in demand, coming short.

### TABLE POULTRY.

To our oft-repeated advice to rear more chickens and produce more eggs, simply because home-raised produce of this kind is always in high demand—commands a higher price than the imported article, and, best of all, is always profitable—we have been told many a time that if every farmer went into this branch of farming largely there would be a glut in the market and down would go prices. Mere argument, and nothing more, is such talk; the glut appears as far off as ever; chickens and “eggs from our own farm” are dearer than ever.

On June 8th we were asked 9s. and 12s. a couple for chickens in Leadenhall Market, those at 9s. being miserable little spring chicks not half grown. On the same date the price at Francis' Stores, Clapham, was 14s. and 16s. a couple; at a fashionable West End poulterer's they would be much dearer. Taking the Leadenhall Market prices as a safe guide, we give them as reasonable, having regard to the fact, well within our own experience, that higglers will give 7s. to 8s. a couple to the breeder for well-grown spring chicks nine or ten weeks old. We have known them do so at the cottage doors of our own workmen in Sussex. Judging from the appearance of the chicks on sale at Leadenhall, most of them are sent to market as purchased from the breeder, because of the demand and high price. But there can be no doubt that when the chickens are raised early, and are well managed, they may be rendered much more profitable.

It is well known that healthy, kindly chicks, will lay on 2 lbs. of flesh in three weeks if shut up and crammed; flesh, too, that is quite first-rate in quality, and which has been pronounced by competent judges to be better, both in colour and flavour, than that found on chickens not so treated. Ground oats, milk, and Australian mutton fat, imported for soap-making, and costing 30s. per cwt., is the fattening mixture that answers so well.

Failures with early eggs and early broods are probably more owing to a common want of proper accommodation, of really good poultry houses, than anything else. Not half enough attention is paid to the provision of warm, light buildings; of adequate shelter for poultry in winter. Among other causes of failure are the keeping of young broods in the fœtid atmosphere of a close coop for ten or twelve hours at night, coops left on the spot too long, food thrown on the ground and eaten soiled by the excrement of the fowls. Not only should the coops be placed on a fresh, unsoiled part of the farm every year, but they should be moved daily, and be well ventilated always. They can be made quite safe from foxes without being shut in so closely as to exclude fresh air. Shelter, thorough cleanliness, pure water, fresh air, wholesome food, and proper feeding are the points which in the main bring success. At one time our greatest difficulty was the serious mortality from gapes; a little attention showed that it could be altogether prevented by placing the broods as they were hatched right away on fresh land free from taint. This was at an old home farm where the mortality among quite young chickens from this disease every year had become so great that it was a difficult matter to rear chicks at all.

In breeding for table poultry avoid what are known as show birds. We want plump, hardy chickens, and get them by crossing carefully selected Dorking hens with an Indian Game cock. Without care in selecting the hens there may—there often are yellow-skinned chickens, but with healthy

white-legged hens we have from this cross chickens with white skin, remarkably plump breasts, and with very little waste. Have a change of cock birds every year, as it is certain that in-and-in breeding leads to much of the loss and disease among farm poultry. When the chickens are not sold off or used quite young the sexes should always be separated, and also kept apart from other fowls. On home farms, especially where birds that are exceptionally large in size are much valued for the household supply if they are as plump and tender as only young birds can be, it always answers to do this, and from a yard of cockerels so kept apart really fine birds are always forthcoming.

Such systematic management as we have indicated is a very different thing to the ordinary rough and ready practice that prevails among most farm poultry. With a proper system, and the exercise of due care and forethought, table poultry of a superior kind ought to be forthcoming in such abundance as to cause a full home supply, and a profitable sale at market.

### WORK ON THE HOME FARM.

Now that cows and cattle are out of the yards, let the first opportunity be taken to thoroughly cleanse the interior of all buildings used for them. The best wash for the walls of such buildings consists of three parts of quicklime and one part of salt. This gives a surface as hard as cement, and to any part at all difficult of access it can be applied by means of a syringe or garden engine. We do this to the interior of pigstyes frequently, and also take special care to have a clean dry floor, preferably of concrete, so as to avoid risk of cramp, especially to young pigs. These are jobs that the workmen can do on wet days very much to the purpose, and we make it a rule never to suffer the interior of any building used for live stock to become offensive or unsightly from filth.

Sheep require close attention now, so that any case of fly-striking may be dealt with at once by a free use of Cuff's dressing. They should be seen twice daily, and be looked over quietly and carefully. To the practised eye fly attacks are generally evident by the restlessness of the sheep, so that a careful look round may suffice, but if there is the slightest doubt let the sheep be at once got into a fold and examined closely.

The safety of drilling Cattle Cabbage and Kale is very apparent as the weather continues so dry, thinning and hoeing being all that is required; then, too, the plant has no check from being transplanted, and if the soil is really as rich as it ought to be the plant is well nourished, and grows away without material harm from drought. On the other hand, where the plants have to be transplanted from a seed bed, the check in such dry weather is so severe that they are long in becoming established, and make way so slowly as to be a backward crop at best.

Both these green crops are so very useful that it is worth while giving attention to the best way of cultivation. It is mere waste of time to sow or plant them in poor land, as they do no good, and only cause waste and disappointment, but then it is obvious enough that any failure of the kind indicated is owing very much to imperfect culture.

### REMARKS.

- 9th.—Sunny and rather oppressive; stormy looking clouds about sunset.  
 10th.—Overcast almost throughout, but gleams of sunshine in afternoon.  
 11th.—Frequent gleams of sun in morning; alternate cloud and sunshine in afternoon; rain at night.  
 12th.—Generally fine and sunny, but spots of rain about 1.30 P.M., and a slight shower about 4 P.M.  
 13th.—Generally sunny in morning, but cloudy afternoon.  
 14th.—Alternate cloud and sunshine throughout.  
 15th.—Cool and generally cloudy in morning; sunny afternoon.  
 Another week of drought, the seventh in succession, with less than 0·20 inch of rain. Temperature almost identical with the average.—G. J. SYMONS.

# LAXTON'S STRAWBERRIES.

TWO GRAND NEW DISTINCT VARIETIES for 1895.  
BOTH FIRST CLASS CERTIFICATES R.H.S.

## MONARCH,

To follow Royal Sovereign, brilliant scarlet colour, flavour very rich, enormous size, and great cropper; compact habit.

## LEADER,

Handsome maincrop, rich crimson colour, of the largest size, fruit weighing 2 oz.; true pine-like flavour.

EQUALLY AS INDISPENSABLE AS ROYAL SOVEREIGN TO ALL GROWERS.  
Price—Open Ground, £3 100, 12s. doz.; in Pots, £4 100, 15s. doz.  
CAN ONLY BE OBTAINED DIRECT FROM US.

Also **ROYAL SOVEREIGN**, 20s. 100; in Pots, 27s. 6d. 100.  
And every other variety worth growing. Lists on Application.

**LAXTON BROTHERS, BEDFORD.**

## PRIMULAS! PRIMULAS! PRIMULAS!

27th YEAR OF DISTRIBUTION.

WILLIAMS' SUPERB STRAIN, 1/6 per dozen; 10/- per 100.  
CINERARIAS same price; also DOUBLE WHITE PRIMULAS, 6d. each. Package and Carriage free for cash with order.

JOHN STEVENS, The Nurseries, COVENTRY.

## FERNS A SPECIALITY.

We have an immense stock of all kinds of Ferns, Stove, Greenhouse, Filmy, Hardy Exotic, and British, including many very beautiful varieties, rarely seen but which ought to be more generally grown. Catalogue free on application.

THURSDAY, JUNE 27, 1895.

### THE WOBURN EXPERIMENTAL FRUIT FARM.

BY the invitation of the Duke of Bedford and Spencer Pickering, Esq., F.R.S., a party of horticulturists assembled at the Woburn Experimental Fruit Farm in Bedfordshire, on Tuesday, June 18th, to inspect the work commenced there last year, and to inaugurate, as it were, an undertaking which cannot fail to yield results of considerable importance and interest to many persons concerned with the cultivation of hardy fruits in this country. As a project which is calculated to promote an industry certainly unworthily neglected in many districts, as a source of independent and reliable information on disputed or doubtful matters connected with fruit culture, and as a means of providing additional employment for men on the estate and in the county, every thoughtful person must appreciate the feelings which prompted the present Duke of Bedford to accord it his earnest support. It is difficult to imagine how a wealthy nobleman can better utilise a small portion of his resources than by testing for the benefit of his tenants and the estate generally the possible advantages to be derived from an extension of fruit culture, which, when successful in any degree, must greatly increase the producing power and value of land, to the ultimate advantage both of occupier and owner. When the results of such an undertaking are rendered of still wider utility by being placed at the disposal of all interested, it becomes of national importance, and the conductors have the satisfaction of knowing that the work commenced with private means bids fair to rival some of the best establishments of the kind in other countries carried on at the expense of the State.

To the Director, Mr. Spencer Pickering, F.R.S., a gentleman of considerable scientific attainments, must be adjudged the credit of projecting the scheme, and the careful thought he has devoted to the matter is certain to produce useful results. Already much local interest has been excited in a county singularly deficient in fruit culture, and the more enterprising cultivators will not be slow to take advantage of the experience that is being bought for their assistance. When it is shown what fruits succeed in the district, many occupiers of

land might test the matter for themselves by planting an acre or two, and be guided by the results as to the desirability of extending the experiment. When there is so much good land suitable for the purpose, which at the present time brings comparatively small returns, the most ordinary man of business should be willing to turn his attention in any direction that affords a prospect of better results. If a shopkeeper finds he cannot obtain a profitable price for any article he offers for sale he endeavours to provide a stock of something which will yield a better return, and this is a common sense proceeding which might recommend itself to many besides shopkeepers.

The experimental farm occupies 20 acres of land, chiefly a heavy loam of moderate depth resting upon clay, the surface soil varying somewhat in depth and heaviness in different parts of the field, but it is throughout very retentive of moisture. The land slopes slightly to a brook on the south-west side, and though the difference in elevation amounts to about 15 feet, the meteorological records for the stations at the upper and lower parts of the farm show some interesting divergences, especially in regard to minimum temperatures, which are usually from 2° to 5° lower at the station near the brook than on the higher ground. On the north-west and north-east sides the boundaries are formed by old Quick hedges, but the other two sides are fenced and open, with the exception of a few small Oak and Ash trees on the south-west. A few similar trees have also been retained on the north-west side, partly for the sake of appearance and partly for shelter, but in addition to these quick-growing Poplars and Maples have been planted to assist in breaking the force of the wind from that direction.

Only a brief review of the experiments already taken in hand can be given here, for they cover a very wide field, as can be judged when it is stated that the last number entered on the books until the present month is 500. Great prominence is accorded to Apples, and one of the most interesting portions of the farm is that devoted to the sixty different experiments with Bramley's Seedling, Cox's Orange Pippin, and Potts' Seedling. These were selected as presenting different habits of growth besides being of good constitution and reliable croppers, and therefore calculated to give some appreciable results under diverse treatment. The method adopted in the arrangement of these trees is planting the varieties in neighbouring plots extending from the higher to the lower portion of the farm, so that there are six trees of each variety in a line across the three plots, each eighteen trees being the subject of one experiment. The trees are all carefully selected, dwarfs on a broad-leaved Paradise stock, and being as nearly equal as possible, it will be interesting to note the behaviour of the respective varieties under precisely similar treatment. The nature of the experiments may be judged from the following list of the subjects especially dealt with and to most of which several experiments are devoted. Treatment of branches, including a comparison of the results from different systems and times for pruning, pinching, or cutting back the shoots and branches. Treatment of roots, in which root-pruning will be performed at different periods, and compared with lifting and other trees not disturbed.

Treatment of surface soil, comprising five experiments dealing with loose and firm soil; the effects of hoeing, hardening the surface, digging close to the roots, and allowing weeds to grow. To manures and their effects twenty experiments are appropriated, the chief chemical manures being compared with farmyard manure and liquids, while in another series the amounts are varied to ascertain which gives the best results, the best times for applying the different manures being also carefully tested in the same way. This section will no doubt give some important results, but much time must necessarily elapse before it will be possible to found any definite opinions upon them.

The methods of planting illustrated include planting high and low, in holes 1 foot deep, and in ground dug 2 spits deep, together with planting in holes with chalk at the bottom. The most

remarkable just now are the three experiments devoted to bad planting, because this dry season has produced results which are most noticeable in contrast with the other plots. In one of these the trees are badly planted, but they have been attended in all other respects, duly cut back, the ground forked, hoed, and kept thoroughly clear.

The next two rows of trees were badly planted but neglected—that is, neither cut back nor attended in hoeing and cleaning—the only difference to be observed being that in one case it is intended to apply manure and in the other none. The ground is a dense mass of weeds, it has hardened and cracked very much, and the trees show the effects in the extremely poor growth made, the small size of the leaves, and the large number of these turning yellow and falling. It is a most striking illustration of what attention will effect, for the trees were all planted exactly alike—namely, in small holes dug with a spade, the soil roughly and heavily trodden in over the roots—and the difference is remarkable, even between the first and two other rows.

The effects of different soils are tested by five experiments, in which the stations were prepared by mixing with the ordinary soil or replacing this by rich compost, gravel, stones, peat, or chalk. Autumn, winter, and spring planting, the removal of flowers, and the behaviour of damaged trees are respectively dealt with in succeeding experiments, all of which may be expected to yield much interest as time goes on. The more important of those enumerated are repeated with dwarf trees of Stirling Castle, and again with standards of Bramley's Seedling, Cox's Orange Pippin, and Lane's Prince Albert in another portion of the farm, so that abundant records will ultimately be available on the various subjects dealt with.

With the object of ascertaining how far the different systems of training Apples may affect their produce or profitableness nearly 300 maiden trees of Bramley's Seedling, Cox's Orange Pippin, and Stirling Castle on a broad-leaved Paradise stock, have been planted to be trained on the various forms of bush, bowl-shaped, or pyramidal trees, espaliers, and cordons. Their respective progress will thus be readily traced from the beginning. Besides these, 120 varieties of Apples have been selected for trial on an equal number of Crab and Paradise stocks, and will be budded or grafted on the farm, so that their progress may be watched from the first stage. Six large plots of ground are devoted to this purpose, and it is interesting to note that many of the weaker Crab stocks suffered during the severe winter, a much smaller proportion of the Paradise stocks have been lost, and the same is observable in another portion of the farm. It is intended to make these plots the subject of experiments in hard and moderate pruning, also as a means of testing insecticides, as a large number of trees of different varieties on the two stocks will be available for the purpose.

Strawberries also come in for a large share of attention, for no less than eighty varieties are grown for comparison, and in the border which is specially devoted to these they are planted in lines of thirteen each, 10 feet apart, to afford space for planting a fresh row each season for five years. By this means the produce of each variety will be tested from plants of five different ages, and the records will show at what period of its life the variety or plant yields the best return. The present season has been a bad one, for in addition to the late planting that was unavoidable in some cases the extreme drought and a severe attack of weevils have been opposed to either large or good crops. Yet some of the Strawberries have yielded satisfactory fruit, and on the occasion of the meeting creditable examples of fifty-six varieties were gathered.

The earliest ripened were Laxton's No. 1 and Crescent Seedling (June 4th) followed by Noble and Scarlet Queen (June 5th), King of the Earlies, Keens' Seedling, and Marguerite (June 6th). Exceptionally large fruits of Sensation and Bothwell Bell have been obtained, 1¼ to 1½ oz. in weight; fine examples

of Noble were also produced, but this variety does not seem to be at home on the heavy soil at Ridgmont. Though the fruits are small Laxton's No. 1 has cropped well, the fruits being firm and of fair flavour when thoroughly ripe. One of the most satisfactory in all points as regards crop, colour of fruit, and especially as to flavour, is Edouard Lefort, a variety sent out from France, which will probably take a place in many gardens when better known. It should be added that in addition to the strictly experimental plots of Strawberries, rows of about eighty plants of each of the varieties are planted in other parts of the farm.

Attention is devoted to the economic side of fruit culture in what are termed the demonstration plots, which consist of half an acre each planted in different methods to suit what may be regarded as the requirements of farmers, market growers, and cottagers. In case of the first named free growing varieties have been selected, and ample space has been allowed in half the plot for cropping between the rows until the land is laid down to grass. In the other half additional rows of dwarf trees and bushes have been introduced. A somewhat similar course has been taken with the market growers' plot, where in one half Strawberries are grown, while in the other Gooseberries and Currants take their place, but a much closer system of planting is adopted in both these with the object of utilising the whole of the ground, and with a view to ultimate thinning when needed. In the cottagers' plot one half is divided equally, fruit being grown on one portion, and vegetables on the other, while in the other half greater space is allowed between the rows, so that vegetables can be grown with the fruit, the same varieties of fruit and a like number of trees or bushes being grown in each quarter acre plot. Throughout these demonstration plots the fruits planted are standard and dwarf Apples, dwarf Pears, Plums, and Damsons, Nuts, Currants and Gooseberries, Raspberries and Strawberries, the Damsons, Nuts, and Raspberries forming the boundaries to the plots. Accurate accounts will be kept of the labour expended and the produce of the respective plantations, so it will be possible to institute a comparison both as to expenses and returns.

Experiments have also been commenced on the different methods of arranging trees in planting, bush Plums being selected for the purpose, and three plots are planted with these—in the square, the rectangular, and the hexagonal (equilateral triangular) systems. Each plot comprises thirty-six trees in three varieties—namely, Monarch, Czar, and Victoria alternately, so arranged that they represent exactly the same number per acre (1210 trees). The plots are surrounded by rows of Early Prolific Plum at the same respective distances, and arranged in the same way; but these are merely intended as protective. In connection with these experiments, it is being endeavoured to obtain some information in regard to the effects of light under the different systems of planting, by shading trees in three ways by means of screens of canvas; but in order to produce an appreciable result, the screens have been placed much closer than other trees would be. How far this will affect the object in view remains to be proved.

Although the whole of the farm is not yet planted, much more of interest is worth attention; for instance, some 3600 feet run of experimental fruit hedges have been planted, comprising Plums, Damsons, Medlars, Quinces, and Filberts. Collections of local varieties of Apples are being tested, including Scotch, Irish, and continental varieties, and a nursery is planted with Crab, Paradise, Pear, Quince, Hawthorn, and Cherry Plum stocks, to be budded or grafted for utilisation on the farm or estate.

Adjoining the nursery a collection of trees and shrubs has been commenced, chiefly representing the more ornamental and distinct forms of *Prunus*, *Pyrus*, and *Cratægus*, but also including representatives of many other genera of the family *Rosaceæ*, together with ornamental flowering shrubs and trees of various kinds. This will become both an interesting and beautiful feature, especially as efforts are being made to utilise the brook banks for ornamental

purposes by suitable planting, and the introduction of rustic bridges with small waterfalls. The ornamental is rigidly subordinate to the useful generally, but the brook and its adjuncts afford a very welcome relief to the other portions of the farm.

It only remains to add that the preparation and laying out of the greater part of the land, with the whole of the fruit tree planting, has been carried out under the superintendence of the Manager, Mr. Castle, to the entire satisfaction of the Duke of Bedford and Mr. Spencer Pickering, and it is impossible to speak too highly of the excellent condition and orderly appearance of the grounds.

### FRIENDLY FLIES.

THOUGH it is not till the summer is at its height that flies seem to be in full force, there are abundance of them on the wing during June, but we do not notice them out of doors so much amongst the leaves and flowers as when various species take a turn indoors later on and enjoy themselves about our houses and conservatories. Commonly, we look on flies in the light of annoying if not always injurious insects, but there are many deserving of a good word, because they do us service either in the winged or in the preparatory state of grub, and this often passes unnoticed, because it is less conspicuous than the attacks made by other species on buds, flowers or fruit. We talk about the ignorance and superstition of the ancients, but perhaps the worship by some of certain flies as gods was not foolish from their point of view. They regarded the insects as benefactors, whose activity produced a wholesome result, removing or decomposing matter that is hurtful to man, and fitting it to promote vegetable growth. But no doubt there were also flies, or fly deities, which would not have been revered had there been no fear of these particular insects.

Now, there are flies and flies. The name is vague, and for the present we leave the hosts of four-winged species, called ichneumon flies, allied to the bees and wasps that are busied in depositing eggs upon the bodies of caterpillars and other larvæ, also sometimes upon pupæ, by which their development is stopped, and the number of our garden foes is much reduced. Confining our attention to two-winged flies of the Dipterous order, we will notice a few of the species that help us considerably by preying upon various insects, some of which are troublesome, because apt to elude us, or they are endowed with the power of rapid increase. Much too, might be said for the flies whose maggots feed on natural manures, as we have remarked; gardeners of the olden time relied a good deal on their labours in changing crude manure so that it was fit to be applied to plants, but unfortunately some of them have a trick of quitting their old food for a new diet, when they happen to be brought amongst roots.

This is indeed one strong argument in favour of the preference now given to chemical manures, which, of course, insects avoid, and when other kinds are used it is desirable they should not contain fly or beetle life in the larval stage. Again, something must be put to the credit of the fly tribe, because there are flies that are fellow-workers with bees, some butterflies, and sundry other insects, in effecting the fertilisation of flowers amongst various orders. This is done not only by the long-trunked bee-flies, but by some species of small size. Quite a party of such flies will enter the tube of an Arum or Aristolochia, where the hairs imprison them for awhile, and after they have obtained a little honey, with a coating of pollen, the hairs shrivel, affording them an escape, so that they may carry the pollen to the stigmas of another flower.

In some instances, however, the flies simply act by effecting the transference of this fertilising medium from the anthers to the stigmas during their visit, by contact or agitation. Amongst the species that are known to be partially impregnated through these insects, are some *Violas*, *Lythrums*, *Sedums*, *Saxifrages*, and other plants. It is one contrast in fly life that not a few of the flower lovers, during their maggot state, fed upon offensive substances; others of the scavengers, when they appear as flies, are household nuisances or else bloodsuckers. Flies generally have a very good muscular development; we often see instances of it in their power of steadying themselves upon the wing, with heads against the wind, and this is of special service to such flies as are predatory. Species of the same habit in the maggot state also exhibit abundance of strength.

We find insect-eaters occur in a group of flies which might be called the tiny fairies of the order, remarkable for their slender forms, rainbow-tinted wings, and long antennæ. Gnats, most people would take them to be; they are properly the *Cecidomyiæ*. A very injurious species is the "Hessian" fly. Many of the larvæ feed on flowers, fruits and leaves, where they produce little knots

or galls frequently, but some of them are aphid-hunters, seeking for these troublesome insects in their retreats within folded leaves, under bark, or amongst roots. Probably the aspect of the soldier-flies, rather stout-bodied insects, having a spiny thorax, might suggest that they were combative. We see them at flowers, but only seeking their honey. The name seems to have been given because red, orange, or yellow, in varied markings, are displayed upon the black ground colour. There is no doubt about the habits of the strong and hairy flies called the Asilidæ; their appearance suggests their carnivorous nature, and some of them are not at all afraid of combating bees.

A brisk fellow noticeable on sunny days is attired in black, white and yellow; when he visits our flowers it is to seize and carry off caterpillars or other insects: he is *A. craboniformis*. Allied to these are the snipe-flies, or *Empidæ*, named from their long tongues and of smaller size. The males chiefly subsist on the nectar of flowers, but the females destroy many insects, gripping them round the body, while they drive the beak deeply in to extract the juices. Familiar to gardeners is the dull-coloured *E. tessellata*, having a thorax streaked with black, and long, spiny legs. Many of these flies hunt out the little moths of the *Tinea* division, parents of those leaf-roller caterpillars which damage and disfigure plants or shrubs, killing thousands of them during the summer, much to our benefit.

Amongst the hawk-flies we have insects useful in the larva state, while a few are injurious from their attacking bulbs. We cannot mistake them for other groups. The head appears almost covered by the eyes, and when they resort to flowers they hover over them as if motionless, but make a dart now and then to the right or left. Having refreshed themselves with honey, those of the genus *Syrphus* deposit eggs in the midst of clustering aphides, frequently selecting the Rose. The grub has a small head, bearing a curious apparatus, by which it spears the aphides one after another rapidly, steadying itself upon the leaf with the aid of its broad tail. Then again the *Tachinæ*, a division of the flies proper, number about a hundred species, and they busy themselves now in the pursuit of caterpillars. From their eggs are produced grubs which eat into and destroy these insects, also sometimes they infest the larva of beetles and bees.—ENTOMOLOGIST.

### THE PROFITABLE EMPLOYMENT OF GLASS STRUCTURES IN WINTER.

[Silver Medal Essay by Mr. PETER WILLIAMS, Oakfield, Nantwich.]

(Concluded from page 538.)

AS is evident, an important consideration in Mushroom culture under glass is, that the cultivator does not depend on the outside temperature, which is often fluctuating, but having heating appliances at command, can keep an even temperature at leisure; therefore a failure in the crop from this direction is impossible. The best Mushrooms I have grown have been in this manner, and I have this last winter grown Mushrooms in boxes 10 inches deep, covered with slates, and placed under a greenhouse stage, of better quality than others grown in beds in a shed; in fact, better could not be desired. Superficial area considered, those grown in boxes in the glass house were far more productive than the others. Thus spaces and places unsuitable for one thing can be made suitable another, *ad infinitum*.

Hitherto no mention has been made as to cropping the raised border over the Mushroom bed, that being reserved for growing what may be termed the "staple industry" of the winter, spring months especially. As the demand for salads is not so great before the end of December, though the demand is annually increasing—salading being so often recommended as a wholesome article of diet, being useful in scorbutic affections and visceral obstructions—a limited supply for that time would perhaps be sufficient. For that purpose the borders named would meet requirements *pro tem*. From the time the seed was sown—*i.e.*, the beginning of October, four crops of Mustard and Cress could be cut, each value £9 6s. The estimation is arrived at thus:—The borders each being 60 feet in length (ends of the house omitted) and 4 feet wide would give 480 square feet, 1 quart of each seed sowing 50 square feet or 5.5 square yards, from which space 20s. value of Mustard and Cress can be cut; therefore the four crops up to January would realise £37 4s. The foregoing is based on a fair test when in the market-growing business, and when commencing to grow this salad for market. I concluded I had "struck ile," and rightly so, for the more I grew the more the demand grew.

Prior to my growing Mustard and Cress to any extent the retailers were obliged to obtain their supply of this salad from large centres by rail. Though there were several other market gardeners in that neighbourhood all were indifferent to this branch of industry beyond sowing a box or two, and there it ended. It must be understood that to be profitable it must, as everything else, be well grown, when there will be a brisk demand for it. In some localities marketing facilities are not so convenient as in others; but on the whole 25 per cent. expenses will be a fair average to meet all cases. I may here assert that expenses, time

of maturity, space occupied, number of crops, there is no produce in a garden indoor or out that will bear comparison with this salading.

*Seeds*—The best of these should be obtained, otherwise it often comes "patchy," and perhaps not at all, thereby causing disappointment. The average price of good Mustard seed (*Sinapis alba*) is 14s. per bushel; but a substitute for Mustard is much used—*viz.*, Rape (*Brassica rapa*). Care should be taken to obtain the true article, the latter not being as wholesome, though preferred by some on account of its being milder. When grown together the difference is easily perceived, the true Mustard being of a bright, fresh green colour, while the Rape is of a dull green and a downy appearance, it moreover cannot be grown to the size of the true Mustard. The price of Cress (*Lepidium sativum*) is about 17s. per bushel, or an average for both of 15s. 5d.

*Culture and Marketing*.—Before sowing the ground must be enriched by an application of old Mushroom manure, forked in and the surface made very fine, after which a thorough watering must be given the day previous to sowing, dryness at any time being detrimental to the crop. The exhausted Mushroom beds having been cleared and placed in a heap outside, the ground space will be at liberty by the beginning of January, which will be necessary, the salading season by this time being in full swing, and after such a winter as we have experienced the demand for any green salading will be doubled or trebled. Having on the borders an area of 480 square feet, on the ground an area of 770 square feet, or a total of 1250 square feet, sow one-eighth the space, 136 square feet, with Cress, for which 6 quarts of seed will be ample. I always preferred sowing equal quantities and placing equal quantities in punnets, though some put less Cress than Mustard. After an interval of seven or eight days sow another one-eighth with Mustard seed, at the same time another one-eighth with more Cress, and so on until the whole space, be it one or a dozen houses, is sown. Treated thus it will come in rotation, as a continuous supply must be kept up from this time until the end of the salading season, or rather Mustard and Cress season. After sowing the seed gently press down with the back of a spade, or a board with handle attached may be made for the purpose, after which sprinkle with water, using a very fine rose.

Early in the season, before the sun gained much power, I simply scattered very fine soil over the whole, but I found by experience that the better course was to cover with mats, or, which is better, coarse packing cloths, as they are not so heavy as mats, or sugar bags cut open. Procure some Y-shaped pegs 3 feet in length, and place in the ground in such a manner that thin strips of wood may be rested on them. When a framework has been made in this fashion lay the covering on them, and keep damp by syringing. The covering must be kept on until the crop has attained to a height of 2 inches, when it may be taken off to expose them to the light, and to give them a fresh green colour.

To obtain the best results the crop should be allowed to grow until the seed leaves are fully expanded, and the stems are from 4 to 6 inches in length; but it must be cut before the second leaves appear. In this way the grower obtains double the quantity in bulk from one-half the amount of seed, in addition to which the salad is sweeter and fresher, and free from the manury smell and flavour which it has when grown thicker and in a stuffy atmosphere. For cutting the crop the most serviceable instrument is a hooked knife with blade about 9 inches in length, but bent at right angles from the handle in the same way as a trowel. With this it can be shorn close to the ground, the left hand following above the blade to keep that which is cut together. The punnets or baskets being in readiness may be filled by another person, or one person after a little practice can fill hundreds in a short time.

Should the grower have the advantage of disposing of his goods direct to the retailers many prefer being supplied with it in clean, square baskets or small sieves, in quantities computed at 6d., 9d., or 1s. worth according to the size of basket. This is much the better way, as the buying of punnets is dispensed with, the baskets being returned when fresh supplies of salads are delivered. For conveying the baskets or punnets to market boxes should be prepared previous to being required, the same boxes being found useful for packing leaves of Raspberries during the fruit season, the most convenient size being about 18 by 24 by 24 inches in dimensions. This should be fitted with four shelves or false bottoms, in addition to its own, and made to slide along a slot on each side.

As each layer of punnets or baskets is placed on these shelves a sprinkling with water will be advantageous to keep them in a fresh and marketable condition. In this way sixty punnets can be packed and conveyed without being in the least injured. As soon as the first crop is cut no time should be lost in resowing, and it is here especially that great care is needed; for if the rootlets of the second and succeeding crops come in contact with those of the first crop failure and disappointment is the sure result. In the first place, then, the surface must be removed to the depth of 6 or more inches, throwing it together in a heap outside, and mixed with lime, when it may be again used when the roots are thoroughly decomposed. Before taking any fresh compost in the subsoil must be given a thorough watering.

The Mushroom bed manure being convenient as before directed will now be found of further value, as much as is required being mixed with soil, or (which is better suited for Mustard and Cress) an old refuse heap in which there is a quantity of decayed vegetable matter. This screened and mixed with the manure in the proportion of one-half of each will suit them admirably. This should be placed to the same depth as that taken off and made moderately firm.

*Temperature*.—An average temperature of 57° should be maintained, giving top ventilation liberally to allow excessive ammonia to escape, as

it otherwise often happens when shut in a close atmosphere it smells rank and soon decomposes. As the sun gains power the temperature may rise to 90° by day with abundance of air, giving them a sprinkling with a fine syringe three times a day, allowing the moisture to escape, however, before closing for the night. It must not be syringed to the extent of laying it on the ground. If it should get dry and need watering spaces must be opened to pour the water in, having for the purpose in the left hand a T square, with the end of which the dense foliage is gently drawn aside, while with the watering pot in the right hand water is given, gently closing the spaces made after watering. No mention has yet been made as to the space under the border, but as Mustard and Cress would not do well underneath, Rhubarb or Seakale or both would do there, the manure after the Mushroom crop having been left would now be useful for forcing these edibles.

For darkening the space underneath mats could be hung from the border above. As the routine of Rhubarb and Seakale growing is well known, it is unnecessary to dwell here on that subject any further than to state that Rhubarb should be lifted carefully without injuring the fibres nor dividing the crowns, then placing them as closely as possible together, working the manure, in which a little soil has been added, well among the roots—keep well watered and syringed.

In preparing for market those most equal in size must be bunched, tying four or more, according to the season, in the bunch; a firm tie at the base and one at the top being all that is needed. In taking Seakale up for forcing the rootlets may be shortened to within an inch of the base of the stem, then planted in the compost about 4 inches apart each way. When about 6 or 8 inches in length, and nicely blanched, it is fit to cut.

*Total Estimated Results.*—The total estimated results derived from various sources may be summarised as follows:—Computing that eighty dozen bunches of Rhubarb (or the equal value of Seakale) may be got from under the border, at 1s. 6d. per dozen would give £6. For the four crops of Mustard and Cress from 1st January to the end of March, at £25 per crop, would produce £100, added to which is the item for Mustard and Cress from the border from November to January, bringing the total to £137 4s. Deduct for seed, of which 8 bushels would be required, and would cost about £5 6s.

Placing the total Mustard and Cress expenses at 25 per cent. a substantial balance is then left, or a total profit from the Mustard and Cress crop of £103. From "Geraniums," after deducting 30 per cent. expenses, a margin is left of £49. From Mushrooms a total profit of £64 5s., or a grand total of £212 5s. Thus, according to the size of structures used, the foregoing bases may be used in proportion to the structures employed, and will be found to be at least one satisfactory way of solving the problem of "The profitable employment of glass structures in winter."

### BEAUTY IN VINE LEAVES.

THE interesting article by "Market Grower" on page 522 of the Journal draws attention to the beauty that often develops in Vine leaves, and more especially in those of Gros Colman. As I happen to know who "Market Grower" is, and have often seen samples of his skill as a Grape grower, and also admired the beauty of the Vine leaves produced at his place, I was the more interested in the article referred to. Barbarossa has generally been looked on as the Vine capable of producing the most beautifully tinted leaves, but Gros Colman as produced by "Market Grower" excels in beauty even the leaves of that variety. As exhibited by "Market Grower" at various autumn shows the leaves of Gros Colman have attracted the attention of many people, and a good trade has been done in the retailing of them to people who were struck with their wonderful beauty.

We have them here in great variety of tint, and they are often much admired, and sought after; but we never have had them as beautiful as those of "Market Grower." Whether it is any peculiar quality in the soil, the treatment given to the Vines, or from whatever cause I cannot say; but one thing is certain, and that is for beauty the Vine leaves produced at "Market Grower's" place are really remarkable. The demand for these leaves is likely to increase, as when properly pressed, sized, and varnished they last for at least two years, and form most beautiful subjects for house decoration.

"Market Grower" is well entitled to give an opinion on modes of Grape culture, as he is a most successful cultivator of the Vine. High finish is always found in his establishment, and Grape-growing can be seen at its best at "Market Grower's" place. Tomatoes are also cultivated with wonderful success, and the crops produced every year are tremendous. "Market Grower" has opinions of his own on most matters, and is not afraid to act up to them. Certainly his opinions on the culture of the Vine and Tomato must be correct, as the success which annually attends his efforts in connection with both is sufficient to prove.

Those who have not seen Gros Colman leaves as exhibited by "Market Grower" can have little idea of the beauty to be found in them. Nowhere else have I ever seen such rich colours and so much variety, and, whatever may be credited with the production of these tints, one thing is certain, and that is the leaves are simply unique. The bloom and general finish of "Market Grower's" Gros Colman are splendid, and testify to high cultural skill, combined, it may be, with some natural advantages of earth, air, and water.—JOHN THOMSON, Clovenfords.

### SOBRALIA MACRANTHA.

ALL the species comprised in this genus are strong growing terrestrial Orchids with upright reed-like stems, producing their flowers from the apices. *S. macrantha* is the best known and most popular kind, and should be included in every collection. When newly imported the plants require a strong moist heat in order to get strong growth, without which it is useless to expect them to establish themselves, but after a season or two, and when the plants are thoroughly established, they are better at the cooler end of the Cattleya house.

*S. macrantha* has very large fleshy roots, and these require ample sustenance and a rough open compost. The pots should be wide rather than deep, and filled about half their depth with drainage. To insure this always being free, and prevent the earthy parts of the compost from swilling downwards, a layer of moss should be placed on this carefully, but thinly. Spread the roots out as much as possible, but carefully avoid snapping them, and fill in with two-thirds of peat fibre to one of good loam, to which has been added a sufficient quantity of potsherds or charcoal to insure porosity and aëration. There is no need to raise the plants above the level of the rim, so no difficulty will be found in fixing the plants if the roots are abundant, if not, a few stakes will be required. After potting the plants may be syringed daily until

FIG. 99.—DENDROBIUM ILLUSTRE. (See page 566.)

new roots are forming, and a surfacing of moss reduces the task of watering at this stage to a minimum. When they have obtained a good hold of the soil a full supply must be given as long as the plants are growing. When this is complete less is needed, but they do not require to be absolutely dried off at any season, or injurious effects are sure to follow.

Old plants that have been flowering several years have often a lot of weak old stems, that, though not absolutely dead, are of no further use. These should be taken out, in order to admit light to the newer growths, and to allow space for their full development. A good plant of this species, when well grown and flowered, makes a fine display, as the blossoms are very large and showy; and although of an evanescent character, the number produced successively on the racemes keeps up the display for a considerable time. The individual flowers are from 5 to 7 inches across, and very fragrant; rosy purple in ground colour, with a distinct yellow throat. *S. macrantha* is an old inhabitant of our Orchid houses, being introduced over half a century ago from Mexico, and there are several varieties of later introduction. *S. m. albida* is an introduction by Messrs. B. S. Williams & Son, and has a light rose lip, and whitish sepals and petals. *S. m. Kienastiana* is a newer and rare variety, with pure white flowers. *S. m. nana* is, as its name implies, a dwarf form of the type of which the names of *S. m. delicata*, *pallida*, and *splendens* are amply descriptive.—H. R. R.

EVENTS OF THE WEEK.—Rose shows will be very numerous during the next week, and on page 563 a list will be found, compiled by Mr. E. Mawley, of the principal exhibitions in the country.

— WEATHER IN LONDON.—Again we have to deplore the almost total absence of rain in the metropolis during the past week. On Monday morning the sky was overcast, and there was promise of a good rain, but only a very slight shower fell, not, in fact, sufficient to lay the dust, since when the sun has shone daily with great power.

— WEATHER IN THE NORTH.—Rain fell towards the middle of last week, and a good deal of thunder occurred; but a great deal more rain is required in this district. The drought is again very severe. Monday was very warm, and Tuesday morning promised a day equally so.—B. D., *S. Perthshire*.

— ALTRINCHAM GARDENERS' SOCIETY.—The Gardens of Dunham Park, Manchester, were visited recently by the members of this Society, and the stately trees, fine masses of Rhododendrons, and bright display of flowers in the pleasure grounds, and the crops of fruit under glass and of vegetables in the open quarters, proved equally attractive to the visitors.

— CALADIUM ARGYRITES.—This dwarf-growing species is perhaps the most useful of all the numerous varieties now in existence as a decorative plant. Not only does it do immense service when growing in pots, but the leaves when cut are much employed by bouquetists and decorators in general. The decided contrast in silver and green of the leaves seem to harmonise with almost any flower. In groups of miscellaneous plants this Caladium is employed most effectively. Many hundreds of tubers or roots are annually lost during the winter through keeping them in too low a temperature. Nothing less than 55° as a minimum is safe.—E. M.

— WILLIAM I. PEAS.—We sowed about 300 pots (3-inch) with William I. and Exonian Peas on February 12th, started them in a vinery, transferred to a cold frame as soon as they were well up, and planted them out in shallow trenches on March 11th. From this sowing we gathered a peck of well filled pods on June 1st, and had it been necessary we could have got a dish some days earlier. Since then we have picked about 4 bushels. The same sorts, sown in an open quarter on March 4th, are now free for picking. I think this will prove that William I. is still able to hold its own with other varieties; whilst as to productiveness with us there are no two opinions about the matter, as dwarf Peas do not do well with us, and have long since been discarded. I may add that Johnson's Wonderful Longpod Broad Bean, sown in boxes on February 13th, and planted out as soon as ready, is now yielding a good crop of Beans.—THOMAS NUTTING.

— ROYAL METEOROLOGICAL SOCIETY.—The last meeting of this Society for the present session was held on Wednesday evening, the 19th inst., at the Surveyors' Institution, Westminster, Mr. R. Inwards, F.R.A.S., President, in the chair. Mr. R. H. Curtis, F.R.Met.Soc., read a paper on the "Hourly Variation of Sunshine at Seven Stations in the British Isles," which was based on the records for the ten years 1881-90. Falmouth is decidedly the most sunny station of the seven, having a daily average amount of sunshine of 4½ hours. This amount is half an hour more than that recorded at Valencia, and three-quarters of an hour more than at Kew. Of the other four stations, Aberdeen, the most northern, but at the same time a coast station, with 3·64 hours, has more than either Stonyhurst or Armagh, both inland stations; whilst Glasgow, with only 3 hours, or about a quarter of its possible amount, has the smallest record of the seven, a result to some extent due to the nearness of the Observatory to the large manufacturing works with which the City of Glasgow abounds. The most prominent feature brought out at all the stations is the rapid increase in the mean hourly amount of sunshine recorded during the first few hours following sunrise, and the even more rapid falling-off again just before sunset. Mr. H. Harries, F.R.Met.Soc., also read a paper on the "Frequency, Size, and Distribution of Hail at Sea."

— THE paper on nitrogenous manures and their effect was read by Mr. J. Guy, not Mr. J. Gay, as given on page 544.

— WE learn with pleasure that Mr. P. C. M. VEITCH, of the firm of ROBERT VEITCH & SON, Royal Nurseries, Exeter, was recently made a Magistrate and Justice of the Peace for the city of Exeter.

— AUSTRALIAN FRUIT.—The Peninsular and Oriental Company's steamer "Massalia" arrived in London recently with the following consignments of Apples:—From Hobart, 16,515 cases, 106 small cases, and 100 half cases; from Melbourne, 208 cases; and from Adelaide, 146 cases, or a total of 17,244 cases large and small.

— CARTER'S UNIVERSAL BROCCOLI.—I noted some time ago that this was the only hearting Broccoli that had come safely out of the winter ordeal. It is not only the one sort that did not succumb, but is also a valuable late variety, and has overlapped early Cauliflower by a few weeks. Of the latter I may say that Veitch's Forcing has been fine, and has not only given a good central head, but most plants have also produced three or four smaller side heads.—R. P. BROTHERSTON.

— WALKS IN BELGIUM AND THE ARDENNES.—To those who anticipate a holiday in Belgium the little book now before us should prove of the utmost value. The notes are of the most interesting, and at the same time elucidatory character, the illustrations being another good feature. To this edition further utility has been added by the excellent maps, and also a chapter on the French Ardennes, a delightful district replete with modern interest and historical romance. As the book is published at 6d, it should be in everyone's hands, and may be procured from 30, Fleet Street, London. To tourists the name of Mr. Percy Lindley as editor will be a sufficient criterion of its worth.

— THE EFFECTS OF THE FROST.—I am forwarding you a few tops of Potato and Runner Bean growths, which were severely damaged by frost on the morning of Saturday, the 15th inst. Is not such an occurrence so late in this month almost if not quite unprecedented? The frost was not general, I believe, even in this neighbourhood. The blackened growths I send were taken from an allotment a quarter of a mile from here, but nothing was injured in my garden. With the days intensely hot during the past week or two the nights have been very cold. At four o'clock this morning, with the sun shining brightly, the temperature was 38°. Rain is badly wanted for all crops, and unless we are favoured with some very soon many things will be partial if not total failures.—CHARLES LOCK, *Mangotsfield, near Bristol*. [It is very unusual for Potato and Runner Bean growths to be blackened and cut off by frost, as those you sent had been, in a serious manner at the middle of June. We have known similar cases as late as the 6th of June, and in one instance on the 13th of that month, but in no case so badly as those shown in your specimen. The extreme drought and consequent evaporation, with condensation during the night, was, no doubt, the cause of the frost's occurrence.]

— A REMARKABLY DRY SEASON IN IRELAND—A PECULIARLY FINE ROSE.—There has been a comparatively small rainfall in Ireland for upwards of two months. A shower now and then merely wets the surface. The soil in my garden I find is dry fully 12 inches, and except plants and flowers are both mulched and watered they show the effects; some of these are unusual and worthy of note. As remarked in a former number of the Journal there is almost an entire absence of slugs and snails, so much so that you rarely notice a Strawberry either eaten or crawled over. There is not a trace of their customary ravages on Lettuce, Marigolds, Dahlias, or such like succulent food. I am not sure that the heavy snowfall and cold of February has not something to do with this. Potatoes, while very healthy and little likely to be affected by blight, owing to the stiff hard leathery ripeness of the foliage, are smaller than usual. Flowers dependent on surface moisture or an imperfect supply of water, will not fill up properly; while others, as Pyrethrums, Pæonies, and all the early flowering perennials, had a very short season's bloom. The outdoor fruit prospect may be safely predicted apart from this season's supply; next year's crop will be unusually prolific, so far as it is dependent on well ripened wood. Never have I seen finer Roses, even Maréchal Niel and William Allen Richardson have been blooming profusely for six weeks in the open air, and now Ethel Brownlow, Kaiserin Victoria, and Mrs. Sharman-Crawford continue the glorious tale. One other Rose that no collection should be without, is the one exceeding all others, the Marchioness of Downshire—fine white satin rose, shaded pink, with petals of great substance and grand foliage.—W. J. MURPHY, *Clonmel*.

— GARDENING APPOINTMENT. — We are informed that Mr. W. H. Godden has been appointed head gardener to F. W. Buxton, Esq., Pishiobury, Harlow.

— ARBOUR DAY IN THE UNITED STATES.—A day has been fixed on annually for the planting of trees by a great number of the States of the American Union. The law which has established Arbour Day in the State of New York dates only from 1888, and in three years it has planted on a fixed day more than 25,000 trees.

— LONDON PANSY AND VIOLET SOCIETY.—A meeting of the members of this Society took place on the 17th inst., Dr. Shackleton of Sydenham occupying the chair. A large number of new members were elected, and final arrangements made for the annual show of the Society, which will take place at the Crystal Palace on Saturday, July 6th.

— FLOWERS FOR THE POOR.—In drawing attention to the pleasure that may be given by the distribution of a few flowers among the London poor, Lord Monkswell asks us to remind readers who have gardens that they can all render some help in this good work. Addresses to which flowers may be sent direct will be supplied on application to the Hon. Sec. of the Flower Distribution Branch, Kyrle Society, 49, Manchester Street, W.

— ROYAL SHOW AT DARLINGTON.—Horticulturists were represented at the Darlington show in fair numbers and with handsome exhibits. Amongst the most prominent were the stands of Messrs. Carter & Co., High Holborn, London; Sutton & Sons, Reading; E. Webb & Sons, Stourbridge; Dicksons (Ltd.), Chester; Little and Ballantyne, Carlisle; W. Fell & Co., Hexham; Harrison & Sons, Leicester; and the Agricultural and Horticultural Association.

— THE NURSERYMEN, MARKET GARDENERS', AND GENERAL HAILSTORM INSURANCE CORPORATION, LIMITED.—The statutory general meeting of this Corporation was held at Simpsons' (Limited), Strand, on Friday, 21st June, 1895. The Chairman, Mr. Harry J. Veitch, reported that the shares had been applied for freely, thus providing perfect security for policy holders. Though established only four months, 100 policies had been issued on 6,720,832 square feet of glass, valued at £80,542 2s. 8d., and producing £415 11s. 8d. in premiums. This amount would be considerably augmented by the midsummer and Michaelmas business. No claims had yet been received. The capital had been invested in Government Stock. Twenty-six agents had already been appointed in the United Kingdom. The Corporation was being worked with economy, and was making good progress. The Directors would take no remuneration in any year when less than 5 per cent. on the subscribed capital was made, and then only such sum as the shareholders in general meeting voted to them. From the tone of the meeting the report was considered very satisfactory. Messrs. Harry J. Veitch, James Sweet, and James Webber were appointed Trustees, and the meeting closed with a vote of thanks to the Chairman.

— WOKING HORTICULTURAL SOCIETY.—This excellent and very courageous Society ventures to hold monthly meetings, and have lectures on set subjects all the year round, let the weather be ever so hot or the evenings ever so fine. Just so was it on Thursday evening of last week, when the usual meeting for June was held in a large room adjoining the Railway Hotel. There was found quite a miniature flower show, Messrs. G. Jackman & Sons setting up a pretty collection of hardy border flowers, including many good Pinks, garden Roses in bunches, and some excellent plants of Streptocarpus. From various amateurs and gardeners came Violas in sprays, Pansies, Gloxinias, and many dishes of capital fruit; cottagers also showed largely of both hardy fruit and vegetables. Some small prizes and certificates are awarded at these meetings, the Judges being at them publicly elected, and these awards seem to encourage quite a lively competition. In the absence of the President (Mr. Orlando Law), the Treasurer (Mr. Taylor) presided, the lecture being given by Mr. A. Dean, representing the Surrey County Council, whose theme was "Spring and Summer Bedding Plants," chief stress being laid on the former because all hardy, and also because the time is both now and approaching when preparations for their propagation should be made. The lecturer specially advocated the use of the very early bloomers, such as Primroses, Polyanthuses, Daisies, Pansies, Violas, Aubrietias, Anemones, and similar plants, as being ready to clear off in ample time for the summer bedding. The changing forms of bedding as now seen in parks and gardens were referred to, and the varieties of plants mostly employed. A very cordial vote of thanks to the lecturer was awarded at the close.

#### ROSE SHOW FIXTURES FOR 1895.

- June 28th (Friday).—Exeter.  
 „ 29th (Saturday).—Windsor.  
 July 2nd (Tuesday).—Diss, Maidstone, and Sutton.  
 „ 3rd (Wednesday).—Brockham, Croydon, Ealing, Farningham, Lee,† and Sittingbourne  
 „ 4th (Thursday).—Eltham and Norwich.  
 „ 6th (Saturday).—Crystal Palace (N.R.S.).  
 „ 9th (Tuesday).—Ipswich, Westminster (R.H.S.), and Wolverhampton.\*  
 „ 10th (Wednesday).—Chelmsford, Farnham, Hitchin, and Redhill (Reigate).  
 „ 11th (Thursday).—Bath, Great Malvern (Hereford Rose Society), Helensburgh, Woodbridge, and Worksop.  
 „ 17th (Wednesday).—Derby (N.R.S.).  
 „ 18th (Thursday).—Canterbury (Kent Hospital Fête) and Halifax.  
 „ 20th (Saturday).—Manchester.  
 „ 23rd (Tuesday).—Tibshelf.  
 „ 24th (Wednesday).—Chesterfield and Newcastle-on-Tyne.\*  
 „ 25th (Thursday).—Trentham.  
 Aug. 3rd (Saturday) and 5th.—Liverpool.†

\* A show lasting three days. † A show lasting two days.

—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

#### NEW ROSES.

IN our last issue (page 547) we made reference to two new Roses of which blooms had been sent to us by Messrs. W. Paul & Son, Waltham Cross. Since then we have discovered another excellent point about them that should certainly be placed on record, and that is their superb lasting qualities. After having been in water for six days the specimens of Queen Mab were as fresh in colour and fragrant as when first received, while those of the Sylph were just commencing to droop. For Roses this is an extraordinary space of time to last in the best condition, and should assist materially in placing both in the highest positions. In examining at more leisure the colour of the former we think deep salmon approaching to coral will be a better description. The colour of the Sylph may perhaps be more simply stated as a deep blush pink.

#### MILDEW.

AS a rule Tea Roses do not suffer so much from this pest or at such an early period of the year as H.P.'s and other Roses, but "exceptions prove the rule," and this year I had mildew among my Teas in May. It was to be accounted for, I think, as a simple case of infection, due to a little of that carelessness which is always to be found, we are told, in the best regulated families.

I believe my remedy to be the best, but it is not practicable when the mischief is widespread, as it takes some time. I hold a tin of sulphur in my left hand, and taking a small pinch in my right between finger and thumb, just rub each leaf at the same time gently on both sides. It does not take very long with a little practice if there are not many curled and whitened leaves to be seen. My theory is that the mycelium is broken and disturbed, and the sulphur applied to the interior—to "the raw"—so to speak, of the pest, at the same time; and in practice I find it more efficacious than anything which does not involve rubbing.—W. R. RAILLEM.

#### COLCHESTER ROSE SHOW.—JUNE 20TH.

THE first show of the restored Colchester Rose and Horticultural Society was held on June 20th in the grounds of C. E. Egerton-Green, Esq., the Mayor. Mr. O. G. Orpen being one of the Hon. Secretaries, and an energetic worker for the Society, it is not surprising that the schedule was drawn out with the care which characterises that gentleman's exhibits, and that Roses and decorations formed the principal features in the prize list. There were not a few who prophesied disaster, at all events in amateur entries, when such an unusually early date was decided on; but good fortune in this respect befriended those responsible for the choosing of the day, and the early season brought a larger muster of exhibitors from a distance than the prophets of evil anticipated. The weather was fine, with the exception of a sharp shower for a quarter of an hour about eleven o'clock, which was not enough to do any harm or (as some muttered) any good. Roses were well shown by the trade growers, but there was a great lack of quality and substance in the H.P.'s shown by amateurs, though the Teas were good.

In the class, for thirty-six Roses, open to all, the first prize was won by Mr. B. R. Cant with a good even stand in quite the old style. Among his best blooms were Mrs. J. Laing, Mrs. Sharman Crawford, and La Fraicheur. Mr. Frank Cant was second, winning the Colchester Rose medal for the best Rose in the open classes with a superb bloom of La Fraicheur. This is truly a very beautiful variety, of dwarf growth, very early, and a bad one to carry, lasting but a short time;

but in shape, colour, and size it is quite first-class. There was a good Souvenir d'Elise in the same stand, and a huge Her Majesty at the top corner, quite twice the size of any other bloom in the row. Messrs. W. D. Prior & Son were not a had third, Dupuy Jamain and S. M. Rodocanachi being among their best.

In class 2, for twelve Teas, open, Messrs. Prior were a good first, their box being very well set up, bright, clean, and effective; Mr. B. R. Cant was second, there being no exceptional blooms in these stands. Mr. Frank Cant was third with smaller flowers, Ethel Brownlow and Corinna being neat and good.

Class 3, open, was a novelty; twelve bunches, not more than seven trusses to a bunch, to be arranged in a certain space in vases or bottles. Tall, plain brown vases, of a very useful nature, were employed by all. The first prize was won by Messrs. Prior, who had relied mainly on Teas, which are bound to beat H.P.'s for decorative qualities; anything besides H.P.'s, H.T.'s, Teas or Noisettes, were not allowed by the schedule. The judges had much difficulty in deciding between the two remaining exhibits, eventually giving the second place to Mr. Frank Cant's group, which was the lighter of the two, and contained an effective bunch of the striped Rainbow, while Mr. Benjamin Cant's collection, which had the finest blooms, had to take third place.

In class 4, twenty-four Roses (amateurs), the first prize was taken by Mr. J. G. Fowler of Woodford; the second by Mr. R. E. West of Reigate; and the third by Rev. A. Foster-Melliard. A poor class.

In class 5, twelve Teas, Rev. A. Foster-Melliard was first; Mr. Orpen second; and Mr. J. C. Tasker third. There was nothing particularly noteworthy here, and it was sad to see Mr. Berners and Mr. Page Roberts present without any Teas to show. The next six classes were for small growers and local residents, and these were fairly filled, Mr. Landon of Brentwood showing six fine Teas.

The principal interest centred round class 12, twelve Roses, open to all amateurs, for a cup given by the Mayor. This was won by Rev. J. H. Pemberton, who alone of the amateurs present seemed to have H.P.'s of any size or quality, and these were not up to his usual form, his Horace Vernet, which gained the Colchester medal as best amateur H.P., being not a Rose of exceptional merit. Mr. Orpen was second with a very neat box, Catherine Mermet, Niphotos, and The Bride being good flowers. The latter bloom gained the medal as best Tea. Mr. Foster-Melliard was third, having also here his three best Teas, Maréchal Niel (which had a long tussle for the medal), Innocente Pirola, and Princess of Wales. Four other boxes were shown.

For four trebles Mr. J. G. Fowler was first; Mr. Foster-Melliard, whose varieties were unfortunately nearly all of one colour, second; and Mr. Orpen third. For six Maréchal Niels Mr. Arthur Cant was first; and Mr. Mawley, of Berkhamsted, second. For six Roses of any sort Mr. Page Roberts was first with Gabriel Luizet; Mr. H. P. Landon second with Souvenir de S. A. Prince; and Miss Penrice, of Norwich, third with La France. There were no entries for a class of garden Roses.

The scribe had literally no time to look into the tent devoted to decorations, for, his Rose task finished, he was simply held fast by a vase of *Calochortus venustus* in variety, exhibited by Messrs. R. Wallace and Co. of Colchester, and was only dragged from a minute examination of these, surely among the most beautiful of flowers on God's earth, by friends who assured him that the brake was just going off to luncheon without him. This very desirable event to exhibitors who have breakfasted very early was most kindly provided by Mr. Frank Cant in a tent adjoining his house and Rose grounds, to a large number of what might really be called "leading horticulturists" from all parts of the country. The trophy prettily filled with Rose Laurette Messimy graced the centre of the table, and the very posts were adorned with climbing Roses in full flower.

At Mr. Mawley's invitation the guests drank to the health of Mr. and Mrs. Frank Cant, and then adjourned to the Rose grounds, a goodly company of critics, who were all pleased to see a much fuller crop of maiden standard Teas than they expected. A stand was made round six plants of Mrs. W. J. Grant from America just planted out, and much wonder was expressed as to how they came to be sent out in a dormant state at this time of year. Some laughter, and I think also some applause, was heard when a tall gentleman was observed bending himself almost double to scribble energetically on the name label with his pencil. Soon after this incident the company dispersed. Some were very anxious to see Mr. B. R. Cant, who was said, to the great regret of all, to be unwell, but there was not time to see him, much less his Roses. Messrs. Prior's ground being much nearer the station, a few invaded them for a very short time, and took away by train an impression that their Rose plants looked very promising, and that their Strawberries, when eaten by handfuls, were very good too.—  
W. R. RAILLEM.

### FIGHTING INSECT PESTS.

IN the article under the above heading, page 534, especial stress is laid on that insidious pest, red spider. It is, indeed, most troublesome when it has obtained a firm footing on the foliage of any plant, and it is perhaps more difficult to deal with when on the leaves of Vines bearing a crop of large bunches that were at one time looked on as likely prizetakers at some exhibition or other.

I cannot agree with "Pomona," however, that washing the leaves with soapy water is the best remedy for the destruction of this insect. I have in years past spent many hours sponging the leaves in the hope of ridding the Vines of this pest, but after carefully using many mixtures,

both original and well known, very little real good was done. I found to my sorrow several times that some of my best bunches had been rubbed, and were consequently minus what all good judges like to see—bloom.

I never attempt to sponge Vine leaves nowadays to rid them of red spider, but apply a much more simple remedy. I have found dry sulphur scattered over and underneath the affected leaves so efficacious that nothing more was wanted. The actual seat of the enemy must be found and thoroughly covered with sulphur. An ordinary hand distributor I find the best to apply the sulphur with, and I like brown sulphur much the better; it is quite as strong and not so glaring in appearance as the ordinary sort. I do not care for the plan of painting the hot-water pipes with sulphur with the notion that the fumes will destroy the pests. When the pipes are extra heated during the time the Vines are in bloom the fumes from the remaining sulphur, even after that lapse of time, have spoilt many bunches by destroying the tender skin of the berries.

Attending a lecture a week since the same subject came up during discussion. A person in the audience promptly gave a recipe for killing red spider on Vines, which was this:—"During the afternoon thoroughly douse the Vines and vinery with water, not just sprinkle them only, but a thorough drenching; then close the house, allowing the heat in the vinery with sun to rise to 140°." He assured us a single red spider could not possibly live!—E. M.

### IRIS ASIATICA.

IRISES have always been popular, and at the present time they are accorded more favour than has ever been the case previously. Considering this, it is no matter for surprise that the handsome new variety as that depicted in the woodcut (fig. 100) should have attracted such an amount of attention when staged by R. Wallace & Co., Colchester, at the Drill Hall on the 11th inst. The habit is robust, and the plants are very floriferous. The standards are of stout texture and bright blue colour, while the falls are of rich violet blue with golden veins. An award of merit was deservedly accorded by the Floral Committee of the Royal Horticultural Society.

### ROYAL HORTICULTURAL SOCIETY.

JUNE 25TH.

WITH such brilliant weather it is perhaps needless for us to say that at the Drill Hall on the above date there was a glorious display of flowers. This was more especially the case in the hardy flower section, which was extremely diversified. The Orchid exhibits were generally of excellent quality, but not large in numbers. Melons and vegetables formed the major portion of the produce before the Fruit Committee.

FRUIT COMMITTEE.—Present: Dr. R. Hogg (in the chair); with the Rev. W. Wilks, and Messrs. G. W. Cummins, A. Young, A. H. Pearson, J. A. Laing, C. Herrin, G. Wythes, F. Q. Lane, G. Norman, R. Fyfe, and A. Dean.

On this occasion the members of the Fruit Committee had more before them than has been the case at recent meetings. Mr. Thomas Coomber, gardener to Lord Llangattock, The Hendre Gardens, Monmouth, sent a dozen creditable Pines and a large Melon (silver Banksian medal). Messrs. Rivers & Son, Sawbridgeworth, staged samples of "Early Rivers" Nectarine, and G. F. Wilson, Esq., Weybridge, sent a small basket of Strawberries, "Laxton's Latest of All." Mr. Norman, gardener to the Marquis of Salisbury, Hatfield, sent a dozen fine fruits of Melon Hatfield Scarlet Flesh.

Mr. A. Bishop, gardener to R. Burrell, Esq., Westby Hall, Bury St. Edmunds, staged a fruit of Melon "Bishop's Favourite" (award of merit). Mr. G. A. Bishop, Wightwick Manor, Wolverhampton, sent a large fruit of "Wightwick Manor Favourite." Mr. B. Ashton, gardener to Lord Howard, Glossop Hall, staged a fruit of Melon Baron Howard. Mr. E. Johnson, gardener to — Gilliet, Esq., staged Melon "Johnson's Seedling." Mr. Owen Thomas, The Royal Gardens, Frogmore, sent fruits of Melon The Duchess, and Cucumber "Frogmore Gem." Mr. Charles Brooks, gardener to H. A. Simmonds, Esq., Andover, Hants, staged fruits of Red Rice Perfection.

From the Society's Gardens at Chiswick came Strawberries of varieties Princess Royale, Acquisition, Leader, Bothwell Bank, and others. Mr. R. Gilbert, gardener to the Marquis of Exeter, sent large fruits of Strawberry "Royal Sovereign." Messrs. Laxton Bros., Bedford, staged a grand collection of Strawberries comprising fifty varieties. Amongst others were fine samples of Laxton's Monarch, Laxton's Royal Sovereign, Waterloo, and Laxton's Sensation. Considering the extreme drought the samples were in every way creditable. Mr. S. Mortimer, Rowledge, sent fruits of New Melon Eclipse, and samples of Cucumber Marvel. Mr. H. W. Ward, gardener to the Earl of Radnor, staged fruits of Melon The Earl's Favourite, and also a collection of Peas.

Mr. G. Wythes, gardener to Earl Percy, Syon House, sent fruits of Melon "The Gem," and good examples of Veitch's "Early Forcing Cauliflower," Peas Daisy, Stratagem, and Sensation. Mr. G. W. Cummins, gardener to A. H. Snee, Esq., Wallington, staged good samples of Runner Bean "Ne Plus Ultra." Messrs. J. Veitch & Sons, Chelsea, staged a splendid collection of Spring Cabbages in variety, and also excellent dishes of Peas of many early varieties.

Mr. J. Corbett, gardener to the Rev. The Marquis of Normanby,

Mulgreave Castle, sent fine examples of Tomato "Excelsior." Mr. R. Filkins, gardener to Miss Alexander, Chislehurst, staged Potatoes Queen of the Earlies and Early Laxton for comparison. Messrs. Jas. Carter, High Holborn, sent samples of "Long Standing" and "The Carter" for comparison. The same firm also sent fine plants in pots of Tomato Duke of York, which were thickly covered with excellent fruit.

— FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. H. B. May, H. Herbst, R. Dean, G. Stevens, H. Selge Leonard, J. D. Pawle, G. Gordon, J. T. Bennett-Poë, J. W. Barr,

Messrs. James Veitch & Sons, Chelsea, were well represented in a fine exhibit of hardy flowers, in which Delphiniums were a feature. Amongst others were noticed True Blue, Castro, George Taylor, Britannia, Lord Balfour, Masterpiece, Lord Brassey, and Diomedes. Amongst other flowers were Phloxes Mrs. J. Ross, Forward, A. McKinnon, and Mrs. Gibson Black, Aquilegia chrysantha, Chrysanthemum maximum, Erigeron speciosus, Heuchera sanguinea, Centaurea montana rosea, Spiraea filipendula, Campanula macrantha, and Veronica latifolia (silver-gilt Flora medal). From the same firm came an excellent exhibit of Roses, consisting of cut blooms of Marchioness of Dufferin,

FIG. 100.—IRIS ASIATICA.

J. Walker, H. J. Jones, C. Blick, G. Paul, C. E. Shea, J. Laing, C. T. Drury, and H. Cannell.

Messrs. Cutbush & Son, Highgate, exhibited a fine bank of Malmaison Carnations in pots, many of the blooms being exceptionally large (silver Banksian medal). From Mr. T. S. Ware, Tottenham, came a large and varied collection of hardy flowers. The exhibit was arranged with taste, and consisted of Delphiniums in variety, Spiraea astilboides, Lilium colchicum, Inula glandulosa, Alstroemeria chilensis, Aquilegia chrysantha, Lilium Dalhamsoni, Erigeron speciosus grandiflorum, Campanula cordata, with Irises, Papavers, and other flowers (silver Flora medal).

Merveille de Lyon, A. K. Williams, Catherine Mermet, Duke of Edinburgh, Viscountess Folkestone, Madame Cusin, Ulrich Brunner, La France, Marie Van Houtte, and others.

Messrs. R. Wallace & Co., Colchester, staged hardy flowers, which included Liliiums, Irises, and a fine collection of Calochortus, of varieties venustus oculatus, venustus pictus, pulchellus, venustus citrinus, venustus vesta alba, venustus roseus, and others (silver Banksian medal). From Messrs. Geo. Jackman & Son, Woking, came a varied collection of cut flowers, consisting of several good stands of Roses, spikes of Delphiniums, fine flowers of Iris pyrenaica, with Pinks Ernest Ladhams and Her Majesty, Potentilla Golden Cup, Phlox Mrs. Baxter,

*Coreopsis grandiflora*, and others, the whole forming a pleasing effect (silver Banksian medal). Messrs. Paul & Son, Cheshunt, sent a group of single and other Roses of varieties Perle d'Or, Perpetual White, Copper Austrian Bride, Maiden's Blush, *Rugosa alba*, Janet's Pride, Paul's Carmine Pillar, Andersoni Celestial, with flowers of Hybrid Perpetuals Bacchus and Alan Cheales, and blooms of *Pæonia Madame de Galhan* (bronze Banksian medal). A superb collection of Carnation blooms was staged by Mr. C. Blick, gardener to M. R. Smith, Esq., Hayes, Kent; principal in the exhibit were Lady Ridley, George Cruikshank, Zoë, Cowslip, Princess May, Corunna, Hayes Scarlet, and Sir Evelyn Wood.

From Messrs. J. Cheal & Sons, Crawley, came a fine exhibit of hardy flowers and Violas, the latter being staged in great variety. Mr. M. Pritchard, Christchurch, staged a fine group of hardy flowers, consisting of *Gaillardias*, *Spiræas*, and *Delphiniums* in variety, with *Potentilla California*, *Dianthus cruentus*, *Papaver nudicaule*, *Orchis foliosa*, *Achillea mongolica*, *Cephalaria alpina*, and many others (bronze Banksian medal). Pots of dwarf Sweet Pea Cupid were staged by Mr. Burpee, Philadelphia.

Mr. G. A. Farini, Forest Hill, sent a collection of *Begonia* flowers, many of which were very large. From Mr. J. Prewett, Swiss Nurseries, Hammersmith, came *Gloxinia* blooms of several delicate tints of colour.

Mr. G. B. Baskett, gardener to Lord Penzance, staged boxes of seedling Roses, both single and double and of several tints in colour. From Messrs. T. Cripps & Son, Tunbridge Wells, came plants *Hypericum Moserianum tricolor* and *Philadelphus Boule d'Argent*. Messrs. F. Sander & Co., St. Albans, staged plants of *Dipladenia atro-purpurea* and *Echinocactus aureus*. A small mixed collection of plants came from Messrs. John Laing & Sons, Forest Hill, consisting of *Begonias* J. T. Bennett Poë, Mrs. H. B. May, Lady Esther Smith, and Prince Adolphus of Teck, together with *Gloxinias* and other plants. Mr. W. Taylor, Osborn Nursery, Hampton, sent a collection of new Rose Robin Lyth.

From Messrs. Dobbie & Co., Rothesay, came an excellent group of Sweet Peas, Pansies, and Violas in great variety. The latter were represented by many of the best kinds, and the former by Princess May, Firefly, Duke of York, Empress of India, Monarch, Orange Prince, Lady Beaconsfield, Mrs. J. Chamberlain, and many others. Mr. T. Mann, gardener to C. F. Thompson, Esq., Penhill, Cardiff, sent a small but varied collection of *Delphinium* spikes (silver Banksian medal).

Messrs. Barr & Son, Covent Garden, staged a large collection of *Pæonies* and other hardy flowers, consisting chiefly of *Phloxes* Charles Downie and Snowdon, *Irises aurea* and *ochroleuca*, *Gaillardias grandiflora hybrida*, Pink Her Majesty, and others (silver Banksian medal). Messrs. H. Cannell & Sons, Swanley, Kent, exhibited a large and interesting group of Cacti, plants of *Zonal Pelargonium* double Henry Jacoby, *Gloxinias*, Cannas, and fruits of new Strawberry Royal Sovereign. Amongst the former were many novelties in the shape of *Agaves*, *Euphorbias*, *Echinocactuses*, *Sempervivums*, *Mammillarias*, *Echeverias*, *Opuntias*, and others (silver Flora medal). From the Royal Botanic Gardens, Glasnevin, came flowers of *Fremontia californica*; and from Mr. Anthony Waterer, Woking, specimens of *Philadelphus Lemoinei*. Mr. R. Dean, Ealing, sent spikes of Dyson's Giant Crimson Ten-week Stock.

ORCHID COMMITTEE.—Present: S. Courtauld, Esq. (in the chair); with Messrs. J. O'Brien, De B. Crawshay, H. M. Pollett, F. Hardy, E. Ashworth, T. Statter, J. T. Gabriel, H. Ballantine, H. J. Chapman, E. Hill, W. Cobb, J. Douglas, and T. B. Heywood.

The group of Orchids arranged by Messrs. J. Veitch & Sons, Chelsea, was very diversified and of much interest. Many very handsome kinds were staged, the flowers being remarkable for brilliant colouration, and the plants for their excellent health. Particularly prominent were *Cattleya Mendeli* in variety, *C. Mossiæ*, *C. Warscewiczii*, *Lælio-Cattleya Arnoldiana*, *L. C. Canhamiana alba*, *Thunia Veitchiana*, *Cœlogyne Dayana*, *Dendrobium illustre* (a hybrid described below, which was accorded a first-class certificate), *D. Deari*, *Odontoglossums vexillarium*, *cordatum*, *Pescatorei*, *Oncidium pulvinatum*, *O. phymatochilum*, *O. macranthum*, *Epidendrum vitellinum majus*, *Disa Veitchi*, *Cypripediums* in variety, and numerous others (silver Flora medal).

A few beautiful Orchids were shown by Messrs. Hugh Low & Co., Clapton, and comprised *Cypripediums* Gertrude Hollington, *C. Masoni*, a hybrid between *C. Stonei* and *Spicerianum*, forms of *Odontoglossum crispum*, *Cœlogyne pandurata*, and others (silver Banksian medal). *Odontoglossum crispum*, *Epidendrum vitellinum majus*, *Cypripedium Elliottianum*, *Lælio-Cattleya eximea* and *Lælia tenebrosa* Walton Grange var. were conspicuous in the small exhibit of Orchids staged by J. Gurney Fowler, Esq., Glebelands, South Woodford (silver Banksian medal).

Orchids were also exhibited in good variety by Mr. R. Aldous, gardener to H. T. Pitt, Esq., Stamford Hill. *Oncidium phymatochilum*, *Lælia tenebrosa*, *Cypripediums* and *Odontoglossums* in variety, and a few others (silver Banksian medal). From A. J. Hollington, Esq., Enfield, came *Cypripedium Millmani*, a seedling from *C. Lawrenceanum* and *C. lævigatum*, and also *C. Aylingi*. Mr. T. Stafford, gardener to Fred Hardy Esq., Ashton-on-Mersey, arranged the brightest collection in the show. *Lælia grandis tenebrosa* (see below), *Cypripediums*, and several handsome *Cattleya* composed this stand (silver Flora medal). A plant of *Odontoglossum Alexandræ Niobe* was shown by Messrs. W. Cutbush & Sons, Highgate; and Messrs. Charlesworth & Co., Heaton, Bradford, showed *Cattleya Mendeli*, Charlesworth's variety. *Orchis latifolia*, Glasnevin variety, was sent by Mr. F. W. Moore, Botanic Gardens, Glasnevin.

De Barri Crawshay, Esq., Rosefield, Sevenoaks, showed *Lælia purpurata Venus* and *Odontoglossum crispum Crawshayanum*. T. Statter, Esq., Stand Hall, Manchester, staged a few Orchids, including *Cattleya Warscewiczii*, which received an award of merit. J. Bradshaw, Esq., Southgate, showed *Lælia grandis tenebrosa*; while F. M. Burton, Esq., Gainsborough, sent *Cypripedium Burtoni*. A botanical certificate was accorded to Mr. H. J. Chapman, gardener to R. I. Measures, Esq., for *Pleurothallis immersa*.

Messrs. F. Sander & Co., St. Albans, did not make such an imposing display as is usually the case; but each exhibit was of good quality and of much interest. Amongst the most noticeable were *Cypripediums*, *Cattleyas*, *Odontoglossums*, *Thunias*, and *Lælio-Cattleya C. G. Roebling*, for a description of which see below.

#### COMPETITIVE CLASSES.

In the class for a collection of Cactaceous plants there was apparently only one competitor, W. C. G. Ludford, Esq., Sutton Coldfield, Birmingham, who was accorded the premier prize. *Mammillarias*, *Echinocactus*, *Opuntias*, and *Cereus* in variety mainly comprised this interesting exhibit.

For twelve bunches of herbaceous flowers there were two exhibitors, and Mr. G. H. Sage, The Gardens, Ham House, Richmond, was deservedly adjudged the first prize. Handsome examples of *Lilium croceum*, *Gladiolus The Bride*, *Chrysanthemum maximum*, *Oenothera Fraseri*, *Lathyrus latifolius*, *Erigeron speciosa*, *Delphiniums*, *Potentilla Wm. Rollison*, *Campanula persicifolia coronata*, *Papaver nudicaule*, *Centaurea macrocephala*, and *Pæonies* comprised the stand. Miss Debenham, St. Peter's, St. Albans, was a fair second.

Mr. Herrin, Dropmore Gardens, Maidenhead, secured the first position in the class for eight bunches of hardy herbaceous flowers with *Delphiniums*, *Verbascum Choixi*, *Campanula persicifolia*, *Clematis recta*, *Irises*, *Spiræa japonica*, *Pæonia Charles Binder*, and *Pinks* Mrs. Sinkins and Dropmore Pink. Mr. H. A. Hare, Much Hadham, Herts, was a rather poor second. Mr. A. Crossman, gardener to J. Brutton, Esq., Yeovil, staged handsome *Delphiniums*, and was accorded the first prize, as also was the same exhibitor for *Pæonies*, but these were almost all poor.

#### CERTIFICATES AND AWARDS OF MERIT.

*Begonia J. T. Bennett-Poë* (J. Laing & Sons).—A handsome double variety with bright scarlet flowers (award of merit).

*Begonia Prince Adolphus of Teck* (J. Laing & Sons).—A handsome double variety with shapely crimson scarlet flowers (award of merit).

*Calochortus venustus pictus* (R. Wallace & Co.).—This is exceedingly beautiful. The upper portion of the flower is pure white, the base being reddish brown and covered with hairs (award of merit).

*Carnation Couslip* (C. Blick).—This is a very charming yellow ground with bright rose markings. The petals are strong and broad, but destitute of scent (award of merit).

*Carnation George Cruikshanks* (C. Blick).—This is a medium-sized variety with bright reddish buff coloured blooms (award of merit).

*Carnation Joe* (C. Blick).—This is very handsome with substantial flowers, which are unfortunately scentless. The colour is pink with a faint bluish shading (award of merit).

*Carnation Lady Ridley* (C. Blick).—This fine double white variety has broad, stout petals of faint clove scent (award of merit).

*Cattleya Warscewiczii* (E. Hill).—The sepals and petals of this Orchid are intense purplish rose in colour, while the lip is rich velvety crimson purple (award of merit).

*Dendrobium illustre* (J. Veitch & Sons).—This handsome *Dendrobium* is a hybrid resulting from *D. Dalhousianum* and *D. chrysotoxum*, each of which is perceptible. The substance of the flower is very good, as also is the form. The sepals and petals are pale yellow, deepening towards the tips. The outer portion of the lip, which is broad, is bright yellow, the inner part being deep maroon. The woodcut (fig. 99, p. 561) sketched at the Drill Hall, admirably portrays this beautiful hybrid (first-class certificate).

*Lælia grandis tenebrosa Charlesworthi* (F. Hardy).—This is a fine variety with rich reddish brown coloured sepals and petals, and a bluish purple lip with a dark velvety throat (award of merit).

*Lælia tenebrosa Pittiana* (H. T. Pitt).—This is a very pale coloured form of the type (award of merit).

*Lælio-Cattleya C. G. Roebling* (F. Sander & Co.).—This is a bigeneric hybrid obtained by crossing *Lælia purpurata alba* and *Cattleya Gaskelliana*. The sepals and petals are a very delicate blush and of great substance. The lip is rich maroon, edged with white and having a canary yellow throat (first class certificate).

*Lilium Dalhamsoni* (T. S. Ware).—This is a dark reddish brown coloured *Lilium*, with occasional yellow markings (award of merit).

*Melon Bishop's Favourite* (A. Bishop).—This is a white-fleshed Melon of handsome appearance and medium size. The flavour is sweet and the flesh very juicy (award of merit).

*Orchis latifolia Glasnevin var.* (F. W. Moore).—This is a grand form of the type, with larger trusses and deeper hued flowers (award of merit).

*Pæonia Madame de Galhan* (Paul & Son).—The outer petals of this *Pæony* are bright rose, the centre of the flowers being very pale blush (award of merit).

*Pea Daisy* (G. Wythes).—This is a prolific Pea, growing about 1½ foot high. The pods are straight, and contain an average of nine peas. Those exhibited were from seeds sown on March 30th (award of merit).

*Philadelphus Boule d'Argent* (T. Cripps & Sons).—This is a double white flowered variety of the well-known type. The plant is of good habit, and extremely floriferous (first-class certificate).

*Potentilla californica* (M. Prichard).—This variety has large double yellow flowers that are freely produced (award of merit).

*Sweet Pea Cupid* (W. Atlee, Burpee & Co.).—This variety only grows about 9 inches high, and carries its pure white flowers with great freedom (award of merit).

*Viola A. J. Rowberry* (G. McLeod).—This is a superb new rayless variety with bright yellow flowers (award of merit).

## HORTICULTURAL SHOWS.

YORK.—JUNE 19TH, 20TH AND 21ST.

YORK has long been famed for its floral fêtes, and thousands of persons look forward with pleasure to them year after year. They have won the proud position of being regarded as the greatest and most representative competitive display of garden produce in the kingdom during the month in which they are held. So great has been the success in past years that the managers are enabled to offer generous prizes in the various departments and command the best competition. This, with other adjuncts, which were declared good and desirable by the Dean of York, have attracted visitors from far and near. Not only do the shows afford pleasure for thousands who enjoy them but comforts for the afflicted, as they enable large sums of money to be granted to hospitals and charitable institutions. It is of course open to those persons who are disposed to take a particular view of the case to say the people do not care to see the flowers but the accessories. Still there is the fact of the crowded tents, and a dense mass of people from end to end, struggling to see all they can. As a fact the streams of visitors go direct to the marquees, and it is not until their contents have been examined and admired that they "take to the field." The bulk of them there listen to the best of music that can be provided, while there is plenty of variety for others of a more or less exhilarating yet perfectly harmless character. It is evident enough, however, that the horticultural display is the first and greatest centre of attraction.

It can be said without any reservation that every section of the show was worthy of the patronage bestowed. The entrance tent was a splendid approach—a promenade of beauty—provided by eleven picturesque groups of plants leading to what looked like a mountain of specimens. Then came the tent of Pelargoniums—a veritable mass, such as can only be seen at York. Beyond it the Roses—such a display as has never before been seen so early in the season anywhere; then there was the first really great fruit show of the year, and a splendid beginning in that line, while of hardy border flowers there was a grand display, to say nothing of other exhibits representative of most kinds of products in season, making a total of great magnitude and diversity. The different sections can only be briefly referred to, anything in the form of a detailed report and complete list of prizetakers being out of the question.

As above indicated there was keen competition in class 1, which was for groups of plants occupying a space of 300 feet square. Mr. Geo. Wilson, gardener to Sir Jas. Reckett, Bart., being first; this was a very artistic group, a number of tall Crotons being used, which gave it a very light appearance, but the margin was somewhat weak. The second, which was very close, contained more greenery, and was arranged by Mr. J. Edmonds, gardener to His Grace the Duke of St. Albans. Third (bold and rich), Mr. J. McIntyre, gardener to Mrs. G. Pease, Darlington. Fourth, Mr. W. Townsend, gardener to E. B. Faber, Esq., Harrogate. Fifth, Mr. Almondbury. It was thought the Council would make grants to some other of the eleven exhibitors in recognition of the splendid competition. A feature in the first group was that practically every plant in it could be seen, while some of the others, rich as they were, had mounds so large as to hide several plants behind them.

In the class for ten stove or greenhouse plants in bloom Mr. James Cypher, Cheltenham, was first with good specimens, Mr. F. Nicholas, gardener to the Marquis of Zetland, being second. Mr. Cypher was also first for six stove and greenhouse plants. For six ornamental foliage plants, first, Mr. J. McIntyre; second, Mr. J. P. Leadbetter, gardener to A. Wilson, Esq., Hull. Ferns were well represented. For six exotic Mr. J. McIntyre was first, his collection contained a grand specimen of *Davallia Mooreana*.

Three prizes were offered for a group of Carnations in pots, of not less than fifty. Messrs. Laing & Mather, Kelso, were an easy first; Mr. G. Mount second. These exhibits were not so good as last year. For twelve Gloxinias J. F. Wood, Esq., first; and for six, W. B. Richardson, Esq. For the collection of Roses in pots, grouped for effect, Mr. G. Mount, Canterbury, well deserved first place; his collection was tastefully arranged, and contained several plants of Turner's Crimson Rambler; Messrs. H. Jackson & Sons were second. For eight varieties in pots, Messrs. H. Jackson & Sons were first. There was not such a fine show of Orchids as is sometimes seen, Mr. J. Cypher being first for ten plants in bloom; and Mr. Robt. Johnson, gardener to Thomas Statter, Esq., Manchester, second. Mr. Cypher was also first for six plants; Mr. Tyson, gardener to J. R. Jessop, Esq., Leeds, second.

Pelargoniums are always a strong feature at this show, but were not quite so numerous as usual. In the class for twelve show Pelargoniums J. F. Hingston was first; Mr. J. Eastwood, gardener to Mrs. Tetley, Leeds, second. These two exhibitors were in the same order for six Pelargoniums. In the Zonal, Nosegay or Hybrid Nosegay sections, Mrs.

Tetley secured first prize for twelve, six, and three; and also firsts for eight double-flowered Pelargoniums, and three double-flowered Ivy-leaved.

There was a grand display of cut Roses, the finest ever seen so early in the season. The competition was keen throughout, and it must have been no easy work for the judges in awarding the prizes. In the class for seventy-two single blooms, not less than thirty-six varieties, there were eleven competitors. Messrs. Harkness & Sons, Bedale, were first with a magnificent stand; Messrs. Prior & Sons, Colchester, were second, and Mr. B. R. Cant, Colchester, a close third. For forty-eight varieties Mr. H. Merryweather, Southwell, Notts, was first among seven competitors; second, Mr. B. R. Cant; third, Harkness & Sons. For thirty-six blooms (twelve competitors) Messrs. G. & W. Birch, Peterborough, were first, D. Prior & Sons second, Harkness & Sons third. For twenty-four varieties, twelve stands, Mr. G. Mount was first, Mr. E. B. Lindsell second, Mr. B. R. Cant third. Ten stands of eighteen blooms were staged, the prizes going to Messrs. Townshend & Son, Worcester, Messrs. G. & W. Burch, and Mr. E. B. Lindsell. In the class for twelve white and yellow Roses Messrs. D. Prior, W. Mount, and G. Prince were the prizewinners respectively. Eight stands of twelve Hybrid Perpetuals, one variety, were staged, Messrs. Townshend being first with superb examples of Mrs. J. Laing, Mr. Merryweather second with the same variety, and Mr. Mount third. In the corresponding class for Teas the prizes fell to Messrs. Townshend, who won the chief position with Marie Van Houtte; Messrs. Burch second with Innocente Pirola; Mr. F. Cant third. The above were open classes. In the amateurs' section, in which there was good competition, Messrs. Moules, Hitchin; H. V. Machin, Gateford; Whitton, Bedale; Mallender, Hodsock; and Adamson, Bedale, were successful competitors. Altogether there were seventy-five competitors, and in such great and close competition several extra prizes were recommended, but the cards were not placed when the above record was taken. Messrs. Harkness's seventy-two stand blooms were splendid in size and colour; but in many stands there was a lack of brightness, as if the sun had affected the colour of the blooms, and although several were small, yet taking the collection in the aggregate it was a splendid opening of the Rose season.

For twelve bunches of stove and greenhouse cut flowers Mr. J. McIntyre was first. In a collection of twelve varieties, Orchids excluded, Mr. F. Nicholas was first, Mr. G. Wilson second. There was an extensive and excellent collection of herbaceous flowers. For twelve distinct bunches or spikes Messrs. Harkness & Sons were first with bunches more than a foot in diameter, and all distinct kinds; Mrs. Mellish second with excellent flowers, not distinct kinds, but within the terms of the schedule. The class for a collection of hardy cut flowers, space not to exceed 20 feet by 3 feet 6 inches, arranged for effect, brought several competitors. Mr. J. Allsop, gardener to Lord Hotham, was deservedly placed first with a very tastefully arranged collection on a groundwork of moss. Second, Messrs. Harkness & Sons, with splendid flowers. Third, Messrs. J. Cocker & Sons, Aberdeen, with a bold collection, but no attempt had been made to give a finish to the arrangement, not even by covering the boards with either baize or greenery, but as a mass of flowers alone the exhibit was very striking.

Messrs. Perkins & Sons, Coventry, carried off all the first prizes in the classes for hand baskets and bouquets. The prizes for Pansies as usual went to the north. For forty-eight Fancy Pansies first Mr. J. Smellie, Glasgow; second, Mr. J. Sutherland, Lenzie, N.B. For twenty-four varieties Mr. Smellie was again first; Mr. M. Campbell, High Blantyre, second. For twenty-four Show Pansies first Mr. Campbell. For twenty-four sprays of Violas, of six blooms each, Mr. J. Smellie first, Mr. J. D. Hutchinson second. The prize offered for the best exhibition of Pansies and Violas was secured by Mr. S. Pye, Lancashire, with capital collection.

The show of fruit was quite first-class, and far in advance of last year. The Grapes were remarkably well finished, and the Peaches and Nectarines beautifully coloured. In the class for ten varieties Mr. G. McIndoe, gardener to Sir J. W. Pease, Bart., M.P., was an easy first with Foster's Seedling and Black Hamburg Grapes, grand bunches, Bellegarde and Early Alfred Peach, British Queen Strawberry, well coloured, Brown Turkey Fig, Best of All Melon. A dish of unripe Oranges was a weak point in this otherwise splendid collection. The second prize went to Mr. G. Edmonds, gardener to the Duke of St. Albans. This collection contained some well coloured Nectarines. Third, Mrs. Ingram, Temple Newsham. For six varieties of fruits Mr. McIndoe was again first, Mrs. Ingram second. For one Pine Apple, Mr. G. Tullett, gardener to Lord Barnard, was first. In the class for three bunches of Black Hamburg Grapes, first Mr. G. Hickson; second, Mr. J. Johnson; third, Mr. W. Wallis, gardener to Sir H. Meysey, Bart. Three bunches of white Grapes Mr. J. Allsop was first with splendidly coloured bunches, Mr. W. Petre, gardener to C. H. Wilson, Esq., M.P., second. Mr. Large, gardener to W. Sheepshanks, Esq., was first for Peaches, Mr. McPherson, gardener to the Earl of Londesborough, for Nectarines. Melons and Figs were well shown. The first prizeworthy of Strawberries contained fine fruit of Royal Sovereign, and was awarded to Mr. J. A. Keywood, gardener to W. H. B. Wrightson, Esq. For Tomatoes, first Mr. G. Picker, gardener to F. R. Pease, Esq., Hull; second, Mr. J. Allsop. Prizes were offered by Messrs. Webb and Sons, and Messrs. Sutton & Sons for the best collection of vegetables, six varieties, grown from their seeds. The first prize in both collections was won by Mr. J. Crawford, gardener to Colonel Thorpe.

Several collections of plants and cut flowers were staged not for competition. Messrs. W. Clibran & Sons had a capital show of herbaceous flowers; Messrs. Dicksons, Chester, a splendid exhibit of Pæonies and other hardy flowers; Messrs. W. Cutbush & Sons, Herts

a fine group of Carnations in pots, as well as a stand of cut flowers. From W. & J. Birkenhead came a large collection of small Ferns in great variety. Messrs. Edwards & Sons, Nottingham, also had a stand of small Ferns in fancy pots and baskets; and Messrs. Sutton & Sons, Reading, a stand of Gloxinias, Begonias, Achimenes, and other plants in pots, also Peas in bearing; and Mr. Tidy, Havant, exhibited various useful appliances, his stand being brightened with a choice assortment of cut Pelargoniums.

Gold medals were awarded to Messrs. F. Sander & Co. for miscellaneous plants, Messrs. Charlesworth & Co. for Orchids, Messrs. Sutton and Sons for stove and greenhouse plants, and Messrs. Cutbush & Sons for Carnations and cut flowers. First-class certificates were granted to Messrs. Laxton Bros. for Royal Sovereign and Monarch Strawberries.

#### RICHMOND.—JUNE 26TH.

IN glorious weather the Richmond Horticultural Society held its twenty-first annual exhibition of plants, flowers, fruit, and vegetables on Wednesday last. Several large marquees were provided, and well filled with excellent exhibits. Roses were well shown in good quantities, and a large amount of space was taken up by the miscellaneous exhibits of nurserymen, by whom large and varied groups of flowers and plants were staged.

The premier prize for a group of plants was awarded to Mr. H. E. Fordham, Twickenham, for a tastefully arranged exhibit, consisting chiefly of Gloxinias, Orchids, Lilliums, and Carnations, with Palms, Crotons, and Maidenhair Ferns. Mr. J. F. McLeod, Roehampton, was second with a good group, but inferior to the former in elegance; and Andrew Pears, Esq., Isleworth, third. Mr. A. Offer, gardener to J. Warren, Esq., Handcross Park, Crawley, was awarded first for six stove and greenhouse plants in flower, his exhibit consisting of well-flowered examples of *Erica magnifica*, *Ixora Fraseri*, *Bougainvillea glabra*, and others.

For six fine-foliaged plants, distinct, Mr. A. Offer was again first with magnificent examples of *Cycas revoluta*, *Croton Williamsi*, *Kentia Belmoreana*, and *Anthurium magnificum*, the second prize falling to Andrew Pears, Esq. For six exotic Ferns Mr. C. Want, gardener to Sir F. Wigan, East Sheen, was first with well grown plants. Mr. J. Simmonds, gardener to W. Cunard, Esq., Twickenham, was a good first for six Caladiums. The premier award for six Fuchsias was awarded to G. Cotterell, gardener to the late W. Davies, Esq., Isleworth. Mr. J. Smith, Isleworth, was first for six Coleus, and Mr. A. Russell, gardener to J. Green, Esq., Isleworth, second.

In the class for forty-eight Roses, distinct (two trusses of each), the first prize fell to Messrs. D. Prior & Son, Colchester, for a fine exhibit of magnificent blooms, consisting of all the popular varieties. Mr. Frank Cant, Colchester, was a good second; and Mr. B. R. Cant, Colchester, third. For twenty-four Roses, distinct, Messrs. G. & W. H. Burch, Peterboro', were first; Messrs. D. Prior & Son second; and Mr. Frank Cant third. For twelve Tea Roses of one variety, J. Garney Fowler, Esq., South Woodford, was first; Mr. B. R. Cant second; and Mr. G. Mount, Canterbury, third. Other classes for Roses were well filled and the competition keen, the Judges baving much difficulty in awarding the prizes.

Floral decorations were shown in quantity, and for dinner table decorations of natural flowers and foliage Mr. F. W. Seale, Sevenoaks, was first; Miss C. B. Cole, Feltham, second; and Miss Lilian Hudson, Gunnersbury House, Acton, third. The first prize for six exotic Orchids was awarded to Mr. A. Howard, Orchid grower to H. Little, Esq., Twickenham; Mr. W. H. Young, Orchid grower to Sir F. Wigan, East Sheen, being second.

Gloxinias were well shown, the best collection being that of Mr. H. G. Fordham, Twickenham. Mr. Watts, gardener to H. Little, Esq., gained first prize for Ivy-leaved Pelargoniums; and for Begonias, the first prize fell to Mr. Jas. Portbury, gardener to W. N. Froy, Esq., Putney Heath. Mr. Chas. Turner, Slough, was first for a collection of Fancy Pelargoniums. For a collection of Begonias, the first prize fell to Mr. Jas. Portbury, gardener to W. N. Froy, Esq., Putney Heath; Mr. R. Johnson, gardener to Alderman Roberts, Richmond, coming second. For six Palms, Mr. J. Simmonds, gardener to W. Cunard, Esq., Twickenham, was first; and Mr. T. P. McGregor, Putney Hill, second.

Fruit of fair quality was staged, Mr. W. Ford, gardener to W. H. Ellis, Esq., being first for collection of six dishes, which consisted of Foster's Seedling and Black Hamburg Grapes, Hale's Early Peaches, Brown Turkey Figs, Melons, and Strawberries. Mr. G. H. Sage, gardener to the Earl of Dysart, Petersham, was second; and Mr. Thos. Osman, Ottershaw, Chertsey, third. For black Grapes, Mr. W. Ford, gardener to H. Ellis, Esq., was first; Mr. T. Osman, second; and Mr. H. W. Blake, gardener to Mrs. Blaine, Clandon Park, Guildford, third. For white Grapes, Mr. W. Tidy, gardener to W. K. D'Arcy, Esq., Stanmore Hall, Middlesex, was first; Mr. T. Osman, second; and Mr. W. Ford, third. Strawberries were fairly well shown, Mr. G. H. Sage gaining first prize with an excellent dish.

Excellent vegetables were shown in the classes set apart for them, the collection of Mr. Thomas Wilkins, Henstridge, near Blandford, which gained first honours for the prizes given by Messrs. Jas. Carter and Co., being exceptionally fine. Another good collection was that of Mr. C. T. Waite, Glenhurst, Esher, which was awarded first for the prize offered by Messrs. Sutton & Sons, Reading. A bright feature in the show was the miscellaneous exhibits, which were numerous and extremely diversified.

#### FRUIT FORCING.

**Peaches and Nectarines.**—*Early Forced Trees.*—Continuous forcing to have the fruit ripe in May and early in June taxes the energies of the trees, as they have to make the growths during the early months of the year and mature them in early summer. After the fruit is all gathered ventilate to the fullest extent, if possible removing the roof lights by the middle of July, or sooner in the case of the very early forced houses, if the weather be hot and the growths sufficiently matured. If the roof lights are not moveable, in addition to ventilating to the fullest extent, the borders should be duly damped and properly watered, so as to keep the foliage fresh, and no check given likely to induce the premature ripening of the young wood and leaves. Keep the latter free from red spider by syringing occasionally, applying an insecticide if necessary, sparing no pains to keep the foliage clean and healthy, thus enabling it to mature naturally. Stop laterals likely to interfere with the principal growths, but moderate lateral extension will promote root action and appropriate any excess of nutriment, which forced into the buds may result in an undue development. All shoots that have supported fruit, and are no longer required, should be removed to let air and light freely to the growths, and if there is too much crowding of the shoots for next year's bearing, thin them well to admit sun for solidifying those left.

*Houses with Fruit Ripening.*—A temperature of 60° to 65° at night and 70° to 75° by day, with 10° to 15° more from sun heat, is essential to the swelling and securing quality in the fruit. Except on cold nights and in dull weather little fire heat will be required, as the weather is bright; but changes come suddenly, and attention must be given to circumstances, so as to maintain steady progress, and admit of a little air constantly for securing flavour and good finish. Afford moderate air moisture, but withhold water from the fruit after it commences to soften, damping the floors and borders whenever they become dry, supplying water as required, and a mulching of spent, rather lumpy material will keep the surface in a condition favourable to the activity of the roots, and that without overdue atmospheric moisture. If the weather continue bright some netting spread over the roof lights will be an advantage in preserving the delicate skinned varieties, such as Noblesse, from unduly heating by the sun's rays, causing the fruit to ripen at the apex greatly in advance of those on the lower parts, and the fruit not infrequently decays there through over-ripeness, whilst the lower part is quite hard. These, indeed all fruits, are better ripened gradually than by being much heated, as is sometimes done under the large and clear panes of glass rightly employed in modern glass structures for growing fruit. A double thickness of herring nets or a single thickness of pilchard net drawn over the roof lights will sufficiently break the most powerful sunlight, insuring the fruit ripening evenly. This shading may remain on after the fruit is gathered, as it greatly conduces to the preservation of the foliage, insures the perfecting of the buds, preventing malformation or premature maturity, and this signifies less danger of the buds falling.

*Young Trees.*—Inattention to disbudding these, or leaving more growths than absolutely necessary for bearing and furnishing the trellis is a great mistake. The principal branches, or shoots to form them, should be 12 to 15 inches apart, and the shoots for next year's bearing, originated from the preceding year's shoots, disposed about 15 inches asunder along them, stopping if necessary at that extent of growth, and the laterals to one shoot as produced. The extension, or main shoots, should be trained in their full length, provided they are evenly balanced. If the shoots on one side are stronger than the other, depress the strong and elevate the weak, so as to induce an equal distribution of vigour throughout the tree. Any gross shoots may be stopped, but it is better to cut out excessively strong wood, as it is difficult to restrain, and often succumbs to gumming, therefore encourage sturdy, short-jointed growths. Ventilate early in the day, increase with the advancing temperature, avoiding a vitiated atmosphere by leaving on a little air constantly. Essential growths must be trained so that sun and air have access to them freely, keeping them thin and the foliage clean.

**Figs.**—*Second Crops.*—The fruits on early forced trees have now swelled to a good size, and being judiciously thinned, there will be a crop of good Figs towards the latter part of the summer. To insure this the foliage must be kept free from insects and the feeding liberal. When the crop is heavy, and the former thinning not having been sufficient, a second thinning should take place at once, leaving the most forward at the base of the shoots, which will ripen earlier than the others, and so afford more time for the ripening of the shoots at their points, these being kept well up to the light. Early forced, planted out trees, should have the young wood ripened and be resting by the middle of October.

*Watering and Feeding.*—If the borders have become dry whilst the first crop of fruit was ripening they must be watered repeatedly until the soil is properly moistened through to the drainage. Liquid manure will be required by trees having their roots in borders of limited extent,

and more frequently than by trees with a larger extent of rooting area; about once a week in the first case, and every fortnight in the other, giving thorough supplies, and always in a tepid state. Top-dressings of the advertised fertilisers may be given at intervals of three weeks or a month, always after watering, and then washing-in moderately. A light mulching is beneficial in supplying nutriment, keeping the soil moist, and encouraging surface roots; but it should be kept moist by sprinkling when it becomes dry.

*Syringing and Insects.*—Syringe the trees twice a day, except in dull, wet weather, when morning or early afternoon syringing will be sufficient, and always early enough to allow of the foliage getting dry before night. Judicious and forcible syringings are usually sufficient to keep down red spider, but if it and scale gains a hold they must be dislodged by the use of an insecticide, for which purpose the carbolic and petroleum soaps are effective. Old scale must be dislodged by using a brush. Painting the hot-water pipes with a cream formed of flowers of sulphur and skim milk, after heating them to 160° to 200°, keeping the house closed for an hour or two, with the sulphur on the pipes, is an effectual remedy for red spider and a good preventive of spotting in the fruit from attacks of fungi. The foliage should be dry, and the following morning the trees should be well syringed. Repeat the heating of the pipes, and brushing them with sulphur in about ten days.

*Temperature and Ventilation.*—Unless the weather be unusually cold and wet artificial heat will not be necessary, but fire heat must be afforded to maintain a temperature of 60° to 65° at night, and 70° to 75° by day. Ventilate early on fine mornings. Keep the house through the day at 80° to 85° with sun heat, and close early so as to run up to 85° or 90°, or even 95° to 100°, providing abundance of atmospheric moisture.

*Succession Houses.—Fruit Ripening.*—When the Figs change colour afford more air, insuring a circulation constantly, and a free movement of the atmosphere by top and bottom ventilation whenever external conditions are favourable. Reduce the moisture gradually, keeping water from the fruit, which expose as much as possible to light and air. Lessened supplies of water at the roots tell in favour of quality, yet the trees must not be allowed to suffer; therefore keep the soil moist, damping the surface occasionally to keep the roots there in a healthy condition.

*Trees Swelling their Crops.*—Afford a light mulching of short manure, and through this supply tepid water, or in the case of trees carrying heavy crops and not over-luxuriant, liquid manure, with alternate dressings of chemical manures. It is scarcely possible to overfeed Fig trees in well-drained, properly constructed, narrow borders, but deep borders and wide favour growth at the expense of fruitfulness. The trees grow splendidly and produce little beyond leaves. In fine weather syringe twice a day, always in good time, and close so as to run up to 90°, 95°, or 100°. As the fruit approaches ripening provide a little ventilation before nightfall, and let it remain, increasing it early so as to dissipate moisture deposited on the foliage during the night before the sun acts powerfully on the house.

*Late Houses.*—Grand Figs are grown in cool houses, one crop ripening in August and September. Calcareous soil, well-drained narrow borders, light well-ventilated structures afford best results. The chief points are to grow thin, feed highly, ventilate early, close soon enough to keep a good heat until the evening, affording abundance of atmospheric moisture. Avoid overcrowding the growths, stop wide shoots at the fifth leaf, and water liberally. Let the shoots grow with their points to the light, just keeping them clear of the glass, and they will fruit abundantly.

*Melons.*—Where fruit is required late a last sowing may be made for growing in frames or pits heated by fermenting material. Make the bed at once, sowing the seeds in 4-inch pots, one or two seeds in each, the pots being half filled with soil, and a supply of soil being given as the plant advances, but not higher than half an inch from the seed leaves; they can be turned out when the bed is ready, giving a good watering at planting, and shading from bright sun until established. One plant in the centre of each light is sufficient, its point being taken out at the second rough leaf; this will result in the production of side shoots, which reduce to four, taking two to the front and two to the back, rubbing off the laterals to within 6 inches of the stem, and stopping the primary shoots a foot from the sides of the frame or pit. The plants will show fruit on the laterals, which being fertilised will set early in August, and ripen towards the close of September.

*Setting Melons in Frames.*—Plants that were raised some time ago, and have been put out, will grow rampantly, and are sometimes difficult to set fruit, especially during moist weather. It arises from the moist atmosphere, crowding, and closeness; therefore thin the growths if too crowded, then fruit will show on the laterals, or if not stop these to two joints, and fruit will appear on the sub-laterals. Water sparingly, pouring what is necessary to keep the plants from flagging between the shoots so as to wet the surface as little as possible. Place hot manure against the sides of the frame, or grass mowings will do, with a little litter over the grass. This will raise a gentle heat, admitting of a little ventilation constantly day and night. Fertilise the flowers when fully expanded, stopping the shoots at the same time one joint beyond the fruit. Admit air freely if the weather permits, increasing the ventilation at 70°, allowing it to rise to 80° or 85° or 90°, at which keep through the day, closing at 80°, except the small portion before alluded to. When the fruit is set reduce to two to four on a plant, according to the vigour, and encourage growth by watering as required, and sprinkling the foliage at closing time. Commence ventilating from 75°, allow the heat

to rise to 85° or 90°, close by or before the temperature recedes to 80°, or between 4 and 5 P.M.

Growers who have well heated light houses will have no difficulty in maintaining a supply of fruit through October or November from sowings made up to the third or fourth week in July.

#### THE KITCHEN GARDEN.

**Cabbage.**—Unless Cabbage is grown quickly it hearts indifferently, and the quality is bad. A free use of liquid manure is most desirable, and a light dressing of nitrate of soda would hasten growth materially. Later rows ought to have the soil drawn up the stems, and the water or liquid manure can then be readily applied along the furrows. When cutting hearts do not strip off all the lower leaves, fresh growths and young hearts forming more quickly when the stems are not so treated. A good supply of tender young Coleworts never fails of appreciation in the late autumn and early winter months, and in order to be certain of these seeds must be sown at once.

**Carrots.**—Quite young Carrots form a good dish at any time. Any variety of Carrot will be found good for drawing in a young state, but the finer stump-rooted or Horn Carrots are the best for present sowing. They form a good succession to early Potatoes. Make the ground quite fine, draw drills 8 inches, or rather more, apart, water, and then sow the seeds moderately thick. The roots of these and later sowings are apt to be disfigured by grubs, and a very light dusting of wood ashes along the drills may well be given by way of preventive. Keep the surface of the soil among the row of maincrop Carrots well loosened, or otherwise undue loss of moisture, cracking, and premature maturation of crop may be the consequence.

**Late Peas.**—A long spell of hot, dry weather has hastened maturation in the case of Peas. There is little likelihood of sowings of Ne Plus Ultra, British Queen, Latest of All, and such like, made at this late date attaining a productive state before frost intervenes—at any rate in the more northern localities—though they might be tried in more favoured districts. If seeds of William I., Day's Sunrise, Exonian, or other good early variety were sown directly it is ripe, there would be a far greater certainty of having a good late crop, as new seeds germinate more strongly. Dwarf varieties may be sown in rather deep drills, from 5 inches to 15 inches apart in succession to early Potatoes, or where they can be protected from frosts.

**Shallots and Garlic.**—These are ripening somewhat earlier than desirable, and in many cases will be smaller than usual accordingly. When they come away freely from the soil remove to where they can be spread out and well harvested prior to storage; underground Onions to be similarly treated. Top of Tree Onions may also be duly dried and stored. These, if planted early, will give young Onions for salad purposes very early next spring.

**Winter Spinach.**—Winter Spinach is of the greatest assistance in keeping up a constant supply of green vegetables, and pays well for any extra pains taken in producing it. Towards the end of July is a good time to make a first sowing. The ground ought to be neither poor nor lumpy, and any, therefore, that is of a somewhat tough, badly working nature, should now be freely manured and dug up roughly. Sunshine will most probably give it a thorough baking, and rain causes it to crumble freely. A well-drained position should be assigned this important crop, and plenty of space allowed.

**Mushrooms.**—Manure should now be got ready for open air beds, and also for forming beds in sheds and other unheated structures. For the ridge system the longest and least stained straw should be forked away from the manure. Flat, or nearly flat, beds ought to be composed principally of short manure or horse droppings. Ridge-shaped beds are particularly liable to become violently hot, and this must be prevented, or otherwise failure to crop will be the result. The manure ought in all cases to be well prepared. In very wet weather it is frequently necessary to ward off saturating rains, but more often than not the watering pot and rose has to be used in preparing the manure, and again when the bed is formed.

*Where Mushrooms May be Grown.*—The sides of the Melon and Cucumber beds may have lumps of spawn inserted 8 inches apart all over them, and be cased over with soil similarly to ridge-shaped beds. After it has become no longer necessary to water the Melon plants in the frame, the inside beds may be spawned, and Cucumber beds nearly exhausted may be served the same. Mulch with strawy litter after the haulm is dead or cleared off, and keep on the lights in either cold or wet weather. When large heaps of manure and other decaying materials are formed for Vegetable Marrows there is usually enough heat to cause Mushroom spawn to run freely. Now is a good time to insert lumps of spawn all over these. Unless a very wet summer is experienced, Mushrooms should be forthcoming in September.

#### APIARIAN NOTES.

THE recent rains have increased the pollen supply to bees, but we want more rain before warm weather sets in, which will bring on a seasonable honey flow where flowers are not spoiled by the drought. We have several reports from the moors to the effect

that the Thyme is in bloom, and that the Heather will be early. In my garden several sprigs of white Heather are in bloom. The earliness of flowers and the backward state of many hives is a condition of matters bee-keepers are not proud of.

#### CHLORIC DROPSICAL FEVER.

This is more general than I had been aware of, one bee-keeper a quarter of a mile from me having five colonies dead out of six. If bee-keepers would turn their attention to discovering the real nature and causes of disease they would be benefactors to their brethren of the craft. Unfortunately for me some of mine are affected, but happily it is not infectious, nor is the disease confined to one breed of bees. I have hitherto looked on it as hereditary, but perhaps pollen from certain sources may have something to do with it, and some queens may be more easily excited than others. In no case have any of my bees died since I was compelled to give up the keeping of Italians.

My latest experiment to effect a cure or stop the disease is so far promising. Out of four cases the disease has left three of them, and is much abated in the fourth, but I am not prepared to say positively that it is due to the medicated food, but shall certainly continue it until I am certain. I dissolve the sugar in sulphurated water. Although I have made no attempt to remove the stores of the hive, it would be advisable to do so.

#### FEEDING.

Feeding at this date (21st June) may appear strange to beginners, but it has heretofore been the rule and not the exception, and but for the previous damage to pastures by drought our hopes would be as high as ever they were. The weather is unsettled, with a drying wind; hives well stored in everything are apt to draw their brood, therefore while the weather remains so bees should not be trusted by appearances, but should be fed, even if super-loaded combs be removed. These are useful to give to swarms or to nuclei.

The beginner will observe that although light hives are not mentioned, both light and heavy ones require the same treatment. From 2 to 4 ozs. of sugar every night is sufficient, and fed by scoops from below is the safest, easiest, and quickest way.—A LANARKSHIRE BEE-KEEPER.

#### SEASONABLE NOTES.

If not already done all hives intended for honey production, where the chief harvest is obtained from field Beans, white Clover, and the Lime trees, should be at once supered. Any stocks that are not of the desired strength should be assisted with a frame or two of brood and bees, as one strong stock will store more honey than half a dozen weak ones. This should always be borne in mind when preparing for the honeyflow.

Those stocks from which bees and brood have been taken may be utilised in various ways. I usually introduce either queen cells or virgin queens raised in stocks that have been noted for producing good workers. These again are introduced to colonies whose queens may for various reasons, require replacing, or for an increase of stock. In this locality (Yorkshire) field Beans are in full bloom and will soon be past their best; white Clover, of which there is a good promise, is fast coming into bloom and will be at its best in a few days. The next three weeks will decide the question whether the present season is to be an improvement on the last few years from a bee-keeper's point of view.

Some swarms that came off from straw skeps a week ago, although placed in frame hives with fully drawn out combs, have had to be fed with thin syrup. Thus no time has been lost, as the queens commenced laying at once. These were from skeps that were experimented with during the late severe winter, one of which was a late cast and had not half filled the skep with comb, and was not fed last autumn. To judge from its appearance at that time it seemed almost an impossibility to preserve the bees alive through an ordinary winter. When the frost broke up in March they were alive but absolutely without stores. They have been fed with thin syrup from a bottle-feeder placed on the crown of hive, and from that time up to now form one of my strongest stocks, thus showing what a little close attention will do by supplying food at the right time.

A good swarm and cast will amply repay me for the trouble entailed. The swarms although late will doubtless store a surplus if favourable weather prevails, as without bright sunshine and a light temperature honey will not be produced. Stocks that were supered a fortnight ago also have without exception done well, having drawn out the combs freely. It is surprising what a large amount of honey a strong colony will store in a few hours of favourable weather during the honeyflow.—AN ENGLISH BEE-KEEPER.

## TO CORRESPONDENTS

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Tomatoes and Bordeaux Mixture** (*Festina Lentè*).—The mixture has been found useful, when applied in good time, as a preventive of disease caused by the *Phytophthora*, and used at half the usual strength applied to Potatoes it did not injure Tomatoes under glass. For further references read the long reply on page 555 last week.

**Tree Ferns** (*Colonel*).—The position you mention will be much too hot and dry in summer. Establish them in pots or tubs in a naturally moist and shaded position, syringing as often as is necessary for keeping the stems moist, and maintaining humid surroundings. They grow well in a mixture of loam and leaf mould. Wednesday morning's letters can only be answered briefly in the current issue.

**Pineapple Nectarine Leaves Eaten** (*J. H. B.*).—The leaves appear to have been eaten by the grooved or black Vine weevil (*Otiorynchus sulcatus*), which does not seem recent. If you spread some white cloths or newspapers beneath the tree in the daytime and after dark at night enter the house carefully with a lantern, with the light concealed, and shake the tree or trellis sharply and then turn on the light, you may find the weevils on the cloths or newspapers, as they drop when alarmed, and can be captured and destroyed.

**Caterpillar on Pea Leaves** (*P. J. Palmer*).—The caterpillar on the Pea leaves is the larva, commonly called slugworm, of the Pea sawfly (*Selandria atra*, or *Tenthredo cerasi* of some authorities). The sawflies deposit their eggs on the leaves, always the upper surface, and hatch in a few days; the slugworms then commencing to feed on the soft substance of the leaf, and soon cause the discolouration of the affected foliage. The best remedy is to dust quicklime on the affected parts, repeating occasionally if necessary at intervals of a day or two.

**Compost for Peaches and Roses** (*J. C. B.*).—Good strong turfy loam, 2 or 3 inches thickness with the turf. It is better to have the soil rather strong than light, but not very stiff, and if intermixed with stones or small pebbles all the better, especially if of a calcareous gravelly nature. Of this five parts, horse droppings or thoroughly decayed manure one part, nuts charcoal half a part, and if deficient in calcareous matter and grit one part. To this you may add, when mixed, about a 9-inch potful of crushed bones to every barrowful of compost, thoroughly incorporating. This compost, with good drainage, well firming the materials, will grow Peaches and Roses well, using chemical manures or top-dressings.

**Insect Eating Holes in Scolopendrium Fronds** (*T. C. B.*).—The insect is the clay or copper-coloured weevil (*Otiorynchus picipes*), a very handsome male specimen in full glow of colour, as this is or soon will be the pairing season. The female is much duller in colour, but the larger of the two. It is very injurious to vegetation, feeds at night on a great variety of plants and trees, which should be taken advantage of to capture the pests. Spread, therefore, a white cloth or newspaper on the stage or floor, stand the pot on it, and place some paper on the surface of the pot nearly, but not quite close, to the crown. This should be done in the afternoon, and after dark at night enter the house carefully with a lantern darkened (a bull's-eye one being best with the light turned off); then shake the plant sharply, brushing the fronds with the hand, after which immediately turn on the light and kill all the pests, which will have fallen on the cloth or paper, scrutinising the base of the plant closely where the soil has not been covered. This is the best remedy, repeating until the weevils are annihilated.

**Tomatoes in Pots** (*Reader*).—The plants are probably at a standstill for lack of nourishment, and they certainly are drawn, possibly from being at a considerable distance from the glass and receiving partial instead of unobstructed light, with too close and moist an atmosphere, this being perhaps the cause of the flowers not opening freely and the fruit setting indifferently. It is best to confine plants in pots to one stem, which in ample light and with free ventilation should give a truss of bloom, and ultimately fruit at every other joint, the laterals being rubbed off or removed whilst quite small, the plant being

PROGRESSIVE AGRICULTURE.

AMIDST all the doubt and difficulty arising from an agricultural depression of an intensity and duration greater than has probably ever been known before, the steady progress of technical instruction under the fostering influence of County Councils is an encouraging sign, an indication of the recognition of a want, as well as of the possibility of doing better in the future than we have in the past, by the acquisition of that exact knowledge which a scientific training alone can give.

A short time ago we called attention to the opening of a new agricultural college at Wye for students from some southern counties. We have now a similar duty to perform in connection with the Midland Dairy Institute at Kingston Fields, in Nottinghamshire, which, as the prospectus sets forth, "Is in connection with the County Councils of Derbyshire, Leicestershire, Lindsey Division of Lincolnshire, Nottinghamshire, and with the Agricultural Department of the University College of Nottingham." Our readers have had some indication of the exceptional abilities of Mr. J. R. Dunstan, head of the Agricultural Department of the College, in our articles upon his pamphlet on Dairying in Denmark, and his connection with the Institute may be taken as a guarantee of good work and a thorough training of the students.

We have been over the farm, and consider it to be admirably adapted to the requirements of such an institution, in regard to which the prospectus shows that it is situated in the south-west corner of Nottinghamshire, within a few miles of the boundaries of that county and the adjacent counties of Derbyshire and Leicestershire. Its position for the Midlands is therefore central, and it is close to the finest dairy land of the kingdom, and to the home of Stilton cheese making. The farm of 160 acres consists of about 100 acres of pasture, the remainder being arable land varying from a light soil to heavy clay, thus affording students lessons in the cultivation of pasture, and in the management of both heavy and light land.

The main object of the Institute is to provide a thoroughly practical course of instruction in dairying, combined with such scientific instruction as is found necessary to explain the principles on which the practice depends. The production of milk, and the causes influencing such production, milking, treatment of milk for transit, methods of creaming, separating, butter-making, with the best methods of packing and marketing, will be taught, and students will be expected to spend the greater part of the day in the actual practical work; whilst in cheese-making practical and theoretical instruction will be given in the manufacture of soft cheese, and of the various kinds of English cheese—Cheddar, Stilton, Derby, Leicester, Trentside, and Cheshire; and of the foreign varieties Gorgonzola, Brie, Camebert, Gruyère, and Edam, accurate records of all work done being kept by the students. Thus the aim is not only to teach the students how to make the best kinds of English cheese in the best way, and so command a better market for home produce, but also to carry the war into the enemy's country by teaching them how to rival the foreign producer in making the most popular sorts of cheese now imported to his benefit, and our serious loss. Mr. John Benson, late manager of the British Dairy Institute at Aylesbury, will be the chief instructor in dairying.

The scope of the work is wide and comprehensive. Thus in Class A a six-weeks course is open to farmers, their wives, sons, daughters or dairymaids, and others requiring practical instruction in hard and soft cheese (not more than two kinds), and butter-making, in the general management of cows, and of a small dairy. Class B offers a three-months course for those requiring a commercial knowledge of dairying or factory management, such as dairymen in a large way of business, factory managers, and intending colonists.

There are four other classes, each having its special object the entire scheme being evidently an outcome of most careful deliberation; for it is one of the best combinations of science with practice that we have ever seen. We may add that the fees for instruction are low, and the premises comprise thoroughly equipped dairy buildings specially designed for the work. Farmers and dairymen in the district are offered advice free of charge at the Institute, which bids fair to prove a great boon, a real help in time of need to Midland dairy farmers.

WORK ON THE HOME FARM.

Haymaking is being pushed on while the weather continues fine and fairly settled. Some of the hay crop on land which came in hand at Lady Day is backward, but we have decided to mow all that is a fair crop, while the herbage is at its best and the hay can be made quickly, rather than wait for more growth. What hay is made will be of the best, and the aftermath will be available for grazing. To wait for a full crop involves a serious loss of quality in the first growth, a risk of broken weather and inferior hay costing much more to save than the best early hay.

Clover hay has also been got into rick in capital condition, some of it being a rather light crop; but the mixed seeds and Rye Grass are a heavy crop, requiring much caution in stacking. We like substantial stacks of good width, and guard against overheating by having one or two air shafts from bottom to top of each stack by drawing up with the building a sack stuffed with straw. The sack is taken out of the shaft at night to give vent to any vapour generated by rapid heating. Such shafts are really simple and efficient safety valves, preventing both discolouration and spontaneous combustion. By all means use rick cloths, but in fine weather have them off the rick early in the morning, in order to have the top dry before carting begins again.

The steam cultivator has been kept going to such good purpose that all our foul land has been gone over twice, Charlock destroyed, and much of the Couch Grass got out and burnt. With a set of steam tackle available now and during harvest foul land and stubble cleaning can be got on with while the horses are all required for carting and mowing. On the score both of economy and efficiency it answers to hire the tackle. We get our arable land done twice over at a cost of 10s. an acre, we finding coal and carting water. This insures clean land, a deep tilth, and by keeping the work well in hand thorough autumn tillage, and though last certainly not the least, economy in horses, only enough being required for carting and implements.

REMARKS.

- 16th.—Bright sunshine and pleasant breeze.
  - 17th.—Bright sunshine in morning, generally cloudy in afternoon.
  - 18th.—Hazy and cloudy at times, but generally sunny.
  - 19th.—Rain from 2 A.M. to 9 A.M., overcast with frequent spots of rain till noon; occasional sunshine in afternoon.
  - 20th.—Bright sunshine almost throughout.
  - 21st.—Bright sunny morning, frequently cloudy in afternoon.
  - 22nd.—Overcast morning; sunny and rather oppressive in afternoon.
- A very fine week, with only one day's rain.—G. J. SYMONS.
