There is little doubt but that these salts are absorbed from the soil by the plants. Almost all cultivated soils contain them in some form or other; and of the value of their addition to the soil in almost every form, there is considerable evidence. Thus, phosphate of lime abounds in all the richest animal manures, such as in bone-dust and the richest excrements of animals; and, again, it is found by the Cheshire graziers, that the earthy salts of bones obtained from the size-makers, after most of the oily matters are removed by the action of steam, and hardly any thing but the salts of lime remain, are quite as fertilizing to their pastures as when used in their fresh state, abounding with animal matters.

Sulphate of lime, or gypsum, is another salt, which is invariably found in and promotes the growth of certain plants.

It must, I think, be regarded as one of those salts which constitute the food or constituents of plants. It is always present in the clover, lucern, and sainfoin, and in smaller proportions in the potato and the turnip. See PLASTER OF PARIS.

That it is a food for plants, was the opinion of Sir Humphry Davy. He remarked, when speaking of gypsum and the alkalies, "It has been generally supposed that these materials act in the vegetable economy in the same manner as condiments or stimulants in the animal economy; and that they render the common food more nutritive. It seems, however, a much more probable idea, that they are actually a part of the true food of plants, and that they supply that kind of matter to the vegetable fibre, which is analogous to the bony matter in animal structures. Thus, those plants which are most benefited by the application of gypsum, are those which always afford it on analysis. Clover and most of the artificial grasses contain it, but it exists in very minute quantity only in barley, wheat, and turnips." (*Ag. Chem.* p. 19.) And it is noticeable, that most of these remarks apply to the phosphate of lime (which can hardly be regarded as a stimulant), since it is not even soluble in water; it is also worthy of observation, that the same salts of lime (the phosphate and the carbonate) which Davy thus supposes to be placed in plants to add to their strength and solidity, are precisely those salts which for that very purpose are placed in the bones of animals. They thus, as it were, mutually nourish each other. The very phosphate of lime, which in the dissolving bone-dust is absorbed by the plant, again becomes, in the food of animals, a material for the formation of other bones.

The carbonate of lime, in some of its forms of chalk, limestone, marl, &c., is the most universally present of all the salts contained in vegetables. It is, in minute proportions, soluble in water, and more so if the water is saturated with carbonic acid gas, hence it is readily absorbed by the roots of plants. It exists in vegetables in very varying proportions; thus, the ashes of the perfect oat plant, straw and seed together, were proved by M. Vauquelin to contain more than 5 per cent. of this earth. (*Ann. de Chem.* vol. xxix. p. 19.) In 32 ounces of seeds of wheat, M. Schraedar found 12 grains of carbonate of lime; and in the same quantity of seeds of rye 13·4 grains; 24·8 grains in seeds of barley; 33·75 in those of the oat; and 46·2 in the same weight of the straw of rye. It is most commonly, although not always, found in vegetables with carbonate of magnesia. These were found together by M. Saussure in the ashes of the following different substances. He obtained from 100 parts of the ashes of the—

	Parts.
Leaves of oak, gathered in May	0·12
Do., September	23·
Bark of the oak	63·25
Wood of oak	23·
Soil from wood of oak	10·
Wood of poplar	27·
Wood of hazel	8·
Wood of mulberry	56·
Wood of hornbeam	26·
Plants of peas, in flower	6·
Do. of vetches, in flower	4·12
Do. raised in distilled water	0·
Wheat in flower	0·25
Do. seeds, ripe	0·25
Do. straw	1·
Do. bran	0·
Oat seeds	0·
Barley seeds	0·
Do. chaff	12·5
Leaves of <i>Rhododendron ferrugineum</i> , raised on limestone	43·25
Do. raised on granite	16·75
Leaves of fir, raised on limestone	43·5
Do., raised on granite	29·

Now, these two soils (the granite and the limestone) contained carbonate of lime in the following proportion:—

	Granite.	Limestone.
Carbonate of lime	1·74	98·
Alumina	13·25	0·625
Silica	75·25	
Petroleum		0·25
Iron and manganese	9·	0·25
	99·24	99·275

Carbonate of lime has also been detected in the sap and white matter of the ulcer of the elm by M. Vauquelin; in the ashes of wormwood (more than 50 parts in 100), by Kuns-muller; in the flowers of the arnica, by M. Chevalier; in the potato, by M. Einhof; in the red bark of St. Domingo, in Peruvian bark, and in the wood of the quingania, by M. Fourcroy. Existing, therefore, so universally in plants, there can be no doubt of the fact that this salt is fulfilling, then, some wise and salutary purpose; not fortuitously, but with design; not by chance, but by the regulation and arrangement of their Divine Architect.

Few if any saline fertilizers act so well alone, as when mixed with others, or with ordinary manures. As a general rule, the more fertilizers are mixed the better they operate upon plants.

Nitrate of potash, which is composed of ni-

tric acid 54·34 parts, and potash 45·66 parts, enters into the composition of a few plants, it is true, but in the greater number, even in those of the farmer's crops, on which on some soils its application produces such luxuriant effects, its presence cannot be detected, even in minute proportions. Some plants, however, do contain it in considerable quantities. Thus it has been found in the common nettle, the horse-radish, and the sunflower. M. Chevalier found it in the *Chenopodium olidum*; M. Vauquelin in the leaves of the deadly nightshade; M. Chevreul in woad; Dr. John in the *Mesembryanthemum crystallinum*. M. Boullion Legrange made various plants, such as the sunflower, vegetate in soils which did not contain any saltpetre: upon examining them, no traces of saltpetre were discernible, but upon watering them with a weak solution, it made its appearance in them as usual. (See NITRATES.) The presence of cubic petre (nitrate of soda), which is composed of nitric acid 62·1, and soda 37·9, is still more rare in plants; it has only been detected in barley.

The salts formed with the vegetable acids existing in the juices of plants are rather numerous. Oxalate of potash, for instance, exists in the *Oxalis acetocella*, and several others; oxalate of lime in rhubarb, parsley, fennel, squills, tormentilla, deadly nightshade, and spinach. Nitrate of lime is contained in the onion, malate of lime in the houseleek, wake-robin, mignonette; and malate of potash in rue, the garden purslane, nasturtians, lilac, madder, &c.

There is, perhaps, no saline substance that exists to so great an extent in marine plants, and which has been used for so long a period and to such an extent for those growing in inland situations, as common salt. (See SALT.) A substance which not only abounds in all plants growing on the sea-shore, but always exists in smaller proportions in many of those growing in upland districts. Thus, Mr. G. Sinclair obtained from 1450 grains of wheat-chaff from Bedfordshire, ashes 50; common salt $2\frac{3}{4}$: from 1450 parts of the seed, ashes 10; common salt $\frac{1}{6}$. But from the same crop, which had been dressed with 44 bushels of common salt per acre, he obtained from 1450 parts of the chaff, ashes 40; common salt 4: and from 1450 parts of the seed, ashes 10; common salt $\frac{1}{4}$.

Common salt is found generally in minute proportions in most cultivated soils. Davy detected in 400 grains of a good silicious soil from a Tonbridge hop-garden, nearly 8 parts of common salt.

Besides being in small proportions a direct food for plants, common salt also seems to perform several other services to vegetation, and the same remark probably applies to other salts; for instance, when applied to the soil in small proportions, it certainly promotes the putrefaction of its organic matters. See SALT.

And again, salt, in common with several others, appears to excite or stimulate the plant, when applied to it in proportions not too excessive; a fact first noticed by Dr. Priestley.

Another use of common and other salts to vegetation is, the preservation of the plant from injury by sudden transitions in the temperature of the atmosphere: salted soils only

freeze in intense frosts. I have repeatedly witnessed in the case of culinary vegetables, such as cabbages, broccoli, &c., that, while the produce of the unsalted portions of the ground were half-killed by the frost, the salted portions have totally escaped. Many salts have also the property of retarding the evaporation of the moisture of the soil; others absorb it from the atmosphere, or are of the class of deliquescent salt; such are the common salt, chloride of calcium, chloride of magnesia, cubic petre, or nitrate of soda, &c., which, in consequence, when they are used as fertilizers, they increase this property, so valuable and so essential to all cultivated soils. Thus I found by some experiments upon a rich soil near Maldon, in Essex, worth 42s. per acre, that 1000 parts, dried at a temperature of 212° , absorbed in 18 hours, by exposure to air saturated with moisture at a temperature of 62° , 25 parts. But 1000 parts of the same field, which had been dressed with 12 bushels of marine salt per acre, under the same circumstances gained 27 parts; and 1000 parts of the same soil, which had been dressed with 6 bushels per acre, gained 26 parts. The attraction of some saline substances for the moisture of the atmosphere is very considerable. I found that 1000 parts of refuse salt manure, dried at 212° , absorbed in 3 hours, by exposure to air saturated with moisture at 60° , $49\frac{1}{2}$ parts. 1000 parts of the sediment or pan-scratch of the salt-makers, gained 10 parts; 1000 parts of Cheshire crushed rock-salt, 10 parts; 1000 parts of gypsum, 9 parts. Chloride of calcium is so powerfully deliquescent, that it absorbs sufficient moisture from the air to dissolve in it and form a solution. Dr. Marcet found that 288 grains in 124 days absorbed 684 grains of water. 288 grains of nitrate of lime, a salt found in some of the richest alluvial soils of the East, absorbs in 147 days 448 grains. Carbonate of potash, another saline fertilizer, also absorbs moisture. Now, it is worthy of the farmers' notice, that chloride of calcium is the very salt which is produced in such abundance by the decomposition of common salt by lime, in the way so successfully recommended first, by the old German chemist Glauber, by Mr. Hollingshead, Mr. Bennett, and Sir Charles Burrell (See **SALT** and **LIME**); for, by the slow action carried on for three months by these substances on each other, this salt and soda are produced by the decomposition; and it is not improbable that when these salts are present in the juices of plants, that by this means the attractive powers of their leaves and roots for aqueous vapour may be increased. Davy alludes to these essential, yet too little understood powers of absorption possessed by vegetables, when he says (*Lectures*, p. 207),—"In very intense heats, and when the soil is dry, the life of plants seems to be preserved by the absorbent power of their leaves; and it is a beautiful circumstance in the economy of nature, that aqueous vapour is most abundant in the atmosphere when it is most needed for the purposes of life, and that when other sources of its supply are cut off, this is most copious."

Of the salts of ammonia, as I have in another place remarked, carbonate of ammonia has

been detected in the *Chenopodium olidum* by Messrs. Chevalier and Lasseigne; and it probably exists in other plants which are distinguished for their powerful disagreeable odour. Muriate of ammonia has been found in wood by M. Chevreul. The salts of ammonia are in general exceedingly fertilizing in their effects upon vegetation. Soot owes part of its efficacy to the ammoniacal salts it contains. The liquor produced by the distillation of coal contains carbonate and acetate of ammonia, and this liquid of the gas-makers is a very good manure. "In 1308," says Davy, "I found the growth of wheat in a field at Roehampton assisted by a very weak solution of acetate of ammonia." The experiments of Mr. Robertson with soot clearly show the fertilizing effects of the soluble portion of it. He mixed together, in order to form a liquid manure, six quarts of soot in a hog-head of water. "Asparagus, peas, and a variety of other vegetables," says this intelligent horticulturist, "I have manured with this mixture, with as much effect as if I had used solid dung." Care must be taken, however, in using this and all other liquid fertilizers, not to make the solutions too strong: it is an error into which all cultivators are apt to fall in their early experiments. Even Davy was not an exception, since, from making his liquids too concentrated, he obtained results which widely differed from his later experiments. There is no doubt but that the salts of ammonia, and all the compound manures which contain them, have a very considerable forcing or stimulating, or, perhaps, from their decomposition, nourishing effect upon vegetation. In the experiments of Dr. Belcher upon the common garden cress, by watering them with a solution of phosphate of ammonia, the plants were 15 days forwarder than plants growing under similar circumstances, but watered with plain water; and he also describes the experiments of Mr. Gregory, who, by watering one-half of a grass field with urine, nearly doubled his crop of hay. Other testimonials in support of the fertilizing powers of the salts of ammonia are furnished by Mr. Handley.

Of the mode in which ammonia operates upon plants, a late valuable work on organic chemistry, by M. Liebig, abounds with observations, with some of which I cheerfully and cordially agree. To understand these remarks, however, the farmer must remember that ammonia is composed, according to the analysis of Davy, of hydrogen 74 parts, and azote or nitrogen 26 parts. "The nitrogen of putrefied animals," he observes, "is contained in the atmosphere, as ammonia in the form of a gas, which is capable of entering into combination with carbonic acid, and forming a volatile salt. Ammonia in its gaseous form, as well as all its volatile compounds, are of extreme solubility in water. Ammonia, therefore, cannot remain long in the atmosphere, as every shower of rain must condense it, and convey it to the surface of the earth: thence, also, rain-water must at all times contain ammonia, though not always in equal quantity. It must be greater in summer than in spring or in winter, because the intervals of time between the showers are greater; and, where

several wet days occur, the rain of the first must contain more of it than the second. The rain of a thunder-storm, after a long-protracted drought, ought, for this reason, to contain the greatest quantity which is conveyed to the earth at one time. But all the analyses of atmospheric air *hitherto made have failed* to demonstrate the presence of ammonia, although, according to our view (says M. Liebig), it can never be absent. If a pound of rain-water contains only one-fourth of a grain of ammonia, then a field of 40,000 square feet must receive annually upwards of 80 lbs. of ammonia, or 65 lbs. of nitrogen; for, by the observations of Schubler, which were formerly alluded to, about 700,000 lbs. of rain fell over this surface in 4 months. This is much more nitrogen than is contained in the form of vegetable albumen and gluten in 2650 lbs. of woad, 2800 lbs. of hay, or 200 cwt. of beet-root, which are the yearly produce of such a field; but it is less than the straw, roots, and grain of corn which might grow on the same surface would contain. Experiments made in the laboratory of Giessen, with the greatest care and exactness, have placed (continues Liebig) the presence of ammonia in rain-water beyond all doubt. It had hitherto escaped observation, because no one thought of searching for it." See AMMONIA.

I cannot recommend the farmer to adopt the able conclusions of M. Liebig without considerable caution: hardly any thing retards the progress of science more than erroneous theories. Fortunately, however, the farmer can in all cases patiently and successfully examine and apply the valuable facts of the skilful chemist without mystifying himself with not always intelligible doctrines. It is very probable that plants have the power of decomposing ammonia, and of assimilating the nitrogen which it contains, in the same way as there is little doubt the hydrogen of water is assimilated by them; but we have no direct evidence of the facts, and the best course, therefore, will be to regard them not as absolute chemical truths, but merely as of the class of what may be perhaps denominated scientific probabilities.

Some of the other compounds of chlorine, the old class of chlorides of the chemist, have been tried as fertilizers, with very doubtful success; for although at first the seeds which had been steeped in them germinated with a considerably increased rapidity, yet they speedily seemed to suffer by this additional stimulus. Davy tried solutions of chlorine, and sulphate of iron (green vitriol): he says, "Though the plume was very vigorous for a time, yet it became at the end of a fortnight weak and sickly, and at that period less vigorous in its growth than the radish sprouts which had been naturally developed, so that there can be scarcely any useful application of these experiments. Too rapid growth and premature decay seem invariably connected in organized structures, and it is only by following the slow operations of natural causes that we are capable of making improvements." Oxymuriate of lime, or, properly speaking, chloride of calcium, however, appears to be beneficial to vegetation: this was ascertained in 1795, by

Ingenhouz; and I have given in my work *On Fertilizers*, p. 367, the result of some trials by Mr. Fincham with this chloride that were highly successful: he says, "Half of some turnip-seed were steeped for 36 hours in a solution of chloride of calcium, composed of 1 part chloride of calcium, and 48 parts water; this was sown under precisely similar circumstances of soil and aspect with the other half unsteeped. The first came up much sooner, was never attacked by the fly, and the produce was half as much again, and the tops made more luxuriant. He attributes the failure of Davy to his having used the chlorine, uncombined with the base lime.

Mr. Owen Mason, of Providence, Rhode Island, has computed the saline contents of the crops raised from a field near that place, during 8 years' cultivation, as follows:—

	lbs.		lbs.
Potash . . .	424.92	Sulphuric acid	113.88
Soda . . .	131.92	Phosphoric acid	108.12
Lime . . .	532.88	Chlorine . . .	58.64
Magnesia . . .	64.08		
Alumina . . .	5.96	Total . . .	1830.80
Silica . . .	590.40		

"It is doubtful," Mr. Mason observes "if the cultivator ever suspected that he carried to his barn two casks of potash, one cask of soda, two casks of lime, a carboy of oil of vitriol, a large demijohn of phosphoric acid, and a variety of other matters contained in his fourteen tons of fodder, which were as certainly stowed away in his mows as if they had been conveyed thither in casks and carboys." This statement will perhaps serve to give some idea of the enormous quantities of saline matters that are removed from the soil by the crops ordinarily raised. When the crops are eaten on the farm, and the manure produced therefrom is returned to the soil, there is established a continued circulation of those ingredients which would be lost if the crops were removed and the stock sold. See SOILS.

SALTPETRE (Germ. and Fr. *salpêtre*). See NITRATES and SALTS.

SALTWORT (*Salsola*, from *salsus*, salt; in allusion to the saline properties of the species). A genus of plants which inhabits the sea-coast, especially abundant on the coast of the Mediterranean, where they are extensively gathered and burnt for the manufacture of barilla and soda. See KELP.

SALT-MARSH CATERPILLAR. See CATERPILLAR.

SALVING or SMEARING sheep is resorted to in various districts, for the purpose of preserving the fleece from the effects of weather, destroying injurious insects, and preventing cutaneous diseases. A mixture of damaged butter, hog's lard, resin, and Gallipoli oil, is found to be the most efficacious salve. Tar stains and spoils the colour of the wool. See SHEEP.

SAMPLE. A small quantity of a commodity exhibited at public or private sales, as a specimen. Wool, wine, corn, seeds, and indeed most species of agricultural produce and merchandise that can be conveyed in small bulk, are sold by sample. If an article be not at an average equal to the sample by which it is sold, the buyer may cancel the contract, an

return the article to the seller. (*McCulloch's Com. Dict.*)

SAND (Germ.). Finely divided silicious matter constitutes common river and sea-sand: particles of other substances are often blended with it, and sometimes it becomes calcareous from the prevalence of carbonate of lime.

Sand is often employed as a manure by the cultivator of the poor, hungry clays, especially if he can obtain calcareous sand. See **EARTHS, MIXTURE OF SOILS.**

SANDWORT. See **CHICKWEED.** (*Arenaria*, from *arena*, sand; referring to the sandy situation in which most of the species are found.) This is an extensive genus of herbs, of humble growth, with numerous slender stems, opposite, mostly narrow, entire, undivided leaves, and small, white or reddish, inodorous flowers, with coloured anthers. This succulent vegetable bears a great resemblance to samphire, and considerable quantities of it are pickled and sold for that plant.

SANICLE (*Sanicula*, from *sano*, to heal.) The wood sanicle (*S. Europea*) is a mere perennial weed, growing in woods and groves abundantly, about a foot high, flowering in May. The root is tufted, with fleshy fibres. The leaves are chiefly radical, simple, with deeply cleft lobes, veiny, and of a deep shining green. Flowers cream-coloured, in capitate umbels, in an irregular, twice compound, partly umbellate panicle. The herb is bitter, with an acrid, somewhat aromatic pungency. Its reputed vulnerary qualities are no longer believed.

SAP. In botany, the fluid which is absorbed by the roots from the earth, and undergoes the first action of the vital chemistry of the plant, is called the sap. It is formed as the absorbed fluid ascends upwards into the stem. It is afterwards conveyed to the leaves, where it is exposed to the influence of light and air, loses a large portion of its water, undergoes a chemical change, and, being returned to the branches and stem, it is analogous to the blood in animals; all the secretions being formed from it. Changed in the leaf into proper juice, it is assimilated to the various parts of the plant. In its crude state it consists of little except water, holding earthy and gaseous matter in solution, especially carbonic acid; but as it rises through the tissue of the stem, it dissolves the secretions it meets with in its course, and thus acquires new properties, so that by the time it reaches the leaves it is entirely different from its state when it first entered the root. The course taken by the sap in its passage through the stem, is by the whole of the tissue included within the bark, provided it is all permeable; but as, in many plants, the central part of the stem becomes choked up with solid matter deposited in the tissue, it usually happens, especially in trees, that the course of the sap is confined to the outer part of the wood, hence called sapwood. It is not certainly known through what kind of tissue the upward motion of the sap takes place, but it is probable that it is carried onwards through all the tubes and vessels of the wood, and their intercellular passages. The dotted vessels of the wood seem more especially destined to

fulfil this office when the sap is in rapid motion; but as they afterwards become empty, while the ascent of the sap continues, there can be no doubt that the woody tubes or pleurechyma offer the most constant means by which the sap is conveyed. See **ALBURNUM.**

SAP-SAGO. A kind of cheese made in Switzerland, having a dark olive-green colour and agreeable flavour, derived chiefly, if not entirely, from the addition of mellilot. See **CHEESE and ZARZIEGER.**

SAVIN. See **JUNIPER.**

SAW-DUST. The refuse or waste powder obtained from saw-pits, after any wood or timber has been separated or cut asunder by the saw. If fresh oak saw-dust be scattered on gravel walks it effectually prevents the growth of weeds, and when mixed with blood and quicklime it forms an excellent manure for the garden. This substance has lately been brought prominently into notice as an adjunct to other manures. There can be no doubt of its usefulness when made into compost with putrescent manures, saline substances, and organic matters. A compost of this kind, which has been well mixed and decomposed, and turned over with the spade at proper time, will produce an excellent crop of turnips.

SASSAFRAS (*Laurus sassafras*). This, on account of its sensible qualities, and real or supposed active medical virtues, was among the first American trees which became known to Europeans. In the United States, the neighbourhood of Portsmouth, New Hampshire, in latitude 43°, may be assumed as one of the extreme points at which it is found towards the northeast. But here it is only a tall shrub, rarely exceeding 15 or 20 feet in height, whilst in the Middle States it attains a height of 50 or 60 feet, being still more stately farther south. It is found in the Western and extreme Southern States, and in the low, maritime parts of Virginia, of the two Carolinas, and of Georgia. The sassafras is observed to grow of preference about plantations and in soils which have been exhausted by cultivation and abandoned. The old trees give birth to hundreds of shoots which spring from the earth at little distances, but which rarely rise higher than 6 or 8 feet. Though this tree is common on poor land, and blooms and matures its seed at the height of 15 or 20 feet, yet it is never of very ample dimensions except in fertile soils, such as form the declivities which skirt the swamps, and such as sustain the luxuriant forests of Kentucky and West Tennessee. About New York and Philadelphia the sassafras is in full bloom in the beginning of May, and six weeks earlier in South Carolina. The wood stripped of its bark is very durable, strong, and resists worms, &c. It forms excellent posts for gates. Bedsteads made of it are never infested with bugs. It is, however, only occasionally employed for any useful purpose, and never found in the lumber-yards of large towns. The pith and dried leaves of the young branches of the sassafras contain much mucilage, resembling that of the okra plant, and are extensively used in New Orleans to thicken potage, and make the celebrated *gumbo soup*. In Virginia and other Southern States, the inhabitants make a

beer by boiling the young shoots of the sassafras in water, to which a certain quantity of molasses or sugar is added, the whole being left to ferment. The beer is regarded as a wholesome and pleasant drink during summer. So is an infusion of the bark of the roots, which is much drunk for the cure of cutaneous and other disorders.

SAW-FLIES. The names of above 60 species of saw-flies, natives of the United States, and found in Massachusetts, are given in Dr. Harris's *Catalogue*. Some of these are very interesting in their caterpillar state. One of the largest flies is called *Cimbex Ulmi*, because it inhabits the elm. The female of this species, at first sight, might be mistaken for the hornet. (The name *Cimbex* was originally given by the Greeks to certain insects resembling bees and wasps, but not producing honey.) The elm saw-fly measures an inch in length, the wings expanding about 2 inches. It appears in the Eastern States from the last of May to the middle of June, during which the female lays her eggs upon the common American elm, the leaves of which serve as food for the young caterpillars hatched out. These come to their growth in August, and then measure from $1\frac{1}{2}$ to 2 inches in length. Like all false caterpillars of the genus *Cimbex*, this insect, when handled or disturbed, betrays its fears or its displeasure by spitting out a watery fluid from certain little pores situated on the sides of its body just above its spiracles. The false caterpillars of other saw-flies prove very destructive to pines and other fir trees. They crawl down the trees and weave cocoons which are concealed in the leaves, &c. In the following spring the insects burst their chrysalids and come forth as winged flies.

No means, says Dr. Harris, for the destruction of the caterpillars of the fir saw-fly have been tried here, except showering them with soap-suds, and with solutions of whale-oil soap, which has been found effectual. They may also be shaken off or beaten from the trees, early in the morning, when they are torpid and easily fall, and may be collected in sheets, and be burned or given to swine. For other means to check their depredations the reader may consult the articles on the pine and fir saw-flies of Europe, contained in Köllar's *Treatise*.

Dr. Harris has described a kind of saw-fly (*Selandria vitis*), which attacks the grape-vine. It is of a jet-black colour, except the upper part of the thorax, which is red, the legs being a pale-yellow or whitish. The body is about $\frac{1}{4}$ of an inch long. The false caterpillars proceeding from the eggs of these flies may be found in swarms of various ages on the lower sides of the leaves, some very small and others fully grown. When fully grown they measure about $\frac{5}{8}$ ths of an inch in length. The body is a light-green, the legs and tip of the tail being black. After the first moulting they become almost entirely yellow, and then leave the vine to burrow in the ground. They come out again from their chrysalis state in about a fortnight, pair and lay eggs for a second brood. The young of the second brood are not transformed into flies until the succeeding spring, remain-

ing in the ground in their cocoons through the winter. "For some years previous to the publication of my *Discourse*," says Dr. Harris, "I observed that these insects annually increased in number, and, in the year 1832, they had become so numerous and destructive that many vines were entirely stripped of their leaves by them. Whether the remedies then proposed by me, or any other means, have tended to diminish their numbers, or to keep them in check, I have not been able to ascertain, and have had no further opportunity for making observations on the insects themselves. At that time, air-slacked lime, which was found to be fatal to these false caterpillars of the vine, was advised to be dusted upon them, and strewed also upon the ground under the vines, to insure the destruction of such of the insects as might fall. A solution of one pound of common hard soap in five or six gallons of soft water, is used by English gardeners to destroy the young of the gooseberry saw-fly; and the same was recommended to be tried upon the insects under consideration.

"All the young of the saw-flies do not so closely resemble caterpillars as the preceding; some of them, as has already been stated, have the form of slugs or naked snails. Of this description is the kind called the slug-worm in this country, and the slimy grub of the pear tree in Europe. So different are these from the other false caterpillars, that they would not be suspected to belong to the same family. Their relationship becomes evident, however, when they have finished their transformations; and accordingly we find that the saw-flies of our slug-worms and those of the vine are so much alike in form and structure, that they are both included in the same genus. Moreover, there are certain false caterpillars, intermediate in their forms and appearance between the slimy and slug like kinds and those that more nearly resemble the true caterpillars; thus admirably illustrating the truth of the remark, that nature proceeds not with abrupt or unequal steps; or, in other words, that amidst the immense variety of living forms, where-with this earth has been peopled, there is a regular gradation and connection, which, in particular cases, if we fail to discover, it is rather to be attributed to our own ignorance and short-sightedness, than to any want of harmony and regularity in the plan of the Creator. In considering the resemblances of species, we cannot fail to admire the care that has been taken, by almost insensible shades of difference among them, or by peculiar circumstances controlling their distribution, their habits of life, and their choice of food, to prevent them from commingling, whereby each species is made to preserve forever its individual identity.

"The saw-fly of the rose, which, as it does not seem to have been described before, may be called *Selandria rosæ*, from its favourite plant, so nearly resembles the slug-worm saw-fly as not to be distinguished therefrom except by a practised observer. The caterpillars of these perform their appointed work of destruction in the autumn; they then go into the ground, make their earthen cells, remain there-

in throughout the winter, and appear, in the winged form, in the following spring and summer."

During several years past, these pernicious vermin have infested the rose bushes in the vicinity of Boston, and have proved so injurious to them, as to have excited the attention of the Massachusetts Horticultural Society, by whom a premium of \$100, for the most successful mode of destroying these insects, was offered, in the summer of 1840. Showering or syringing the bushes with a liquor, made by mixing with water the juice expressed from tobacco by tobaccoists, has been recommended; but some caution is necessary in making this mixture of a proper strength, for if too strong it is injurious to plants; and the experiment does not seem, as yet, to have been conducted with sufficient care to insure safety and success. Dusting lime over the plants when wet with dew has been tried, and found of some use; but this and all other remedies will probably yield in efficacy to Mr. Haggerston's mixture of whale-oil soap and water, in the proportion of two pounds of the soap to fifteen gallons of water. For particular directions to use this, see APHIDES.

For a species of minute saw-fly, destructive to the turnip crops in England, see FLY IN TURNIPS.

SAW-GRASS. See Bog-Rush.

SAXIFRAGE (*Saxifraga*; from *saxum*, a stone, and *frango*, to break; in allusion to its reputed medical qualities in that disease). This is a very extensive genus of beautiful alpine plants, the greater part of which are particularly suitable for ornamenting rock-work, or growing on the sides of naked banks. They are all readily increased by seeds or divisions. These herbs are, for the most part, perennial, various in habit, often in some degree hairy and glutinous, with stalked, simple, undivided or lobed leaves. Flowers either panicled, rarely solitary, on a long naked stalk, or corymbose at the top of a round leafy stem; erect, white, yellow, or purple, frequently spotted, inodorous. Dr. Darlington describes two American species under the names of *Virginia* or *Early Saxifrage*, and *Pennsylvania* or *Tall Saxifrage*. Canada and Labrador have some species.

SAXIFRAGE, BURNET. See BURNET.

SAXIFRAGE, GOLDEN. See GOLDEN SAXIFRAGE.

SCAB. A contagious disease incident to sheep, which, like the mange in cattle, horses, and dogs, and the itch in the human subject, is the effect of certain minute insects belonging to the class *Acari*; at least these insects always are present in this disease. In the human subject the itch insect obtains its food from the pustules of the disease. The cure of scab, however, is supposed to be in the destruction of this insect. Washes, whether infusions of tobacco, hellebore, or arsenic, appear to be objectionable, and a safer and more effectual method of curing the disease and benefiting the wool is the application of a mercurial ointment. The ointment should be made of two strengths. That for bad cases should consist of common mercurial or Trooper's oint-

ment, rubbed down with three times its weight of lard. The other, for ordinary purposes, should contain five parts of lard to one of the mercurial ointment. (*Youatt on the Sheep*, p. 536.) See SHEEP, DISEASES OF.

SCABIOUS (*Scabiosa*, from *scabies*, the itch; the common kind is said to cure that disorder). Some of these plants are well adapted for ornamenting the flower-border. The herbaceous species are readily increased by division at the root, or by seed. The seeds of the annual kinds merely require sowing in the open border. There are three indigenous species, all perennials; viz., the devil's-bit scabious (*S. succisa*), which is common in grassy, rather moist pastures, flowering from August to October (see DEVIL'S-BIT SCABIOUS); the field scabious (*S. arvensis*), growing in corn-fields and pastures, with a bristly stem a yard high. The radical leaves are lanceolate, serrated, stalked, the rest pinnatifid and quite sessile. The flowers, which appear in July, are large and handsome, of a fine pale purple. Sheep and goats are said to eat this herb; but its bitter and nauseous flavour is not agreeable to domestic cattle. The small scabious (*S. columbaria*) is a less common species, attaining to the height of twelve or eighteen inches. The leaves and flowers are smaller and more delicate than the last.

SCALD CREAM. Provincially, cream raised by heat, or clouted cream. See DAIRY, MILK, BUTTER, LACTOMETER, &c.

SCALLION. See ONION.

SCAPE. In botany, a stem rising from the roots, more frequently from a rhizome or underground stem, bearing nothing but the flowers. The iris is an example.

SCARIFIER. A tillage implement for stirring and loosening the soil, without bringing up a fresh surface. Under the same head may be included the grubber, the cultivator, and the scuffler, all of which act on the combined principles of plough and harrow at the same time. Some of these implements have wheels, by the raising or lowering of which the tines or prongs may be made to sink more or less into the earth. See HARROW.

Amongst the earliest of the many varieties of this implement that I am acquainted with (says Mr. J. A. Ransome, in his work upon the *Implements of Agriculture*), is one which the late T. Cooke used, attached to the framework of his drill, the coulters and apparatus of which, being removed, gave place to a bar, or head, suspended by joints to the axle, on which a row of strong tines was fixed. See Pl. 14, fig. 2.

On a similar plan to this, but working on a plough-carriage, another invention by Robert Fuller, a practical farmer of Ipswich, came into operation, and worked exceedingly well.

Biddell's Scarifier and *Extirpator* (Pl. 15, fig. 3) is held in deservedly high repute in Suffolk (where it originated) and the eastern and midland counties, where it is now in very general use. It is an implement of immense power, and well calculated to supersede the extensive use of the plough, otherwise indispensable in the cultivation of strong land, and we are inclined to believe with better effect. There cau

be no question that in a general way a finer tilth may be obtained with Biddell's scarifier than with any plough; and, for this reason, strong and tenacious clays and even many of the better loams, though dry at the surface and apparently in good order for ploughing, frequently turn up coarse and "loamy." In the early part of the spring, the combined action of frost and the atmosphere may probably in time effect what a scarifier would do at once, viz., reduce the clods to a comparatively fine mould, without which the hope of a good barley crop is but slender. There is no reason why the process of scarifying should not prove equally beneficial to the turnip or any other crop. Indeed, some are of opinion that what is usually called a *stale* furrow, in contradistinction to a newly ploughed one, is more favourable to the germination and after-growth of a plant like the turnip than a sowing on soil freshly turned up.

A great improvement on Fuller's extirpator, was *Finlayson's Patent Self-cleaning Harrow*. Pl. 15, fig. 5. This well-known implement may be called the parent of several of the same description, which, in improved forms, have subsequently come into use. It is formed of iron, and, according to the inventor, has the following advantages:—1. From the position in which the tines are fixed, their points (*aaaa*) hanging nearly on a parallel to the surface of the land, it follows, that this implement is drawn with the least possible waste of power. 2. From the curved form of the tines, all stubble, couch, &c., that the tines may encounter in their progress through the soil, is brought to the surface, and rolled up to the face of the tines; when it loses its hold, and is thrown off (at *bbbbbb*), always relieving itself from being choked, however wet or foul the land. 3. The mode by which this harrow can be so easily adjusted to work at any depth required, renders it of great value; this is done as quick as thought by moving the regulator (*c*) upwards or downwards between the lateral spring (*de*); and by each movement upwards into the openings (*fghik*), the fore-tines (*llll*) will be allowed to enter the soil about $1\frac{1}{2}$ inch deeper by each movement into the different spaces, until the regulator is thrown up to (*e*), when the harrow is given its greatest power, and will then be working at the depth of 8 or 9 inches. Also the axletree of the hind-wheels is moved betwixt *o* and *p*, a space of 7 or 8 inches, by a screw through the axletree, which is turned by a small handle (*g*), so that the hind part of the harrow, by this simple mode, is also regulated to the depth at which it is found necessary to work. 4. When the harrow is drawn to the head or foot lands, the regulator is pressed down to *d*, and the fore-wheel (*m*) is then allowed to pass under the fore-bar (*n*), by which the nose of the harrow is lifted, and the points of the fore-tines (*llll*) will then be taken 2 or 3 inches out of the soil, which affords the means of turning the harrow with the greatest facility. 5. Being made of malleable iron, its durability may be said to be endless; whereas, if made of wood, the prime cost would be entirely lost at the end of every 5 or 7 years. Lastly, the mode of working is so

easy, that any boy of 10 or 12 years of age is perfectly qualified to manage it. Next to Wilkie's brake, we consider this the most valuable of pronged implements, and think that, like Wilkie's implement, it might be substituted for the plough, after drilled green or root crops, on light soil generally. Some account of the astonishing powers of the implement, as exemplified in breaking up Hyde Park, London, in 1826, will be found in the *Gardener's Magazine*, vol. ii. p. 250.

Wilkie's Parallel Adjusting Brake is very nearly allied to the implement last mentioned; its chief improvement consists in the triangular adjustment of the teeth or prongs, and the facility with which they may be completely thrown out of work; whereas, with Finlayson's harrow this can only be partially done, the hind-teeth of the latter still retaining some hold of the ground, even though the first row be lifted up. This we are aware has been represented as an advantage, inasmuch as the slight hold retained by the back-row of tines prevents the implement from running on the horse's heels, when turning at the ends of the stiches on hilly ground. We see but little in this as an argument in favour of any implement of the kind. Indeed, we are rather disposed to give the preference to one like Wilkie's brake, which, by a parallel movement of the frame in which the tines are fixed, can, either at the turnings or while in action, be elevated or depressed *en masse*.

Kirkwood's Grubber in its operation somewhat resembles those last described, but is superior to them in working. The leverage that is obtained by pressing on the handles or stilts of the machine, whether in action or rest, is so simple, and yet so powerful in its effect, as to regulate the depth of the tines to the greatest nicety; or, in cases of obstruction, to throw them out of work altogether. It is an admirable implement, and well deserving the high commendation which has been bestowed on it.

SCORE. A term signifying 20 lbs. in speaking of the weight of cattle or swine.

SCORING. A provincial term signifying the glossing or making the furrow-slice in ploughing or turning land up, by the plough acting as a trowel. It is sometimes written scowering.

SCORPION-GRASS (*Myosotis*, from *myos*, a mouse, and *otos*, an ear; fancied resemblance in the leaves.) All the perennial species of this genus are very beautiful, especially the well-known Forget-me-not (*M. palustris*). They grow best in moist places, or by the edges of ponds or ditches; they may also be grown in pots among alpine plants. The annual species like a dry, sandy soil; most of the perennial kinds may be increased by divisions of the roots, and all by seeds. Sir J. E. Smith describes seven species of scorpion-grass indigenous to England, two of which are annuals, the rest perennials. Besides the *M. palustris* and *M. arvensis*, there are one or two other species found in the United States.

SCOTCH FIR. A common but improper name for the Scotch pine (*Pinus sylvestris*). See PINE and FIR.

SCOURING. See PURGING.

SCRAPER. See **MOULDBART.**

SCUFFLER. An implement of somewhat the same kind as the scarifier, but which is mostly lighter and employed in working after it. See **HARROW.**

SCULL-CAP (*Scutellaria*). There are several species of this plant found in the United States. The common hairy scull-cap (*S. pilosa*) has a perennial root, and stem 12 or 18 inches high, more or less hairy, and often purplish. The flower is a purple-blue colour, and opens from June to August. There are several varieties of this species. The large-flowered or entire-leaved scull-cap (*S. integrifolia*) is distinguished for its handsome, large, bluish flowers, which bloom in June. It is intensely bitter to the taste. The lateral-flowered scull-cap (*S. laterifolia*), has acquired the name of mad-dog scull-cap, from its having acquired much notoriety some years ago as a supposed remedy for hydrophobia. "Like its numerous predecessors of the same pretensions," says Dr. Darlington, "it had its day of importance among the credulous, and then sank into the oblivion which necessarily awaits all such specifics." Several other species of scull-cap are enumerated in the United States.

SCURVY-GRASS (*Cochlearia*). A genus of plants of little interest, with the exception of horse-radish (*C. armoracea*), and the common scurvy-grass (*C. officinalis*). Besides these there are three other indigenous species: the Greenland scurvy-grass, the English scurvy-grass, and the Danish scurvy-grass. They are either annual or biennial herbs, and were once celebrated as antiscorbutics, but have lost their reputation. The plants are mostly smooth and rather succulent, with branched, spreading stems, and simple leaves, the radical ones stalked and most entire. Flowers white, or pale-purplish.

The common scurvy-grass is cultivated in gardens for its leaves. It flourishes best in a sandy, moist soil, but will succeed in almost any other, especially if abounding in moisture. The situation must always be as open as possible. It is propagated by seed, which should be sown as soon as it is ripe in July or June, for if kept from the ground until the spring, they will entirely lose their vegetative power, or produce plants weak and unproductive. The sowing is performed in drills 8 inches apart, and half an inch deep.

SCYTHE. This implement for mowing grass has been latterly much used for cutting grain crops, and with great success, when it has been properly mounted with a rake or cradle, and put into expert hands.

Drummond's iron-handled scythe is considered in Scotland very effective. A good mower will cut down with it from an acre and a half to two acres in the day, and with this scythe he can either cut *out* from the standing corn when *upright*, or cut *in*, as he may deem the better way at all times.

The common grass-scythe will cut oats and barley also very well when upright, but the mower will perceive his inability to lay down evenly and at right angles with the standing corn, for the convenience of the binders, a

heavy crop of wheat with this scythe, even if furnished with a bow.

The Hainault or Flemish scythe, the favourite Belgian implement for severing corn, appears to be a very efficient instrument, but although all the trials made with it in Scotland and England report favourably of it, it has not come into use even partially; prejudice and the results of habit and custom rendering the old sickles, scythes, and reaping-hooks more popular. See **HAY-MAKING**, **REAPING-HOOK**, **SICKLE**, &c.

SCYTHE AND CRADLE. The well-known American implement called the *scythe and cradle* used in the United States for harvesting wheat and all other kinds of small grain, is much preferable to the Hainault scythe. The cradle is made with 5 long teeth extending the full length of the scythe, and bent to the same shape. These teeth are generally made of the strong and pliant ash, shaved down so as to be as light as is consistent with the necessary strength. The handle is bent in such a manner as contributes greatly to the convenience of using the implement. It is slowly becoming introduced into England.

SEA-BUCKTHORN. See **SALLOW-THORN.**

SEA-HOLLY. See **ERYNGO.**

SEA-KALE. See **KALE.**

SEA-LAVENDER. See **THRIFT.**

SEA-MUD or **OUSE.** This rich saline deposition from salt-marshes and the sea-shores is found to possess very enriching properties, and to be a useful addition to the soil where it can be obtained in any quantity. See **ALLUVIUM**, **MARSH-MUD**, and **WARPING.**

SEAM. A provincial term applied to any fatty substance, as tallow, grease, or lard. A seam of corn is also a quarter or 8 bushels, and a seam of wood a horse-load, or about 3 cwt.

SEA-MILKWORT (*Glaux*, from *glaukos*, gray, in allusion to the colour of the leaves). The common sea-milkwort, or black salt-wort (*G. maritima*), is in England a pretty little indigenous perennial plant, growing abundantly in muddy salt-marshes.

SEA-SHELL. All marine shells, where they can be obtained in sufficient quantity, form a durable and lasting addition to the soil. See **OYSTER-SHELLS.**

SEA-WARE. A term frequently applied to the weeds thrown up by the sea in many situations, and which is collected and made use of as manure and for other purposes. It consists principally of the *Quercus marina*, and various species of *Fuci*, and has often the names of sea-wrack, ore-weed, sea-tangle, &c. See **KELP.**

SECHIUM (*Sechium edulis* or *Siegos edulis*). A new vegetable from South America; in size and form resembling a very large bell-pear; the skin smooth, of a pale-green colour; the flesh solid. For the table it is prepared in a manner similar to the squash, and is stated to be of a more delicate flavour. It has but one single flat seed, which is larger than a Lima bean. A new vegetable, imported by Mr. Buist, of Philadelphia, and altogether unlike any thing before known or cultivated here.

SEDGE (*Carex*, from *carco*, to want, the upper

spikes being without seeds). This is a very extensive genus, the species of which are uninteresting; part of them are natives of marshy situations, while a few thrive on dry, sandy eminences; they seed freely, by which they are increased. The roots are, perhaps without exception, perennial, mostly creeping; sometimes fibrous and tufted only; herbage grassy; stem simple, generally with thin, finely serrated, and sharply-cutting angles, without knots or joints. Leaves linear, pointed, flat, roughish, with similarly cutting edges; their bases more or less tubular and sheathing, membranous at the summit, often auricled, the upper ones becoming bractes. Sir J. E. Smith enumerates and describes no less than 62 species of *Carices* indigenous to Great Britain. There are a great many species of sedge found in the United States.

SEED is the reproductive part of a plant, resulting from a change effected in the ovules by the process of impregnation: it contains the embryo or rudiment of a future plant.

For the preservation of the seed from insects and decomposition, and for food for the embryo, seeds contain fecula, saccharine, oily, and gummy matter within their coverings, and sometimes acrid, poisonous principles. In their coverings they also contain mucilage, oil, both fixed and volatile, and other principles

which man makes subservient to his use, either as diet or condiments, or for other purposes. Seed is a form of reproductive matter peculiar to flowering plants, its equivalent in flowerless plants being the sporuli. It is commonly and very justly remarked, that, as the seed is the part intended by nature to multiply the races of plants, in this respect it resembles the egg, and, like it, long retains its vitality.

The choice of the seed intended to be sown is an object of greater importance than many farmers seem to imagine. It is not sufficient that the finest grain be chosen for this purpose, unless it be likewise clean from weeds. In procuring seed, it should be a rule with the farmer to purchase or reserve such as is the most full, plump, sound, and healthy, whatever the kind may be, as it is perhaps only in this way that crops of good corn can be insured. And this practice is still more obvious from the circumstance of its being in some measure the same with plants as with animals, that the produce is in a degree similar to that from which it originated. See BARLEY, GRASSES, OATS, TEMPERATURE, WHEAT, &c.

The usual quantity of seed applied per acre for the ordinary crops of the English farmer, when either broadcast, drilled, or dibbled, is as follows:—

	Time of sowing.	Broadcast.	Drill.	Dibbled.
Wheat - - - -	September to December	2½ to 3½ bushels.	2 to 3 bushels.	1½ to 2 bushels.
Oats - - - -	February to April	4 to 6	3½ to 4½	2½ to 3
Barley - - - -	February to May - -	3 to 4	2½ to 3½	
Rye - - - -	August and September -	2½ to 3½	2 to 3	
Beans - - - -	November to March -	3 to 4	2½ to 3½	2 to 3
Peas - - - -	January to March - -	3½ to 4½	3 to 4	3
Tares - - - -	August to March - -	2½ to 3	2 to 2½	
Buckwheat - - - -	May - - - -	2 to 2½	2	
Clover, Red - - - -	March and April - -	12 to 16 lb.	10 to 14 lb.	
" White - - - -	Do. - - - -	3 to 4		
Trefoil - - - -	Do. - - - -	2		
Red Clover - - - -	Do. - - - -	2		
Rye Grass - - - -	Do. - - - -	1 peck		
Turnips - - - -	May to August - -	2 to 3 lb.	1½ to 2 lb.	
Mangel-wurzel - - - -	April and May - -			
Potatoes - - - -	March to June - -	-	20 to 25 bush.	

The quantities here given are those common throughout the island. But from the general custom in Flanders, and from the extensive practice which I have witnessed on the farms of Mr. Hewitt Davis and other excellent farmers, I am inclined to think that these quantities may be considerably reduced. As in most cases it is usual to have on the land many more seedling plants than the soil can properly mature, thinner sowing has the effect of producing stronger, healthier, and more prolific heads; and I am still inclined to this opinion in favour of thinner sowing, notwithstanding I am aware that such excellent agriculturists as Lords Leicester and Western practise, and strongly recommend, thick sowing.

As to the season for sowing, only general directions can be given. It is a highly important subject, much too little attended to in general. In the north of England they are frequently sowing weeks earlier than in the south.

SEED-LIP. A sort of basket in which the sower carries the seed he is about to scatter over the ground.

SEEL. A term provincially applied in England to time or season in respect to crops, as hay-seel, or hay-time, and barley-seel, or barley-seed time, bark-seel, barking-season, &c. It is sometimes written *seal*.

SENNA, WILD (*Cassia Marylandica*). This plant, which is abundant in the Middle States, is quite ornamental, and often introduced into gardens. It has a perennial root and erect stem, growing to the height of 3 or 4 feet, and branching. The leaves resemble those of the imported senna (also a species of cassia), for which they are a good substitute, the medical properties being nearly similar. Its flowers are yellow and in clusters, followed by a seed-pod or legume 3 or 4 inches long.

SENSITIVE PLANT, WILD, commonly called Twinkling Cassia (*Cassia nictitans*). This plant is found in the Middle States, on roadsides, &c. Its root is annual, and the stem grows 6 to 12 inches long, mostly oblique, slender, branching, and roughish-hairy. It produces yellow flowers in August, succeeded by seed-pods an inch to an inch and a half long, and two or three lines wide.

SEPTA. In botany, the partitions which divide the interior parts of a fruit.

SERRATE. A botanical term, implying notched, or cut like the teeth of a saw.

SERVICE TREE (*Pyrus*). There are in England two species of this tree, the wild service tree (*P. torminalis*), and the true service tree (*P. domestica*). Both are indigenous trees, often of considerable size, of extremely slow growth, and the wood is very hard. The service tree is still occasionally to be met with in the hedgerows in Kent, and in the wealds of Sussex, as also in the north of England and Wales. The leaves of the wild service tree are dark-green, deciduous, simple, somewhat heart-shaped, serrated, seven-lobed, on long stalks. Flowers white, numerous, in large, terminal, corymbose, downy panicles. The umbilicated fruit, which is not larger than that of the hawthorn, becomes agreeably acid and wholesome when the frost has touched it, or when, like the medlar, it has undergone a kind of putrefactive fermentation. Ray prefers its flavour to the true service, which latter is now become obsolete. See **JUNE BERRY**.

SESSILE. A botanical term, applied to leaves without footstalks, which are seated close upon the stem.

SETACEOUS. In botany, implies shaped like bristles.

SETON. In farriery, a small cord constituted of a number of threads laid together and passed through the skin by a proper needle, for the purpose of keeping open an issue.

SHALOT or **ESCALOT** (*Allium ascalonicum*). Having a stronger taste than the onion, yet not leaving, as it is said, the strong odour on the palate which that species of *Allium* is accustomed to do, the shalot is often preferred, and employed instead, both in culinary preparations and for eating in its natural state. Each offset of the root will increase if planted in a similar manner to its parent. The planting may be performed during October or November, or early in the spring, as February, March, or beginning of April. The first is the best season, especially if the soil lies dry, as the bulbs become finer; but otherwise the spring is to be preferred, for excessive moisture destroys the sets. Mr. Henderson supports the practice of planting in autumn, and says, "if the smallest offsets are employed for planting, they never become mouldy in the ground, and are never injured by the most intense frosts." They are to be planted 6 inches asunder each way, in beds not more than 4 feet wide, being usually inserted in drills, by the dibble, or with the finger and thumb.

SHAMROCK. The national emblem of Ireland. The term "shamrock" seems a general appellation for the trefoils, or three-leaved plants. There has been much dispute as to what is the true Irish shamrock; it has generally been considered to be the clover or *Trifolium repens*. A writer in the *Journal of the Royal Inst.* No. 3, advances abundant testimony in proof of the wood-sorrel (*Oxalis acetosella*) being the true shamrock.

SHARE OF A PLOUGH. That part which cuts or breaks the ground. See **PLOUGH**.

SHAW. A country term applied to a wood that encompasses a close.

SHEARING OF SHEEP. The operation of cutting off the fleece or coat of wool with a pair of shears.

This is performed in different ways, but the best mode is that of the circular or round the sheep, instead of the longitudinal, which is now mostly in use in Britain. Shearing is usually performed about June or July, according to situation and season, but should not be done either too early or be too long protracted, as injury and inconvenience may attend either extreme. A good clipper is capable of clipping from 14 or 15 to 20 or 25 sheep in the day, and more are frequently done by very expert persons. Great care should be taken not to cut or prick the animals; but where this accident happens, in the northern parts of the kingdom, they touch the part with a little tar or sheep-salve; and in Sweden it is often done with train-oil and resin melted together. After shearing, the sheep should be turned into a warm, dry pasture. See **SHEEP**.

SHEARLING. The name given to a sheep that has been once shorn.

SHEARS. A name applied to some instruments employed in agriculture. The shears used for sheep-shearing are of very ancient origin: they were termed *forfex* by the Romans; and it appears that no improvement has been made on the instrument. In a collection of antique gems at Berlin, called the Stosch collection, is a gem bearing a representation of a newly shorn sheep, and the shears, which are exactly the same as those now used. Shears are also employed for clipping hedges.

SHEATH. In botany, the lower part of the leaf that surrounds the stem.

SHEEP (*Ovis aries*, nat. ord. *Ruminantia*). Of the original breed of this invaluable animal, which is in modern English farming almost equally important for furnishing the farmer with a dressing of manure, and the community at large with mutton, clothing, and other almost necessaries of life, nothing certain is known. Several varieties of wild sheep have, by naturalists, been considered entitled to the distinction of being considered the parent stock. Of these are, 1. The musmon (*O. Musimon*), still found wild in the mountains of the larger islands of the Mediterranean and in European Turkey. 2. The argali (*O. Ammon*), or wild Asiatic sheep, which are the tenants of the highest mountains of central Asia, and the elevated, inhospitable plains of its northern portions. 3. The Rocky Mountain sheep (*O. montana*), which is found on the mountains of North America; and, 4. The bearded sheep of Africa (*O. tragelaphus*), found in the high lands of Egypt, and in Barbary. It is doubtful whether sheep are indigenous to Britain, but they are mentioned as existing there at very early periods. The Romans established a woollen manufactory at Winchester, at which city the first guild of fullers was established. The natural habits of the sheep attach it to the highest ground, to the upland slopes, where the heath and other aromatic plants abound. Nature never intended this animal to occupy

the deep alluvial turnip lands of our rich arable farms, or to consume the succulent grasses of our water-meadows: every shepherd is aware that their natural instinct, after being for ages domesticated, still leads them invariably to the elevated portions of the field in which they are placed. All these facts tell the farmer in very intelligible language that it is change of food, of pasturage, and, if possible, the giving them occasionally aromatic food, that will best conduce to the prosperity of his flock. With this view parsley has been successfully cultivated. Then, again, the wild sheep are found to frequent all those places where saline exudations are to be found. In common with the deer and other ruminating animals, they lick the salt clay of some of the American uplands to such an extent, that these places are denominated *licks*. Some of the most skilful of the English flock-masters never allow their sheep to be without salt. The female sheep goes with young twenty-one weeks, produces one, and rarely more than two at a birth; her milk yields abundance of strong-tasted cheese, but a very limited quantity of cream. The sheep, in temperate climates, is clothed with wool, which is annually renewed, but in warmer countries the animal is furnished with hair. In its wild state it has generally horns, but these have nearly disappeared in most of the breeds of domestic sheep. The domesticated sheep is known in England by different names, according to its age or sex. "The male," says Mr. Youatt, "is called a *ram* or *tup*. While with his mother he is denominated a *tup*, or *ram* lamb, a *heeder*, and in some parts of the west of England a *pur* lamb. From the time of weaning until he is shorn he has a variety of names; being called a *hog*, a *hogget*, a *hoggerel*, a *lamb hog*, a *tup hog*, or a *teg*; and, if castrated, a *wether hog*. After shearing, when probably he is a year and a half old, he is called a *shearing*, a *shearling*, a *shear hog*, a *diamond*, or *dinmont ram* or *tup*, and a shearling wether when castrated. After the second shearing he is a *two-shear ram* or *tup* or *wether*; at the expiration of another year he is a *three-shear ram*, &c., the name always taking its date from the time of shearing. In many parts of the north of England and Scotland he is a *tup lamb*, after he is salved and until he is shorn, and then a *tup hog*, and after that a *tup*, or if castrated, a *dinmont* or *wedder*. The female is a *ewe* or *gimmer lamb* until weaned, and then a *gimmer hog* or *ewe hog*, or *teg*, or *sheeder ewe*. After being shorn she is a *shearing ewe* or *gimmer*, sometimes a *theave* or *double-toothed ewe*, or *teg*; and afterwards a *two-shear* or *three-shear*, or a *four* or *six-tooth ewe* or *theave*. In some of the northern districts, ewes that are barren or that have weaned their lambs are called *eild* or *yeld ewes*." (*Youatt on Sheep*, p. 2.)

The teeth of the sheep are in number the same as those of the ox, viz., eight incisor or cutting-teeth in the lower jaw, and six molar teeth on each side, and in each jaw.

When the lamb is born he has either no incisor teeth or only two, but before he is a month old he has eight. The two central teeth of these are shed, and again at two years old at-

tain their full growth: when between two and three years of age, the two next incisors are shed; at three years old, the four central teeth are fully grown; at four, he has six complete teeth. That the primitive breed of sheep were horned, we have direct evidence. (*Gen.* xxii. 13; *Joshua* vi. 6.) Immense flocks of this animal have in all ages of the world been kept by man, but more universally for their wool and skins than for their flesh: for that is yet to many nations by no means a favourite meal. The Calmucs and Cossacks still prefer that of the horse and the camel; the Spaniard who can procure other flesh rarely eats that of the Merino; to many North Americans it is still an object of dislike. Englishmen, perhaps, consume more mutton than the people of any other country, but the taste for this is certainly of modern origin. It has rapidly extended, as better breeds and sweeter kinds of mutton have been produced.

My limits will not allow me to describe the great variety of breeds of sheep which belong to various countries; I shall, therefore, confine myself to a brief notice of those which tenant the British islands, referring those of my readers who need further information on the valuable work of Professor Youatt *On the Sheep*, and to Professor Low's *Illustrations of the Breeds of Domestic Animals*, from whence this article is chiefly taken; there is also an excellent essay upon the sheep by Mr. Ellman in Baxter's *Library of Agricultural Knowledge*.

CLASS I.—SHEEP WITHOUT HORNS.

The *new Leicester Sheep*, says Mr. Youatt, which comprehends the most excellent of Bakewell's own breed, and of Culley's variety or improvement on it, is precisely the form for a sheep provided with plenty of good food, and without any great distance to travel or exertion to make in gathering it. It should have a head hornless, long, small, tapering towards the muzzle. Eyes prominent, with a quiet expression; ears thin, rather long, directed backwards; neck full and broad at its base, gradually tapering towards the head, particularly bare at the junction with the head; the neck seeming to project straight from the chest, so that there is, with the slightest possible deviation, one continued horizontal line from the rump to the pole. The breast broad and full; the shoulders broad and round, no uneven or angular formation, no rising of the withers, no hollow behind the situation of these bones. The arm fleshy throughout, even down to the knee. The bones of the leg small, standing wide apart, no looseness of skin about them, and comparatively bare of wool. The chest and barrel deep and round; the ribs forming a considerable arch from the spine; the barrel ribbed well home; the carcass gradually diminishing in width towards the rump; the quarters long and full; the legs of a moderate length; the pelt moderately thin, soft, and elastic, covered with a good quantity of white wool, not so long as in some breeds, but considerably finer. The principal recommendations of this breed are its beauty, and its fulness of form; in the same apparent dimensions greater weight than any other sheep; an early matu-

urity and a propensity to fatten, equalled by no other breed; a diminution in the proportion of offal, and the return of most money for the quantity of food consumed. (*Culley on Live-Stock; Marshall's Midland Counties; Youatt on Sheep*, p. 111.)

For Bakewell's views, when engaged in improving sheep, see **DISHLEY BREED**.

The Teeswater Sheep was bred originally on the banks of the Tees; it came from the stock of the old Lincolnshire, and, like them, it is nearly extinct. It was a tall, clumsy animal, polled, and with white face and legs; they were crossed by the Dishley sheep, because a smaller and a better breed, and few traces are now to be found.

The Lincolnshire Sheep.—Culley described the old breed of Lincolnshire sheep, half a century since, as having "no horns," white faces, long, thin, and weak carcasses; the ewes weighing from 14 to 20 lbs. per quarter, the three year old wethers from 20 to 30 lbs; thick, rough, white legs, large bones, thick pelts, and long wool, from 10 to 18 inches, and weighing from 8 to 14 lbs. per fleece, and covering a slow-feeding, coarse-grained carcase of mutton. Culley, however, ran into the opposite extreme; if the Lincolnshire farmers bred only for the wool, he regarded only the mutton. A cross between the two produced a very profitable and much improved animal.

The Cotswold Sheep have been long celebrated for the fineness of their wool. In 1467, a flock of these sheep were carried into Spain by license from Edward IV. Gervas Markham, in the time of Queen Elizabeth, describes them "as long-woolled and large-boned breed." Few of the original Cotswold breed, however, now remain; they have been gradually improved by crossing with the Leicester sheep, and it is this half-bred Cotswold and Leicester which now chiefly tenants the Gloucestershire and Worcestershire farms. The old Cotswold sheep are described by Mr. Youatt, as being taller and longer than the improved breed, comparatively flat-sided, deficient in the fore-quarter, but full in the hind-quarter, not fattening so early, but yielding a longer and heavier fleece. (*Youatt on Sheep*, p. 340.) The mutton of this breed is well described by Mr. Ellman, as fine-grained and full-sized, but capable of great improvement by proper crossing. "The Cotswold," he adds, "differ from the South Down in several particulars; the skin of the Cotswold is much thicker than the South Down; the head long and thin; ears wide and not too thin, having no wool but a tuft on the poll; wool below the hock considered objectionable. On the Cotswold they never allow two rams to run together." He thinks twin ewes have much more to do with getting twins than twin rams; both, however, should be attended to, as well as a still more important particular, their keep. (*Baxter's Lib. of Agr.*)

The Dartmoor Sheep.—"The short or rather middle-woolled sheep of Devonshire," says Mr. Youatt, "a few of which are still seen in South Devon, and on the greater part of the hills in the northern district, but most numerously on the forests of Dartmoor and Exmoor, are everywhere of nearly the same character, and betray

on a smaller scale a great affinity with the Dorsets; have white faces and legs; some with and some without horns; small in the head and neck, and generally small-boned; carcase narrow and flat-sided, weighing when fat from 9 to 12 lbs. per quarter; the fleece 3 or 4 lbs. in weight in the yolk; wool short, with a coarse and hairy top."

The South Down Sheep.—The remarks of Mr. Ellman of Glynde, in Sussex, who has done more than any one to improve the race of South Down, are so practical and clear, that what he has done so well it is useless to give in any other language; he says, when speaking of this valuable breed, "the head should be neither too long nor too short, the lip thin, the neck neither too long nor too short, but thin next the head, and tapering towards the shoulders. South Down breeders object to a long, thin neck; it denotes delicacy. The breast should be wide and deep, projecting forward before the fore-legs; this indicates a good constitution, and disposition to feed. The shoulders should not be too wide between the plate-bones, but on a level with the chine; if the shoulder-blades are wide on the top, the animal generally drops behind the shoulders. The chine should be low and straight from the shoulders to the tail; the ribs should project horizontally from the chine, for the animal will then lay its meat on the prime parts; the sides high and parallel; the rump long and broad; the tail set on high, and nearly on a level with the chine; the hips wide; the ribs circular, and barrel-shaped; the legs neither very long nor very short; the bones moderately fine." (*Baxter's Lib. of Agr* p. 570.)

Romney Marsh Sheep.—Towards the beginning of this century, Mr. Price described "the pure Romney Marsh bred sheep as distinguished by thickness and length of head, a broad forehead with a tuft of wool upon it, a long and thick neck, and carcase flat-sided; chine sharp, tolerably wide on the loins, breast narrow and not deep, and the fore-quarter not heavy nor full; the thigh full and broad, the belly large; the tail thick, long, and coarse, the legs thick, feet large, the muscle coarse, bone large. Wool long and not fine; have much internal fat, much hardihood; requiring no artificial food during the hardest winter, except a little hay." (*Youatt on Sheep*, p. 334.) With all these good properties, however, the old Romney Marsh sheep has been nearly obliterated by occasional crossings with the Leicester sheep; which, by judicious management (taking care not to render the breed too tender by the introduction of too much of the Leicester), has produced a sheep possessing sufficient hardiness for these bleak marshes, yet producing more symmetry of form, with earlier maturity, and greater propensity to fatten.

The Cheviot Sheep are a peculiar breed, which are kept on the extensive range of the Cheviot Hills. They are described as having "the face and legs generally white; the eye lively and prominent; the countenance open and pleasing; the ear large, and with a long space from the ear to the eye; the body long; and hence they are called 'long sheep,' in distinction from the black-faced breed. They are full

behind the shoulder, have a long, straight back, are round in the rib, and well-proportioned in the quarters; the legs clean and small-boned, and the pelt thin, but thickly covered with fine, short wool: they possess very considerable fattening qualities, and can endure much hardship, both from starvation and cold. He is fit for the butcher at three years old, and at two when crossed with the Leicester." (*Youatt on Sheep*, p. 285; "On crossing the Mountain and Cheviot Sheep," by Mr. Hogg, *Quart. Journ. Agr.* vol. i. p. 175.)

CLASS II. HORNED SHEEP.

The Dorset Sheep.—"Most of these," says Mr. Youatt, "at least of the pure breed, are entirely white; the face is long and broad, and there is a tuft of wool on the forehead; the shoulders low and broad; the back straight; the chest deep; the loins broad; the legs rather beyond a moderate length, and the bone small. They are, as their form would indicate, a hardy and useful breed. They are good folding sheep; their mutton well-flavoured, averaging, when 3 years old, from 16 to 20 pounds a quarter. Their principal distinction and value is the forwardness of the ewes, who take the ram at a much earlier period of the year than any other species, and thus supply the market with lamb at the time when it fetches the highest price. These sheep are principally bred within a circle of 12 miles round Dorchester, where a considerable quantity of house lamb for the London market is produced. In other parts of Dorset the South Down breed prevails; except in Portland and on poor, sandy, heath soils near Warebone and Poole, where a poor small-horned breed prevails, with black muzzles, well adapted for this locality. Their meat is tender."

The Norfolk Sheep.—"A peculiar variety of heath sheep," says Mr. Youatt, "has been found in the localities of Norfolk and Suffolk from time immemorial. The carcass was long and slender; legs long; face and legs black or mottled; face long and thin; the countenance lively and expressive of mingled timidity and wildness: taken altogether, there was more resemblance to the deer in the Norfolk sheep than has been observed in any other species. They were attempted to be improved by being crossed with the South Downs; but at length the pure South Down was generally preferred to the pure Norfolk, and, in consequence, the race is now nearly extinct."

The Merino Sheep.—This celebrated breed are, in Spain, divided into the *estantes*, or *stationary*, and the *transhumantes*, or *migratory*. The first are those which remain during the year in one place or farm: the last travel some hundred miles every year in search of pasture. They are thus described by Mr. Low in his excellent *Illustrations of the Breeds of Domestic Animals*.

"The stationary sheep consist partly of the larger sheep of the lower country, partly of mixed races, and partly of pure Merinos, which do not differ in any respect from the migratory sheep of that name, except in the method of treatment. The stationary Merinoes are reared where the district or farm affords them sufficient food during the whole season. They are most numerous in the central countries, where the pastures are less apt to be scorched by

heats of the summer, as in Segovia, and the mountain ranges to north of Madrid.

"The migratory sheep have been reckoned to amount to ten millions, which is probably equal to half the whole number of the sheep of Spain. They may be divided into two great bodies: those which are to pass further to the eastward, to Soria, or even beyond the Ebro. These vast hordes of sheep break up from their winter cantonments, south of the Guardina, about the 15th of April, and proceed chiefly northward. The rams having been admitted to the ewes in the month of July, the lambs are born in November. In the course of their journey northward, they are shorn in large buildings erected for that purpose. The western, or Leonese division, crosses the Tagus at Almaray. The eastern, or Sorian division, crosses the same river further to the eastward, at Talavera, and in its course approaches the city of Madrid. Having reached their destination, they are pastured until the end of September, when they recommence their journey southward. Each of these journeys, of several miles in length, occupies about 6 weeks in travelling. The older sheep, it is said, when April arrives, know the time of setting off, and are impatient to be gone. In the ten or twelve latter days, increased vigilance is required, on the part of the shepherds, lest the sheep should break out. Some of them do so, and pursue their accustomed route, often reaching their former year's pastures, where they are found when the main body arrives; but, for the most part, these stragglers are carried off by wolves, which abound along the course which the migratory flocks pursue.

"These migratory sheep are divided into flocks of a thousand or more, each under the charge of its own mayoral, or chief shepherd, who has a sufficient number of assistants under his command. It is his province to direct all the details of the journey. He goes in advance of the flock; the others follow with their dogs, to collect the stragglers, and keep off the wolves, which prowl in the distance, migrating with the flock. A few mules or asses accompany the cavalcade, carrying the simple necessaries of the shepherds, and the materials for forming the nightly folds. In these folds the sheep are penned throughout the night, surrounded by the faithful dogs, which give notice of the approach of danger.

"When the sheep arrive at the *esquilcos*, or shearing-houses, which is in the early part of their journey northward, a sufficient number of shearers are in attendance to shear a thousand or more in one day. The *esquilcos* consist of two large, rude rooms, and a low, narrow hut adjoining, termed the sweating-house. The sheep are driven into one of the large rooms, and such of them as are to be shorn on the following day are forced into the long, narrow hut as close as it can be packed, where they are kept all night. They undergo in this state a great perspiration, the effect of which is to soften the hardened unctuous matter which has collected on the fleece. They are then shorn without a previous washing, and the wool is left in the *esquilcos*, where it is sorted, and made ready for sale. By this arrangement

1000 sheep, or more, are shorn with only the delay of a day.

"The shepherds employed in tending these sheep amount to 50,000, which, supposing there to be 10,000,000 of sheep, is at the rate of 200 to each shepherd. The number of dogs is calculated at 30,000. These shepherds form a peculiar class of men, strongly attached to their pursuit, and living in a state of great simplicity. Their food is chiefly black bread, oil, and garlic. They eat the mutton of their sheep when they die or meet with accidents. In travelling they sleep on the ground, wrapping themselves in their cloaks; and in winter they construct rude huts to afford shelter. They seldom, it is said, marry, or change their calling.

"The whole of this extraordinary system is regulated by a set of laws; and an especial tribunal, termed the *mesta*, exists for the protection of the privileges of the parties having the right of way and pasturage. These parties claim the right of pasturage on all the open and common land that lies in their way, a path of 90 paces wide through the enclosed and cultivated country, and various rights and immunities connected with the pasturage of the flocks. The system is opposed to the true interests of Spain. A change of pasture may be required for the flocks in the drier countries at certain seasons, but the periodical migration of so vast a body of sheep cannot be necessary to the extent to which it takes place. Enormous abuses are committed on the cultivated country as they pass along. A fourth part of the year consumed in travelling must be prejudicial to the health of the animals in a greater degree than the benefits they derive from a change of pasturage. A prodigious mortality accordingly takes place among these sheep; and more than half the lambs are voluntarily killed, in order that the others may be brought to maturity. The sale of the lamb-skins, which form a subject of export to other countries, is indeed a source of profit, but nothing equal to what the rearing of the animals to their state of maturity would produce. That these extensive migrations are necessary to preserve the fineness of the wool is conceived to be an error. Attention to breeding and rearing would more certainly produce this effect than a violent change of place. In Spain itself there are numerous flocks of stationary Merinos, whose wool is of all the fineness required; and in other countries of Europe, where the sheep are never moved off the farms that produce them, wool is produced superior to that of the migratory flocks of Spain. The system is of great antiquity, and is so riveted in the habits of this ignorant and intractable people, that it is likely to be one of the last of those ancient abuses which will yield to the desire of change which at this moment agitates the feelings of men in this distracted country. The Spaniards long preserved the monopoly of this race of sheep with jealous care; but other countries at length were able to carry off the Golden Fleece of Spain, and the Merino race is now spread over a great part of Europe.

"The Merino breed, which had extended to so many countries, was at a period more recent introduced into the British Islands. George

III., a zealous and patriotic agriculturist, resolved to make a trial of this celebrated breed on his own farms, and means were taken to obtain a small Merino flock. This was done clandestinely; the animals were selected from the flocks of different individuals where they could best be got; were driven through Portugal, and embarked at Lisbon. They were safely landed at Portsmouth, and conducted to the king's farm at Kew. The flock was bad; the selection had been carelessly or ignorantly made; and the animals being taken from different flocks, presented no uniformity of characters. It was then resolved to make direct application to the Spanish government for permission to export some sheep from the best flocks. The request was at once complied with; a small and choice flock was presented to his majesty, by the Marchioness del Campo di Alange, of the Negretti flocks, esteemed to be the most valuable in Spain; and in return his majesty presented to the Marchioness eight splendid coach horses. This flock arrived in England in 1791, and was immediately transferred to the royal farms, while all those previously imported were disposed of or destroyed.

"On the first change of these sheep to the moist and luxuriant pastures of England, they suffered greatly from diseases, and, above all, the rot, which destroyed numbers of them; and from foot-rot, which affected them to a grievous extent. By a little change of pastures these evils were remedied; and, after the first season, the survivors became reconciled to their new situation, and their progeny seemed thoroughly naturalized, and remained as free from diseases as the sheep of the country. The wool was from year to year carefully examined; that of the original stock remained unaffected by the change of climate, while in that of their descendants little degeneracy could be detected either in its felting propensities or its fineness.

"The most distinguished breeders of Merinos at this time in England are Lord Western and Mr. Bennet, M. P. for Wiltshire. Lord Western's stock is either Saxon, or has been crossed by Saxon rams; Mr. Bennet's is pure Spanish, and has undergone progressive improvement by selection of individuals of the same blood. The number of his flock amounted at one time to 7000; it was subsequently reduced to 3500. It was treated in the ordinary manner of sheep in England. Lord Western's, it is believed, is managed more in the Saxon manner, with respect to protection from the weather. Mr. Bennet's fine flock, notwithstanding it had been thus acclimated, perished in great numbers in a severe winter some years ago, proving that the race had not yet lived sufficiently long in England to be perfectly inured to its cold and variable climate. Other gentlemen have imported Merinos direct from Saxony, and thus obtained at once the highest perfection of the fleece; but there is little reason to believe that their experiments will be more successful than those previously made. Merinos have lately been carried in some numbers to Ireland, and may perhaps prove more advantageous than some of the existing breeds; but this will not show the great value of the Merinos, but the

comparatively little value of the races which they have supplanted.”

The first impression (says Mr. Youatt) made by the Merino sheep on one unacquainted with its value would be unfavourable. The wool, lying closer and thicker over the body than in most other breeds of sheep, and being abundant in yolk, is covered with a dirty crust, often full of cracks. The legs are long, yet small in the bone; the breast and the back are narrow, and the sides somewhat flat; the fore-shoulders and bosoms are heavy, and too much of their weight is carried on the coarser parts. The horns of the male are comparatively large, curved, and with more or less of a spiral form. The head is large, but the forehead rather low. A few of the females are horned, but, generally speaking, they are without horns. Both male and female have a peculiar coarse and unsightly growth of hair on the forehead and cheeks, which the careful flock-master cuts away before shearing-time: the other part of the face has a pleasing and characteristic velvet appearance. Under the throat there is a singular looseness of skin, which gives them a remarkable appearance of throatiness, or hollowness in the pile: the pile, when pressed upon, is hard and unyielding; it is so from the thickness with which it grows upon the pelt, and the abundance of the yolk detaining all the dirt and gravel which falls upon it; but, when examined, the fibre exceeds in fineness, and in the number of serrations and curves, that which any other sheep in the world produces. The average weight of the fleece in Spain is 8 pounds from the ram and 5 from the ewe: when fatted, these sheep weigh from 12 to 16 pounds per quarter. The excellence of the Merino consists in the fineness and felting quality of their wool, and the weight yielded by each sheep; the ease with which they adapt themselves to the climate, the readiness with which they take to the coarsest food, their gentleness and tractableness. Their defects are their unprofitable and unthrifty form, voracity of appetite, a tendency to barrenness, neglect of their young, and inferior flavour of the mutton. (*On Sheep*, p. 148; *Dr. Parry on the Merino sheep*, *Com. Board of Agr.* vol. v. p. 337; *Sir Joseph Banks on ditto*, *Ibid.* vol. vi. p. 269; *Mr. Downie on ditto*, *Ibid.* vol. vii. p. 61.)

The *Irish Sheep* have been much improved by the importation of English rams. Culley describes them as ugly and ill-formed. Bodies large. Legs long, thick, crooked, and of a gray colour. Faces gray. Heads long, large flagging ears, sunken eyes. Neck long, and set on below the shoulders. Breast narrow, short, and hollow; flat-sided.

The *Shetland Sheep* are described by Mr. Wilson (*Quart. Jour. Agr.* vol. ii. p. 557) as small and handsome; hornless, seldom exceeding 40 pounds in weight; hardy, feeding on even seaweed: wool soft and cottony.

The *Hebridean Sheep* is described by Mr. Wilson as the smallest of its kind. Shape thin and lank. Face and legs white. Tail short. Wool of various colours, bluish-gray, brown, or deep russet. Even when fat, this sheep weighs only 20 pounds: the wool rarely weighs more than 1 pound.

With regard to the profitable management of sheep, it is only possible to offer general suggestions to assist the farmer. I have alluded already to the advantages of varying the food of sheep, and I shall refer at the end of this article to various important testimonials in favour of the superior profit derived from keeping sheep dry and warm. In every case they should have access to dry food, and, if possible, occasionally to those lands where heath and other plants which are indigenous to upland soils are to be found: in all cases, too, they should have access to common salt.

The importance of salt to the general health of sheep is now, in fact, generally admitted. Every farmer observes that his cattle, horses, &c., are remarkably fond of licking the salt earth of the farm-yard, stables, &c. In Spain, they give their sheep salt with great regularity: 112 lb. in 5 months to 1000 sheep. I subjoin the statement of the late Mr. Curwen. He employed salt to his live-stock daily for years:

For horses he gave	-	-	6 oz. per day.
Milch cows	-	-	4
Feeding oxen	-	-	6
Yearlings	-	-	3
Calves	-	-	1
Sheep	-	-	2 to 4 per week,

if on dry pastures; but if they are feeding on turnips or coles, then they should have it without stint. Some give it to the live-stock on a slate or stone, some lay lumps of it in the cribs or mangers. It is an asserted fact, that if *sheep are allowed free access to salt, they will never be subject to the disease called the rot*. Some recent experiments also lead me even to hope that I shall one day or other be able to prove it to be a *cure* for this devastating disease. I have room but for one fact. “Mr. Rusher, of Stanley, in Gloucestershire, in the autumn of 1828, purchased, for a mere trifle, 20 sheep *decidedly rotten*; and gave each of them, for some weeks, an ounce of salt every morning. Two only died during the winter; the surviving 18 were *cured*, and have now,” says my informant, “lamb by their sides.”

The late Mr. Butcher, of Brook Hall, in Essex, for years employed salt for his cattle and sheep on his farm near Burnham, in Norfolk. One of his fields was so very unfavourable for sheep, that before he used salt he had lost 10 and 12 sheep in a night, when feeding on the turnips; but after he had adopted salt, he never lost one. He used to let the sheep have the salt without stint; and he remarked, that *the sheep always consumed four times the salt on this particular field than when feeding on any other on the farm*. Mr. Butcher one year let this field of turnips to a neighbour, who did not use salt; and consequently, after losing 10 sheep the first night, gave up the field in despair.

There are several points in the management of sheep to which I can only briefly allude. *Coupling the male and female* is too rarely attended to; and yet, by an attention to this important point, properties are added in one sex which may be deficient in the other; but extreme care is necessary in arranging this, not to introduce other points which may be still more objectionable than those attempted to be removed. Mr. Ellman is of opinion that *twid-*

getting is hereditary: "Experience," he says, "has satisfied me that a ram which may be a twin would get double the number of twin lambs than other rams." He advises that, just previous to lambing-time, the ewes should not be kept too well, but that their food should be increased a few days after parturition. Cleanliness in the lambing-yards he very properly deems to be of the greatest importance. Lambs are best castrated at from 8 to 12 days old. In the performance of this operation it is calculated that, when properly performed, the deaths do not average 1 in a 1000. Mr. Ellman recommends 80 to 100 ewes to each ram, or, when lamb rams are employed, only 40; and that they should remain with the ewes 3 weeks, in separate lots.

Statistics.—The number of sheep in Great Britain has long been gradually on the increase, with the demands of an enlarging population. To this the introduction of turnips and other better supplies of winter food, which much increased the facilities for their keep, has mainly contributed. In 1698, Gregory King calculated that there were 12,000,000 sheep in Great Britain; in 1741 the number had increased to 16,640,000; in 1774, according to Arthur Young, the number was 25,589,754; in 1801, Mr. Luccock estimated them at 26,148,463. Mr. McCulloch, in 1834, states the number to be 32,000,000; the value of the wool 7,000,000*l.*; and that of the manufactured woollen articles 21,000,000*l.*; and the number of persons employed in the manufacturing of these goods about 332,000. (*Youatt on Sheep; Low's Pract. Agr., and Breeds of Dom. Animals; Baxter's Agr. Lib.; McCulloch's Com. Dict.*)

Of the many valuable papers upon sheep dispersed through the British agricultural periodicals, I can, in this place, only give a brief catalogue. There is a letter by Mr. T. Escount, *Com. to Board of Agr.* vol. iv. p. 294, "On keeping Sheep warm when feeding," which shows very clearly the advantages of sheep being kept dry and warm when feeding, a subject not nearly so well understood as is desirable; see also "On Sheep Stells (Timber Clumps)," by Dr. Howson, *Trans. High. Soc.* vol. vi. p. 332; "On Rain-proof Feeding Troughs," by Mr. Buist, *Quart. Journ. of Agr.* vol. ii. p. 114; "On Canvass Sheds for Sheep," by Mr. Munro, *Ibid.* vol. xii. p. 290; "On Shed-feeding," by Mr. Childers, *Journ. Roy. Agr. Soc.* vol. i. p. 169—407; "On the Improvement of the fine-wooled Breed," *Com. to Board of Agr.* vol. vi. p. 65; the Rev. Edmund Cartwright "On feeding Sheep on Muscovado Sugar," *Ibid.* p. 405; "On the Braxy in Sheep," *Trans. High. Soc.* vol. i. p. 43; "On the Flesh Fly and Maggot," by Mr. Hogg, *Ibid.* p. 325, and by Mr. Mather, *Ibid.* vol. iv. p. 221, and *Quart. Journ. of Agr.* vol. i. p. 210. "On Salving Sheep," by Mr. J. Graham, *Ibid.* vol. ii. p. 243; this salve is composed of 7 lb. of rosin, 17 lb. of butter, 16 lb. of palm oil, 2 chopins of fish oil; and by Mr. Harkness, *Ibid.* vol. iv. p. 125. "On the Louping-ill," by Mr. Tod and Mr. Laing, *Ibid.* vol. iii. p. 73; "On the Foot Rot," by Mr. Hogg and the Rev. H. Riddell, *Ibid.* p. 307; by Mr. Dick, *Quart. Journ. of Agr.* vol. ii. p. 852, and by Mr. Black, *Ibid.* vol. iii. p. 654; "On Blindness in

Sheep," by Mr. McFarlane, *Trans. High. Soc.* vol. iv. p. 393; "On Rabies," by Mr. Dickson, *Ibid.* vol. vi. p. 261; "On certain Diseases of Sheep (the Pining, Scab, &c.)," by Mr. Hogg, *Quart. Journ. of Agr.* vol. ii. p. 697; "On the Origin and Natural History of the Sheep," by Mr. Wilson, *Ibid.* p. 354—536; "On drafting Sheep," *Ibid.* vol. iii. p. 1005; "On the acute Dysentery," by Mr. Dick, *Ibid.* vol. p. 411; "On the Rot," *Ibid.* p. 503; and vol. vi. p. 117; "On the Physiognomy of Sheep," *Ibid.* vol. x. p. 298; "On different Breeds, and on feeding and dressing Tups," by Mr. Hogg, *Ibid.* vol. xi. p. 105—108; "On a peculiar Affection of the Liver in Ewes," by Mr. Buckley, *Journ. Roy. Agr. Soc.* vol. ii. p. 116. See FOOD, MEAT, MUTTON, WOOL.

All the best varieties of sheep known in Europe have been introduced into the United States, where the raising of sheep, both for the profits of carcass and wool, is a highly productive branch of agriculture. The number of sheep in the United States, in 1840, was estimated at about 20,000,000. Immense numbers of these are raised in the high and cool districts in Northern Pennsylvania, New York, and the Eastern States. Various American agricultural periodicals contain valuable observation in regard to sheep in the United States. Jonathan Roberts, Esq., a veteran farmer of Montgomery county, Pennsylvania, who has taken much interest in this kind of stock for the last half-century, has favoured us with the following valuable observations:

"Many of the diseases which prevail among sheep in Britain are little known in this part of the United States, where the air is drier. Such air, associated with a broken and even mountainous country, seems best adapted to the breeds of this animal. Early in my experience I witnessed the renovation of a flock of what we call country sheep, that had been too long propagated in the same blood. This was about the year 1789. An imported ram from England, with heavy horns, very much resembling the most vigorous Spanish Merinoes, was obtained. The progeny were improved in the quality of fleece and in vigour of constitution. On running this stock in the same blood for some 12 years, a great deterioration became apparent. A male was then obtained of the large, coarse-wooled Spanish stock; improvement in the vigour of the progeny was again most obvious. A Tunis mountain ram was then obtained, with a result equally favourable. In this process, fineness of fleece or weight was less the object than carcass. In 1810, a male of not quite pure Merino blood was placed with the same stock of ewes; and a change of the male from year to year, for some time, produced a superior Merino stock. Wool of a marketable quality for fine cloths was now the object, and it was not an unprofitable husbandry, when it would sell in the fleece unwashed, from 86 cents to \$1. The Saxon stock then became the rage, and the introduction of a tup of that country diminished greatly the weight of the fleece, without adequately improving its fineness. A male of the Spanish stock would give sometimes 9 lbs., and the marsh graziers say that they went so high as 15 lbs. Saxon males

scarcely exceed 5 lbs., and the ewes 2½ lbs. By running in the same blood, and poor keeping, the fleece may be made finer, but it will be lightened in proportion, and of a weak and infirm texture. There are few stock-keepers who have mixed the Spanish with the Saxon breeds but what either do or will have cause to regret it. In this part of the country a real Spanish Merino is not to be obtained. Sheep-raising has ceased to be a business of any profit nearer to the maritime coast than our extensive mountain ranges, whether for carcass or fleece. I sold, the last season, water-washed wool of very fine quality, for 30 cents per lb. At such a price for wool, land near our seaports can be turned to better account, even in these dull times, than wool-growing. Stock-sheep do best in stony and elevated locations, where they have to use diligence to pick the scanty blade. Sheep on the seaboard region should be kept more for carcass than fleece: and feeding more than breeding, ought to be the object for some 100 miles from tide-water. It is now a well ascertained fact, that health and vigour can only be perpetuated by not running too long on the same blood. The evils I have witnessed were due to a want of care on this head more than to any endemical quality in our climate. Sheep kept on smooth land and soft pasture are liable to the foot-rot. I have found this readily relieved by a little spirits of turpentine or salted grease and tar, or tar only. The hoofs of the Merino require paring occasionally, for want of a stony mountain-side to ascend. It is no longer a problem that this is to be a great wool-growing country as well as a wool-consuming one. There is, in our wool-growing country, land in abundance, held at a price that will enable the wool-grower to produce the finest qualities at 30 cents per lb., the cloths to be manufactured in proportion, and the market to be steady. I have seen Merino wool since 1810 range from \$1 per lb. to 18½ cents, though I do not recollect selling below 22 cents. The best variety of sheep stock I have seen, putting fineness of fleece aside, was the mixed Bakewell and South Down, imported by Mr. Smith, of New Jersey. The flesh of the Merino has been pronounced of inferior flavour. This, however, does not agree with my experience, as I have found the lambs command a readier sale than any other, from being preferred by consumers."

In regard to the particular distribution of sheep through the several states, we find, according to the returns accompanying the census of 1840, that there were in Maine, 649,264; New Hampshire, 617,390; Massachusetts, 378,226; Rhode Island, 90,146; Connecticut, 403,462; Vermont, 1,681,819; New York, 5,118,777; New Jersey, 219,285; Pennsylvania, 1,767,620; Delaware, 39,247; Maryland, 257,922; Virginia, 1,293,772; North Carolina, 538,279; Tennessee, 741,593; Kentucky, 1,008,241; Ohio, 2,028,401; Indiana, 695,982; Illinois, 395,672; Missouri, 348,018.

SHEEP, DISEASES OF. *Apoplexy*.—Bleed copiously; then give 2 ounces of Epsom salts in a quarter of a pint of water.

Blackwater.—Keep the bowels open with Epsom salts; and give a tea-spoonful of elixir of

vitriol, or sulphuric acid, diluted with 7 parts of water, in an infusion of oak bark.

Blackmuzzle.—Mix an ounce of verdigris (acetate of copper), 4 ounces of honey, half a pint of vinegar; simmer them together over a fire for 10 minutes in an earthen pipkin. Apply it to the mouth on a piece of rag.

Cough, or Cold.—Bleed; give a solution of Epsom salts.

Diarrhæa. See CALVES, DISEASES OF.

Dysentery. See DIARRHŒA.

Fly.—Fly powder: Two pounds of black sulphur, half a pound of hellebore; mix them together, and sprinkle the sheep from the head to the tail with a dredging-box. Sheep wash: The farmer will find this an excellent recipe: Half a pound of powdered white arsenic (arsenious acid), 4½ pounds of soft soap. Beat these for a quarter of an hour, or until the arsenic is dissolved, in 5 gallons of water. Add this to the water sufficient to dip 50 sheep. The quantity of arsenic usually recommended is too large.

Foot Rot.—One drachm of verdigris (acetate of copper), 1 drachm of blue vitriol (sulphate of copper), 1 drachm of white vitriol (sulphate of zinc), 2 ounces of water, 2 drachms of nitric acid, 2 drachms of butter of antimony; pare away the horn, and apply the lotion upon a feather to the part affected.

Redwater. See REDWATER.

Rot. See ROT.

Scab, or Schab.—Apply a lotion formed of 1 ounce of corrosive sublimate, 4 ounces of sal ammoniac, dissolved in 4 quarts of rain-water. This is a powerful stimulant, and must be used with caution.

Ticks. See FLY.

Wounds.—Wash the part, and apply a lotion formed of vinegar 1 pint, spirits of wine 1 ounce, spirits of turpentine 1 ounce, Goulard's extract 1 ounce. If the wound be a recent one, it is better to stitch it up with separate ligatures, which can be easily withdrawn, and dress with cold water.

SHEEP-FOLD. A yard or other contrivance for the purpose of confining and keeping sheep during the nights or in bad weather, in order to afford them protection and shelter. They are sometimes fixed, being constructed of any convenient sort of light material, so as to enclose a space in proportion to the number of sheep, which is kept constantly well littered with some dry substance, such as stubble, refuse straw, dry sand, &c., during the time the sheep are folded and foddered in them, in order that as much manure may be raised as possible. In some cases, also, for the more perfect protection of the sheep, they have sheds all around them, under which the sheep may lie without injury from rain, snow, or any sort of moisture. These usually are termed *standing folds*, and are either formed about the homestead or on some dry, rather elevated situation on the farms, having the bottoms well laid with some sort of material that is capable of keeping the sheep dry and clean. See FOLD, FOLDING, and HURDLES.

SHEEP-HOUSE. A slight wooden building constructed for the purpose of containing and protecting sheep in bad weather, &c. **HOUSE**

of this kind are usually made low for the sake of warmth in the winter, being mostly a third part longer than they have breadth: they should also be sufficiently large for the quantity of sheep that they are to contain. The side should be lined with boards, and the bottoms be laid in an even manner with stone or some other material, that the litter may be well impregnated with the urine of the sheep. The sides exposed to the sun should be lined with movable hurdles, that when it shines the whole may be laid open, to give due refreshment and afford the sheep an opportunity of feeding upon the pasture wherein they stand. They should be well and securely covered with some sort of proper material upon the tops. They are sometimes fixed in particular situations; but in other cases, which is the more improved method, so constructed as to be capable of being removed as they may be wanted.

SHEEP-PENS. The divisions made by the small movable gates or hurdles which are set up to keep sheep in some particular spot. They are usually formed on a dry place about the corners where different enclosures of the pasture meet, so as to be convenient for the whole. Pens are useful for examining and selecting the sheep, being divided so as to contain about 3 dozen sheep each, as by this means they are always at the command of the shepherd for any purposes he may have in view. The bottoms should be firm and dry, so that the sheep may not be soiled.

SHEEP-STEALING. By the 7 W. 4, & 1 Vict. c. 90, every person convicted in England of stealing any horse, mare, gelding, colt, filly, bull, cow, heifer, ram, ewe, sheep, or lamb, is liable to be transported for a term not exceeding 15 years, nor less than 10 years; or be imprisoned for any term not exceeding 3 years.

SHEEP'S SORREL (*Rumex acetosella*). A perennial species of dock, which in England is found growing abundantly in dry, gravelly fields and pastures. The herb is acrid, with some astringency. The root is creeping. The stem wavy, slender, often decumbent. The flowers are diœcious, small, separate, in numerous whorled leafless clusters. The leaves lanceolate-hastate above, but hastate in the lower part of the stem. The acid which they contain is the oxalic, combined with potassa, as a binoxalate; but it is less used than its fellow-species *R. acetosa*. See **SORREL**.

Dr. Darlington informs us that there are in the United States 10 or 12 additional species of sorrel, but it is difficult to say how many of these are indigenous.

SHEPARDIA, SILVER-LEAVED. See **BUFFALO BERRY**.

SHEPHERD. The person who has the care and management of a flock of sheep. Mr. Bannister says, that it is necessary to have for this employment "a person who is well skilled in the nature and management of sheep, and hath been brought up in that employment from his infancy; who is sober, diligent, and good-natured; qualities essentially necessary in a shepherd, who, although he may seem to lead a life of indolence, when contrasted with the more laborious servants of the farm, need rarely to

have a minute's time hang heavily on his hands, if he will be attentive to his business, which will furnish him with sufficient employment throughout the day, particularly in the lambing season, or where there are two folds at work; nor will he want opportunity for the exercise of his patience and good temper in his attendance on the sheep, which is by nature an animal of great obstinacy and perverseness, and hath often paid the forfeit of its life to these innate qualities, where the shepherd was a man of a morose and surly disposition."

SHEPHERD'S NEEDLE (*Scandix Pecten Veneris*). This is a troublesome annual weed, very common in cultivated fields in England. The root is tapering. The fruit is nearly smooth, with a bushy edge, having a beak from 1 to 2 inches long; whence the specific name.

SHEPHERD'S PURSE (*Thlaspi*, from *thlao*, to compress; the seed-vessels are compressed). In England this is a genus of worthless plants, the principal species of which is the common shepherd's purse (*T. bursa pastoris*), which occurs in almost every part of the globe. It is an annual plant, with a tapering, whitish root, having a peculiar smoke-like scent. The herbage is rough, with prominent hairs. Stem branched, leafy, from 6 to 12 inches high. Radical leaves deeply pinnatifid. Flowers small, corymbose, often tinged with purplish-brown. Pouch inversely heart-shaped, somewhat triangular. Seeds about 5 or more in each cell. Small birds eat the seeds and flowers.

SHEPHERD'S STAFF. See **TRASEL**.

SHERARDIA (named by Dillenius in honour of his patron, W. Sherard, LL.D., consul at Smyrna). This is a genus of uninteresting plants. One species, the blue sherardia, or little field-madder (*S. arvensis*), is indigenous to England, where it grows in fallow fields, or among corn, on a light or gravelly soil. The plant is annual; herbage generally hairy; stems several, branched, spreading, mostly decumbent, 3 to 6 inches long. Leaves whorled, pale-green. Flowers pale purplish-blue, in a sessile terminal umbel.

SHERDS. In gardening, fragments of earthen pots, &c., employed to drain the soil supplied to potted plants, and also as under-draining for gravel walks.

SHIFTS. See **ROTATION OF CROPS**.

SHIM. A tool of the tillage kind, used in breaking down and reducing the more stiff and heavy sorts of land, as well as cutting up and clearing them from weeds. They are made of different forms and constructions, to suit different purposes.

SHOCK. See **SHUCK**.

SHOREWEED (*Littorella*, from *littus*, the shore, in allusion to its place of growth). The plantain shoreweed (*L. lacustris*) is a pretty little perennial sub-aquatic, indigenous to England, flowering in June. It has no stem; but the root, which is fleshed and tap-shaped, throws up many long, linear, channelled leaves. The flowers are whitish-green.

SHORT-HORNS. See **CATTLE**.

SHRUB. A small, low, dwarfish, woody plant, resembling a tree, which, instead of one single stem, frequently puts forth from the

same root several sets or stems. The most hardy, indigenous shrubs are the box and ivy, which resist the severest winters. Next, in point of hardiness, are the holly, juniper, and furze; but there are besides numerous ornamental shrubs, well calculated to diversify parks and lawns.

SHUCK. A husk or shell. In husbandry, it also signifies a shock or stook of 12 sheaves of corn set up together in the harvest field. See **REAPING**.

SHY. In norsemanship, the starting suddenly aside of a horse.

SICKLE (Sax. *ricol*; Dutch *sickel*; from Lat. *secale*). A hook with which corn is reaped. See **REAPING-HOOK**, **SCYTHE**, &c.

SILICA. The name of the earth which forms almost the entire substance of common sand or silex, and also of quartz and flint. Potash renders silex soluble in water, and capable of entering into the sap of plants. Hence one of the great advantages of potash as a fertilizer, especially adapted to wheat, which demands much silica, as well as potash, in the soil. Silica enters into the composition of all plants, forming the shining outer coating of straw, corn-stalks, reeds, grasses, &c. See **EARTHS**; **MIXTURE OF SOILS**; **ANALYSIS**.

SILK CULTURE. The United States being, like China, situated on the eastern side of a great continent, offer peculiar advantages for the production of silk. From the general predominance of westerly winds in extra-tropical regions, the eastern sides of continents in these possess a dry and warm summer climate, peculiarly adapted to the prosperity of the silk-worm. In Europe, the region of the silk-culture is confined to the southern portions, and commences at a distance from the sea, on the eastern side of the mountain ridge of the Cevennes. These mountains offer a barrier to the moisture borne far inland by the prevailing westerly winds sweeping from the Atlantic. In the United States the prevalence of the same winds keeps off a large amount of the moisture from the sea, and leads to a comparatively dry atmosphere. So far as this characteristic of climate is concerned, the culture of silk may be extended to the very shores of the Atlantic. At various times attempts have been made to introduce it into the United States, but it is only within a very few years past that the subject has received the attention which it merits as an important and most valuable agricultural resource. Among other obstacles which have tended to prevent the development of the silk culture, the comparatively tardy growth of the ordinary kinds of mulberry trees cultivated for feeding the silk-worm has been not the least, since where immediate sources of profit exist in other products of the soil, few will engage in enterprises, the profits of which have to be so long anticipated. The introduction of a new kind of mulberry, the *Morus Multicaulis*, a tree of rapid development, having in a great measure removed the obstacle referred to, the silk culture has, to a greater or less degree, been introduced from one end of the country to the other. Strange as it may seem, the Eastern States, with a comparatively rigor-

ous climate, have heretofore been almost the sole producers of domestic silk as an object of profit. In some of the townships of Connecticut and Massachusetts, silk has for many years been an object of domestic culture; but this was carried on to great disadvantage, the cocoons having been usually wound off upon common wheels, and spun into sewing silk. No such thing as a regular filature for converting cocoons into reeled silk, and thus preparing it for being woven into different fabrics, existed in the Eastern States; so that, instead of using only the refuse cocoons in making *sewings*, the very best were thus appropriated. The introduction of suitable reels for winding off silk and placing it in the best form for mercantile purposes, has been comparatively slow, owing in a great degree to the introduction of many contrivances intended to curtail labour by winding immediately from the cocoons and twisting by the same process into sewing silk. Most or all such contrivances have proved very unprofitable, and have yielded, or may be expected to yield, to the simple but effective operation of the *Piedmontese reel*, the most perfect of all devices for taking silk from the cocoons, and placing it in the best forms for market. Many very skilful reelers have been made in various filatures in the United States. Although in every part of the Union the mulberry can be reared, and the silk-worm successfully fed, still it cannot be doubted that the southern portions of the Middle, and all the Southern States, afford peculiar advantages to the silk culture. An agricultural resource, which in France and other countries is so highly appreciated and fostered with so much zeal by the government, by the establishment of model filatures, and the zealous attentions of men of skill and science, should be regarded as well worthy the protection of the general and state governments of the Union. Many states already allow liberal premiums for cocoons and raw silk produced within their borders, and these inducements to individuals should be continued until the silk culture becomes fairly established as a regular branch of rural labour; after which it will, like most other branches of industry once fairly set on foot, take care of itself.

Large crops of cocoons were last year produced in Pennsylvania, Ohio, Kentucky, Tennessee, and Indiana. The comparatively small cost of conveying to market an article so highly valuable as silk, should encourage its culture in districts from which the heavy and bulky products of agriculture cannot be transported so as to leave a fair profit to the producer. In Ohio many thousand yards of silk stuffs were woven in 1842, the manufacturers paying for the cocoons about \$4 per bushel. The culturists find their advantage in having the silk reeled from the cocoons into organzine, instead of the formerly unprofitable mode of turning the most valuable silk into *sewings*. American raw silk, when properly reeled, is superior to that generally produced in Europe. A person who had been many years engaged in weaving silk in different establishments in London, having had (as he says) for 15 years from 250 to 300 lbs. of the raw material, of

every grade and name, passing through his hands weekly, expresses the following opinion relative to silk produced in the United States:

"I am qualified to affirm, from various experiments I have tried, that the silk is superior to any I have seen from Italy, China, France, Piedmont, or Valencia, where the worms are fed upon multicaulis, or Italian. Its brilliancy, strength, and scent are superior. I am aware that an exposure to the saline air, in the passage across the ocean, may be the cause of the loss of fragrance to imported silk; but the brilliancy is peculiar to American silk, if reeled in a proper manner, with cleanliness.

"I am confident that the mammoth sulphur-worm is the pure Fossam brown. To try this, I had about 3 lbs. of silk reeled, and enclosed it in an air-tight box for 3 weeks. When I took it out it had the fragrance of the Fossam brown stronger than any that I ever smelt in England, which convinced me that the mammoth sulphur is the identical silk which is always from 5 to 8 shillings per pound higher than ordinary silk. The mammoth white and the peanut white is a Novi, and superior to any I have seen in England. The yellow or orange I cannot, satisfactorily to my own mind, yet define, but am trying experiments in order to ascertain. I am strongly persuaded it is a Bergam. Should this be the case, it will prove a great acquisition to manufacturers of silk velvet. Some have supposed the pea-nut white is the Piedmont, but they are mistaken. The Piedmont cocoon is lily-white, very diminutive, with a sharp point."

Where legislative patronage has been extended in the allowance of bounties on cocoons and raw silk, the state treasuries may be referred to as criterions showing the increase or diminution of the silk crop with great precision. The treasurer of Massachusetts has furnished the following report, indicating how the matter stands in that state:

1836 - -	\$71 37	1840 - -	\$1,233 59
1837 - -	198 00	1841 - -	2,111 42
1838 - -	350 52	1842 to Oct. 1	3,351 91
1839 - -	431 32		

"Another consideration, calculated to urge the business forward," says the Northampton Silk Convention, "is found in the fact that all our present agricultural staples are now extremely depressed, and are likely to remain so. The market is completely glutted. Our farmers must take up something new, or their sufferings will be prolonged indefinitely. In this crisis, silk comes to their aid. In the production of this article they cannot glut the market for one whole generation, most assuredly."

Without desiring to excite undue expectations, it is a question which deserves serious consideration, whether much more may not be realized from the prosecution of this business than has hitherto been? The little town of Mansfield, in Connecticut, by a persevering devotion to it, undiscouraged by the ill-success of others, has been enabled to derive therefrom a good profit; and it appears from the last census that, with a population of 2276, not less than \$20,000 is annually received from this business.

The bounty paid in Ohio, in 1841, amounted

to \$2681 76; in Pennsylvania \$4418 55. In 1842 there was paid as bounty, in Ohio, \$6699 61. The whole amount of reeled silk produced in Ohio is set down at 3000 pounds. One person sold 300 pounds of reeled silk for \$1600. The whole aggregate of the silk crop throughout the United States, for 1842, is given in a tabular view, by Mr. Ellsworth, at 244,124 pounds of cocoons. (*Ellsworth's Report to Congress.*)

Under the head of MULBERRY, some observations have been made in relation to the varieties of the tree best adapted to the silk culture in the United States. Besides the numerous communications to be found in most of the American periodicals devoted to agriculture, and some specially to the silk culture, many excellent original treatises have been written upon the same subject. Among the last we may name the essay published under the auspices of P. S. Duponceau, Esq., of Philadelphia, one of the greatest champions of the legitimate silk culture that the Union has produced. By *legitimate silk culture*, is meant the employment of the Piedmontese reel, the use of which is absolutely necessary to give the product of the cocoonery its proper value. The work thus referred to is a duodecimo printed in Philadelphia, and bears the name of M. d'Homergue. It is particularly useful in relation to the subject of the Piedmontese reel. A summary of the principal Chinese treatises on the culture of silk, &c., was published, in 1838, by P. Force, Esq., Washington. An excellent *Treatise on the Mulberry Tree, and the Production and Manufacture of Silk*, was published in Philadelphia, in 1839, by Mr. John Clarke. Several *Manuals* on the silk culture, furnishing abundant information, embracing the most minute details, have been published by Roberts, Cobb, Kenrick, Comstock, Clarke, &c., &c. Among the periodicals specially devoted to the subject, the *Silk Culturist*, edited by F. G. Comstock, of Hartford, Connecticut, in 1835-6, and the *Burlington Silk Record*, by E. P. Morris, may be mentioned. In the latter are given the interesting views of Mr. Morris, with a description of his newly invented and valuable feeding-shelves, together with the results of many experiments in raising worms upon an extensive scale.

SILK-GRASS or BEAR-GRASS. See YUCCA.

SILK-WEED. See COTTON, WILD.

SILLS. A country name for the shafts of a cart, &c.

SILVER BELL. See HALEZIA.

SILVER FIR. See FIR and PINE.

SILVER-WEED, or WILD TANSEY (*Potentilla anserina*). An indigenous perennial plant, which, according to Linnæus, indicates clay under the surface. Although it is found frequent in osier holts and spongy meadows, it grows most commonly upon cold, stiff land, and is a sure mark of the sterility of the soil. Flowers large, bright-yellow, the calyx hairy; and each on a long, simple stalk, mostly erect, blowing all the summer. See CINQUEFOIL.

SINCLAIR, GEORGE. An able and successful writer and experimentalist on the artificial and other grasses. He carried on a se-

ries of valuable researches on these in the grass garden at Woburn Abbey, under the direction of the Duke of Bedford, the results of which he gave to the world, in his justly celebrated work, the *Hortus Gramineus Woburnensis*. He also edited a fragment of a work of Mr. Holdich on *The Weeds of Agriculture*. He died in 1835, in the 52d year of his age.

SIT-FAST. In farriery, an ulcerated sore in which a part of the skin has turned horny; if it cannot be dissolved and softened by rubbing with mercurial ointment, it must have a mild blister applied, which will cause it to separate. It generally proceeds from a warble or little tumour resulting from the pressure of the saddle. See **BACK-SORE** and **GALLS**.

SIZE. See **GLUE**.

SKEGS. A kind of oat, sometimes cultivated as a crop in Nottinghamshire. It is the *Avena stipiformis* of Linnæus. See **OATS**.

SKEP. A coarse, round, farm-basket. It is also provincially used to signify a bee-hive.

SKID. The chain by which the wheel of a wagon is fastened, so as to prevent its turning round, upon descending a steep hill. See **DRAG**.

SKIM COULTER. See **PLOUGH**.

SKUNK-CABBAGE; Swamp-cabbage; Skunk-weed. Familiar names applied to a plant common in low grounds in the United States. It is the *Symplocarpus fetida* of some botanists, and the *Pothos fetida* of others. It has a perennial root, and very large leaves, often, when fully grown, measuring 2 feet long and 1 foot wide. "This plant," says Dr. Darlington, "is notorious for the pole-cat-like odour which it emits, when wounded; and is said to possess some medicinal virtues, as an antispasmodic. The root, when chewed, produces a tingling or pricking sensation in the mouth. It is the only species of the genus in the United States: Dr. Barton, however, describes a pretty distinct variety, near Philadelphia."

SLATE. A well-known, neat, convenient, and durable material for the covering of the roofs of buildings. There are many varieties of slate, and it likewise differs very greatly in its qualities and colours. In some places it is found in thick lamina or flakes, while in others it is thin and light. The colours are white, brown, and blue. Slate is so durable in some cases as to have been known to continue sound and good for centuries.

SLAUGHTER-HOUSE. See **ABATTOIR**.

SLEET. See **SNOW**.

SLOE. The American species of sloe belong to the viburnum family, and are not to be confounded with the black hedge thorn. See **BLACKTHORN**.

SLOUGH-HEAL. See **SELF-HEAL**.

SLUG. A genus of molluscous animals, or naked snails, comprehending several species, which differ only in colour. Slugs infest gardens and fields, and are very injurious to the growing crops; hence it becomes essential to destroy them. Dry lime and slacked lime have been recommended, which, being dissolved by the dew and moisture of the atmosphere, act as a poison to these animals. But pulverized lime is not suitable to all soils, and may even prove injurious to some crops. Lime-water appears to

be preferable. But as many husbandmen may not have an opportunity of liming their fields or gardens, or of keeping a sufficient stock of geese, fowls, ducks, &c., to turn in and devour the slugs, common salt will be found an effectual cure; and tar-water or other refuse of gas-works will prove destructive to them, if sprinkled on the land. See **INSECTS** and **SNAILS**.

The disgusting slug infesting pear and cherry trees in the United States is a slimy false caterpillar, the nature and characteristics of which, and the parent-fly, are particularly described by Professor Peck and Dr. Harris. See **SAW-FLIES**.

SMALLAGE PARSLEY. See **CELERY**, **WILD**.

SMITHFIELD. The principal market for the sale of live cattle in the United Kingdom. It is very inconveniently situated in the heart of the metropolis. The numbers of cattle slaughtered have been more than double during the last century. (See **CATTLE**, *antè*, p.293.) Although this increased consumption is scarcely proportioned to the increase of population, it should be remembered that a very different description of cattle are now slaughtered to what were then killed. The present average dead weight of the bullock is about 656 lbs., of the calf 144 lbs., of the pig 96 lbs., and of the sheep and lamb 90 lbs.; approaching to double the weight of these animals in 1730. This renders the number of cattle slaughtered in the metropolis, and the increasing number of the inhabitants, a little more proportionate. From this estimate, and the number of cattle sold in Smithfield market in the year 1830, we may now form some not very inaccurate idea of the amount of this branch of the provision trade in London.

		Average Weight.	No. of lbs.
Cattle	-	159,907	656 lb.
Sheep, &c.	-	1,287,070	90
Pigs	-	254,672	96

Number of lbs. of meat consumed - 248,423,804

This, estimated at the average price of 6d., would be 6,210,595l. 2s. 0d.; at 8d., it would produce 8,268,293l. 9s. 4d., exclusive of bacon, hams, and all salted provisions brought from a distance (the importation of Irish bacon and hams into Great Britain is 500,000 cwt.), and also fish and poultry. This calculation will enable us to determine another curious question,—what is the average quantity of meat consumed by each individual in the course of a year? If we divide the gross number of pounds, 248,423,804, by 1,450,000, the estimated number of inhabitants in London and its environs, the quotient will be 170, or each individual consumes nearly half a pound of meat every day. This is a very high calculation compared with that of Paris, where each person is supposed to consume but 80 pounds in the year; and Brussels, where 89 pounds form the allotment of each; but the English is a meat-eating population, and composed chiefly of Protestants; and when we remember that this includes the bones as well as the meat, half a pound a day is not too much to allow to each person.

Cattle are sent from every part of the king-

dom to Smithfield market, but many more from some districts than from others. The farmer has personally little to do with the sale of his cattle, but custom and interest induce him to consign them to a salesman, who is acquainted with all the butchers and dealers of the district, and with the contractors. He sees at a glance what is the state of the market; he can tell whether it is likely to rise or fall; and comparing the lot which is intrusted to him with others, and with the market generally, he knows what they ought to fetch. The salesmen are generally honourable men; they procure for the owner the value of his cattle under all the circumstances of the market, and although it may not always be so much as the grazier had expected, it is more than he could have got himself, and he is always sure of receiving his money. See POULTRY, SHEEP, SWINE, &c.

SMUT. A disease affecting almost every species of corn, the grains of which become filled with a fetid black powder, instead of containing farinaceous matter. Wet seasons, animalculæ, organic weakness, deficiency of the parts of generation, and other circumstances, have been assigned as the primary causes of this disease, but all the results of experience are against the opinion that these are more than contingencies which aggravate the symptoms, and accelerate the progress of the infection. That the smut does not arise from a deficient fecundity is apparent, because it affects and destroys the grain long before the sexual organs are fully developed. Fogs, exposure to intense sunshine when moist, or other atmospheric influences upon the ear after it has been protruded, have been assigned as causes; but these cannot be productive of the mischief, for the disease has been observed during an early stage of the vegetation of the ear, and long before it has escaped from the leafy envelopes; this also dismisses the opinion entertained by some that the disease occurs after the grains are fully formed. It does not arise from the too abundant moisture of the soil, because I have universally observed that the driest parts of a field are as liable to bear an infected grain as the most wet; and we all know that an infected plant stands surrounded by others entirely uninfected. Some persons have thought that insects are the origin of the disease; but the most accurate observations have refuted this opinion, and shown that the diseased grains may be an agreeable nidus for the larvæ, but that these always appear after the disease is matured. Upon examining some of the diseased grains, Mr. R. Somerville found upon them a minute insect, in form like a wood-louse, which I know from observation to be a species of the acarus, and these he considered the cause of the disease. But this is a conclusion unwarranted by observation, for similar vermin are found upon the roots of the Brassica tribe that are infected with anbury; and, indeed, this genus of insects is invariably found upon decaying vegetable matter; it is their habitat.

Other persons have thought that the grains injured by the process of thrashing are most liable to the disease; but this is refuted by the fact that it appears in some years, and is

scarcely to be detected in others. The Rev. Dr. Hales bruised numerous grains of wheat of different sizes with a hammer, but the result convinced him that this opinion is erroneous. Wolfins thought it arose from a monstrosity of the embryo; but M. Cymen has shown that the male flowers of some plants suffer from smut as well as the female, and the former we know have no embryo.

Some farmers have considered that pigeons' dung induced the disease, but general experience is against this idea. Nor is the disease the consequence of any defect of the sap, for all the parts except the ear are healthy; and there are some plants, observes M. Cymen, having perennial roots, and which are vigorous, yet their seeds are annually attacked with this disease.

Having thus disposed of the several causes which have been erroneously assigned, I will now proceed to detail the more correct knowledge that has been accumulated respecting this plague of our corn crops.

This disease is severally termed *smut*, *dust-brand*, *blight*, *burnt corn*, &c. In France it is commonly known by the names of *charbon* and *nille volante*. Botanists, aided by the microscope, have discovered that the cause of smut is a parasitical fungus, which preys not only upon the sap, but destroys the very organic structure of the grain and chaff upon which it fixes. The majority of naturalists agree in distinguishing the fungus by the title of *Uredo segetum*; but as it has other synonymes, these, and the authors who have employed them, may be usefully enumerated. *Uredo segetum*, Pursh, n. 27; *Chaos ustilago*, Lin. Syst. Nat. 1326, n. 4; *Réticulaire des blés*, Bulliard's *Fungi*, vol. i. p. 90, plate 472, f. 2. *Reticularia segetum*, Withering, iv. p. 388. *Charbon*, Tessier, *Des Maladies des Grains*, 299. Bulliard describes this fungus as globular, extremely fine, and attached to a fine elastic thread. They are exceedingly numerous, enveloping the seed and chaff of the plants they affect, and are, as well as their own still more minute seed, of an intense black colour, having a disagreeable fetid smell, which has been not inaptly compared to stale lobsters. Mr. Kirby tells us that Mr. Lathbury examined the dust of this fungus under a powerful magnifier, and found it consisted of numerous minute particles, uniform in shape and size, much smaller and blacker than those of the pepper brand, and less easily separable: they seemed to be contained in little irregular cells. This dust or seed is the food of a small, shining, black insect, the *Dermestes ata* of Marsham.

Chemical analysis has demonstrated that this fungus effects an entire decomposition of the vegetable particles of the grain it infects, the saline constituents remaining nearly unaltered in the grain. Parmentier, Cornet, Girot, Chantians, Fourcroy, and Vauquelin, have successively examined it, and the result of their researches is, that smutted grains of wheat are composed, 1st, of about one-third their own weight of a green, butyraceous, fetid and acrid oil; 2d, nearly one-fourth of a vegetable substance, perfectly similar to that which comes from *putrid gluten*; 3d, a *black coal*, one-fifth of their weight, similar to that

which is found in all remnants of putrefied organic compounds; 4th, free *phosphoric acid*, amounting scarcely to more than .004 of the smut; 5th, phosphates of ammonia, magnesia, and lime, in the proportion of a few thousandths. "We must remark," say MM. Fourcroy and Vauquelin, "that in one examination of putrefied gluten, we found characters very similar to those of the smut of wheat; and that the products of the one are so like those of the other as to render it difficult, in certain cases, not to confound them together. It requires a man to be well practised in chemical experiments to discern the slight differences that exist between these two putrefied matters, because the differences are only delicate shades, not easily discernible. The contagion attacks especially the gluten, and precedes, indeed prevents, the formation of the starch; since we know positively that this fecula, no traces of which are found in the smut of wheat, suffers no alteration from the septic process which so powerfully attacks the glutinous substance." The ravages of this disease are chiefly, though not exclusively, confined to the cereal plants. Mr. Kirby says it is common to wheat, oats, barley, and rye; and that he has seen the flote fescue (*Glyceria fluitans*), and some other grasses, affected with it. Barley and oats are more frequently affected by it than wheat, which may proceed from the latter being usually steeped before sowing. Wildenow, who, in his *Principles of Botany*, § 331, describes the smut under the name of "Ustilago," and as being a small fungus, says, "This singular variety of gangrene occurs most frequently in the species of Gramineæ, rarely in other plants, sometimes in Scorzonera, Tragspogon," &c. The ear of corn which is attacked is in general totally destroyed, but sometimes the same ear contains sound as well as smutty grains; and even one end of the same grain has been found diseased and the other end sound. However, as all the grains in an ear are usually infected, so, when one stalk is smutty, it generally happens that all the ears from the same root are so too. In March or April, upon carefully opening the hose or blade (*folium vaginans*) which covers the ear, and examining the young ear, although it was not above one-sixth part of an inch long, and almost close to the roots, M. Du Hamel found this embryo already black and distempered; a fact confirmed by the researches of Mr. Kirby. When the diseased ear comes out of the above-mentioned envelope, it looks lank and meager. About half an inch of the upper part of its stalk is commonly not quite straight. If cut asunder at not more than a quarter of an inch below the ear, it will be found nearly solid or filled with pith; the circulation above is therefore obstructed. The next most important point for consideration is, from whence is the infection communicated; and the following experiments will be found to have demonstrated that it is capable of being conveyed to the plants by the agency of the parent seed. These experiments are satisfactory and decisive; for, although they are only in accordance with the most prevalent opinions of farmers upon the point, yet prevalent opinions are not always in accord-

ance with truth, and are never to be implicitly received until sustained by evidence, which is independent of prejudice, and more accurate than surmise.

Mr. R. Somerville, in a paper published in the *Communications to the Board of Agriculture*, details experiments fully substantiating the fact, that the disease is communicable to the crop from the parent seed. He mixed some smutted grains with others perfectly healthy, and kept them in a box for two months; after which, previously to sowing, he rubbed them together between his hands. The sample was then divided into two equal parts, one of which was well washed with clear water three or four times, and then sown in a drill in his garden. The other half was sown similarly, but without being washed or otherwise prepared. The blades appeared above the surface at the same time, and during the first two months of their growth there was no visible difference in their appearance. Soon afterwards many of the plants from the unwashed seed were observed to have a darker and more dirty green hue than those from the seed that had been cleansed with water. This difference of colour by degrees became more striking, and increased until the grain was protruded from the blade, at which time many of the dark-coloured plants evinced symptoms of decay; and the whole of them, when fully developed, were found to be completely destroyed by the smut. The plants from the washed seed produced scarcely a single diseased ear. These results were not fortuitous, for the experiment afforded a similar testimony when repeated the next season.

The experiments of Mr. Harrup agree with the preceding. In these, wheat, consisting half of sound and half of smutted grains, was sown without being previously at all prepared, and this produced a crop of which nearly two-thirds were smutted. Similar wheat, soaked for twelve hours in a saturated solution of common salt, and then mixed with quicklime, produced on the same soil, in the same situation, and in the same season, a crop in which not a smutted ear could be found.

Similar, but more extended, and even more accurate experiments, were completed by Mr. Bevan, and are recorded in the ninth volume of *The Agricultural Magazine*. They give the result of his trials with various liquids as steepers for seed-wheat. The wheat was grown on a sandy soil, at Leighton in Bedfordshire. The columns in the accompanying table which are marked A. contain the results from the sound grain that was sown; and those marked B. are the results from smutted samples. (See Table at top of the next page.)

The conclusion from these and many other accordant experiments is, that washing the seed is effective in preventing the communication of the disease to the crop to which it gives birth. If the washing was frequently repeated, or the cleansing made complete, by passing a continual stream through the seed for some hours, it is probable that simple water might be employed for this purpose as effectually as any saline solution. But as this would require more labour than is desirable, and as the salts,

&c., employed are beneficial in other ways, by protecting the seed from vermin, and ministering to the future vigour of the plants, *sleeps* are generally and very properly adopted.

Liquid employed.	Specific Gravity of the Solution.	Number of smutted Ears in three Sheaves.		Bushels of good Wheat per Acre.		Cwts. of Straw per Acre.

* The seed treated with this acid did not vegetate.

The experiments of Mr. Bevan indicate that lime-water is the most effective of these preparations; and, if this be adopted, it may be prepared by mixing 1 pound of fresh lime with 3 gallons of boiling water, and the clear liquor then to be poured off and immediately used. In this liquor the wheat should be soaked for 12 hours, stirred twice or thrice during the time, and then mixed upon a floor, with the powder made by pouring 3 gallons of boiling water upon 4 pounds of lime. I have had no experience of the effects of lime-water as a preventive of the smut; but with stale urine, and a solution of common salt, I have witnessed numerous and extensive experiments. The results, without exception, were favourable and nearly similar; and this being the case, a preference is to be given to common salt, as being decidedly the most cleanly and the least disgusting. The mode which I have observed to be the most effective is, to wash the seed with pure water, pouring this off with all the floating grains, and then allowing the seed to soak for 12 hours in a solution of common salt, having a strength or specific gravity sufficient to float a hen's egg. I have no doubt that lime, like common salt, is effectual against the disease, by reason of its powerful action upon the texture of the fungus tribe. Every housekeeper knows how completely mushrooms dissolve away when sprinkled with salt; and in experiments I have made upon the *Uredo segetum*, I found that the effect of common salt upon this fungus is not less remarkable.

Mr. Tull, MM. de Lignerolle, Douat, and others, agree in recommending that the seed to be sown upon any farm should be frequently obtained from other soils; but, however beneficial this may be for securing other desired effects, I do not understand how it can prevent the occurrence of smut unless the seed is obtained from a crop and a district notably free from the disease. There is little doubt but that the method in which the disease is imparted to the plant is by its root imbibing the extremely minute seeds of the *Uredo* along with the moisture of the soil. This opinion is confirmed by the observation that the disease is most prevalent when the winter has been mild and the spring wet; for, in such seasons, the abundant moisture passing through the soil is most likely

to convey the seeds to the mouths of the plants' radicle fibres.

I remember trying some experiments, the full details of which I have accidentally lost, in which I buried some of the *Uredo segetum* about an inch below the surface of the soil, in a garden pot in which some wheat was growing, supplying those plants, during their after growth, plentifully with water poured upon the surface of the soil. Not one of these plants escaped infection.

Another garden pot, in which wheat from the same sample was growing, and similarly treated in every respect, but to which moisture was supplied solely by means of the saucer in which it was placed, both pots being sheltered entirely from the rain, produced plants which were not at all infected. Although it is very apparent that the smut is generally imparted to a wheat crop by the agency of the seed sown, yet I am by no means of opinion that this is the only source of infection. I have kept ears of wheat that were covered and destroyed by the *Uredo* during more than twelve months in a situation where they experienced the vicissitudes of temperature during all the seasons, unprotected by more than the paper envelope in which they were suspended in an outhouse. Yet when the *Uredo* that had been thus exposed was mixed with healthy well-washed seed-wheat, this produced diseased plants in a triplicate proportion more numerous than that not so mixed. This experiment demonstrates that frost and drought, acting in concert with a damp atmosphere, do not destroy the vegetating power of the *Uredo's* seed. Such being the fact, why may not this seed remain in the soil ready to impart the plague? We know that, owing to its extreme lightness, the seed floats buoyantly in the air, and may be carried by winds to distant soils, which in the autumn of the same year, before any extremity of cold has been endured, will have to bear the wheat crop for the following harvest. The opinion that the soil is one source of infection, is sustained by the fact that fields in the vicinity of the sea are rarely injured, and never extensively, by the ravages of the smut. Such soils are impregnated more than any other with common salt, and the effect of this saline compound upon the *Uredo* has been

noticed already. These considerations suggest that applications to the soil as well as to the seed are necessary for the banishment of the disease; but a more full notice, and some curious particulars upon this point, will be found detailed under the head MILDEW.

I have frequently examined the roots of wheat plants affected by the smut, but have never perceived that they had a diseased appearance; a fact which I find confirmed by the researches of Mr. Kirby. Although the root is not affected, yet I have invariably found the smutted plants of a form and habit much less robust than those undiseased. The average result of Mr. Bevan's experiments is, that smutted wheat produces straw in the proportion of only 30 to 36·75, when compared with wheat unattacked by the smut. This is not a result contrary to that which might be anticipated; for in plants, as well as animals, an organic affection so serious as this is usually accompanied by a general emaciation of the frame. So decidedly is this effect produced upon wheat, that a practised eye can at once detect by its appearance, before the diseased ear is protruded, a plant that is thus distempered. The stem and leaves look upright, thin, and stiff, wearing the aspect that is best described, to those who know the appearance, by the term *staring*. I cannot conclude without remarking that these facts strengthen the analogy I am so fond of tracing between plants and animals. The atrophy exhibited by both, when under the influence of disease, is strikingly illustrative of their close relationship; and this is further carried on by their being equally liable to the ravages of parasites. The skin of every animal is liable to be infested by vermin, as its intestines and other viscera are by worms and various other creatures. So plants are not only subject to invermination, but, like animals, they are preyed upon by various genera of their own race. Their barks are assailed by numerous lichens and fungi, whilst internally they are a prey to the *Uredo* I have just described, and to several others of the fungus tribe. Animals have their larger parasites, as the tick, &c., and vegetables similarly bear the missestoe, dodder, and others. This repeated urging that plants are closely allied to animals in every particular is not without its use. Every year's experience convinces me that it is not less beneficial to cultivate plants with the least possible injury to their various parts, than it is to treat our farming stock with gentleness and an attention to their comfort; and it is by demonstrating the analogy between the two great divisions of created beings, that the reason of the cultivator is to be drawn to regulate his practice.

Finally, I will observe, that the farmer is much too prone to regard the diseases of his crops as of trivial importance. In such cases as where the curl destroys whole fields of his potatoes, or the mildew reduces the produce of each acre of wheat to a few bushels, he is miserably sensible of the injury he has sustained; but if, within the circle of corn-ears around him, as he surveys his crops, he only sees a sprinkling of those affected with the smut, he looks upon this as of insignificant

consequence. Yet, in the experiments of Mr. Bevan, in the instances where only two smutted ears occurred in three sheaves, the weight of the straw was reduced nearly one-third, and that of the grain three-sevenths. (Essay by G. W. Johnson, *Quart. Journ. Agr.* vol. ix. p. 45.) See BLIGHT and MILDEW.

SMUT-MILL. Of late years the millers in the United States avail themselves of contrivances called *smut-mills*, the passage of the wheat through which clears it very effectually from the offensive dust. Wheat affected with smut was formerly much objected to by the grain merchants and millers, but since the introduction of the machines referred to, is so readily cleansed that smut is scarcely objected to in the sample, and the market price reduced but little, if at all.

An inquiry made, in March, 1842, into the merits of a smut-mill invented by Mr. Wm. C. Grimes, of York, Pennsylvania, by a committee of the Franklin Institute of Pennsylvania, warranted them in recommending the machine to the notice of millers, as capable not only of making good white flour from wheat so badly smutted as to be generally considered unmerchantable, but which will also improve the general quality of flour, by the removal of cheat, and of the down or furze which covers one end of the grain, and of most other accidental foreign matters which tend to injure the quality of the flour. (*Jour. of the Franklin Inst. of Penn.* vol. iv., third series, p. 32.)

SNAILS (*Helix—Helicida*). A well-known genus of molluscos animals, comprising a great many species. They live throughout the winter in a torpid state, in cavities in the earth, which are covered over with a calcareous kind of wall, partly formed with its mucous secretion. The animal escapes from its cell in April, bursting its operculum, and again breathes as before its hibernation. The species of shell-snails are very extensive. In the garden, snails do much damage to the vegetables in cultivated grounds, biting off pieces of the leaves by means of a semicircular, dentated, horny plate which is affixed to the upper lip. To extirpate them, it has been recommended to strew the ground with lime and ashes, or salt. Snails seldom annoy farmers, unless it be under the hedges; and if they venture out into the middle of a field, the roller is a certain destructive implement to their fragile coverings. The red, or great vine-snail (*H. pomatia*), formed one of the luxuries of the tables of the ancient Romans, and by peculiar feeding and other treatment was brought to attain an immense size. It is still an article of food in certain cantons of Switzerland and France, and some of the provinces of Spain and Portugal. This species of helix was brought to England by the Howard family, and placed on the grounds in the neighbourhood of Box-hill, where it is still found; but it does not attain to the size it often displays in Italy. It is supposed to be a good article of food for the consumptive.

SNAKE-ROOT. Several plants in the United States go under this appellation. The Virginia snake-root (*Aristolochia serpentaria*) is the well-known fibrous root, noted for its intense bitterness, and extensively employed in medicine as

as a tonic. It is found in rich woodlands, in the Middle States. The root is perennial.

SNOW. This well-known precipitation from the atmosphere serves to defend winter grain-crops and all other vegetables from the severity of frosts; for, being a very bad conductor of heat, it prevents the internal warmth of the earth from being carried off through the surface of the land, and consequently ameliorates the soil. The plants being thus sheltered, shoot forth in the spring with renewed vigour; and, cherished by the genial rays of the sun, vegetate with increased luxuriance. As ammonia and other saline matters, possessing fertilizing matters, have been detected in snow, it not only cherishes vegetation by the protection it affords, but by the direct influence of the fertilizers referred to.

SODA. See **KELP**; **SALTS**, *their uses to vegetation, &c.*

SOD BURNING. See **PARING** and **BURNING.**

SOFT-GRASS. See **HOLCUS.**

SOIL. The upper surface of the earth which furnishes a medium or basis for the growth of plants. Prof. Johnston, in his *Elements of Chemistry*, has remarked, that the earthy part of the soil is not, as some have supposed, a mere substratum, in which the plant may so root itself as to be able to maintain its upright position against the force of winds and tempests, but it is a storehouse of food also, from which the roots of the plant may select such earthy substances as are *necessary or fitted to promote its growth.* And the young farmer, when he is endeavouring to understand the true theory of the food of plants, and the operation of fertilizers, must discard from his mind all suspicion that these earthy and saline substances, found in the substance of his crops, are merely there by accident, or absorbed by their roots accidentally in the moisture of the soil; for, on the contrary, it has been shown that these substances are always found in the plant, and that they vary in amount at different stages of its growth. Thus, to give a single instance, Mr. J. P. Norton (*Trans. High. Soc.* 1845, p. 321; *Farmer's Almanack*, vol. iii. p. 19) has shown that the ashes of the stalk of the unripe potato-oat contained

	June 4.	June 18.	July 2.	July 16
Potash and soda	24.94	26.49	36.25	42.43
Common salt	32.66	24.94	11.62	4.46
Lime	2.40	3.74	2.64	4.12
Magnesia	0.88	2.20	1.17	1.47
Oxide of iron	0.39	0.40	0.88	0.62
Sulphuric acid	6.15	8.51	7.98	7.84
Phosphoric acid	16.15	12.55	2.21	6.31
Silica	16.29	20.41	36.64	34.85

It is true that the *amount* of these fixed or inorganic substances varies in the same species of plant grown on different soils; but, although the *proportions* vary, the *ingredients* do not alter; and so closely is the *proportion* preserved in which they exist, that Professor Johnston has been able to determine pretty accurately the general amount of the inorganic ingredients carried off the soil, per acre, by the ordinary rotation of the four-course system. As the basis of this calculation, he supposes the turnips to consist of 25 tons of bulbs, and 7 tons of tops; the barley, of 38 bushels of 63 lbs. each, and 1 ton of straw; the clover and rye-grass, of 1 ton of each in hay; and the wheat crop to be composed of 25 bushels of 60 lbs., and 1 $\frac{3}{4}$ tons of straw.

These, he calculates (*Elements of Chemistry*, p. 51), will contain and carry away from the soil (supposing none of them to be eaten on the land)—

	lbs.		lbs.
Potash	280	Sulphuric acid	111
Soda	150	Phosphoric acid	90
Lime	242	Chlorine	39
Magnesia	50		
Silica	318	Total	1280

So that, if we carry off the entire produce, and add none of it again in the shape of manure, we ought every fourth year to add to the soil per acre, if we wish to restore it to its original condition,

Pearl or potash	390 lbs.	at a cost of	£3 10 0
Crystallized carbonate of soda	500 "	"	2 12 0
Common salt	65 "	"	0 2 0
Gypsum	60 "	"	0 1 6
Lime	160 "	"	0 0 8
Epsom salts (sulphate of magnesia)	250 "	"	1 5 0
Bone-dust	360 "	"	1 2 0
Total	1785		£5 13 2

We may safely, then, adopt the conclusion of Liebig, when he tells us (*Organic Chemistry*, p. 63) that "many of these inorganic constituents vary according to the soil in which the plants grow, but a certain number of them are indispensable to their development. All substances in solution in a soil are absorbed by the roots of plants, exactly as a sponge imbibes a liquid, and all that it contains, without selection. The substances thus conveyed to plants are retained in greater or less quantity, or are entirely separated when not suited for assimilation."

The results of these chemical researches it will be found very serviceable to bear in mind, in the investigation of the composition and uses of all fertilizers.

The chief cultivated soils with which the farmer has to encounter, although in reality mixtures of sand, clay, and lime with various saline and organic matters, may, for the convenience of something like a classification, be arranged under the heads of sand, clay, and lime. These, it must be remembered, are fertilizing according to the proportions in which they are blended together; and, as a general rule, it may be taken that, whenever any one of these earths is deficient in a soil, the addition of such earth will add to its fertility; and hence they all, in some situation or other, are found to be useful additions or fertilizers to soils in which the added earth naturally exists in insufficient proportions.

In burning a piece of wood or any other vegetable substance, a small portion of it remains behind, called the ash or inorganic part;—which is a compound substance consisting of various mineral substances, gases, &c., that have served as the food of the growing plant or tree, and which it is the proper function of soils to supply. Such are silica or flint; alumina, or the basis of clay; potash, soda, lime, magnesia, oxide of iron, chlorine united with the soda in the form of common salt, sulphuric acid, phosphoric acid, carbonic acid. The portions of the wood or other vegetable matter lost or dispersed in the burning are termed the organic constituents. Sand, clay, and lime, although they compose such a large amount of the inorganic constituents of soils, have associated with them many other substances

which exert important influences upon the growth of plants, and the ratios of which it is of the highest importance to the practical farmer to understand. The presence of the substances constantly found in fertile soils in their due proportions, however small these may appear, is just as necessary to maintain fertility, as that of the substances existing in the largest proportions. All the essential ingredients of a good soil must be present to secure a good crop, although they need not always exist in precisely the same proportions. Any one of these primary constituents of soils in superabundant quantity

will lessen or destroy fertility. Too much potash, salt, magnesia, iron, lime, or clay, will all impair or entirely destroy productiveness in soils, until these have had the superabundance washed away by rains. The barrenness of a soil may arise from its containing too small or too large a proportion of one or other of the essential ingredients. The proportions of the several inorganic substances required by plants which are the most common objects of cultivation in England, are presented in the following table from Prof. Johnston's Lectures.

Percentage of	Wheat	Straw of Wheat	Oats with husk.	Straw of Oats.	Husk of Oats.	Barley	Straw of Barley	Rye.	Straw of Rye.	Field Beans.	Straw of Beans.	Peas.	Straw of Peas.	Tur-tips.	Potatoes
Potash	23.72	12.44	26.18	19.14	8.13	13.64	6.31	22.08	17.36	33.56	53.08	36.05	4.73	39.82	55.75

Although some of these substances make up a comparatively large amount of the ashes of plants, potash composing 23 per cent., and phosphoric acid nearly one-half the ash of wheat, oats, barley, and rye, the proportion of these in the soil appears exceedingly small, compared to the whole bulk. How eagerly then must such substances be sought after by the roots of plants and appropriated as food! Straw contains but a very small quantity of phosphoric acid. The potash taken up by Indian corn, is in very much the same proportion as that abstracted by wheat. The phosphoric acid ascends into the grain, whilst the silicious matter lodges in the straw or stalk, giving these strength to support the ears. In the potato more than half the ash consists of potash, whilst the proportion of phosphoric acid is very small. Thus do plants of various kinds and families differ materially in their demands on the soil for sustenance. Even different parts of the same plants require various proportions of the nutritious substances. How is it possible for the delicate fibrous roots of plants to derive any nourishment from such hard materials as flint, limestone, shells, bones, &c.? The answer is that these hard substances must all undergo solution in water before they can be absorbed by delicate roots and circulated through the infinitely minute sap-vessels. The perfection of refined agriculture consists in knowing how to adapt with precision the elements requisite as food and the modes of culture necessary in different soils to favour in the highest degree the growth and fullest development of plants of various descriptions. One of the most important points connected with practical farming is to be able to specify what particular plants take from the soil, and what must be applied in order to restore the deficiency with least expense.

Professor J. F. W. Johnston has given the following tabular view of the composition of soils of different degrees of fertility.

The soil, of which the composition is given in the first column, had produced crops for 60 years without manure,—and still contained a sensible quantity of all the substances required by plants. That in the second column produced good crops when regularly manured,—it was in want of three or four substances only, which were given to it by the manure. The third was hopelessly barren,—it was in want of many substances which ordinary manuring could not supply.

	Fertile, without Manure.	Fertile, with Manure.	Barren.
Organic matter	97	50	40
Silica (in the sand and clay)	648	833	778
Alumina (in the clay)	57	51	91
Lime	59	18	4
Magnesia	8½	8	1
Oxide of iron	61	30	81
Oxide of manganese	1	3	½
Potash	2	trace	trace
Soda	4
Chlorine, } chiefly as com. salt	2
Sulphuric acid	2	¾
Phosphoric acid	4½	1¾
Carbonic acid (combined with the lime & magnesia)	40	4½
Loss	14	4½
	1000	1000	1000

Soils generally have in them some of the elements of fertility so locked up by strong union with other substances, that plants cannot appropriate them to their uses, unless something be added which has the power to destroy the natural combination, release the fertilizers, and render them accessible to the wants of vegetables. Under such circumstances, the application of lime will unlock potash where granite or felspar and mica exist, and the freed potash will in turn render silix soluble. [See SILEX, LIME, SALTS.]

Heavy and stiff clays, which cannot be cultivated in grain crops to profit, will often pay well for grazing purposes.

SOILING. The practice of supporting animals in the summer season, with green food, cut daily and given to them in their houses, stalls, or yards. A number of different plants and grasses are resorted to for this purpose, particularly those which have a quick and luxuriant growth; as lucern, sainfoin, tares, clover, maize, turnips, &c.

Soiling appears to be highly advantageous, in a variety of ways, by the food being consumed with much less waste, by the great increase of good manure that is produced, and by the stock feeding with less interruption and inconvenience, from their being more effectually shaded from the excessive heat of the sun, and better protected from the attacks of flies and other insects. In all these respects it would seem to have a great superiority over that of letting the animals range indiscriminately in the pastures or other grass lands.

Soiling has been found, by the most careful experiments, to answer perfectly both with horses, neat cattle, and swine; and with cows it has been found very beneficial in the trials of Mr. Curwen and several others.

By an extensive and judicious use of soiling, the farmer may derive benefit in being enabled to have a considerably larger extent of land both under the states of tillage and grass, from the considerable increase of manure that is produced.

That a great saving of food is effected by keeping cattle and other stock in pens, yards, or stables, and supplying them with fresh-cut green herbage, is undoubted. Many say that three, and some assert even four animals can be well kept upon the produce of land where soiling is practised, more than the same land would sustain if pastured. Besides the very great advantage of enabling double or treble the stock to be kept on a given number of acres, soiling offers another in the greatly increased amount of manure, which is far beyond what would be supposed by persons unacquainted with the practice. Where proper arrangements are made and care taken, all the manure of animals may be saved, instead of being scattered and partially lost, as is the case with a large proportion dropped in the lanes or fields. It gives the farmer an opportunity of applying all his straw and coarse litter to the best advantage, by spreading and using it as an absorbent for the less solid portions of the excrements of his animals. A good supply of litter is indispensable in order to derive the fullest advantages from soiling. By such means, and properly arranged gutters leading to tanks or cisterns, the farmer has the power of saving nearly all of the liquid or best portion of the manure of his cattle, his main dependence for keeping up the productiveness of his lands. (See LIQUID MANURE, and NIGHT-SOIL.)

Another advantage derived from soiling—and a most important one, too—is the saving of fencing in the interior of farms.

Among the objections urged against the practice, are the great amount of labour required for cutting and carrying the feed for a large stock, and the difficulty of getting a supply of green food fit to mow sufficiently early in the season. It has also been asserted, that cows soiled will not give so much milk as when grazed; but the experience of others shows results entirely contrary, and that, by judicious feeding and management, the amount of milk may be regulated almost at pleasure. The success of the plan depends almost as much upon securing to the animals proper ventilation, cleanliness, and com-

fort, as upon the nature of the food. Whatever system of soiling may be adopted, it would seem of great importance that the animals should, for the promotion of their health, be occasionally turned out into the open air, during some portion or portions of the day. As this cannot be done in many large dairy establishments in or adjacent to large cities, cows are often kept tied up in their stalls for weeks, and many for months together, to the great injury of their health, and deterioration of their milky secretions. In an interesting report made by the Commissioners on the State of Health in Large Towns in England, the following observation occurs: "It is known that tubercular consumption is very prevalent among the cows which supply milk to the inhabitants of some large towns, where they are immured during part of every year in dairies perfectly closed; and which, being too small for the number of animals which they contain, soon become filled with heated, vitiated air, for the removal of which no provision is made. This is remarkably the case with the cows belonging to the milkmen of Paris, which are annually carried off by consumption in considerable numbers. A confirmation of the influence of this cause is afforded by the exemption of the horse from consumption, although frequently placed in the same circumstances with the cows, but with intervals of exposure to fresh air, and the enjoyment of exercise. Where a number of horses, however, are collected together in ill ventilated stables, they may become consumptive. A discovery of this kind was lately made, as to the influence of defective ventilation on the cavalry horses in some of the government barracks in England; and it is stated that a saving of several thousand pounds per annum was effected by an easy improvement of the ventilation of the barracks near the metropolis." (See VENTILATION.)

In feeding cows, it must be remembered that they are very capricious in their appetites, and do not like to be kept constantly on the same kind of food. A variety should therefore always be resorted to, when practicable. The food may be given to them several times a day, never less than three times, viz. early morning, noon, and night, and oftener when convenient. Water should be allowed morning and evening, and salt must be at hand, so that they can help themselves at pleasure.

SOLAR INFLUENCE. See TEMPERATURE, LIGHT, and ATMOSPHERE.

SOOT is very extensively employed in the east of England, as a powerful manure, and produces, when used at the rate of 12 or 20 bushels per acre, most luxuriant crops of wheat and other grain. This valuable fertilizer is composed of a mixture of charcoal, an oil, salts of ammonia, some muriatic acid, lime, magnesia, silica, and other foreign substances; but the charcoal is by far the largest ingredient, and has a powerful influence on vegetation; and, according to Liebig, it can "completely replace vegetable mould or humus. Plants thrive in powdered charcoal, and may be brought to blossom and bear fruit if exposed to the influence of rain and the atmosphere." (*Organ. Chem.* p. 61.) All the substances contained in soot are the natural food of vegetables; the carbon gradually combines with the oxygen of the atmosphere, and is converted into carbonic acid gas, which is readily absorbed by the roots and leaves of plants.

In Essex, the chief employment of soot is for wheat, and it is generally applied by the chimney sweepers to the land, out of a basket, in the same manner that seed is sown. This is usually done in the spring of the year, in March, April, or May. Wheat so treated speedily assumes a very deep green, and on some soils grows with greatly increased luxuriance. Soot was employed by the Rev. E. Cartwright as a manure for potatoes, both by itself and in combination with various other fertilizing substances. The experiments were made on a portion of the same soil as that described in the article ASHES. The following were the results obtained :

	Per Acre.
1. The soil, without any manure, yielded bushels of potatoes - - - - -	157
2. Soot 30 bushels - - - - -	192
3. Soot 30 bushels, salt 8 bushels - - - - -	240

Various agriculturists have noticed the good results from mixing salt and soot. Mr. George Sinclair, in his prize essay *On Salt as a Manure*, mentions it as "remarkable" in the case of carrots. Mr. Belfield of Elford has done the same with regard to wheat.

In Mr. Sinclair's experiments upon carrots,

	Per Acre.	
	Tons.	lbs.
The soils without any manure produced carrots - - - - -	23	9 107
Soil with 6½ bushels of salt dug in - - - - -	44	14 17
Soil with 6½ bushels of salt, and 6½ bushels soot - - - - -	40	4 97

In both the liquid and solid state, it has been employed by Mr. John Robertson of Kilkenny, with great success. "On meadows," he says, "I have used soot with great advantage in substance; and though sown by the hand, one dressing gave me always heavy crops of hay for two successive seasons. But this is a wasteful mode of applying it, a great portion of its ammonia, one of its most active ingredients, being volatilized, and dissipated in the atmosphere: when dissolved in water, there is no waste,—it is all available; and for horticultural purposes I have mostly used it in that state, mixing it up in the proportion of about six quarts to a hogshead of water. Asparagus, peas, and a variety of other vegetables, I have manured with it, with as much effect as if I had used solid dung; but to plants in pots, particularly pines, I have found it admirably well adapted; when watered with it, they assume a deep, healthy green, and grow strong and luxuriant." Mr. A. Main makes some pertinent remarks on soot as a top-dressing to crops, and describes a machine for distributing it, in the sixth volume of the *Trans. of the Highland Soc.* p. 535.

SORREL (the genus *rumex*, from the shape of the leaves in many of the species, resembling a pike or spear). There are in England several indigenous species of sorrel, some of which have already been described. The common English sorrel (*Rumex acetosa*) is a perennial plant, met with almost everywhere in meadows and pastures, flowering in June. The root is long and tapering, astringent, and somewhat woody. The herbage is smooth, powerfully and agreeably acid. Stem from 1 to 2 feet high, erect, simple, leafy, striated. Leaves oblong, arrow-shaped. Flowers dic-

eous, with permanent tuberculated petals. The acidulous taste of sorrel depends on binoxalate of potassa and tartaric acid: the astringency on tannic acid.

The flavour of the wood-sorrel (*Oxalis acetosella*) is much more grateful, and the leaves are more juicy, than those of the common sorrel (*R. acetosa*) and the French or Roman sorrel (*R. scutatus*). The acid is merely the oxalic, free and also combined with potassa and ammonia. It likewise contains some saccharine matter. The garden cultivation required by them is identical. The leaves are employed at all seasons of the year, in salads, sauces, &c. The wood-sorrel requires a silicious, yet moist and moderately fertile soil, in a shady situation, as beneath a hedge with a northern aspect. The garden sorrel thrives best in any mouldy garden soil that tends to lightness rather than tenacity, and is not too poor. The situation must be open. French sorrel is most healthful in a light, dry soil, that is tolerably fertile, in an open compartment. The rumexes are propagated by seed, and all of them by parting the roots, both which modes may be practised from the middle of February until the same period in May, and by the latter also in September and October. The finest plants are raised by seed, but those from portions of the roots are soonest in production.

Sheep-sorrel, or field-sorrel (*R. acetosella*), is abundantly diffused throughout the United States, and often forms a great pest to the farmer. The best way to subdue it is by means of liberal dressings with lime. This has been disputed by some, but where the application has been made in large quantity, it will seldom or ever fail. Of this genus two other species, troublesome to farmers, have been already mentioned. These are the sour or curled dock (*R. crispus*), and the bitter or broad-leaved dock (*R. obtusifolius*). See DOCK.

SORREL TREE (*Andromeda arborea*). This is the only species of *andromeda*, which rises to a sufficient height to be ranked among forest trees. It begins to appear on the Alleghanies in Virginia, and is found to their termination in Georgia. In the fertile mountainous regions of North Carolina, it attains a height of 50 feet, with 12 or 15 inches in diameter. The name is derived from the acidity of the leaves, which in drying become black. When sumac is not to be obtained, these leaves are used as a substitute in dyeing wool. The tree will endure much cold, and grows well in the vicinity of New York. It has small, white flowers, formed into spikes 5 or 6 inches long. These render the tree a very pretty ornament to gardens, &c.

SOUTHERNWOOD (*Absinthium*). The field southernwood (*A. campestre*) is a rather rare species. It is perennial in habit. The whole herb is without any aromatic or bitter flavour. Stems at first prostrate, becoming more or less upright as the flowers appear, branched, leafy, straight and wand-like, smooth, often reddish, near 2 feet high. Leaves irregularly and doubly pinnatifid, in many linear; blunt segments. Flowers drooping, small, ovate, yellow with a purplish calyx, forming numerous slender leafy clusters at the ends of the stems and branches. See WORMWOOD.

SOWING. See SEED.

SOWING MACHINE. See DRILL.

SOW-THISTLE (*Sonchus*, from *somphus*, hollow; the stems being hollow). A rather large genus of annual or perennial plants, rarely shrubby, generally tall. They have hollow stems, and more or less pinnatifid or lyrate leaves, toothed or prickly at their edges. The surface of the herbage is usually smooth, that of the inflorescence hairy or glandular, often viscid. They contain a bitter white juice, and are plants of easy culture in any common soil. The herbaceous species are increased by division; the seeds of the annual and biennial kinds only require to be sown in the open ground. There are in England three indigenous perennial species: the blue sow-thistle (*S. caruleus*), the tall marsh sow-thistle (*S. palustris*), one of the largest herbaceous plants, growing from 6 to 8 feet high; and the corn sow-thistle (*S. arvensis*). The most common native species is annual in habit, viz., the common sow-thistle (*S. oleraceus*), which is found almost everywhere, in cultivated and waste ground; flowering from July to September. Hares and rabbits are very fond of the herbage, which, like the root, is milky and bitter. The leaves are sometimes dressed and eaten among other culinary herbs, and the roots have occasionally been converted into bread.

SPADE HUSBANDRY. There are many situations in which, from the small size of the enclosures, or the want of sufficient power for the easy working of the common or the subsoil plough, the cultivator may prefer the employment of manual labour with the spade; and it is fortunately found by experience that the difference in the expense of deep-digging, or spade husbandry, is not materially different from that of the subsoil plough. A great mass of information on this head was collected by the late Dr. Yelloly; not, however, so much with the view of showing the increased fertility of the soil by deep-stirring, as with the intention of demonstrating the immense field which is thus opened for the profitable labour of a teeming and increasing population. (See Dr. Yelloly on *Spade Husbandry*; also *British Farmer's Magazine*.)

The trials which have been hitherto made of spade husbandry, in various parts of the kingdom, have been insufficient, in point of extent, to afford any adequate criterion of the general applicability of that practice. Such trials, indeed, have been usually regarded either as matters of speculation and experiment, or as charitable efforts adopted by the benevolent to give employment to the poor, without reference to pecuniary expediency.

In most parts of Biscay and the north of Spain, the fields are commonly cultivated by the spade: great crops of potatoes and turnips are raised by these means." (*Sinclair*, p. 394; *Brit. Husbandry*, vol. ii. p. 571.) See FLANDERS, HUSBANDRY OF.

SPANISH NEEDLE (*Bidens*). See BURMARIGOLD.

SPAN-WORMS. A common appellation applied to those caterpillars called also loopers, and geometers. In New England they are called canker-worms.

The caterpillars of the *Geometra* of Linnaeus, earth-measurers, as the term implies, or geometers, span-worms, and loopers, have received these several names from their peculiar manner of moving, in which they seem to measure or span over the ground, step by step, as they proceed. Most of these caterpillars have only 10 legs; namely, 6, which are jointed and tapering, under the fore-part of the body, and 4 fleshy prolegs at the hinder extremity; the 3 intermediate pairs of prolegs being wanting. Consequently, in creeping, they arch up the back while they bring forward the hinder part of the body, and then, resting on their hind-legs, stretch out to their full length, in a straight line, before taking another step with their hind-legs. They have the power of letting themselves down from any height, by means of a silken thread, which they spin from their mouths while falling. Whenever they are disturbed they make use of this faculty, drop suddenly, and hang suspended, till the danger is past, after which they climb up again by the same thread. These span-worms are naked, or only thinly covered with very short down; they are mostly smooth, but sometimes have warts or irregular projections on their backs. They change their colour usually as they grow older, are sometimes striped, and sometimes of one uniform colour, nearly resembling the bark of the plants on which they are found. When not eating, many of them rest on the two hindmost pairs of legs against the side of a branch, with the body extended from the branch, so that they might be mistaken for the twig of the tree; and in this position they will often remain for hours together. When about to transform, most of these insects descend from the plants on which they live, and either bury themselves in the ground, or conceal themselves on the surface under a slight covering of leaves fastened together with silken threads. Some make more regular cocoons, which, however, are very thin, and generally more or less covered on the outside with leaves. A very few of the span-worms fasten themselves to the stems of plants, and are changed to chrysalids, which hang suspended, without the protection of any outer covering.

In their perfected state these insects are mostly slender-bodied moths, with tapering antennæ, which are often feathered in the males. Some of the females are without wings, and are distinguished also by the oval and robust form of their bodies. These moths are most active in the night; but some of them may be seen flying in thickets during the day-time. They are very short-lived, and die soon after their eggs are laid.

It was formerly supposed that the canker-worm moths came out of the ground only in the spring. It is now known that many of them rise in the autumn, and in the early part of the winter. In mild and open winters I have seen them, says Dr. Harris, in every month from October to March. They begin to make their appearance after the first hard frosts in the autumn, usually towards the end of October, and they continue to come forth, in greater or smaller numbers, according to the mildness or severity of the weather after the frosts have

begun. Their general time of rising is in the spring, beginning about the middle of March, but sometimes before, and sometimes after this time; and they continue to come forth for the space of about 3 weeks. It has been observed that there are more females than males among those that appear in the autumn and winter, and that the males are most abundant in the spring. The sluggish females instinctively make their way towards the nearest trees, and creep slowly up their trunks. In a few days afterwards they are followed by the winged and active males, which flutter about and accompany them in their ascent, during which the insects pair. Soon after this, the females lay their eggs upon the branches of the trees, placing them on their ends, close together, in rows, forming clusters of from 60 to 100 eggs or more, which is the number usually laid by each female. The eggs are glued to each other, and to the bark, by a grayish varnish, which is impervious to water; and the clusters are thus securely fastened in the forks of the small branches, or close to the young twigs and buds. Immediately after the insects have thus provided for a succession of their kind, they begin to languish, and soon die. The eggs are usually hatched between the first and the middle of May, or about the time that the red currant is in blossom, and the young leaves of the apple tree begin to start from the bud and grow. The little canker-worms, upon making their escape from the eggs, gather upon the tender leaves, and, on the occurrence of cold and wet weather, creep for shelter into the bosom of the bud, or into the flowers, when the latter appear. Where these insects prevail, they are most abundant on apple and elm trees; but cherry, plum, and lime trees, and some other cultivated and native trees, as well as many shrubs, often suffer severely from their voracity. The leaves first attacked will be found pierced with small holes; these become larger and more irregular when the canker-worms increase in size; and, at last, the latter eat nearly all the pulpy parts of the leaves, leaving little more than the midrib and veins. A very great difference of colour is observable among canker-worms of different ages, and even among those of the same age and size. It is possible that some of these variations may arise from a difference of species; but it is also true that the same species varies much in colour. When very young, they have 2 minute warts on the top of the last ring; and they are then generally of a blackish or dusky brown colour, with a yellowish stripe on each side of the body; there are 2 whitish bands across the head; and the belly is also whitish. When fully grown, these individuals become ash-coloured on the back, and black on the sides, below which the pale yellowish line remains. When fully grown and well fed, they measure nearly or quite 1 inch in length. They leave off eating when about 4 weeks old, and begin to quit the trees; some creep down by the trunk, but great numbers let themselves down by their threads from the branches, their instincts prompting them to get to the ground by the most direct and easiest course. When thus descending, and suspended in great numbers under the limbs of trees overhanging the

road, they are often swept off by passing carriages, and are thus conveyed to other places. After reaching the ground, they immediately burrow in the earth, to the depth of from 2 to 6 inches, unless prevented by weakness or the nature of the soil. In the latter case, they die, or undergo their transformation on the surface. In the former, they make little cavities or cells in the ground, by turning round repeatedly and fastening the loose grains of earth about them with a few silken threads. Within 24 hours afterwards, they are changed to chrysalids in their cells. The chrysalis is of a light brown colour, and varies in size according to the sex of the insect contained in it; that of the female being the largest, and being destitute of a covering for wings, which is found in the chrysalis of the males. The occurrence of mild weather after a severe frost stimulates some of these insects to burst their chrysalis skins and come forth in the perfect state; and this last transformation, as before stated, may take place in the autumn, or in the course of the winter, as well as in the spring; it is also retarded, in some individuals, for a year or more beyond the usual time. They come out of the ground mostly in the night, when they may be seen struggling through the grass as far as the limbs extend from the body of the trees under which they had been buried. As the females are destitute of wings, they are not able to wander far from the trees upon which they had lived in the caterpillar state. Canker-worms are therefore naturally confined to a very limited space, from which they spread year after year. Accident, however, will often carry them far from their native haunts, and in this way, probably, they have extended to places remote from each other. Where they have become established, and have been neglected, their ravages are often very great. In the early part of the season the canker-worms do not attract much attention; but in New England it is in June, when they become extremely voracious, that the mischief they have done is rendered apparent, when we have before us the melancholy sight of the foliage of our fruit trees and of our noble elms reduced to withered and lifeless shreds, and whole orchards looking as if they had been suddenly scorched with fire.

In order to protect our trees from the ravages of canker-worms, where these looping spoilers abound, it should be our aim, if possible, to prevent the wingless females from ascending the trees to deposit their eggs. This can be done by the application of tar around the body of the tree, either directly on the bark, as has been the most common practice, or, what is better, over a broad belt of clay-mortar, or on strips of old canvass or of strong paper, from 6 to 12 inches wide, fastened around the trunk with strings. The tar must be applied as early as the 1st of November, and perhaps in October, and it should be renewed daily as long as the insects continue rising; after which the bands may be removed, and the tar should be entirely scraped from the bark. When all this has been properly and seasonably done, it has proved effectual. The time, labour, and expense attending the use of tar, and the injury

that it does to the trees when allowed to run and remain on the bark, have caused many persons to neglect this method, and some to try various modifications of it, and other expedients. Among the modifications may be mentioned a horizontal and close-fitting collar of boards, fastened around the trunk, and smeared beneath with tar; or four boards, nailed together, like a box without top or bottom, around the base of the tree, to receive the tar on the outside. These can be used to protect a few choice trees in a garden, or around a house or a public square, but will be found too expensive to be applied to any great extent. Collars of tin-plate, fastened around the trees, and sloping downwards like an inverted tunnel, have been proposed, upon the supposition that the moths would not be able to creep in an inverted position, beneath the smooth and sloping surface. This method will also prove too expensive for general adoption, even should it be found to answer the purpose. A belt of cotton-wool, which it has been thought would entangle the feet of the insects, and thus keep them from ascending the trees, has not proved an effectual bar to them. Little square or circular troughs of tin or of lead, filled with cheap fish-oil, and placed around the trees, 3 feet or more above the surface of the ground, with a stuffing of cloth, hay, or sea-weed between them and the trunk, have long been used by various persons in Massachusetts with good success; and the only objections to them are the cost of the troughs, the difficulty of fixing and keeping them in their places, and the injury suffered by the trees when the oil is washed or blown out and falls upon the bark. Mr. Jonathan Dennis, Jr., of Portsmouth, Rhode Island, has obtained a patent for a circular leaden trough to contain oil, offering some advantages over those that have heretofore been used, although it does not entirely prevent the escape of the oil, and the nails, with which it is secured, are found to be injurious to the trees. These troughs ought not to be nailed to the trees, but should be supported by a few wooden wedges driven between them and the trunks. A stuffing of cloth, cotton, or tow, should never be used; sea-weed and fine hay, which will not absorb the oil, are much better. Before the troughs are fastened and filled, the body of the tree should be well coated with clay-paint or white-wash, to absorb the oil that may fall upon it. Care should be taken to renew the oil as often as it escapes or becomes filled with the insects. These troughs will be found more economical and less troublesome than the application of tar, and may safely be recommended and employed, if proper attention is given to the precautions above named. Some persons fasten similar troughs, to contain oil, around the outer sides of an open box enclosing the base of the tree, and a projecting ledge is nailed on the edge of the box to shed the rain; by this contrivance, all danger of hurting the tree with the oil is entirely avoided. In the *Manchester Guardian*, an English newspaper, of the 4th of November, 1840, is the following article on the use of melted Indian rubber to prevent insects from climbing up trees. "At a late meeting of the Entomolo-

gical Society [of London], Mr. J. H. Fennell communicated the following successful mode of preventing insects ascending the trunks of fruit trees. Let a piece of Indian rubber be burnt over a gallipot, into which it will gradually drop in the condition of a viscid juice, which state, it appears, it will always retain; for Mr. Fennell has, at the present time, some which has been melted for upwards of a year, and has been exposed to all weathers without undergoing the slightest change. Having melted the Indian rubber, let a piece of cord or worsted be smeared with it, and then tied several times round the trunk. The melted substance is so very sticky, that the insects will be prevented, and generally captured, in their attempts to pass over it. About 3 pennyworths of Indian rubber is sufficient for the protection of 20 ordinary sized fruit trees." Applied in this way it would not be sufficient to keep the canker-worm moths from getting up the trees; for the first comers would soon bridge over the cord with their bodies, and thus afford a passage to their followers. To insure success, it should be melted in larger quantities, and daubed with a brush upon strips of cloth or paper, fastened round the trunks of the trees. Worn-out Indian rubber shoes, which are worth little or nothing for any other purpose, can be put to this use. This plan has been tried by a few persons in the vicinity of Boston, some of whom speak favourably of it. It has been suggested that the melted rubber might be applied immediately to the bark without injuring the trees. A little conical mound of sand surrounding the base of the tree is found to be impassable to the moths, so long as the sand remains dry; but they easily pass over it when the sand is wet, and they come out of the ground in wet as often as in dry weather.

Some attempts have been made to destroy the canker-worms after they were hatched from the eggs, and were dispersed over the leaves of the trees. It is said that some persons have saved their trees from these insects by freely dusting air-slacked lime over them while the leaves were wet with dew. Showering the trees with mixtures that are found useful to destroy other insects, has been tried by a few, and, although attended with a good deal of trouble and expense, it may be worth our while to apply such remedies upon small and choice trees. Mr. David Haggerston, of Watertown, Massachusetts, has used, for this purpose, a mixture of water and oil-soap (an article to be procured from the manufactories where whale-oil is purified), in the proportion of 1 pound of the soap to 7 gallons of water; and he states that this liquor, when thrown on the trees with a garden engine, will destroy the canker-worm and many other insects, without injuring the foliage or the fruit. Jarring or shaking the limbs of the trees will disturb the canker-worms, and cause many of them to spin down, when their threads may be broken off with a pole; and if the troughs around the trees are at the same time replenished with oil, or the tar is again applied, the insects will be caught in their attempts to creep up the trunks. In the same way, also, those that are coming down

he trunks to go into the ground will be caught and killed. If greater pains were to be taken to destroy the insects in the caterpillar state, their numbers would soon greatly diminish.

Even after they have left the trees, have gone into the ground, and have changed their forms, they are not wholly beyond the reach of means for destroying them. One person told me that his swine, which he was in the habit of turning into his orchard in the autumn, rooted up and killed great numbers of the chrysalids of the canker-worms. Some persons have recommended digging or ploughing under the trees, in the autumn, with the hope of crushing some of the chrysalids by so doing, and of exposing others to perish with the cold of the following winter. If hogs are then allowed to go among the trees, and a few grains of corn are scattered on the loosened soil, these animals will eat many of the chrysalids as well as the corn, and will crush others with their feet. Mr. S. P. Fowler thinks it better to dig around the trees in July, while the shells of the insects are soft and tender. He and Mr. John Kenrick, of Newton, Mass., advise us to remove the soil to the distance of 4 or 5 feet from the trunk of the trees, and to the depth of 6 inches, to cart it away and replace it with an equal quantity of compost or rich earth. In this way, many of the insects will be removed also; but, unless the earth, thus carried away, is thrown into some pond-hole, and left covered with water, many of the insects contained in it will undergo their transformations and come out alive the next year. (See *Yankee Farmer*, of July 19, 1840, and *New England Farmer* of June 2, 1841, for some valuable remarks by Mr. Fowler.)

Canker-worms are subject to the attacks of many enemies. Great numbers of them are devoured by several kinds of birds, which live almost entirely upon them during their season. They are also eaten by a very large and splendid ground-beetle (*Calosoma scrutator*), that appears about the time when these insects begin to leave the trees. These beetles do not fly, but they run about in the grass after the canker-worms, and even mount upon the trunks of the trees to seize them as they come down. The latter are also stung by a four-winged ichneumon-fly, which deposits an egg in every canker-worm thus wounded. From the egg is hatched a little maggot, that preys on the fatty substance of the canker-worm, and weakens it so much that it is unable to go through its future transformations. I have seen one of these flies sting several canker-worms in succession, and swarms of them may be observed around the trees as long as the canker-worms remain. Their services, therefore, are doubtless very considerable. Among a large number of canker-worms, taken promiscuously from various trees; I found that nearly one-third of the whole were unable to finish their transformations, because they had been attacked by internal enemies of another kind. These were little maggots, that lived singly within the bodies of the canker-worms, till the latter died from weakness; after which the maggots underwent a change, and finally came out of the bodies of their victims in the form of small two-winged

cuckoo-flies, belonging to the genus *Tachina*. Mr. E. C. Herrick, of New Haven, Connecticut, has made the interesting discovery that the eggs of the canker-worm moth are pierced by a tiny four-winged fly, a species of *Platygaster*, which goes from egg to egg, and drops in each of them one of her own eggs. Sometimes every canker-worm egg in a cluster will be found to have been thus punctured and seeder for a future harvest of the *Platygaster*. The young of this *Platygaster* is an exceedingly minute maggot, hatched within the canker-worm egg, the shell of which, though only one-thirtieth of an inch long, serves for its habitation, and the contents for its food, till it is fully grown; after which it becomes a chrysalis within the same shell, and in due time comes out a *Platygaster* fly, like its parent. This last transformation Mr. Herrick found to take place towards the end of June, from eggs laid in November of the year before; and he thinks that the flies continue alive through the summer, till the appearance of the canker-worm moths in the autumn affords them the opportunity of laying their eggs for another brood. As these little parasites prevent the hatching of the eggs wherein they are bred, and as they seem to be very abundant, they must be of great use in preventing the increase of the canker-worm. Without doubt, such wisely appointed means as these were once enough to keep within due bounds these noxious insects; but, since our forests, their natural food, and our birds, their greatest enemies, have disappeared before the woodman's axe and the sportsman's gun, we are left to our own ingenuity, perseverance, and united efforts, to contrive and carry into effect other means for checking their ravages.

Apple, elm, and lime trees are sometimes injured a good deal by another kind of spanworm, larger than the canker-worm, and very different from it in appearance.

Probably more than one hundred different kinds of geometers may be found in Massachusetts alone. Seventy-eight are already known to me. Some of these are small, and are not otherwise remarkable; some are distinguished for their greater size and beauty in the moth state, or for the singularity of the forms and habits of their caterpillars. None of them, however, have become so notorious on account of their devastations as the species already described. (*Harris's Treatise*.) See LIME TREE, INSECT ENEMIES.

SPATTLING POPPY. A name sometimes applied to chickweed.

SPAVIN. In farriery, a disease in horses, consisting of a swelling in or near some of the joints, by which a lameness is produced, and of which there are three kinds; the *blood-spavin*, the *bog-spavin*, and the *bone-spavin*.

SPAYING. The operation of castrating or extracting the ovaries of the females of different kinds of animals, as sows, heifers, mares, &c., in order to prevent any future conception, and promote their fattening.

SPEAR GRASS. The American name for the great smooth-stalked meadow-grass. See POA PRATENSIS.

SPEARMINT (*Mentha viridis*). This species of mint is employed in sauces and salads, as

well as dried for soups in winter. There are two varieties, the broad and narrow-leaved, equally good. See MINT.

SPEEDWELL (*Veronica*). An extensive genus of herbaceous or somewhat shrubby plants, with annual or perennial roots.

Common or male speedwell (*Official veronica*), called by the French Thé d'Europe, is a common plant in the Middle States, found on dry banks, woodlands, and commons, flowering in June and July, and ripening its seed in August and September. Water speedwell, or long-leaved brooklime, is also occasionally found along the muddy margins of rivulets, and also the scull-cap speedwell, or shield-like *Veronica*, with some other species. (Dr. Darlington's *Flora Cestrica*.) See BIRD'S EYE.

SPELT. A species of coarse wheat. It will afford to be cropped once or twice in its early growth, affording excellent pasturage. Compared with wheat, its weight, with the hull on, is as 42 to 76. See WHEAT.

SPICEWOOD (*Laurus Benzoin*). An American shrub or small tree, called also in the United States by the common names of wild allspice, fever bush, and Benjamin tree. The stems grow to the height of 8 or 10 feet, and are branched, the wood being very brittle, and when broken giving out a very pleasant aromatic odour. It is found in moist low grounds. An infusion of the branches is often used medicinally, more especially in the spring of the year, as a drink for horned cattle. See LAURUS.

SPIGNET. See FENNEL.

SPIKENARD, PLOUGHMAN'S (*Conyza*, from *konis*, dust; because it was supposed to have the power of driving away flies; whence also one of the common names, flea (fly) bane. The genus *Erigeron* is, however, the real fly-bane; some of its viscid species, dipped in milk, being used in the south of Europe to catch the various little winged insects so troublesome in warm climates). This is a numerous herbaceous or shrubby genus, of which the only British species (*C. squarrosa*) is the type. This is a perennial plant, growing in chalky or lime-stone countries, frequent in woods, or a marly soil. The root is tapering, fleshy, much branched; the herbage soft and downy, bitter, somewhat aromatic, with a portion of mucilage. The stem is upright, angular, leafy, 2 or 3 feet high, terminating in a corymbose, leafy panicle of numerous dull yellow flowers. The radical leaves bear some resemblance to those of foxglove, but when rubbed are readily distinguished by their aromatic scent.

SPIKE ROLLER. See ROLLER.

SPINACH (*Spinacea oleracea*. From *spina*, on account of its prickly seed). There are two varieties, the round-leaved or smooth-seeded, and the triangular-leaved or prickly-seeded. The first being the most succulent, and consequently less able to endure a low degree of temperature, is employed for the spring and summer crops, and the latter for autumn and winter. For the round-leaved variety, a rich, moist, and mouldy loam, in an open situation, is preferable; but for the triangular-leaved a light, moderately fertile, and dry one, which may likewise be an open compartment, but a sheltered border is most conducive of a continued

supply throughout the winter. The earth should always be well pulverized at the time of digging, as a fine tilth is one of the greatest inducements to its vigour. It is propagated by seed. The first sowing of the round-leaved variety may take place at the close of January, in a warm situation, to be repeated in larger but still small breadths at the commencement and end of February; and thence to be continued, as the plants rapidly advance to seed, every 3 weeks until the middle of April, when, as this affection increases, it must be performed once a week until the close of May, when it may be reduced to once a fortnight, and so practised until the end of July. With August, the sowing of the triangular-leaved variety commences, the main crop of which should be sown during the first 10 days of that month. The sowing may be repeated, after intervals of 3 weeks, until the early part of September.

The sowings may be performed broadcast and regularly raked, which is the mode generally practised for the principal crops, and for the winter-standing always, or in drills an inch deep and a foot apart; in either mode the seed being scattered thin.

Tetragonia, or New Zealand spinach (*Tetragonia expansa*), is much admired as a substitute for summer spinach, being of more delicate flavour, and not so liable to run to seed. It is propagated by seed, which is sown, in the seed-vessel, as gathered the preceding autumn, at the latter end of March, in a pot, and placed in a melon-frame. The seedlings must be pricked while small singly into pots, and kept under a frame without bottom heat until the third week in May, or until the danger of frost is past.

SPINAGE, WILD. See GOOSEFOOT.

SPINDLE TREE (*Euonymus Europæus*.) This shrub or small tree grows wild in English hedges and thickets. The very hard and fine-grained wood is preferred for spindles and for skewers. It is fetid in every part when bruised, and esteemed poisonous. The branches are smooth and even angular when young; afterwards round, with a green, smooth, not warty bark. Leaves ovate, pointed, finely serrated, about 2 inches long, furnished with awl-shaped stipules. Flowers fetid, small, greenish-white, mostly four-cleft. The capsules usually of a fine rose colour: seeds orange-coloured.

SPINDLE-WORM. These American insects are fatal to the plants attacked, the greater part of which, however, are without value to the farmer. Indian corn must be excepted; for it often suffers severely from the depredations of one of these Nonagrians, known to our farmers by the name of the spindle-worm. This insect receives its common name from its destroying the spindle of the Indian corn; but its ravages generally begin while the corn-stalk is young, and before the spindle rises much above the tuft of leaves in which it is embosomed. The mischief is discovered by the withering of the leaves, and, when these are taken hold of, they may often be drawn out with the included spindle. On examining the corn, a small hole may be seen in the side of the leafy stalk, near the ground, penetrating into the soft centre of the stalk, which, when cut open, will be found to

be perforated, both upwards and downwards, by a slender, worm-like caterpillar, whose excrementitious castings surround the orifice of the hole. This caterpillar grows to the length of an inch or more, and to the thickness of a goose-quill. It is smooth, and apparently naked, yellowish, with the head, the top of the first and of the last rings black, and with a band across each of the other rings, consisting of small, smooth, slightly elevated, shining, black dots, arranged in a double row. With a magnifying glass, a few short hairs can be seen on its body, arising singly from the black dots. This mischievous caterpillar, says Dr. Harris, is not confined to Indian corn; it attacks also the stems of the dahlia, as I am informed both by Mr. Leonard and by the Rev. J. L. Russell, both of whom have observed its ravages in the stems of this favourite flower. The chrysalis, which is lodged in the burrow formed by the spindle-worm, is slender. It is shining mahogany-brown, with the anterior edges of four of the rings of the back roughened with little points, and four short spines or hooks, turned upwards, on the hinder extremity of the body. The moth produced from this insect differs from the other Nonagrians somewhat in form, its fore-wings being shorter, and more rounded at the tip. It may be called *Gortyna Zea*, the corn Gortyna; *Zea* being the botanical name of Indian corn. The fore-wings are rust-red; they are mottled with gray, almost in bands, uniting with the ordinary spots, which are also gray and indistinct; there is an irregular tawny spot near the tip, and on the veins there are a few black dots. The hind-wings are yellowish-gray, with a central dusky spot, behind which are two faint, dusky bands. The head and thorax are rust-red, with an elevated tawny tuft on each. The abdomen is pale-brown, with a row of tawny tufts on the back. The wings expand nearly one inch and a half.

In order to check the ravages of these insects, they must be destroyed while in the caterpillar state. As soon as our corn-fields begin to show, by the withering of the leaves, the usual signs that the enemy is at work in the stalks, the spindle-worms should be sought for and killed; for, if allowed to remain undisturbed until they turn to moths, they will make their escape, and we shall not be able to prevent them from laying their eggs for another brood of these pestilent insects. (*Harris's Treatise*.)

SPINES. In botany, branches that, being imperfectly formed, lose their power of extension, become unusually hard, and acquire a sharp point. They are very different from aculei, or prickles, which are a kind of hardened hair. In leaves they are processes formed either by an elongation of the woody tissue of the veins or by a contraction of the parenchyma: in the former case they project beyond the surface or margin of the leaf, as in the holly; in the latter case they are the veins themselves indurated, as in the palmated spines of *Berberis vulgaris*.

SPLINT. In farriery, a hard excrescence growing on the shank-bones of horses. It appears first in the form of a callous tumour, and afterwards ossifies. If the splint interfere with the action of some tendon or ligament, the

hair should be removed, a little strong mercurial ointment be rubbed in for two days, and then an active blister applied. (*Youatt on the Horse*, p. 244.)

SPRING WHEAT. See **WHEAT**.

SPRUCE PINE (*Pinus Canadensis*). Hemlock spruce. A tree which abounds in the northern parts of Pennsylvania, New York, and the Eastern States. See **FINES**.

SPUD. An implement used advantageously in cutting up weeds. It consists of a chisel-formed tool, about 2 inches wide on the cutting edge, inserted into a handle of some 4 or 6 feet in length; it is often made use of by the farmer as a useful substitute for the walking-cane, affording an opportunity of destroying weeds with the utmost facility whilst walking over his grounds. Every farmer ought to own a spud.

SPURGE (*Euphorbia*; Linnæus named this genus after Euphorbus, a physician to Juba, King of Mauritania). This is an exceedingly variable and a very extensive genus of plants, comprising a number that are entirely unworthy of cultivation. The hardy perennial species thrive in any common garden soil, and increase by divisions of the roots or by seeds. The hardy annuals and biennials merely require sowing in the open ground. The tender kinds must be sown in the hot-house or in a hot-bed frame, and, when potted off, must be set with other tender annuals and biennials. The root of *E. ipecacuanha* is said to be equal to that of the true ipecacuanha. *E. antiquorum*, *E. canariensis*, and some other fleshy species, produce the drug "euphorbium," which is the inspissated milky juice of such plants. There are in England 13 indigenous species, but the only one necessary to be noticed is the lesser spurge (*E. lathyris*). It is a biennial, flowering in June and July. The stem rises from a strong, fibrous root to the height of 3 to 4 feet, purplish, smooth, round, hollow. The leaves opposite, spreading, in fours, sessile, oblong, acute, entire, and glaucous. The flowers are in a terminal, solitary umbel, consisting of 4 repeatedly forked branches, furnished with cordate, entire bractes: the flowers are variegated with yellow and dark purple. Capsules are large and smooth, and, when half-ripe, are pickled as capers. The seeds, when pressed between moderately heated iron plates, yield a fixed, acrid oil, which might be advantageously substituted for castor oil. See **MOLE TREE**.

SPURGE-LAUREL (*Daphne laureola*.) A British evergreen shrub, growing in woods, thickets, and hedges, flowering in March. The stem is 2 or 3 feet high, with round, pale, smooth, brown, upright, tough, and pliant branches, crowned with tufts of evergreen leaves, elegantly drooping in all directions, and about 2 or 3 inches long, on short foot-stalks. The flowers are deep-green, in axillary clusters, with orange anthers. Their scent, resembling saffron, with an overpowering sweetness, is perceptible in an evening only. The berries, which are oval and black, are poisonous to all animals except birds. Every part of the plant is very acrid, producing, like the mezereon, a burning heat in the mouth and throat. The bark of its root is commonly used

instead of mezereon. It is powerfully excitant and diaphoretic. The bark of the stem, soaked in vinegar and beaten out flat, forms an excellent agent for keeping blisters open.

SPURGE, OLIVE. See MEZEREON.

SPURREY (*Spergula*, from *spurgo*, to scatter, because it expels its seeds.) A genus of herbaceous, annual, or perennial plants, with slender linear leaves and white flowers. There are in England four indigenous species, the most common of which is the rough-seeded corn spurrey (*S. arvensis*), an annual plant, which grows in sandy corn-fields, and flowers from June to August. (See Pl. 9, b.) The stems are spreading, lax, 6 inches to 2 feet long, moderately branched, jointed, leafy, angular, and hairy and viscid in the upper part. Leaves whorled, linear, narrow, fleshy, downy, obtuse, with short stipules. The flowers are white, on slender, downy flower-stalks. The rough-seeded spurrey is a common weed in sandy soils, and is in Scotland called yarr, and in Norfolk pick-purse. It is devoured with avidity by all cattle, and appears to be conducive to their health, while it remarkably tends to increase the milk of cows, and to fatten sheep. Hence a large, smooth-seeded variety of this weed (*S. sativa*) is industriously cultivated in Flanders, because it is so far superior to other pasture grasses that it continues green till a late period of autumn, and often throughout the winter. Its seeds afford on expression a good lamp oil; the flour obtained from them, when mixed with that of wheat or rye, produces wholesome bread, for which purpose it is often used in Norway and Gothland. Poultry eat spurrey greedily, and it is supposed to make them lay a great number of eggs. Whether given as hay, or cut green, or in pasture, Von Thaer observes that it is the most nourishing, in proportion to its bulk, of all forage, and gives the best flavoured milk and butter. It has been recommended to be cultivated in England, but it is not likely that such a plant can ever pay the expense of seed and labour in that country, even on the poorest soil; or, at all events, as Professor Martyn observes, we have many better plants for such soils.

SQUASH (*Cucurbita*). Of this plant there are many varieties, distinguished by peculiarities of shapes, colours, &c. The young fruit is a rich and excellent vegetable for boiling, stewing, or baking. The common round kind (*Cucurbita malopepo*) is also called *Cymbuling* (and by the French *Bonnet de Prêtre*). The warty or long squash (*C. verrucosa*), is said by Mr. Nuttall to be cultivated by the Indians of the Missouri to its source. Mr. Kenrick, of Boston, notices the following varieties:

1. Early orange;
2. Early long warty;
3. Early scallop;
4. Acorn;
5. Canada crook neck;
6. Long yellow crook neck;
7. Commodore Porter's Valparaiso;
8. Autumnal marrow;
9. Scarlet summer.

The early orange is a new summer variety, very early, and of superior quality. The Canada crook neck is, without doubt, far superior to any and all others, for the late or main crop. It is fine-grained, mealy, and of a sweet, excellent flavour. By being kept in a dry and suitable temperature, they may be preserved till the

following summer. Sow in April or May, as soon as the frosts are over, and the earth becomes warm; the early or summer varieties in hills 6 feet asunder; the winter varieties in hills 8 feet asunder, and 4 plants may remain in a hill.

Autumnal marrow squash (*Cucurbita maccado*), introduced to notice by John M. Ives, Esq., of Salem. A fine, new variety, of an ovate form, pointed; the skin extremely thin, of a cream-colour; the flesh orange; the grain delicate, flavour excellent; seeds large, pure white. Average weight, 8 pounds. It keeps well in winter.

The scarlet summer squash is a new and beautiful flat variety, from France, of the acorn species, of a fine scarlet colour.

The Valparaiso squash, the seeds of which were brought from the Pacific by the late Commodore Porter, is a splendid vegetable, without any neck, in shape and size somewhat resembling a long watermelon, flattened, and of a rich citron or orange colour. Mr. Comfort, of Bucks county, near Philadelphia, has raised some weighing 100 lbs., which have been greatly admired at agricultural and horticultural exhibitions. This vegetable possesses all the good qualities of the common kinds of pumpkin and squash, of which it would seem to be a hybrid variety, very superior to either. Being neither watery or stringy, it makes a delicious pie, far more rich and delicate than that of the ordinary pumpkin. It is also served up at table with meat, like the common squash, either boiled, or baked like a loaf of bread or sweet potato: containing a large amount of saccharine and other nutritious properties, they are also excellent food for farm-stock, especially milch cows. They are cultivated like other vegetables of the same family, but much care must be observed to keep them at a considerable distance from other varieties, with which they have a strong tendency to mix, thus leading to depreciation. They keep well in winter.

SQUASH-BUG. The common American squash-bug (*Coreus tristis*), so well known for the injurious effects of its punctures on the leaves of squashes, is one of the most remarkable insects belonging to the natural division, which includes bed-bugs, fruit-bugs, and various other fetid bugs (*Hemiptera*). It was first described by De Geer, who gave it the specific name of *tristis*, from its sober colour, which Gmelin unwarrantably changed to *maustus*, having, however, the same meaning. Fabricius called it *Coreus rugator*, the latter word signifying one who wrinkles, which was probably applied to this insect, because its punctures cause the leaves of the squash to become wrinkled. Mr. Say, not being aware that the insect had already been three times named and described, redescribed it under the name of *Coreus ordinatus*. Of these four names, however, that of *tristis*, being the first, is the only one which it can retain. About the last of October squash-bugs desert the plants upon which they have lived during the summer, and conceal themselves in crevices of walls and fences, and other places of security, where they pass the winter in a torpid state. On the return of warm weather, they issue from

winter-quarters, and when the vines of the squash have put forth a few rough leaves, the bugs meet beneath their shelter, pair, and immediately afterwards begin to lay their eggs. This usually happens about the last of June or beginning of July, at which time, by carefully examining the vines, we shall find the insects on the ground or on the stems of the vines, close to the ground, from which they are hardly to be distinguished on account of their dusky colour. This is the place where they generally remain during the daytime, apparently to escape observation; but at night they leave the ground, get beneath the leaves, and lay their eggs in little patches, fastening them with a gummy substance to the under-sides of the leaves. The eggs are round, and flattened on two sides, and are soon hatched. The young bugs are proportionally shorter and more rounded than the perfect insects, are of a pale ash-colour, and have quite large antennæ, the joints of which are somewhat flattened. As they grow older and increase in size, after moulting their skins a few times, they become more oval in form, and the under-side of their bodies gradually acquires a dull ochre-yellow colour. They live together at first in little swarms or families beneath the leaves upon which they were hatched, and which, in consequence of the numerous punctures of the insects, and the quantity of sap imbibed by them, soon wither, and eventually become brown, dry, and wrinkled; when the insects leave them for fresh leaves, which they exhaust in the same way. As the eggs are not all laid at one time, so the bugs are hatched in successive broods, and consequently will be found in various stages of growth through the summer. They, however, attain their full size, pass through their last transformation, and appear in their perfect state, or furnished with wing-covers and wings, during the months of September and October. In this last state the squash-bug measures six-tenths of an inch in length. It is of a rusty black colour above, and of a dirty ochre-yellow colour beneath, and the sharp lateral edges of the abdomen, which project beyond the closed wing-covers, are spotted with ochre-yellow. When handled, and still more when crushed, the latter give out an odour precisely similar to that of an over-ripe pear, but far too powerful to be agreeable.

In order to prevent the ravages of these insects, they should be sought and killed when they are about to lay their eggs; and if any escape our observation at this time, their eggs may be easily found and crushed. With this view the squash-vines must be visited daily, during the early part of their growth, and must be carefully examined for the bugs and their eggs. A very short time spent in this way every day, in the proper season, will save a great deal of vexation and disappointment afterwards. If this precaution be neglected or deferred till the vines have begun to spread, it will be exceedingly difficult to exterminate the insects, on account of their numbers; and if at this time dry weather should prevail, the vines will suffer so much from the bugs and drought together, as to produce but little if any fruit. Whatever contributes to bring forward

the plants rapidly, and to promote the vigour and luxuriance of their foliage, renders them less liable to suffer by the exhausting punctures of the young bugs. Water drained from a cow-yard, and similar preparations, have, with this intent, been applied with benefit.

The leaves of the squash are also preyed upon by another insect of a very different description, namely, the *Coccinella borealis* (See Pl. 16, fig. 11). Although the genus of insects to which this belongs destroys Aphides, there are, as Professor Halderman, of Pennsylvania, observes, a few exceptions, among which is the species named, which may be found, both in the larva and perfect state, eating the leaves of the squash.

SQUAW-ROOT (*American orobranche*).

SQUILL (*Scilla*, from *skylla*, to injure, the bulbs being poisonous). An extensive genus of interesting bulbous plants. A light soil is most suitable for them; and they are readily increased by offsets from the bulbs. The leaves are radical, linear. The flowers in clusters, blue, purplish, or white. There are four indigenous species, the vernal squill (*S. verna*), the two-leaved squill (*S. bifolia*), the autumnal squill (*S. autumnalis*), and the harebell squill, or wild hyacinth (*S. nutans*). The bulb of the wild hyacinth contains much mucilage, which can be readily separated from an acrid principle which is conjoined with it. It is much employed by calico-printers.

SQUITCH-GRASS. See **BENT** and **COUCH**.

ST. JOHN'S WORT. See **JOHN'S WORT**.

STACK. Corn in the sheaf, piled up in a circular or rectangular figure, brought to a point or ridge at the top, and afterwards thatched to protect it from the influence of the weather, and more especially from rains. The term is also sometimes applied to hay piled up in the same manner, which, however, in most places is called a *rick*. The foundation of a corn stack is commonly made on a platform of wood or iron, raised on props to protect it from the moisture of the soil, and also from rats and mice; in which respect stacks of corn differ from ricks of hay, which are built always on the ground. It is of great advantage to soak the props in corrosive sublimate, which not only preserves the wood, but also destroys vermin. Stacks are of various forms and dimensions, according to circumstances; but for grain those of a long, narrow, square shape are probably the most advantageous, where the quantity of corn is considerable; as they are found to stand more firmly, have a better appearance, are more conveniently and readily built, and preserve the grain better than those of any other form. And they have the great advantage of requiring less thatch as well as labour in putting it upon them than the round stack. But where the corn is only in a small proportion, the round or oblong shape may be more proper and suitable, as being more readily drawn up in the roof; but the circular, with a conical top and cylindrical body diverging a little at the eaves, is esteemed the best form by some. For hay, the form of the rick or stack is a matter of still less consequence; the long square or oblong shapes are perhaps the most safe and convenient, especially when not too

broad, as they admit the air most fully, and are besides the most convenient to cut from in trussing hay for sale at the market.

STAG. A term applied provincially in England to a young horse. Also to the male of the deer kind. See **DEER**.

STAGGER-BUSH (*Andromeda Mariana*). This American plant grows in the Middle States, with a stem 2' to 3 and 4 feet high. It is very abundant in New Jersey, where the farmers are of opinion that it is destructive to sheep, when eaten by them, producing a disease called the staggers.

STAGGERS. See **APoplexy**.

STALL-FEEDING. The process of fattening cattle in the stall. The best practice in this mode of fattening is probably that of wholly confining them to the stalls, as by this means they are kept quiet, and free from interruption, and of course feed more quickly and with greater regularity, which seem to be points of great importance in this system of management. There are, however, many other methods adopted in different situations and circumstances.

In regard to the sorts of food that may be employed in the way of winter-fattening animals, they are very numerous, but the principal succulent kinds are carrots, parsnips, potatoes, Swedish turnips, cabbages, common turnips, grains, &c.; and of the more dry sorts, oil-cake, oats, barley-meal, rye-flour, bean and pea-meal, and others of the same nature, with different kinds of straw cut into chaff by means of machinery, or hay cut in the same manner. It is usual with some to employ the different meals in a state of mixture in nearly equal proportions, except bean-meal, which, from its heating quality, is mostly made use of in smaller quantities. But on the principle of fresh kinds of food having a more powerful effect on the systems of animals when first applied, it may be more beneficial to have them given in alternation, or at distant intervals, as their effects may in this way be more fully experienced.

In respect to the cut straw and hay that is made use of in this way, the first should be prepared from that which is fresh thrashed out. The hay, instead of being of the inferior kind, should be the best that the farm affords, and such as is not in the least injured in the smell or taste by keeping. The more inferior kinds of hay have, however, by the addition of a very small proportion of common salt, been made to be preferred to the best when not prepared in that way. See **CATTLE**, **FOLDING**, **FOOD**, **SOILING**, and **VENTILATION**.

STANDARDS. The young trees reserved at the felling of woods, for the growth of timber. It also signifies such fruit trees as are intended to grow in an open exposure, and not to be hacked and mangled with the knife, as the dwarf trees and those planted against walls are.

STARR, or **BENT**. See **ARUNDO** and **ELYMUS**.

STARCH (Germ. *stärke*). One of the common proximate principles of vegetables. It is characterized by its insipidity, and by insolubility in cold water, in alcohol, and in ether. The term "starch" is commercially applied to

that obtained from wheat, which for this manufacture is ground and diffused through vats of water, where it remains two or more weeks, and undergoes a slight fermentation, and acquires a peculiar sour smell. The sour liquor is drawn off, and the precipitate washed in sieves, through which the impure starch passes with the water. It is afterwards passed through other waters, drained through boxes lined with linen or canvass, and ultimately stove-dried in paper. When drying, it cracks into the prismatic pieces, resembling miniature basalt, which is its usual form. Starch may be obtained from many other grains, and from potatoes and several esculent vegetables. Arrowroot is the starch of the *Muranta arundinacea*; British arrowroot that of the root of *Arum maculatum*; sago, of the *Sagus furanifera*, an East Indian palm tree; and tapioca and cassava, of the *Jatropha manihot*. In the process of germination, and by various chemical agents, starch may be converted into a species of gum and sugar. Pure starch is white, tasteless, and inodorous. It consists of two distinct substances, that are readily recognised under a good magnifying lens, namely, a membrane called *amylin*, and a gummy semifluid matter named *amolin*; the one the husk, the other the contents of the granules. In cold water, unless triturated in a mortar, the grains do not burst, but remain entire and insoluble; but in boiling water they burst and form a mucilage. Starch is a compound of 42.8 parts of carbon, 6.35 of hydrogen, and 50.85 of oxygen in 100 parts. Starch is much less nutritious than wheat flour, or the farina of any grain which contains gluten; and on this account the starch of arrowroot, sago, &c., is used as a diet for the sick. Starch is detected from other mucilages by forming a blue colour with iodine, when the mucilage is cold. Starch in England is charged with a duty of 3½d. per lb., and its manufacture is consequently placed under the control of the excise.

STAR OF BETHLEHEM. See **BETHLEHEM**, **STAR OF**.

STAR-THISTLE. A name applied to some species of *Centaurea*, viz. Jersey star-thistle (*C. isnerdi*), the common star-thistle (*C. calcitrapa*), and the yellow star-thistle, or St. Barnaby's thistle (*C. solstitialis*). The first is a perennial weed, the others are annuals. See **BLUE-BOTTLE**, **KNAPWEED**, &c.

STARWORT (*Aster*, a star; whence also the common name, the flowers resembling little stars from the rays of their circumference). Many species of this extensive genus are stately and handsome plants. The swellings or galls as large as a walnut, so often found on the stems of some American species of starwort, or aster, are caused by the punctures of a fly.

STARWORT, THE WATER (*Callitriche*, named by Pliny from *kalos*, beautiful, and *thrix*, hair). Annual aquatic plants, which grow in ditches, ponds, and lakes.

STEAM. Water converted into an elastic fluid by the application of heat. It would be foreign to our subject to go into any detail of the various mechanical uses and improvements to which steam has been applied with

so much success. Latterly, however, a spirit of inquiry has led to an investigation into the application of steam to purposes of husbandry, such as engines for ploughing, draining, &c.; and, though there are obstacles in the way of their successful operation, there is little doubt that eventually the spirit of research and improvement will overcome these difficulties, and create a singular revolution in the practical operations of agriculture, whereby a vast amount of animal power will be saved, and an increased impetus be given to production. A series of very able papers on this subject appeared a few years ago in the *Quart. Journ. of Agr.* vols. v., vi., vii.

STEAMING FOOD. The advantages to be derived from boiling or preparing the food of live-stock are now very generally understood and appreciated; although it is still a question whether it always compensates for the extra labour and time consumed. We have already gone into this subject under the head **FOOD**, and merely revert to it now to call attention to some articles describing apparatuses for steaming food, which will be found in the *Quart. Journ. of Agr.* in vols. iv—vi. Steaming is also popularly treated of and explained in the first volume of *Brit. Husb.* p. 129, and has been frequently discussed in American periodicals.

STEARINE (Gr.). That part of oils and fats which is solid at common temperatures. Both in fats and in fixed oils it is associated with a fluid principle, which cannot be rendered solid at the lowest known temperatures. Stearine is only found in animal fats; or, at least, is rarely present in those of a vegetable origin. See **FAT**.

STEELYARD. A well-known balance, by which the weights of bodies are determined by means of a single standard weight.

STEEN KROUT (*Lithospermum arvense*). Stone Seed, Wheat Thief. See **RED WEED**.

STEERING. See **BRINGING OF GRAIN** and **SMUT**.

STEPPES (Russ.). The name given to the vast extent of plains peculiar to Asia; synonymous with the prairies of North America, and the llanos of South America. The steppes of Russia are not unlike the heaths of Germany; being in part susceptible of cultivation, and affording pasturage for numerous herds belonging to nomadic tribes.

STITCHWORT (*Stellaria*, from *stella*, a star; the flowers are star-like). A genus of herbaceous plants which are mere weeds. Some are annual, the others are perennial. See **CHICKWEED**.

STIGMA. In botany, the upper extremity of the style without a cuticle, in consequence of which it has almost uniformly a humid and papillose surface. It is the part upon which the pollen falls, and where it is stimulated into the production of the pollen tubes, which are indispensable to the act of impregnation.

STILES. A well-known contrivance for the admission of foot-passengers, without permitting the stock of the enclosures to escape. Stiles are made in very different forms and manners in different districts, according to the materials, situations, and purposes for which they are intended.

STINGERS and PIERCERS. A class of insects embracing bees, wasps, ants, saw-flies, ichneumon-flies, &c.

STIPULES. In botany, small scales or appendages situated on each side at the base of the petioles or leaf-stalks, most commonly of a less firm texture than the latter, and having a subulate termination.

STOCK-NUT. See **HAZEL**.

STOLONIFEROUS. Bearing runners which root at the joints.

STOMATA. In botany, orifices through the epidermis of plants, chiefly of the leaves, having the appearance of an areola, in the centre of which is a slit of various form and size, that opens or closes, according to circumstances, and lies over a cavity in the subjacent tissue. They are universally regarded as spiracles, or breathing pores. In leaves of trees and plants exposed to the air they usually occupy the under disk; on those that lie upon the surface of water, the upper disk.

STONE. An English common weight estimated at 14 lbs.

STONECROP (*Sedum*). A genus of herbs, with alternate, very succulent, either flat, cylindrical, or tumid leaves. Root mostly perennial. Flowers yellow, white, or reddish, usually cymose, rarely axillary. There are, in England, ten indigenous species, which inhabit, for the most part, old walls, roofs, and dry sandy ground. See **HOUSE-LEEK** and **ORPINE**.

STONE-PARSLEY (*Athamanta*). These are chiefly weeds.

STONE PINE. See **FIRS**.

STONE WEED (Field *Lithospermum*). See **RED-ROOT**.

STOOKING. The Scotch term for setting up sheaves of corn in stocks or shocks. The operation is performed soon after the corn is cut, it being previously tied into bunches or sheaves.

STOOL. The root of a timber tree, which throws up shoots. Coppice wood consists chiefly of the shoots sent up by the roots of stools, or trees or shrubs which have been cut over by the surface. In general, all dicotyledonous trees are endowed by nature with the property of sending up shoots from the stumps or stools; but this is not the case with most of the gymnosperms or coniferous trees. A wood of pines or firs, therefore, when once cut down, can never be renewed, except by seeds. It is a curious fact that the shoot, however large the stool may be, can be traced to the pith, and therefore appears to have been originally a shoot of the first year's growth of the plant. That its growth has been impeded is evident; but when the tree is cut down, and the whole sap is thrown into a small space, the latent, yet vital gum is stimulated, and a twig thence produced.

STORK'S-BILL (*Erodium*, from *erodios*, a heron; the carpels resemble the head and beak of that bird). This is an extensive genus of plants of considerable beauty: they thrive well in any common soil with the usual treatment.

STRAINS. In farriery, accidental injuries arising from over-distension of the muscles or tendons, in consequence of which the animals suffer great pain, and are generally lamed.

STRANGLES. In farriery, a disease which is principally incident to young horses; usually appearing between the fourth and fifth year, and oftener in the spring than at any other season. It is preceded by cough, and is a disease to which all horses are subject, but it never returns. A blister will be found the best application to hasten the formation and suppuration of the tumour under the jaw, which, from its situation, has probably given the name to this disease.

STRATH, in Scotland, is generally understood to signify a valley of considerable size, whose appellation is determined by some river running through it, or some particular characteristic.

STRATUM. When different rocks lie in succession upon each other, each individual forms a *stratum*. See **GEOLOGY**.

STRAW. The stalks or culms on which corn and other grasses grow, and from which the grain has been separated by thrashing. When chopped or cut small, it affords a wholesome provender for horses and oxen, especially if it be mixed with green food. (See **CHAFF** and **CHAFF ENGINES**.) When not allowed to be carried off the premises, the chief value of white straw for farm purposes lies in its conversion into manure; for although it may carry store cattle through the winter, it will neither fatten them nor enable any animal to work; and its intrinsic worth for the uses of litter and of occasional feeding has been estimated by experienced farmers in England at 20s. to 30s. the ton. See **HAULM**.

STRAWBERRY (*Fragaria*, from *fragens*, fragrant; the perfumed fruit of the strawberry is well known). The strawberry is our earliest fruit, and as the harbinger of the *fructus horæi*, its appearance is as welcome as its flavour agreeable. The cultivation and propagation of this plant is so familiar to every one, as are the wholesomeness and deliciousness of the fruit, that neither need be particularized here. Three species of strawberry found wild in the United States are enumerated by Mr. Nuttall: 1. *F. vesca*, in the state of Ohio, near Lake Erie. 2. *F. Virginiana*. 3. *F. Canadensis*, both common in the Southern, Middle, and Northern States. The species indigenous to Britain are two, the wood strawberry (*F. vesca*), and the hautbois strawberry (*F. elatior*). The covering of strawberry plants with sea-weed in the winter has been found to increase the size of the fruit to a prodigious degree. This is much practised in the island of Jersey.

STRAWBERRY-LEAVED CINQUEFOIL. See **CINQUEFOIL**.

STRAW-CUTTER. See **CHAFF-ENGINE**.

STRAW-YARD. The yard into which straw is thrown in thrashing. Also the enclosure in which cattle are confined in winter, for the purpose of being foddered on straw. There ought to be open sheds for shelter in the straw-yard; for though pure air is essential to the health of store and working cattle, cold winds and rain are highly injurious to them. The great use of a straw-yard is for the accumulation of manure, which cannot be rich unless the cattle get some food besides straw to support them.

STREET DUNG. The mixture of animal and vegetable matters, comminuted particles,

&c., swept up from the streets of large towns, which is found to be an excellent fertilizer; it is composed of a mixture of horse dung, *débris* of the paving stones, soot, lime, and metallic particles.

STRENGTH, in mechanics, is used in the same sense as force or power. Thus, strength of animals is the muscular force or energy which animals are capable of exerting; strength of materials is the resistance which bodies oppose to a force acting upon them. It is obviously a matter of much importance to be able to estimate with tolerable accuracy the efforts which an animal of the average strength employed in labour is capable of exerting, and, accordingly, very numerous observations have been made on the subject; but this species of force is subject to variation from so great a number of circumstances, both physical and mechanical, that the results given by different authors present very little agreement with each other, though they are of great value as affording data for determining the modes in which animal labour is most advantageously employed.

Of all animals employed as first movers, the horse is, beyond question, the most useful, and that whose labour is susceptible of the most numerous and varied applications. For the purpose of determining his muscular power, the dynamometer may be conveniently used; but, as the action of the animal is very quickly reduced by continued exertion, it is more usual to estimate it according to the amount of daily labour performed. Desaguliers and Smeaton estimate the strength of a horse as equivalent to that of 5 men; the French authors have commonly stated it as equal to 7 men; and Schulze makes it equal to that of 14 men in drawing horizontally. According to Desaguliers, a horse's power is equal to 44 lbs. raised 1 foot high in 1 minute. Smeaton makes this number 22·916, Hachett 28, and Watt 33. The last estimate is commonly understood by the term *horse-power* as applied to steam-engines. The quantity of action which a horse can exert diminishes as the duration of the labour is prolonged. Tredgold gives the following table, showing the average maximum velocity with which a horse unloaded can travel according to the number of hours per day:—

Time of March in Hours.	Greatest Velocity per Hour in Miles.	Time of March in Hours.	Greatest Velocity per Hour in Miles.
1	14·7	6	6·0
2	10·4	7	5·5
3	8·5	8	5·2
4	7·3	9	4·9
5	6·6	10	4·6

The useful effect a horse is capable of producing, depends much upon the manner in which his strength is applied. See **CARTS**, **DYNAMOMETER**, **HORSE-POWER**, **THRASHING MACHINE**.

Strength of Materials.—There are four different ways in which the strength of a solid body may be exerted: first, in resisting a longitudinal tension, or force tending to tear it asunder; secondly, in resisting a force tending to break the body by a transverse strain; thirdly, in resisting compression, or a force tending to crush the body; and, fourthly, in resisting a

force tending to wrench it asunder by *torsion*. Mr. Hodgkinson gives the following results of his experiments on the resistance of a crushing force of short pillars of some of the most common descriptions of wood, the force being applied in the direction of the fibres.

Description of Wood.	Strength per square Inch in lbs.
Alder - - - - -	6831 to 6960
Ash - - - - -	8683 9363
Bay - - - - -	7518 7518
Beech - - - - -	7733 9363
English birch - - - - -	3297 6402
Cedar - - - - -	5674 5863
Red deal - - - - -	5748 6686
White deal - - - - -	6781 7293
Elder - - - - -	7451 9973
Elm - - - - -	10331
Fir (spruce) - - - - -	6499 6819
Mahogany - - - - -	8198 8198
Oak (Quebec) - - - - -	4231 5982
Oak (English) - - - - -	6484 10058
Pine (pitch) - - - - -	6790 6790
Pine (red) - - - - -	5395 7518
Poplar - - - - -	3107 5124
Plum (dry) - - - - -	8241 10493
Teak - - - - -	12101
Walnut - - - - -	6063 7227
Willow - - - - -	2898 6128

(*Brande's Dict. of Science; Barlow's Treatise on the Strength of Timber.*)

STUBBLE. The root ends of the culms of corn left in the field, standing as they grew, after the corn has been reaped by the sickle or scythe. In some parts of England only a small portion of the straw is cut off with the ears of corn, and the stubble in that case is a foot or 18 inches in length; but in others the corn is cut as close to the surface as possible, in which case the stubble is quite short. In general, long stubble is a symptom of bad farming, because a quantity of straw is in this case left to waste in the field, which might have been carried home and rotted into manure.

STYLE. In botany, is that elongation of the ovarium which supports the stigma. It is an extension of the midrib of the carpellary leaf, or is formed by the rolling up of the attenuated extremity of the latter.

SUBSOIL-PLOUGH (Pl. 17, o, g). See **PLOUGH** and **SUBSOIL-PLOUGHING**.

SUBSOIL-PLOUGHING. In farming, the operation of breaking the substratum by means of a plough constructed especially for that purpose. Considerable discussion has taken place with regard to the advantages of subsoil-ploughing; a difference of opinion which appears to have been principally caused by an inattention to the chemical effects produced by the subsoil, or Deanstonizing system of tillage, so named from being first employed, or at least first brought into general notice, by Mr. Smith, of Deanston, in Stirlingshire, when he was examined, in 1836, before the Agricultural Committee of the House of Commons. By this system, by means of a subsoil plough, of which there are several kinds, the subsoil, or under crust of earth, is merely broken and pulverized, say to the depth of from 14 to 20 inches, without being brought to the surface, or mixed with the upper soil; after a lapse of 4 or 5 years, a portion of the previously disturbed substratum is found, by experience, in a state to be advantageously (by deep ploughing) brought to the surface; it being in this

time, by the action of the atmosphere, and perhaps by a partial mixture with the surface-mould, rendered sufficiently friable and fertile. It is of necessity a consequence of this subsoil-ploughing, that the permanent drains of all lands thus cultivated must be constructed rather deeper in the soil than is usual with farmers; the top of those at Deanston are placed at a depth of 22 inches from the surface, so as to be completely out of the way of the subsoil which the plough has turned over.

As the description of this valuable plough cannot be too generally circulated, I will here introduce it in Mr. Smith's own words:—

“The subsoil-plough has been constructed on principles appearing the best fitted to break up the subsoil completely to a depth sufficient for thorough cultivation, say 14 to 16 inches, whilst the active soil is still retained on the surface; to be of the easiest possible draught in reference to the depth of furrow and firmness of the subsoil; to have strength and massive weight sufficient to penetrate the hardest stratum; to resist the shocks from fast stones, and to throw out all stones under 200 lbs. in weight. All this has been accomplished and practically proved at Deanston, over an extent of at least 200 acres of various soils; and also in various parts of England, Scotland, and Ireland, during several seasons. The plough requires 4 good horses, an active ploughman, and a lad to drive the horses and manage them at the turnings. Six horses, yoked three and three abreast, may be necessary in some very stiff or stony soils. A common plough, drawn by two horses, goes before the subsoil-plough, throwing out a large open furrow of the active soil; the subsoil-plough following, slits up thoroughly and breaks the subsoil, and the next furrow of active soil is thrown over the last opened furrow of the subsoil; the stones brought to the surface by the subsoil-plough being thrown aside on the ploughed part of the land by a lad: thus the work proceeds until the whole field is gone over. The lad should carry a bag of wooden pins, that he may mark the site of the large fast stones which the plough cannot throw out, and which must afterwards be dug out with the pick, and perhaps blasted.

“The charge of subsoil-ploughing a Scotch acre may be estimated at 24s. or 30s. per statute acre, being one-fifth of what a similar depth with the spade would cost, and, upon the whole, as effectually done. When land which has been opened up by the subsoil-plough shall have undergone the first rotation of cropping, several inches of the subsoil may be taken up by the plough to mix with the active soil; and in proportion as the subsoil is ameliorated, so may the greater depth be taken up with advantage. In the richer subsoils it is sometimes expedient to plough to the whole depth of the moved subsoil on the first application of the trench-plough. The trench-plough recommended for this process should be made in the form of Wilkie's plough, having all its dimensions made of double size; or, what is found to answer fully as well, by a plough in the fashion of the old Scotch plough, but also of double dimensions. Such ploughs require six horses, yoked three and three abreast, with one man to

hold the plough, and another to manage the horses, to do the work effectually. This operation should be performed in turning over the winter furrow preparatory to a green crop, and the sooner the work is performed after harvest the better. In estimating the expense of this operation, the horses may be charged at 4s. each, to cover all expenses, tear and wear, &c., which will amount to 24s.; two men, 2s.=4s.; and an attendant lad to pick out stones, 1s.; in all 29s. As the work is heavy, the motion of the horses is necessarily slow, and it will, in general, take 8 hours' working to accomplish one statute acre. The expense of this operation may appear alarming; but when it is considered that one such ploughing will be more effectual in killing weeds, and in exposing the soil to the air, than two ordinary ploughings, we may deduct the cost of two such=20s., leaving 9s. to be charged against the deep working.

"When land has been thoroughly drained, deeply wrought, and well manured, the most unpromising sterile soil becomes a deep, rich loam, rivalling in fertility the best natural land of the country; and from being fitted for raising only scanty crops of common oats, will bear good crops of from 32 to 48 bushels of wheat, 30 to 40 bushels of beans, 40 to 60 bushels of barley, and from 48 to 70 bushels of early oats per statute acre; besides potatoes, turnips, mangel-wurzel, and carrots as green crops, which all good agriculturists know are the abundant producers of the best manure. It is hardly possible to estimate all the advantages of dry and deep soil. Every operation in husbandry is thereby facilitated and cheapened; less seed and less manure produce a full effect; the chances of a good and early tid (a Scotch term for that state of the ploughed soil which is most suitable for receiving the seed, neither too moist nor too dry) for sowing are greatly increased, a matter of great importance in our precarious climate; and there can be no doubt that even the climate itself will be much improved by the general prevalence of land dry."

In this instance, as in most other novel agricultural efforts, the zeal of its promoters has sometimes carried them too far; they have even confidently contended that in most situations subsoiling will render draining unnecessary; a result which would hardly have been arrived at by the most sanguine subsoiler, if he had paused to recollect that deepening the soil, however it may promote the absorption of atmospheric moisture, can in few situations enable land-springs and stagnant waters to escape. The objects to be attained by these operations are, in fact, diametrically opposite. The one is adopted to increase the gradual healthful supply of food and moisture by the earth to the roots of the crop, in the degree the most grateful to its habits. The other expensive practice is to remove that moisture when (from any cause) it becomes too abundant for healthful vegetation; this removal can only be obtained in very peculiar situations by the mere use of the subsoil-plough, and then to a very limited extent; such, for example, as when the crust or subsoil is of such a degree

of thinness as to be completely penetrated by the plough, and thus the upper soil brought, by breaking up the separating crust, into immediate contact with a substratum of earth of greater absorbent properties than the pan-crust which has hitherto separated them.

The farmers of the chalky soils of Sussex, Dorsetshire, Wilts, and Hampshire, very advantageously raise the substratum of chalk existing under their lands, and spread it in considerable quantities on the surface. Those of Essex and Suffolk in many places do the same with the under-stratum of clay or marl on which their surface-soils immediately rest; and they find this a very profitable practice, because the earths which constitute all fertile soils being also the necessary constituents of the commonly cultivated grasses, are gradually and incessantly carried off from thence by continual cropping, and consequently in time an advantageous opportunity is afforded for their being replenished with the earths, perhaps contained in the subsoil, in which they may have become deficient.

The chemical effect of pulverizing and breaking up a subsoil is certainly advantageous to the plant in two ways, besides others with which we are very likely at present unacquainted; first, it renders the soil penetrable to a much greater depth by the roots, or minute fibres of the plant, and consequently renders more available any decomposing matters, or earthy ingredients, which that substratum may contain; and, secondly, it renders the soil much more freely permeable by the atmosphere, rendering, in consequence, a greatly increased supply, not only of oxygen gas to the roots of the plants, but also yielding more moisture, not only from the soil, but from the atmospheric air; which moisture, let it be remembered by the cultivator, is in all weathers as incessantly absorbing by the soil as it is universally contained in the atmosphere, abounding most in the latter, in the very periods when it is most needed by the plants—that is, in the warmest and driest weather.

It is, perhaps, needless to prove, that the roots of commonly cultivated plants will penetrate, under favourable circumstances, much greater depths into the soil, in search of moisture, than they can, from the resistance of the case-hardened subsoil, commonly attain. Thus the roots of the wheat plant in loose, deep soils, have been found to descend to a depth of 2 or 3 feet, or even more; and it is evident, that if plants are principally sustained in dry weather by the atmospheric, aqueous vapour absorbed by the soil, that that supply of water must be necessarily increased, by enabling the atmospheric vapour and gases, as well as the roots of plants, to attain to a greater depth; for the interior of a well-pulverized soil, be it remembered, continues steadily to absorb this essential food of vegetables, even when the surface of the earth is drying in the sun.

And by facilitating the admission of air to the soil, another advantage is obtained, that of increasing its temperature. The earths are naturally bad conductors of heat, especially downwards; thus it is well-known, that, at the siege of Gibraltar, the red-hot balls employed

by the garrison were readily carried from the furnaces to the batteries in wooden barrows, whose bottoms were merely covered with earth. Davy proved the superior rapidity with which a loose, black soil was heated compared with a chalky soil, by placing equal portions of each in the sunshine; the first was heated in an hour from 65° to 88°, while the chalk was only heated to 69°. (*Elements of Agr. Chem.* p. 178.) This trial, however, must not be regarded as absolutely conclusive, since the surface of the black soils naturally increases more rapidly in temperature when exposed to the direct rays of the sun than those of a lighter colour. A free access of air to all soils also adds to their fertility, by promoting the decomposition of the excretory matters of plants, which otherwise would remain for a longer period, to the annoyance of plants of the same species.

In a recent communication to the secretary of the *English Agricultural Society*, Sir E. Stracey has given some of the results of his experience with the Rackheath subsoil-plough, and they are of a description which cannot be too generally known:—"On my coming," he remarks, "to reside on my estate at Rackheath, about 6 years since, I found 500 acres of heath land, composing 2 farms (which had been enclosed under an act of parliament about 40 years), without tenants; the gorse, heather, and fern, shooting up in all parts. In short, the land was in such a condition, that the crops returned not the seed sown. The land was a loose, loamy soil, and had been broken up by the plough to a depth not exceeding 4 inches, beneath which was a substratum (provincially called an iron pan) so hard, that with difficulty could a pickaxe be made to enter in many places; and my bailiff, who had looked after the land for 35 years, told me that the lands were not worth cultivation—that all the neighbouring farmers said the same thing—and that there was but one thing to be done, viz., to plant with fir and forest trees; but to this I paid but little attention, as I had the year preceding allotted some parcels of ground, taken out of the adjoining lands, to some cottagers; to each cottage, about one-third of an acre. The crops on all these allotments looked fine, healthy, and good, producing excellent wheat, carrots, peas, cabbages, potatoes, and other vegetables in abundance. The question then was, how was this done? On the outside of the cottage allotments all was barren. It could not be by the manure that had been laid on, for the cottagers had none but that which they had scraped from the roads. The magic of all this I could ascribe to nothing else but the spade; they had broken up the land 18 inches deep. As to digging up 500 acres with the spade, to the depth of 18 inches, at an expense of 6*l.* an acre, I would not attempt it. I accordingly considered, that a plough might be constructed so as to loosen the soil to the depth of 18 inches, keeping the best soil to the depth of 4 inches, and near the surface, thus admitting air and moisture to the roots of the plants, and enabling them to extend their spongioles in search of food; for air, moisture, and extent of pasture, are as necessary to the thriving and increase of vegetables as of animals. In this attempt I succeeded, as

the result will show. I have now broken up all these 500 acres, 18 inches deep. The process was by sending a common plough, drawn by two horses, to precede, which turned over the ground to the depth of 4 inches; my subsoil-plough immediately followed in the furrow made, drawn by four horses, stirring and breaking the soil 12 or 14 inches deeper, but not turning it over. Sometimes the iron pan was so hard, that the horses were set fast, and it became necessary to use the pickaxe to release them before they could proceed. After the first year, the land produced double the former crops, many of the carrots being 16 inches in length, and of a proportionate thickness. This amendment could have arisen solely from the deep ploughing. Manure I had scarcely any, the land not producing then stover sufficient to keep any stock worth mentioning, and it was not possible to procure sufficient quantity from the town. The plough tore up by the roots all the old gorse, heather, and fern, so that the land lost all the distinctive character of heath land the first year after the deep ploughing; which it had retained, notwithstanding the ploughing with the common ploughs, for 35 years. Immediately after this subsoil-ploughing, the crop of wheat was strong and long in the straw, and the grain close-bosomed and heavy, weighing full 64 pounds to the bushel. The quantity, as might be expected, not large (about 26 bushels to the acre), but great in comparison to what it produced before. The millers were desirous of purchasing it, and could scarcely believe it was grown upon the heath land, as in former years my bailiff could with difficulty get a miller to look at his sample. Let this be borne in mind, that this land then had had no manure for years, was run out, and could only have been ameliorated by the admission of air and moisture by the deep ploughing. This year the wheat on this land has looked most promising; the ears large and heavy, the straw long; and I expect the produce will be from 34 to 36 bushels an acre: the wheat, the "golden drop." My Swedish turnips on this land this year are very good; my pudding and sugar-loaf turnips failing in many parts, sharing the fate of those of my neighbours, having been greatly injured by the torrents of rain which fell after they had shown themselves above the ground. Turnips must have a deep and well-pulverized soil, in order to enable them to swell, and the tap-roots to penetrate in search of food. The tap-root of a Swedish turnip has been known to penetrate 39 inches into the ground."

Sub-turf Plough.—"Being on the subject of the sub-soil plough," says Sir Edmund Stracey, "I may as well tell you I have contrived another plough, from the use of which the greatest benefit has been derived by my park land. I call this my 'sub-turf plough.' It is used to loosen the turf about 10½ inches deep below the surface, without turning over the flag; loosening the soil underneath, consequently, admitting the air and the rain, and permitting the roots of the herbage to spread in search of food. There are no marks left by which it can be known that the land has been so ploughed, except from the straight lines of the coulter, at

the distance of about 14 inches one from another. In about three months from the time of ploughing these lines are totally obliterated, and the quantity of aftermath, and the thickness of the bottom, have been the subject of admiration of all my neighbours. Another advantage from this subsoil-ploughing is, that, before that took place, water was lying stagnant in many parts (after heavy rains), especially in the lower grounds, to a great depth: now no water is to be seen lying on any part, the whole being absorbed by the earth." (*Journ. of Eng. Agr. Soc.* vol. i. p. 253.)

And for heavier soils, the evidence in favour of subsoil-ploughing is equally valuable. In the year 1838, an experiment was made by Sir James Graham, which is important in several respects. It was on a field of about 8 acres, of the poorest and wettest land. "The surface-soil is about 5 inches deep of black earth, of a peaty quality. The subsoil is a weeping retentive clay, with sand and rusty gravel intermixed. This clay extends to the bottom of the drains, which are of tile, laid 30 inches deep in every furrow. This field was rented by the out-going tenant at 4s. 6d. per acre. It was in pasture of the coarsest description, overrun with rushes and other aquatic plants. After draining, on one-half of this field I used Mr. Smith's subsoil-plough. On the other half I trench-ploughed to the depth of 10 inches, by two ploughs following in succession. In the first part, not mixing with the surface any of the subsoil; in the last part, commingling the surface and the subsoil in nearly equal proportions. The whole field was heavily, but equally manured, and planted with potatoes; and though the potato crop, even on good land in this neighbourhood (Cumberland), was below an average, yet the crop in this field exceeded an average, and yielded about 12 tons per acre. The field is equally drained in every part. The crop was so equal throughout the field, that I am unable to pronounce positively which part was the best, but I am inclined to give the preference to that portion where Mr. Smith's subsoil-plough was used."

SUBSTRATUM. A stratum lying under another stratum. The term *subsoil* is generally applied to the matters which intervene between the surface soils and the rocks on which they rest; thus, clay is the common substratum, or subsoil, of gravel.

SUCCORY. See **CHICORY.**

SUCCULENT. A botanical term, signifying fleshy, or filled with juice.

SUCKER. A young twig or shoot from the root of a plant. See **PROPAGATION.**

SUDORIFIC. Having the power of producing perspiration.

SUET. The fat situated about the loins and kidneys, which is harder and less fusible than that from other parts of the same animal. That of the ox and sheep is chiefly used; and, when melted out of its containing membranes, it forms tallow, and is largely used in the manufacture of candles and the ordinary soaps. Beef and mutton suet, when fused, concrete at a temperature of about 100°. Like other kinds

of fat, it is a compound of carbon, hydrogen, and oxygen. See **ADEPS, FAT, LARD, &c.**

SUFFRUTICOSE (Lat. *suffrutex*, an under-shrub). Any plant which is not exactly either a shrub or an herbaceous plant, that is, which has not hard woody twigs and complete buds, like the one, nor perishable, succulent leaves and shoots, like the other, is so termed. Lavender is an instance of a suffruticose plant.

SUGAR (Fr. *sucre*; Germ. *zucker*). The great commercial demand for sugar is almost exclusively supplied from the sugar-cane (*Arundo saccharifera*), which contains it in greater quantity and purity than any other plant, and consequently affords the greatest facilities for its extraction. Cane sugar is combined, in the juice of the plant, with a number of other substances. The following analysis of M. Avequin shows the nature and proportions of these:—0.46 albumen, 0.81 gum, 101.2 crystallizable sugar, 41.6 uncrystallizable sugar, 0.85 chlorophyll and oil, 0.75 stearin, 1.23 resin, 3.58 salts, and 700.8 water, in 1000 parts. The juice, after expression, is freed from some acid which it contains, by means of lime, and then concentrated by boiling; after which, as soon as brown grains form, the syrup is purified, and allowed to crystallize. The crystals are next separated from the molasses, or uncrystallizable sugar, by dripping. This forms muscovado or brown sugar, which is afterwards purified. The purest raw sugar comes from Demerara. Pure sugar is a compound of 44.44 of carbon, 6.18 of hydrogen, and 49.78 of oxygen, in 100 parts. Sugar is nutritive, demulcent, and powerfully antiseptic. Grape sugar undergoes fermentation more readily than cane sugar. A large quantity of sugar, identical to cane sugar, is contained in the sap of the American maple (*Acer saccharinum*), that of the cocoa-nut (*Cocos nucifera*), and in the juice of the beet-root (*Beta vulgaris*), from each of which it may be economically obtained: it has also been extracted from grapes or raisins, and, as is well known, is contained abundantly in many ripe fruits and esculent vegetables. It is, however, in these seldom so pure or in such quantity as to admit of ready separation, or crystallization. The total average quantity entered annually for home consumption in England, is, in round numbers, nearly 4,000,000 cwts. See **MAIZE, MAPLE, MOLASSES, &c.**

The sugar-cane, under the name of the sugar-reed, is mentioned in the oldest records of antiquity as a product of the Eastern world. It would also appear, that the sugar-cane was found growing luxuriantly in Hispaniola, when Columbus first discovered America, according to the account given by Peter Martyr, written during the second voyage of Columbus. There are many varieties or species of the reedy grass producing sugar, both cultivated and growing wild on the banks of rivers and meadows, in both the Indies, China, Africa, the South Sea Islands, and America. The common sugar-cane (*Saccharum officinarum*), Plate iv. d, is a perennial-rooted plant, very susceptible to frost, and therefore restricted in its cultivation to a belt or zone extending from 35° to 40° on each side of the equator. In the Southern

United States the cultivation cannot be carried on advantageously higher than about the 32d degree of latitude, and here the cane dies down annually, unless cut in time to escape the effects of frost. It attains the height of 7 or 8 feet, or more, and its broad leaves, and large, silky panicles, give it a beautiful aspect. The stems are jointed, very smooth, shining, and filled with a spongy pith: the flowers of the sugar-cane are small, and very abundant, being clothed externally with numerous silky hairs. But, in the regular course of cultivation, it never flowers in Louisiana, and but rarely in the West Indies. Consequently, seed is difficult to be procured, short of Otaheite or China. It is well known that where the plant is allowed to go to seed, this natural process interferes with the development of the saccharine materials. In the West Indies, it is propagated by cuttings from the main stalk, planted in hills or trenches in the spring or autumn. The cuttings root at the joints under ground, and send up shoots, which, in 8, 12, or 14 months, are from 6 to 10 feet long, and fit to cut down for the mill. A plantation lasts from 6 to 10 years, but in Louisiana the planting has to be renewed every 2 or 3 years.

The juice of the sugar-cane is so palatable and nutritive, that, during the sugar harvest, every creature which partakes freely of it, whether man or animal, appears to derive health and vigour from its use. The meager and sickly negroes exhibit at this season a surprising alteration; and the labouring horses, oxen, and mules, though constantly at work, yet, as they are allowed to eat, almost without restraint, of the refuse plants and scummings from the boiling-house, improve infinitely more than at any other period of the year. The sugar-cane is now cultivated in all the warm parts of the globe. The variety from Otaheite has lately, in the West Indies, superseded all other kinds of cane, and succeeds in soils too poor for the common varieties. The qualities of the sugar are also very superior.

Sugar is now cultivated to considerable extent in the United States. On the northern coast of the Gulf of Mexico, for the distance of about 300 miles, the sugar region is almost entirely embraced within the limits of Louisiana. Here, the soil being all alluvial and of the richest description, the cane is forced by its exceeding fertility, together with the warmth of the long summers, to a state of maturity which enables it to yield sugar in the greatest abundance, and of the finest quality. Thus, the natural strength of the soil and warmth of the summer compensate in a great degree for other defects of the climate. The extent of lands in this portion of the United States admitting of the profitable culture of sugar, is sufficient not only to supply the entire amount required for home consumption, but for large exportation. From 1835 to 1846, sugars imported into the United States paid duties of 2½ cts. per lb. on muscovado or brown, white havannas 4 to 4½ cts., and refined 6 to 12 cts. per lb. according to quality. This protection of the planter was reduced by the tariff of 1846, to only 30 per cent. ad valorem in all kinds.

Varieties of the Cane. There are five varie-

ties of cane mostly planted in the West Indies and Louisiana. The *Otaheite* cane is, as has been before observed, more extensively cultivated at present in the West Indies than any other. It will grow better on the lighter and older cultivated soils, and has several peculiar advantages over the *Brazilian* or *Creole* canes in former use, but now generally superseded. The last named is more delicate and requires more culture than any other variety, but produces sugar of the finest quality. The varieties most extensively cultivated on the rich lands of Louisiana, are the *Bourbon*, *Red-Ribbon* and *Blue-ribbon*, the last being the most luxuriant. All the varieties "ratoon," that is to say, produce a growth from the roots two and sometimes three successive years in Louisiana. The consumption of England now amounts to upwards of 400,000,000 pounds, which gives an average of about 30 pounds for each individual. That of the United States is about 250,000,000 lbs. per annum, which, considering the population, gives a larger individual rate of consumption than any other country in the world.

In an interesting communication in the *Farmers' Register*, vol. iii., Mr. Macrae, a Florida sugar planter, speaks of the sugar culture in that region as profitable, but still, he thinks, too uncertain, from the effects of frost, to be depended upon to the exclusion of other southern crops. The season for manufacturing, he observes, may not admit of the saving of 500 acres of cane; but it assuredly admits of 100 acres being profitably saved, with 50 effective hands, and the requisite machinery; and that, too, without any serious sacrifice of cotton, or great loss of labour. The opinion there generally maintained, that the manufacture of a sugar crop will essentially interfere with and diminish the cotton crop, he regards as erroneous. In the proportion of one-fifth cane, he says there need be no such interference—admitting that the earliness and severity of frost is such as to compel the immediate service of all other labours to the security of the cane. "Your 50 hands will mattress it (100 acres) in from 3 to 5 days, where it may lie for a month. Half your force, with tried machinery, will then manufacture it in a fortnight, without any extra labour; and your other remaining half of labourers will certainly, at that season, save all the cotton that is liable to fall. It is not, however, one year in ten, that the season would compel this entire disposition of your labourers; and certainly your chance of revenue from two crops, not liable to the same disasters (for none can deny that the cotton plant has nearly as many risks to run before its fruit is saved, as the cane), is more than equivalent to a moderate loss by a heavy blow of cotton. No one should attempt the cane cultivation as a source of revenue, with a less force than 50 effective hands; and I attribute the heretofore failures of sugar here, in a great measure, to overcropping, and a poverty of labourers."

The operation termed "*mattressing*," consists in piling the cane which is cut, to prevent injury from frost, in rows in the field. The plan recommended by Mr. Macrae, is to cut the cane down close to the ground, and

throw three rows into one, thus forming wind-rows across the field, taking care to place the foliage of one stool of cane over the *butts* of the previous one, and laying them to the height of 3 or 4 feet, like a thatched roof. In this way the cane can be kept several weeks for grinding and pressing. "Mattressing" the cane for a limited period, even after the frost, so far from injuring its product, will, he says, increase it in Florida. Mr. Macrae says, that in Florida, no prudent man will under any circumstances attempt a sugar crop alone, and he advocates the sugar culture only in connexion with cotton. In the West Indies from 3000 to 6000 pounds of sugar are produced to the acre, whilst in Louisiana about 1000 lbs. of sugar per acre is considered an average yield. The crop in that state in 1847-48, was 240,000 hogsheads, each estimated at 1000 lbs. gross, with 20 gallons of molasses, and sold at the very low price of $2\frac{1}{2}$ to 5 cts. on the plantation. It is calculated that \$300 capital is required for the production of each hogshead of sugar and barrel of molasses. The expenses of working an estate, including wear and tear of machinery, have been stated at \$60 to \$75 for each slave employed. The average product 5 hogsheads to the hand, or about 10 per cent. profit upon the capital. Mr. Forstall, in his communication to the Commissioner of Patents (1847), estimates the profits at 5, and some years only $2\frac{1}{2}$ per cent. He says that when sugars average $4\frac{1}{2}$, and cotton $6\frac{1}{2}$ cents, the results per slave are nearly the same, with the advantage in favour of the cotton crop of requiring only $\frac{1}{4}$ less cost of machinery. The slaves employed in the sugar culture increased from 1828 to 1844, from 21,000 to 50,670; the total capital from \$34,000,000 to \$60,000,000. The report of the Commissioner of Patents for 1848, contains much highly valuable information relative to the sugar crop, especially the article, with drawings, by C. L. Fleischman.

Whilst the crop of cane sugar is increasing annually at the South, that from the maple is becoming greater in the Northern and Western States. The amount of sugar made in 1840, from both sources, has been reported at 155,100,809 pounds. In Michigan alone, there is said to be no less than 30,000 acres abounding with the maple. These trees have been estimated at an average as worth to the farmer, for the purpose of sugar-making alone, from 2 to 3 dollars each. The proportion of sugar-maples per acre in the sugar districts has been computed at 30. See MAPLE.

Under the head of MAIZE reference is made to the proposed manufacture of sugar from Indian corn, one acre of which, of luxuriant growth, has been estimated to produce from 600 to 1000 pounds and more of good sugar. The manufacture of sugar from the beet, so extensively carried on in France, Germany, and other European countries, has never been successfully introduced into the United States. To succeed fully, the manufacture must be carried on upon a large scale, with ample capital. Many excellent essays upon the subject may be found either separate or published in various agricultural periodicals.

Chemical composition of Sugar.—The progress of modern chemistry in ascertaining the precise elements of various substances, has de-

veloped some highly interesting facts relative to sugar, showing the very slight difference between its composition and that of many other matters to which it apparently bears not the least resemblance, such as starch, saw-dust, or common woody fibre, linen rags, &c., which by slight additions have been actually converted into sugar. By some chemists, and particularly Prout, starch is considered as sugar partly organized, containing but a small quantity of carbon and hydrogen more than sugar, the excess however being sufficient to prevent crystallization or conversion by nature into sugar. The following table, prepared from the statements of Berzelius, Raspail, and Dumas, by Dr. Prout, shows in a curious and interesting light, by what mere shades of difference in their constituent atoms, substances, which to the sense appear as far apart as the zenith from the nadir, are separated. Water is composed of definite and well-ascertained proportions of oxygen and hydrogen, and in the formation of sugar, starch, acetic acid, and lignin, or the pure woody fibre of trees and plants, these two materials are found united in the same proportions as in water; the only ingredient added for their completion being carbon. These substances, sugar, acetic acid, starch, and lignin, may therefore be considered as composed of carbon and water in the proportions here given.

	Carbon.	Water.
<i>Sugar.</i> —100 parts of sugar from starch contain		
From honey - - - -	36.20	63.86
From East India moist - -	36.36	63.64

Dr. Prout, in his Bridgewater Treatise, remarks, "that both starch and wood can by different artificial processes be converted into sugar or vinegar. But we are unable to reverse the process, and convert vinegar into sugar, or starch into wood." The chemist Bracconet has ascertained that a pound of linen rags yields rather more than a pound of sugar.

Mr. Guthrie of Sackett's Harbour, in his attempts to make sugar from potatoes, produced large quantities of molasses, but with all his skill was unable to crystallize or grain it, without the introduction of some deleterious substance, lead, for instance; and consequently all his was used in a liquid form, of the consistency of thick syrup, or rather honey. The potatoes were first converted into starch, and then, by boiling in sulphuric acid, diluted, for some hours, into sugar. The directions in the *Encyclopedia Americana* for this process are, 2000 parts of starch, 8000 parts of water, and 40 parts strong sulphuric acid—the mixture to boil some 36 hours in silver or lead; but Mr. Guthrie accomplishes the conversion by the use of steam in about 6 hours. The production of sugar or molasses is possible from a great variety of materials provided by nature, such as the cane, maple, beet honey—all plants

that afford starch, or substances that by chemical process can be converted into gum, as flax, linen rags, &c.; still none have yet been found, which can successfully enter into competition with the cane.

SUGAR BEET. The white beet already mentioned under the head **BEET**. As it is not probable that this root will soon be brought into requisition for the production of sugar in the United States, where so many other sources exist from which this may be readily procured, we shall confine our observations to it as an article of food for farm-stock.

The following information relative to the beet culture, &c., is from Mr. Colman's *Fourth Report upon the Agriculture of Massachusetts*:

"Beets are often a very profitable crop. They are raised in considerable quantities; are packed in barrels and shipped to the south. One dollar and a half is a common price for a barrel containing $2\frac{1}{4}$ bushels. The farmer giving this statement has often produced 600 bushels to the acre. They are planted on ridges about 4 feet apart, in double rows; and the intermediate spaces are often sown with turnips. The ridge planting is decidedly preferred here for all vegetables of this kind. In my opinion, and so far as my own experience goes, which has not been small, it would be better to make the ridges about 27 inches apart, plant the beets in single rows, and cultivate them with a plough. A very useful machine for planting beets is a wheel, set like that of a wheel-barrow, with pins projecting from the rim 2 inches, and placed 8 inches apart, which is passed along on the top of the ridge, and the seeds dropped by hand into the holes marked by the pins. They may then be covered by drawing a rake-head along the top of the ridge. Too much care cannot be taken to perform all operations in planting, where the vegetable is afterwards to be cultivated, in straight lines. The work is by this means greatly facilitated."

A crop of sugar beets was raised at Nahant, in 1840, by Mr. Frederick Tudor, of 42,284 lbs. on 93 rods, or at the rate of 36 tons $746\frac{63}{100}$ lbs. net weight per acre, being about 1300 bushels per acre, allowing 56 lbs. per bushel. One of the roots cropped and cleaned, weighed 31 lbs. The ground was trenched to the depth of 20 inches, and well manured, the stones removed being all laid at the bottom of the trenches. Allowing the beets worth \$5 a ton, this would give \$180 to an acre, leaving the land in high tilth for further rich crops. The expenses of cultivating an acre of sugar beets in the New England States, have been thus stated by the editor of the *Yankee Farmer*.

Use of an acre of land well prepared for beets, and manured, or managed in the previous crop	\$12 00
Ploughing	4 00
Cultivating, horse, cultivator and hand, two hours	50
Twice more before sowing	1 00
Harrowing	50
Seed \$2 25, sowing with a machine 75	3 00
First hoeing	4 00
Second hoeing, thinning, and transplanting to supply deficiencies	4 00
Hoeing again, and loosening the ground with machines	2 00
Harvesting	9 00
	<hr/>
	\$40 00

This we think a high estimate. Still, it must be admitted that the cost of cultivating an acre of sugar beets much exceeds that of an acre of Indian corn. In some places the proportional expense of a root over a corn crop is double, in others treble. The following observations upon the mode of cultivating the beet crop, are also taken from the *Yankee Farmer*.

Make the rows 2 feet 4 inches apart, and then a cultivator can be used in hoeing. If the beets stand one foot apart in the rows, and weigh $2\frac{1}{4}$ lbs. each, the yield will be 20 tons. In rich ground, at that distance a great number will weigh 4 or 5 lbs. each; 20 tons is a good crop, but not extremely large, for in some cases 25 or 30 tons to the acre have been raised in this country. At the above expense of \$40 to the acre with a yield of 20 tons, the cost would be \$2 per ton. We make this estimate, to show how cheap beets may be raised under favourable circumstances, such as good land at a fair price, convenient machinery and implements, and the most prudent management in the culture, with labour at a moderate price, and a favourable season.

Supposing we reckon the produce only two-thirds as much as above, say $13\frac{3}{4}$ tons, and the cost $32\frac{1}{2}$ per cent. more, which will be \$53 33; then the cost of the beets will be only \$4 per ton, one-fifth less than Mr. Bosson reckoned in his calculation on the cost of beet sugar. If we reckon 50 lbs. to the bushel, $13\frac{3}{4}$ tons per acre would be only 533 bushels, which would be no more than a middling crop; not half as much as has been raised in a number of cases that have been named.

In estimating the value of sugar beets for feeding stock, &c., Mr. P. Diehl, of Pennsylvania, says that in his neighbourhood, persons feeding the beet to cows, readily procure 2 cents per lb. more for their butter than their neighbours who do not use the beet. His hogs are wintered entirely on beets and kitchen slop, and kept in fine condition. He states that he has fattened solely on sugar beets, beeves, which when sold, were pronounced by the butchers the best they had killed for many years before. In contrasting the probable amount of profit to the farmer, per acre, of a crop of corn and a crop of beets, he says: Allowing for the average crop of beets 1000 bushels per acre, which is moderate, this quantity will fatten 11 head of steers in 90 days, at one bushel per day for each steer. Allowing the average corn crop to be 50 bushels per acre, which is very large, this product will fatten only $1\frac{1}{2}$ head, in the same time, feeding at the usual rate of $1\frac{1}{2}$ pecks per day. This leaves a balance in favour of beets, fractions aside, of about 800 per cent. (See *Cultivator*, vol. viii. p. 119.) There is perhaps no food which will contribute in winter so much to increase the quantity and quality of the dairy products as the sugar beet. But it should be used along with good hay, fodder, and other dry provender.

Under the head of **MANGEL WURZEL**, a tabular view is given of the comparative nutritive materials in several of the roots most usually cultivated for agricultural purposes. From this it will be seen, that in saccharine matter as

well as in the total amount of soluble matter, the beet transcends all the other roots taken into the estimate. See table, Art. Food, p. 499.

SULPHATES. A class of concentrated fertilizers, in which sulphuric acid is combined with different substances, as with lime to form gypsum; See PLASTER OF PARIS. Ammonia, to form sulphate of ammonia, a new fertilizer of great power, enjoying high repute in England, costing about \$5 per 100 lbs., and used at the rate of 100 to 150 lbs. per acre as a top-dressing or otherwise. Sulphuric acid with soda, forms the well known Glauber's Salts, also used as a fertilizer at the rate of 100 lbs. to 200 lbs. per acre, and costing in England about \$35 per ton. Copperas, or sulphate of iron, has been mentioned as a great destroyer of disagreeable odours when added to putrid animal substances. See NIGHT-SOIL.

SUNDEW. A most singular and beautiful genus of plants, having leaves ornamented with red glandular hairs, discharging at their ends a thick acrid juice resembling dew. The hairs are irritable when touched, and contract upon insects.

SUNFLOWER (*Helianthus*, from *helios*, sun, and *anthos*, a flower; on account of the brilliant colour of the flowers, and from the erroneous idea that the flowers always turned towards the sun). A highly ornamental and extensive genus of plants; and from their tall growth they are particularly adapted to the back of flower-borders or the front of shrubberies, in which situations they make a splendid appearance in autumn: they grow well in any common garden soil, the tender kinds being protected in winter. It appears to possess far more profitable qualities than were hitherto supposed, and, besides forming a beautiful object in a bed of flowers, it may be cultivated with advantage, and applied to many useful purposes. An acre of land will contain 25,000 sunflower plants, 12 inches distant from each other. The produce will be according to the nature of the soil and mode of cultivation; but the average has been found to be 50 bushels of the seed per acre, which will yield 50 gallons of oil. The oil is excellent for table use, burning in lamps, and for the manufacture of soaps. The marc, or refuse of the seeds after the oil has been expressed, made into cake, will produce 1500 lbs., and the stalks, when burnt for alkali, will give 10 per cent. of potassa. The green leaves of the sunflower, when dried and burnt to powder, make excellent fodder for milch cows, mixed with bran. From the ease with which sunflowers are produced in gardens (for they seem to flourish in any soil, and to require no particular care), we may safely say that an acre of land will yield a considerable return. Poultry are very fond of the seeds.

SUNFLOWER, WILD or FALSE. *Sneeze-weed* (*Helium autumnale*). A plant with a biennial root found in the United States.

SWAMP. Ground habitually so moist and soft as not to admit of being trod by cattle, but at the same time producing particular kinds of trees, bushes, and plants. A swamp differs from a bog and a marsh in producing trees and shrubs, while the latter produce only herbage, plants, and mosses. In autumn and spring, the exhalations from swamps are pro-

ductive of agues, consequently it is important to fill them up or drain them.

SWAN (*Cygnus*). Of the noble web-footed birds so called there are three British species: the Hooper, or Bewick's; the wild, and the tame swan. The wild swan and Hooper ought, perhaps, to be regarded as the only true native species. The tame swan (*C. olor*) is superior in bulk to either of the wild species, and is at once distinguished by a large, black, callous knob on the base of the bill. Our remarks in this place will be exclusively directed to the domesticated swan. These graceful birds are rarely dressed for the table; they are considered too ornamental to destroy. They are not destructive to fish, and they keep the water free from weeds. Mr. Main, who long studied their habits, in his work on *Domestic Poultry*, says the tame swan is herbivorous and granivorous; that is, they feed upon weeds and grain. They love also bread, vegetables, &c., which they eat greedily from the hand.

The swan lays from 5 to 8 eggs in the summer, and breeds only once in the year. They love an islet to breed their young upon, for the sake of its quiet; and a little straw deposited there is all they require for making their nest. The swan sits a month, but if the weather is bad, they are known to remain longer before they hatch. The cygnets, or young swans, remain a year with their parents; but when the breeding season approaches, the old cob or male bird drives them away. This is the period to sell; and if the birds have paired, they fetch a higher price in the market. Swans are not in full plumage till the third year. These birds often take flight at the fall of the year, therefore the old birds should have the first joint of one wing removed, which would prevent their roving. Two pair of swans will seldom agree together upon the same piece of water. The cob, or male swan, is larger than the female, and bolder. They require feeding in very severe winters, and the ice should be broken for them to swim about. At other times they feed on weeds growing in the water, or herbage on the banks of it. Swans and cygnets are caught most easily with a swan-hook, which is a long pole of 10 or 12 feet, with a blunt hook 10 inches in length, bent at right angles to the pole; the angle should be turned like a ring, and open in the inner side, to let in the neck of the bird. The swan has a peculiar kind of snort, but no voice. They hiss when angry.

SWARD. Green turf; that is, the surface of land under pasture grasses. A fine sward may be called the characteristic feature of British landscape, not being found in the same degree of perfection in any other country, not even in Ireland.

SWEAL. To singe or burn off the hair, as in hogs.

SWEET-BRIER. See EGLANTINE.

SWEET FLAG. See ACORUS and AROMATIC REED.

SWEET-GRASS (*Glyceria*, from *glukeros*, sweet, alluding to the herbage; whence also the common name). A genus of grasses of which some of the species are aquatics. Dr. Smith enumerates 6 species indigenous to

England: viz. the reedy sweet-grass (*G. aquatica*), the floating sweet-grass (*G. fluitans*), the reflexed sweet-grass (*G. distans*), the creeping sea sweet-grass (*G. maritima*), the procumbent sea sweet-grass (*G. procumbens*), and the hard sweet-grass (*G. rigida*). The only species which have been thought worthy of trial by Mr. Sinclair and other experimental cultivators of grasses are:—

1. The floating sweet-grass (*G. fluitans*). Marona grass. The panicle is oblong, branched, divaricating. Spikelets close pressed. Florets numerous, obtuse, seven-ribbed, with short intermediate ribs at the base. Nectary obtuse, tumid. This species appears capable of being cultivated as a permanent pasture grass. The seed will not vegetate unless kept very moist. It flowers from the first or second week of July till the end of summer. Birds are fond of the seeds, and generally strip the panicle ere the seeds are all perfected. Schreber informs us that it is cultivated in several parts of Germany for the sake of the seeds, which are esteemed a delicacy in soups and gruels. When ground into meal, they make bread, very little inferior to that from wheat. The bran is given to horses that have the worms; but they must be kept from water for some hours afterwards. Fish, particularly trout, are said to be very partial to the seed.

2. The reedy sweet-grass (*G. aquatica*). In this species the panicle is erect, repeatedly branched, spreading. Florets numerous, obtuse, with seven ribs. Nectary cloven, acute. This grass is common on the banks of rivers, and frequent on the margins of standing pools. On the banks and little islands of the Thames, where it is generally mown twice in the year for hay, it affords abundant crops of valuable winter fodder. Mr. Curtis informs us that in flat countries, which do not admit of being sufficiently drained, it is almost the only grass for hay and pasturage. In the fens of Cambridge, Lincoln, &c., immense tracts which used to be overflowed and produce useless aquatic plants, and still retain much moisture, though drained by mills, are covered with this grass, which not only affords rich pasturage in summer, but forms the chief part of their winter fodder. Its powerful creeping roots make it a dangerous and troublesome weed in ditches, where, with other aquatic plants, it soon chokes them up. In the fens of the Isle of Ely this grass grows to the height of six feet, and proves excellent fodder for milch cows, though horses are not fond of it. The nutritive matter of this grass contains a greater proportion of sugar than exists in any of the superior pasture grasses. The best manner of propagating it is by planting the roots either in autumn or spring. It flowers about the second and third weeks of July, and the seed is ripe in the second week of August.

SWEET POTATO (*Convolvulus battatus*). Carolina potato. The fine, esculent, tuberous root of this species of low-creeping vine or convolvulus, is perennial. It flourishes in the Middle and Southern States—to which last it is native—wherever the soil is light and sandy, refusing to grow and perfect itself on clay or stiff loam soils. The plant is propagated by

planting the tubers in beds early in the spring, from which the young sprouts are subsequently planted out in hills 5 or 6 feet apart. The trailing vines must not be allowed to strike root. The long roots are of different colours, being rich yellow, red, or white, and attain a large size, from a few ounces to several pounds in weight. When boiled, baked, or roasted, they have a sweet and very agreeable taste, and are very nutritious.

SWEET SCENTED SHRUB (*Calycanthus Floridus*), Carolina Allspice. An American spicy shrub, the flowers of which are extremely odiferous, the perfume resembling that of the strawberry. The wood and especially the root are strongly camphorated, and may, Mr. Nuttall thinks, probably produce this drug as abundantly as the *Laurus camphora*. By cutting off the terminal leaf-buds after the usual season, it is said that a succession of flowers may be obtained throughout the summer, every leaf-bud so extracted being constantly succeeded by two flowers. The flowers of the *Calycanthus* rarely produce seed, even in its native mountains of Carolina.

SWINE (Genus *Sus*). The hog has been generally described as a creature of gross habits and unclean tastes, as having the senses of touch and taste obtuse, and even as being so insensible that mice may burrow in his skin without his seeming to feel. But these opinions are most unjust and incorrect. Far from being unclean, nature has furnished him with powerful organs of digestion, enabling him to derive sustenance from a variety of substances, and his voracity is only the result of the extent and perfection of his digestive and respiratory organs. Although one of the pachydermatous, or thick-skinned animals, the hog feels blows acutely, and manifests his suffering by loud cries. Indeed, the inference that his sense of touch is dull, because of the thick layer of fat with which his body is enveloped, is most erroneous, for it is well known that the plexus of nerves which gives sensibility to the body is exterior to this fatty layer. So far from being insensible to pain, the hog even suffers under the irritation arising from the punctures of gnats, mosquitoes, and other small insects, and endeavours to protect himself from their persecution by rolling in moist places and covering himself with mud.

Natural History of the Hog.—"The hog (says Prof. Low) is subject to remarkable changes of form and characters, according to the situations in which he is placed. When these characters assume a certain degree of permanence, a breed or variety is formed; and there is none of the domestic animals which more easily receives the characters we desire to impress upon it. This arises from its rapid powers of increase, and the constancy with which the characters of the parents are reproduced in the progeny. There is no kind of live-stock that can be so easily improved by the breeder, and so quickly rendered suited to the purposes required; and the same characters of external form indicate in the hog a disposition to arrive at early maturity of muscle and fat as in the ox and sheep. The body is large in proportion to the limbs, or, in other words, the limbs are

short in proportion to the body; the extremities are free from coarseness; the chest is broad, and the trunk round. Possessing these characters, the hog never fails to arrive at earlier maturity, and with a smaller consumption of food, than when he possesses a different conformation."

The wild boar, which was undoubtedly the progenitor of all the European varieties, and also of the Chinese breed, was formerly a native of the British Islands, and very common in the forests until the time of the civil wars in England.

The wild hog is now spread over the temperate and warmer parts of the old continent and its adjacent islands. His colour varies with age and climate, but is generally a dusky brown with black spots and streaks. His skin is covered with coarse hairs or bristles, intersected with soft wool, and with coarser and longer bristles upon the neck and spine, which he erects when in anger. He is a very bold and powerful creature, and becomes more fierce and indocile with age. From the form of his teeth he is chiefly herbivorous in his habits, and delights in roots, which his acute sense of smell and touch enables him to discover beneath the surface. He also feeds upon animal substances, such as worms and larvæ, which he grubs up from the ground, the eggs of birds, small reptiles, the young of animals, and occasionally carrion; he even attacks venomous snakes with impunity.

The female produces a litter but once a year, and in much smaller numbers than when domesticated. She usually carries her young for 4 months, or 16 weeks.

In a wild state the hog has been known to live more than 30 years; but when domesticated he is usually slaughtered for bacon before he is 2 years old, and boars killed for brawn seldom reach to the age of 5. When the wild hog is tamed, it undergoes the following amongst other changes in its conformation. The ears become less movable, not being required to collect distant sounds. The formidable tusks of the male diminish, not being necessary for self-defence. The muscles of the neck become less developed, from not being so much exercised as in the natural state. The head becomes more inclined, the back and loins are lengthened, the body rendered more capacious, the limbs shorter and less muscular; and anatomy proves that the stomach and intestinal canals have also become proportionately extended along with the form of the body. The habits and instincts of the animal change: it becomes diurnal in its habits, not choosing the night for its search of food; is more insatiate in its appetite, and the tendency to obesity increases.

The male, forsaking its solitary habits, becomes gregarious, and the female produces her young more frequently, and in larger numbers. With its diminished strength and power of active motion, the animal also loses its desire for liberty. These changes of form, appetites, and habits being communicated to its progeny, a new race of animals is produced, better suited to their altered condition. The wild hog, after it has been domesticated, does not appear to

revert to its former state and habits; at least the swine of South America, carried thither by the Spaniards, which have escaped to the woods, retain their gregarious habits, and have not become wild boars.

In its wild state the hog has 6 incisor teeth in the upper, and 6 in the lower jaw; but when domesticated the number is reduced to 3 in each jaw, and this number is not constant. The vertebræ of the back vary from 14 to 15 in number; the lumbar and the sacral from 4 to 6; the caudal from 2 to 3 or 4, the tail being often rudimental in the domesticated races.

Mr. T. E. Eyton (*Trans. of Zool. Soc.*, Feb. 1837), amongst other osteological differences in the races of hogs, points out the following as applicable to the number of vertebræ:—

	English male.	African male.	Chinese male.	Wild Boar.	Domestic Hog.
Cervical	7	7	7	7	7
Dorsal -	15	13	15	14	14
Lumbar	6	6	4	5	5
Sacral -	6	5	4	4	4
Caudal	21	13	19	20	23
	55	44	49	50	53

The hog family includes several species, but these have usually been divided into three genera.

1. The true hog, which is the most diffused and important class, comprehending the wild boar (*Sus aper*) of Europe, Asia, and Africa; the babiroussa (*Sus babiroussa*) of the islands of the Eastern Archipelago, which is of lighter form than the common wild hog; the Papuan hog (*Sus papuensis*) of New Guinea, and the wood swine, or masked African boar (*S. larvatus*), of Southern Africa and Madagascar.

2. The wart-bearing hogs of Africa (*Phacochæres*).

3. The peccaries of America. Of these there are two species, the collared peccary (*Dicotyles torquatus*) and the white-lipped peccary (*D. labiatus*), both inhabiting the countries of the Atlantic from Guiana and Paraguay, extending into the northern continent, being common on Red River. The peccaries are rather smaller than the common swine of Europe: they are covered with stiff bristles, very long upon the neck and spine, which they erect when irritated, are nearly destitute of tail, and are further characterized by a glandular opening in the back, whence the generic term *dicotyles*, signifying a double navel.

The true hog does not appear to have been indigenous to America, but was taken over by the early voyagers from the old world, and it has now spread and multiplied throughout the continent.

The first settlers of Canada, the British North American settlements, and the United States, carried with them the swine of the parent country, and a few of the breeds still retain traces of the old English character. From its nature and habits the hog was the most profitable and useful of all the animals bred by the early settler in the distant clearings. It was his surest resource during his first years of toil and hardship. It arrived earlier at maturity, required less care, sought out, for the most part, its own food, was the least subject to ac-

cidents and diseases in a new situation, and therefore best repaid any portion of attention bestowed on the breeding and rearing it.

Their widely extended foreign commerce afforded the Americans opportunities of procuring the varieties from China, Africa, and other countries. The large consumption of pork in the United States, far exceeding the consumption of any other country, has also contributed mainly to the improvement of the breeds, by causing the Americans to pay considerable attention to the rearing of swine, which have thus become one of the most important articles of commerce, and a source of considerable profit to the breeder on a large scale.

Breeds.—The various breeds which have been reared by crosses between those procured from different countries are so numerous, that to give any thing like a detailed description of all would fill a volume instead of an essay. I shall, therefore, confine myself to a short notice of those which are either considered as the origin of some peculiar race, or most generally bred for their fattening or other profitable qualities. The celebrated English breeder, Culey, only distinguishes four breeds, the Berkshire, the Chinese, the Highland, and the Irish species.

The principal breeds of England have been usually named after the particular counties or localities where they have been, for the most part, reared. Thus, we have the Berkshire, the Hampshire, the Essex, the Suffolk, and a dozen others, each supposed to be distinguished by a certain set of common characters. Those approved on account of their superior size, and therefore usually reared for the purpose of making bacon, are the Berks, Hants, Hereford, Salop, Norfolk, and Chester breeds. The breed best adapted for table pork is the small white Chinese. There are, however, particular breeds preferred by individuals.

The Berkshire Breed. This was one of the earliest improved of the English breeds, and it is now the most widely distributed, as it is the most superior, of the numerous varieties of England. It is a breed which is distinguished by being, in general, of a tawny white, or rufous-brown colour, spotted with black or brown; head well placed, large ears, generally standing forward, though sometimes hanging over the eyes; body thick, close, and well made; legs short, small in the bone; coat rough and curly, wearing the appearance of indicating both skin and flesh of a coarse quality. Such, however, is not the case, for they have a disposition to fatten quickly: nothing can be finer than the bacon, and the animals attain to a very great size, averaging from 50 to 60 stone, although they have not uncommonly reached to the prodigious weight of 100 stone and upwards.

The county of Berkshire has long been celebrated for its famous breed of swine, and the breed has, by frequent and judicious crossing, been much altered for the better. The original breed was of the larger race of swine, and is described as being long, and rather crooked-snouted, with uncouth, heavy ears; body long and thick, though not very deep; legs short, and much bone; although slow feeders, they

always made great weights. The character of the true Berkshire seems to indicate that one of the earliest means employed to improve them was a cross with the wild boar. The improved breed is lighter in the head and ear, shorter in the carcass, with somewhat less bone, and higher in the leg: in colour generally dark spotted. They have little offal, thin rind and hair, and few or no stout bristles. The native breed is still occasionally crossed, either with the pure Chinese or the Tonquin race; and it is asserted, on good authority, that if not crossed once in 6 or 7 years with the Asiatic breed, they will degenerate in shape and quality. The improved Berkshires will be found excellent in all respects, but particularly as a cross for heavy, slow-feeding hogs. The unqualified approbation which this breed has obtained, renders it incumbent on every breeder who wishes to improve his stock of swine to obtain a cross with that race. Although hardy and thrifty in its nature, the Berkshire hog requires constant good keep, or it will decline fast.

The old English Breed.—The original native breeds of Great Britain may be arranged into two general classes; but between these extremes there are so many varieties, that numbers cannot be reduced to either class.

1. Those of small size, with the ears erect, or partly so, of which the most marked are those of the Highlands and islands of Scotland. They are hardy creatures, usually of a dusky-brown colour, having an arched back, with coarse bristles on the neck and spine; and approximate closely in character and habits to the wild hog. They are, for the most part, left to provide for themselves, ranging at large over the heaths and moors, grubbing up roots and destroying the eggs of birds, and even newly-born lambs, when they come in their way. These hogs are usually very meager and thin; flesh coarse and fibrous; but it is greatly improved when the animals are confined and properly fed. When roaming at large on the sea-coast, their flesh, from feeding on shell-fish, sea-weed, and the bodies of fish which are cast up by the tide, acquires a rank and unctuous taste.

2. The second class comprises those of a larger body, with long, pendent ears.

Although their colour varies considerably, they are, for the most part, white, or white spotted with black. The characteristics of this old race, where it exists without intermixture with foreign blood (which is not often the case in the present day), are a huge, uncouth form, large bones, long limbs, arched and narrow back, low shoulder, and long snout, with the ears large and flapping, covering the greater part of the face. They consume much food, are slow feeders, and their only recommendation is that of being prolific breeders, and attaining to a large size when fattened at the age of two or three years. The old English breed, and many other once celebrated local races of that country, have all had their distinctive characters more or less effaced by crossing.

The Chinese or Siamese breed.—The varieties of this widely-extended race which are the most common in England, were brought to

America and England from Canton and other Indian ports, for the most part as sea-stock, by the vessels employed in the tea trade, &c. Owing to the much larger consumption of pork by the Chinese than of any other animal food, they pay great attention to the rearing and fattening of their swine. It is said they even use the milk of the sow for domestic purposes. The pure Chinese breed is too delicate and sensible of cold to be of much value in climates liable to frequent changes of temperature. It is chiefly, therefore, by intermixture that its value is recognised; and it is for this reason that its introduction has proved so beneficial in England, by correcting the coarseness of form, quieting the restless disposition, and adding a greater tendency to mature quickly and fatten kindly. The flesh of the Eastern hogs is more suited for pork than for bacon. Mr. Culley subdivides the Chinese breed into seven varieties, but there appear to be only two distinct species—the white and the black; the former better shaped than the latter, but less hardy and prolific. Both are, however, small-limbed; ears and head thin and transparent, small and fine; neck thick; the body close, compact, and well formed; legs very short; flesh delicate; round in the carcass, thin-skinned, and the head so embedded in the neck that, when quite fat, the end only of the snout can be seen. They are rather difficult to rear; the sows are bad nurses; and, from their small size, they seldom reach to a greater weight than from 10 to 12 stone when one year old, and 16 to 18 stone when two years old.

The black race, from their valuable properties of fattening on a small proportion of food, being very thrifty, and prolific breeders, notwithstanding their inferior size, have been advantageously crossed with other breeds.

There is a mixed tawny breed, or patched with black and white, which is valuable for breeding sows and roasters.

Hampshire breed.—This is a very large breed, which is longer in the neck and body, but not so compact in form as the Berkshire. They are mostly of a white colour, or spotted, and are well disposed to fatten, coming up to a great weight when properly managed in respect to food. The goodness of the Hampshire hog is proverbial; it is principally fattened for large hams and bacon.

The Shropshire breed is large and coarse; but these hogs are found profitable where the keep is in sufficient abundance for their support; hence they are held in estimation in England by distillers, and are commonly fed to 30 score weight and upwards. They are neither so well formed as those of the Berkshire breed, nor do they equal them in their disposition to fatten and thrive on cheap food. The standard colour of the Shropshire hog appears to be white, or brindled with black, and sometimes sandy patches. The breed may be described as flat-boned, deep and flat-sided, harsh or rather wiry-haired, the ears large; head long, sharp, and coarse; leg too long, low, although very substantial, yet not sufficiently wide, considering the great extent of the whole frame. Within the last 15 or 20 years this breed has been much improved by a cross with the Berkshire,

which has reduced the length both of their legs and carcass, and rendered the head lighter.

The Rudwick breed.—This is the most enormous breed in Great Britain, and is reared about the neighbourhood of a village on the borders of Sussex and Surrey, whence it takes its name. They feed to an extraordinary size without any peculiar care, and weigh, at two years old, on an average, full 70 stone, which is nearly double what other kinds will weigh at the same age. The Rudwick sows are accounted good mothers, very prolific and hardy, and are particularly noted as being an extremely large sort, having been known to weigh from 80 to 116 stone, 8 lbs. to the stone. Indeed, some have reached to the extraordinary weight of 182 stone. As large breeds pay the farmer the best in many cases, such a breed as the Rudwick deserves to be attended to in the system of hog management.

The Suffolk and Norfolk breeds have been long in repute as hardy and prolific species, and when crossed with either the Dishley or the Berkshire hog, produce animals which are held in very general esteem.

The Norfolk breed.—This is described as being a small, short set-eared, thin-skinned porking sort, various in colour, white, bluish, striated; generally an inferior kind. But on the Lincoln side of the county there is a large spotted variety of very good form and quality.

The Suffolk breed is a small, delicate, white race, which has for many years been held in good estimation. They are shorter and more pug-formed than the Norfolks; and by their dish face and pendent belly, it is to be presumed that the variety proceeded originally from the white Chinese breed. Their defects are, that they are great consumers in proportion to their small bulk, and that they produce little flesh.

The Woburn breed.—This is a large, hardy, well-formed, and very prolific variety, introduced by the late Duke of Bedford, which is generally white, spotted with various colours, round in the carcass, small-limbed and headed, and so kindly disposed to fatten, that they are said to attain about twice the size and weight of other sorts of hogs within the same given period of time.

The Tonkey or Tonquin breed is a cross between the Berkshire and the Chinese, which has produced a species possessing very many good points.

The Dishley breed, reared by the celebrated cattle-breeder, Bakewell, are remarkably fine-boned and delicate, besides possessing considerable beauty, and are said to lay on a larger quantity of meat, in proportion to bone and offal, than any other kind known. When fat, they are nearly equal in height, length, and thickness, their bellies almost touching the ground, the eyes being deep-set and sunk from fat, and the whole carcass appearing to be a solid mass of flesh. As a set-off to these good qualities, are the defects of their being slow of growth, tender constitutioned, bad nurses, not very prolific, and requiring more food in fattening than the larger hogs. By a cross with a Dishley boar, several of the native breeds of the different English counties have been much

improved. A roundness has been given to the frame, with a proportionate depth of body; the legs have been shortened, a finer bone produced, with a better appearance when growing as a store, and a disposition to feed quicker and more kindly in the sty.

Small white English breed.—This breed of small hogs is met with in several districts, but prevails most in the northern parts of England. It is of a white colour, thick, compact, and well made in the body, short in the leg; the head and neck well formed, ears slouching a little downwards; hardy, and well disposed to fatten.

The Essex breed.—The original Essex breed was not held in much repute. Their peculiar character was a long, sharp head round-backed; carcass flat, long, and generally high upon the leg; bones not large; colour white, or black and white; bare of hair; quick feeders, but great consumers, and of an unquiet disposition. A variety known as the *Essex half-blacks*, which were introduced some years ago by the late Lord Western, as descendants from the Berkshire, have now justly acquired such very great celebrity, as to be considered by many good judges superior to most breeds in the kingdom. They are described in the *Essex Report* as black and white, short-haired, thin-skinned, with smaller heads and ears than the Berkshire, but feathered with inside hair, which is a distinctive mark of both; having short, snubby noses, very fine bone, broad and deep in the belly, full in the hind-quarters, but light in the bone and offal. They feed remarkably quick, grow fast, and are of an excellent quality of meat. The sows are good breeders, and bring litters from 8 to 12; but they have the character of being bad nurses.

The Wiltshire Breed.—Originally this was a long-bodied, low hog, hollow about the shoulders, and high on the rump; with middling large pointed ears; round bone; and light in colour. But of late years this breed has been advantageously crossed with the pig and Berkshire sorts, and a smaller and better variety produced.

The Gloucester, the Yorkshire, the Northampton, and the Hereford breeds, call for little notice. The Hereford appears to be a descendant of the Shropshire, and is a large, useful race; but the others are very inferior kinds, possessing few good points.

In reviewing the various breeds of swine, a brief survey of the principal continental varieties and distinct races may not be out of place. I shall therefore give a slightly altered abridgment of a diffuse article which some time since appeared in the *Quart. Jour. of Agr.* vol. iii. p. 49.

France.—In the time of Buffon, the greater portion of the hogs of Vivarez and the north of France were white; while in Dauphiny, Languedoc, and Provence, they were all black: black pigs still prevail both in Spain and Italy. The variety known in France under the name of *porc de nobles* appears to be derived from the improved English breed, which originated in a cross between an Anglo-Chinese sow and an emancipated American boar. The French breeds of swine are in general bad, but excel-

lent hams are sent from Bretagne from hogs reared on acorns and fattened off with maize. The principal breeds of France at the present time are—

1. *The race of the Pays d'Auge*, in which the head is small and sharp, ears narrow and pointed, body long, legs broad and strong, hair coarse, white, and bones small. It attains to the weight of 800 lbs.

2. *The race of Poitou.*—The distinguishing characters of which are, head long and thick, with the point projecting, ears large and pendulous, body long, bones large, but broad and strong, bristles coarse. Its weight seldom exceeds 500 lbs.

3. *The race of Périgord.*—Neck thick and short, body broad and compact, hair black. This race, crossed with others, has produced the pied swine, so common in the south of France.

4. *The race of Champagne.*—These do not fatten well, they are of large dimensions, with long, flat sides, broad, pendent ears, and coarse white hair.

5. *The race of Boulogne* are also of considerable size, and disposed to fatten quickly; ears very broad, general colour white. This breed has sprung from a cross between the larger English breed and one of the common races of France.

The French pigs, although they have excited many facetious observations from travellers, and not unfrequently been compared to greyhounds, may be fattened, we are assured, at a small expense; and the method of doing this is now beginning to be understood. The Chinese and English breeds are also getting into use for crossing. The fact that 4,000,000 pigs are killed yearly in France, shows of how great importance they are to the small agriculturist. (*For. Quart. Rev.*)

OTHER EUROPEAN BREEDS.—In some parts of Hungary the breed of swine is excellent. In Germany swine are common, but the breed is everywhere indifferent. Of the other continental races only a very few require particular notice.

The Jutland swine, which are of a large size, and form an important branch of Danish commerce, have the ears large and pendent, body elongated, back somewhat curved, legs long.

The Swedish swine.—The most peculiar and characteristic breed of Sweden are supposed to contain a cross of the wild boar, and have the head broad, turned upwards; ears unusually erect, body lengthened, legs long.

The Polish and Russian pigs are generally small, and of a reddish or yellowish colour.

Race of the Cape of Good Hope.—This breed is somewhat less in size, but else approaches closely to the Siamese pig, and is nearly identical with the breed of the South Sea Islands. It probably originated in India. The hair is black or deep chestnut, hard, and thinly scattered; the ears are straight, and tail pendent and terminated by a tuft of bristles. This race is now very generally distributed; it has been propagated extensively in Australasia, and now occurs not only in Southern Africa, but in several parts of South America.

The smooth or short-legged swine, a breed derived from the Chinese, are bred in Spain, Por-

tugal, Savoy, and the north and south of Italy. This pig is of small size, very productive, and a ready fattener; it is usually of a copper colour, but sometimes occurs of a bright fiery red. The head is unusually short, the jaws thick, the forehead stunted; the skin falls in folds above the eyes; the ears are short, pointed, and almost erect; the neck is thick and strong, the chest very vigorous, the body round and lengthened, the legs short and strong, the skin very thin, and the bristles short and slender.

The Zealand hog is of a mixed Chinese race, and weighs from 160 to 240 lbs. about the end of its second year. It has the ears erect, body short, back strongly bristled, tail small.

The Turkish hog fattens in half the time required by many of the larger and more common breeds, and weighs from 300 to 400 lbs. It prevails throughout European Turkey, and a great portion of the Austrian dominions. Ears straight and pointed; legs short and fine; body scarcely longer than high, and covered all over with slender frizzled bristles, of a gray colour, more or less deep, approaching to rufous brown.

The pig of Guinea (not the Guinea pig) is a remarkable variety, which is little known. The back is bare; head small; ears long, slender, and much pointed; tail long, naked, reaching to the ground; hair short, red, shining, finer and softer than that of any other known race.

In Asia only Europeans and the low Hindoos eat pork. Wild hogs are abundant, and do so much injury to the rice fields that it is a material part of the ryot's business to watch them, which he does night and day, on a raised platform of bamboos.

Of the Mediterranean breeds there are several, which are approved and held in much estimation; among these are the Maltese, the Neapolitan, &c., and hogs are occasionally brought from the sea-ports of Turkey and Spain.

The Maltese breed was at one time in great favour in England; it was of small size, of a black colour, nearly destitute of bristles, with an aptitude to fatten readily. A breed from the country near Naples has been recently introduced, which is extensively employed as a cross with the existing native breeds. This Neapolitan breed is very similar to the Maltese breed already alluded to. Their flesh is good and delicate, but the animals are not hardy, and quite unfit for general use. The duchy of Parma is said to produce the best hogs of Italy, which possess all the good qualities of those about Naples. They are also more hardy, and of larger size.

In Mexico they have a very fine race of hogs, which are regarded as an important article of commerce. They are kept very clean, and often given a cold bath, as the breeders find from experience that cleanliness contributes mainly to their rapid growth, upon less food. This is fully corroborated by the following experiment, which was recently made by a gentleman from Norfolk. Six pigs of nearly equal size were put to keeping at the same time, and treated the same as to food and litter for seven weeks. Three of them were left to shift for

themselves as to cleanliness; the other three were kept as clean as possible by a man employed for the purpose, with a currycomb and brush. The last consumed in seven weeks fewer peas by five bushels than the other three, yet weighed more when killed by two stone and four pounds upon the average.

Bullock informs us that the Mexicans are very curious in rearing and feeding swine, and that an essential requisite in a Mexican swine-herd is an agreeable voice, in order that he may sing or charm the animals into peace when they quarrel and fight, and lull them to sleep at proper times, to promote their fattening. (*Travels*, 1824.) There are many wild swine in Paraguay.

Characteristics of a good hog.—There is evidently much diversity in swine in different circumstances and situations. Like other descriptions of stock, they should be selected with especial reference to the nature of the climate, the keep and the circumstances of the management under which the farm is conducted. The chief points to be consulted in judging of the breeds of this animal are the form or shape of the ear, and the quality of the hair. The pendulous or lop ear, and coarse, harsh hair, are commonly asserted to indicate largeness of size and thickness of skin; while erect or prick ears show the size to be smaller, but the animals to be more quick in feeding.

In the selection of swine, the best formed are considered to be those which are not too long, but full in the head and cheek; thick and rather short in the neck; fine in the bone; thick, plump, and compact in the carcass; full in the quarters, fine and thin in the hide; and of a good size according to the breed, with, above all, a kindly disposition to fatten well and expeditiously at an early age. Depth of carcass, lateral extension, breadth of the loin and breast, proportionate length, moderate shortness of the legs, and substance of the gammons and forearms, are therefore absolute essentials. These are qualities to produce a favourable balance in the account of keep, and a mass of weight which will pull the scale down. In proportion, too, as the animal is capacious in the loin and breast, will be generally the vigour of his constitution; his legs will be thence properly extended, and he will have a bold and firm footing on the ground.

For head and ears, the small Berkshire or Oxford pigs are good models; and for true shape, the improved Shropshire, Hereford, and Gloucester. If colour deserve any consideration, perhaps the light, sandy, and yellow spotted are to be preferred, as these appear to afford by far the most delicate meat when dead.

Procreation.—The sow generally goes with young four lunar months, but the period of gestation in different species varies considerably. According to the experiments of M. Teissier on the gestation of animals, it appears that the extreme periods of 25 sows were 109 to 143 days, which would lead to the inference that they go on an average 127 days from the time of taking the boar until they farrow; but experience proves that they most commonly farrow within little more than 16 weeks, although they occasionally go with young 20 weeks. Both

the sexes manifest a desire for coition at 7 or 8 months old; and although frequently brought together at a still earlier age, it is more preferable to restrain them until they have attained to the age of 12 months, as a larger and stronger litter will be produced. The boar should not commence serving until at least a year old, and he may be considered in his prime at 2 years old. He should not be strained by being allowed to serve too many sows; from 12 to 14 being sufficient. The sow should rarely be put to the boar before 8 months old. See GESTATION.

The animals when collectively spoken of are usually either termed swine, hogs, or pigs; but when distinctively named, the young gelded male is called a "barrow," the male when not castrated is called a "boar," and the female a "sow," or "shoot;" their progeny when very young being styled "sucking pigs," and when advanced somewhat larger in size, "porkers."

There is much difference of opinion as to the best age for breeding sows. Some considers that sows at 3 years old throw their stock much larger and stronger than when of a less age; while others are of opinion that they are never such good breeders as at the age of from a year and a half to two years and a half old; after which they throw the pigs unevenly.

Regarding the sex of the progeny, it is asserted in a recent French work on the subject of generation (*Giron, sur la Réproduction des Animaux Domestiques*), that among females those which receive the male *first* produce generally more males than females. This is not a matter of much consequence in swine; but in horses and cattle it is a question of some moment: and if this theory is borne out by experience, the hint thrown out may prove useful to breeders. The sow will produce two litters in a year (occasionally five in two years), and from 8 to 12 pigs in each farrow. The number of pigs to be kept will be easily indicated by the number of teats which the mother has; and on no account should more be attempted to be retained than nature has thus provided for.

"The choice of a boar," says a modern writer, "depends so much upon fancy, or local prejudice, in favour of a particular breed, and is so little governed by either soil or climate, that no other general rule can be laid down upon the subject, than to avoid an animal which is not small-headed, deep and broad in the chest, the chine rather arched, the ribs and barrel well rounded, and the haunch falling full down nearly to the hock. He should also be more compact in his form and rather smaller than the sow; for, if she be coarse, her progeny will be improved in form and flesh by the cross, and the more roomy she is, the better chance will she afford of producing a large and healthy litter." (*Brit. Husb.* vol. ii. p. 511.) The boar cannot be too well kept; but the sow should not be highly fed before taking the boar.

The plan or custom of *breeding in and in* from close relations is a most injudicious course, and seems to bring on degeneracy in the offspring. In selecting both sows and boars, a due regard must be paid to the object for

which the progeny are designed. Small bone is desirable in stock reserved for breeding, as this description produces the least offal.

Uses.—A pig, for its size, is one of the most useful animals in the whole creation, inasmuch as he is food from top to toe, and there is no part of him which cannot be turned to account. His fat is made into lard, which is used in medicine, as well as by housekeepers, confectioners, and others. That about the loins is the firmest and the most dense. For ordinary use it must be separated from the membranes, which is effected by melting it over a slow fire and straining through cloths. It should be stirred as it cools, to prevent the separation of the solid part or stearine from the eluine or oily part. The flesh is either eaten fresh when young, or of the adult animal, bacon hog, salted in brine or with dry salt, and then either kept moist, as *pickled pork*; or merely dried, *white bacon*; or cured, dried, and smoked, *bacon*; that of the hind legs, *ham*, equally nutritive, but less easily digested; the collar and head of the old boars are made into *brawn*; the skin or rind is eaten with the flesh, if not smoked, and is also tanned for saddle-seats, shoes, covers for pocket-books, &c.; the bladders are prepared as ox bladders. The bristles clean our teeth and brush our clothes: those of superior quality from Russia, fetch 14*l.* to 26*l.* the cwt.; the second quality, from 5*l.* to 10*l.* The abdominal fat is used; as also the blood for food, and it yields a bezoar, principally from a morbid concretion in the stomach of the wild hog. Even the intestines are used for chitlings, and converted into an inferior kind of lard, by being cut open and washed clean, and (after the water is well pressed out of them) melted in the same way as lard: this substance is very useful for making common candles, greasing wheels, and other general purposes. To sum up all, the hog multiplies his species in a degree proportioned to his usefulness.

The flesh of the hog, when fresh, is easy of digestion and nutritive; but it is not a food capable of being eaten for a length of time with impunity. It is apt to cause derangements of the mucous membrane, and diseases of the skin.

Bacon.—In Great Britain the curing of bacon, as an article of commerce, prevails most in the counties of York, Hants, Cumberland, Northampton, Dumfries, Galloway, and the northern and other ports of Ireland.

For bacon slices, the larger breeds, such as will weigh, when killed, from 18 to 22 *imperial* stone, are always preferred, from being the most profitable to the farm and readily taking the market. In selecting pigs for this purpose, the sow should be of a large, deep carcass; head long, with deep ears, straight chine, and of equal symmetry from the shoulders to the tail; of fine skin, which shows an aptitude to fatten, and the boar should be of a thicker and closer make than the sow.

Small hogs for bacon will be ready for the knife in 12 weeks, and the larger from 16 to 20 weeks. The girth of fat bacon hogs is about as follows:—When ten score, 4 feet 1 inch; twelve score, 4 feet 4 inches; fourteen score, 4 feet 7 inches; sixteen score, 4 feet 11 inches; eighteen score, 5 feet 2 inches; twenty

score, 5 feet 7 inches. (*Hillyard's Pract. Farm.* p. 51.)

"In Hampshire, and some adjoining counties, after the hog is killed, they first swale him, or singe off the hairs, by kindling a fire round him, which is far preferable to scraping off the bristles with warm water, as the latter mode softens the rind, and injures the firmness of the flesh. He is then cut into flitches, which are well rubbed with common salt and saltpetre mixed, and are laid in a trough, where they continue for three weeks or a month, according to size, and are often turned. They are then taken out, suspended in a chimney, over a wood or turf-fire, or in regular curing-houses, till they are quite dried. In Kent they are dried before a slack fire, which requires a similar method and time to that employed in salting. They are hung up or deposited on racks for use. Somersetshire or Wiltshire bacon, which is the best in England, is cured as follows:—The sides of the hogs are laid in large wooden troughs, sprinkled with bay salt, and left unmoved for 24 hours, to drain off the blood and juices. Then they are taken out, and wiped quite dry, and some bay salt, previously heated in an iron fryingpan, is rubbed into the flesh, till enough of it is absorbed. This is continued for four successive days, during which the flitches are turned every second day. With large hogs, the flitches must be kept in brine for 3 weeks, and must be turned every other day, after which they are dried as usual. In these methods the hide or skin is left on; but in some counties there is a different practice, which has been recommended abroad as preferable, because it affords an opportunity of converting the skin into leather, while the meat takes the salt and is cured as well as in the former mode. The hides of swine have long been made into shoes in China. Where the consumption of bacon is very rapid, the last-mentioned practice may be adopted; but it is certain that bacon will in a short time become rusty, and consequent loss be incurred, if it be not cured with the rind, and kept in a dry room." (*The Complete Grazier.*) See BACON.

Pork.—In England, mess or table pork, or that for the London market, is generally cured near the principal sea-ports, and along the coast, from whence it can easily be shipped to the metropolis. If the object of breeding hogs is for pork and hams only, it is evident that pork from a hog of 25 to 35 stone (8 pounds to the stone) is by far more profitable than those from 35 to 50 stone; in which case a cross between the Chinese and Essex will be found to answer very well, as the progeny come to early maturity. (*Baxter's Agr. Lib.*)

The middle-sized hogs, such as the Northumberland, the Berkshire, the Suffolk, and Oxford breeds, are those generally preferred for this purpose, and their ordinary weight will be from 8 to 10 or 12 imperial stone.

For delicate pork for family use, the smaller kindly-feeding pigs are chosen. The Berkshire and the Suffolk breeds, when not too large, will be the best for this purpose. The Chinese will answer well at 6 or 8 months old, when it will weigh 4 to 8 imperial stones. By higher feeding it may be made, when a little

older, to attain to double this weight; but the meat will then be found coarse. Weanlings are generally fatted in a very short period. A pig of 5 or 6 months old will fatten, in good condition, in 8 or 10 weeks.

The fat of the hog is neither mixed with the flesh nor collected at its extremities, but covers the animal all over, and forms a thick, distinct, and continued layer beneath the integuments, and in this respect may be said to resemble the whale and other cetaceous animals. It is termed lard, and differs in chemical composition and properties from the fat of the ruminating animals. It more readily imbibes salt than any other kind of fat; and the same property being possessed by the flesh, there is no animal food better suited than pork for preservation by salting. See LARD.

Statistics.—The number of swine sold in Smithfield market in 1830 was 254,672, which, at the average weight of 96 lbs. each (a very moderate computation), gives the number of pounds of pork consumed annually at 24,448,512. (*Youatt on Cattle.*) The swine sold in Glasgow market in 1822 were 6539. The exports of swine from Ireland in 1825, were 65,919; in 1835, 376,191. Estimated value in the latter year, 893,839*l.* Increase between these two periods, 310,272.

In the United States of America a very large number of hogs are reared; and latterly much attention has been paid to the improvement of the breed by judicious crosses. The piggeries are on an extensive scale; and it is no uncommon thing in some of the Western States for a drover to have from 3000 to 4000 pigs. In a letter written from Michigan city, dated 11th September, 1841, the writer, a farmer, states that he had then 3500 pigs up to fatten! The bountiful crops of Indian corn raised on the fertile Western lands afford greater advantages than any other part of the world for the rearing of this kind of stock. Corn-fed bacon is proverbially excellent.

Swine in the British North American colonies, and the United States:—

	1832.*	1836 †	1841.
Upper Canada	220,000	250,000	
Lower Canada	350,000	400,000	
New Brunswick	65,000	80,000	
Nova Scotia and Cape Breton	98,214	100,000	
Prince Edward's Island	30,000	22,000	33,521
Newfoundland and Labrador	16,000	20,000	
United States	-	-	26,301,293

The states producing most swine are—Tennessee, 2,926,607; Kentucky, 2,310,533; Ohio, 2,099,746; New York, 1,900,065; Virginia, 1,992,155; North Carolina, 1,649,716; Indiana, 1,623,608; Pennsylvania, 1,503,964; Illinois, 1,495,254; Georgia, 1,457,755; Mississippi, 371,161. The swine in the whole six Eastern States, according to the census returns of 1840, numbered only 851,698.

Diseases.—This subject has been so much neglected by practical men, that but little is known in the way of cure in the absence, therefore, of scientific prescriptions, it will be most advisable to study prevention rather than hazard a trial of the numerous recipes recom-

* *M. Gregor's North America*, 2d ed. vol. ii. p. 589.
 † *Martin's British Colonies*.

mended as cures. The diseases of swine are generally the result of want of care and cleanliness, or arise from injudicious and irregular feeding; from their being kept in loathsome and uncomfortable situations, inhaling the most noxious vapours, and at one time overfed, and another stinted in their supply of food. Is it to be wondered at that they become subject to internal and cutaneous diseases? Fortunately they will generally eat when even sick; and salts (1 to 2 oz.), sulphur (2 to 3 drachms), antimony, and such like aperients, may be mixed with their food for measles, and other disorders arising from an impure state of the blood. If they will not eat, there can of course be no cure applied.

In swine-pox, sulphur and madder may be administered in small quantities, with treacle, in the wash; fresh brewer's grains, or pollard, may also be given. Madder and sulphur will also be found the best alterants in foulness of the skin or habit. Salt, mixed with ground ivy, leeks, or other similar vegetables, is one of the best applications for the sores of swine. But for cutaneous diseases in general, an ointment formed of equal parts of mutton suet and tar, with the addition of a little sulphur, will be found beneficial. Strong beer and pea-porridge are recommended as tonics.

In cases of surfeit, indigestion, or injury from eating slightly poisonous matter, swine will refuse their food, constantly lie down, and have the stomach distended. In this case, two heads of garlic, mixed with 6 oz. of fresh butter, will afford relief, given every 6 hours. Soap-suds are said to have the effect of emptying the stomach.

The most formidable of the diseases to which swine are liable, is inflammation of the lungs, and other internal parts. This disease has been known to destroy a fourth of the hogs in a distillery in the course of a few weeks. The chief indications of the disease will be the distressing cough, the heaving of the flanks, and the refusal of all food. Bleeding must be promptly resorted to, and moderate purges cautiously administered. The safest aperients are castor oil or Epsom salts, after which the following sedative powder may be given: fox-glove (*digitalis*) 2 grs., antim. powd. 2 grs., nitre half a drachm.

In cases of murrain, a species of leprosy, which prevails chiefly in hot seasons, the best advice that can be given is to keep the animal cool, and not suffer carrion or portions of animal food to be given.

The health of swine is to be estimated by their cheerfulness, by the gloss upon their coats, their skin being wholly free from eruption. If pigs snort on being disturbed, it is an excellent sign of sound health and good keep. The state of the excrement or digestions will generally indicate pretty correctly the thriving condition of the animal, for unless these are of a firm consistence, the hog will not fatten rapidly. If store or stock-pigs are kept well and in good condition, it will prevent most of the diseases to which the animals are subject, and they will also thrive and fatten at half the expense when shut up for that purpose. From the confinement of the hog, and the nature of

this food, a description of dyspepsia takes place, a superabundant acid is formed in the stomach, and, the skin sympathizing, cutaneous eruptions display themselves; one of the best prophylactics in such a condition of the animal are cinders or charcoal. It operates as a most salutary tonic, and improves the general powers of digestion. Hogs are so fond of cinders, that when a handful of them is thrown into a sty, the animals fight for them.

Weaning.—If the young pigs have been well fed, they may be weaned after six weeks, and in all cases in two months. In their after treatment, when separated from their mother, they should be regularly fed 3 times a day, and their food should at first consist of warm liquid food, such as whey, milk, or the refuse of the dairy and kitchen, &c., raised to the temperature of the mother's milk by the addition of a little warm water. They will soon learn to partake of more solid substances.

The rearing and fattening of the hog presents little difficulty, for this animal is reared equally well on a small or a large scale; by the cottager, from the wash and refuse of his house and garden, or by the extensive breeder, who has more abundance and variety of food at command.

As the situation, climate, crops, and other local circumstances must to a great extent regulate the breeding and feeding of swine, it is quite impossible to lay down rules of general application, or to describe a practice which necessarily varies in almost every district. I shall content myself, therefore, with noticing a few of the substances upon which the animals are usually fed and found to thrive best.

It constitutes the principal value of swine, that they can be maintained on almost any kind of aliment. In America, Indian corn or maize is largely used. In the West Indies, the cane tops, refuse trash from the cane after the juice has been expressed, and the washings of the sugar-coolers, boilers, distillery vats, &c., form their principal food. In Newfoundland, Labrador, and other parts where fish is plentiful, they are freely fed upon the waste refuse from the fisheries; and although they thrive well upon this food, their flesh is coarse and strong.

Where the farmer or breeder has a rich piece of grass or clover unemployed, hogs which are not put up for feeding may be turned into it with advantage; but there is an objection to this on the score of the manure which is lost. When the field is so situated that the hogs can return at night to the well-littered sties, the practice may then be found beneficial.

But roots, rather than herbage, is their natural food, such as earthnuts, the roots of couch grass, &c.: acorns, chestnuts, beechmast, hazel-nuts, and other dry seeds and fruits, are eagerly consumed by them; and hence, in the countries in the south of Europe, in the neighbourhood of forests where these abound, they are frequently suffered to range at large and collect their own food. Hogs are also very partial to juicy and pulpy fruits, such as the grape, the orange, the refuse of apples, pears, olives, &c., after the juice has been expressed. Although hay and dried fodder is not adapted

to the feeding of swine, if these substances are chopped and boiled they will not refuse them.

Moist, succulent, green food, such as clover, tares, lucern, sainfoin, buckwheat, succory or chicory, cabbage, lettuce, &c., is more suited to their taste. Every kind of farinaceous substance, such as oat-meal, barley-meal, bran, maize, millet, pease or beans bruised, and indeed the seeds of all gramineous and leguminous plants, are the most fattening substances that can be given to them. They will feed greedily, and thrive surprisingly, on most kinds of roots and tubers, such as carrots, turnips, beets, potatoes, the Jerusalem artichoke, &c., particularly when prepared by boiling. It may be taken as a general rule, that boiled or prepared food is more nutritious and fattening than raw or cold food; the additional expense and labour will be more than compensated by the increased weight and quality. Thus cabbage, turnip and potato tops, the husks of peas and beans, and even many green weeds, such as nettles and thistles, fatten; and others, void of poisonous qualities, will be found very fattening if boiled and mixed with other food, and given, as most food should be, lukewarm. The refuse of the kitchen, garden, and dairy, the grains and wash or liquid refuse of breweries, distilleries, and sugar manufactories, where they can be obtained, the sweepings of barns and granaries, will all be found exceedingly fattening. Animal substances, particularly fish, should, however, be seldom or never given as food, since they will necessarily impart a strong and disagreeable flavour to the meat. A little salt should be generally added to all their victuals, which will create thirst, and induce the animals to consume a greater quantity of food. Fermented wash is found to fatten swine much quicker than fresh food.

Ringing.—The practice of ringing swine, which was usually performed at the time of weaning, is growing into disuse, and the ringing is not advisable, inasmuch as it not only proves painful to the animal, but troublesome to the owner; for it frequently happens that the ring breaks, or is worn out; the cartilage gives way, and the ring has to be as often replaced by a fresh operation. A more preferable and lasting process is now adopted, which consists in either cutting the two strong tendons of the snout (the cartilaginous and ligamentous prolongations) about an inch and a half from the nose, by a slight incision with a sharp knife, or else to shave or pare off the gristle on the top of the nose, which may be done without prejudice to the animal, when about two or three months old. The place heals over in a short time, and the animals are thus prevented from grubbing or tearing up the ground. (*Prize Essay on Swine*, by P. L. Simmonds; Wilson "On the Hog," *Quart. Jour. of Agr.* vol. iii. p. 38; *Low's Illustrations of the Breeds of Dom. Animals.*)

SWINGLE-TREE. See PLOUGH.

SWING PLOUGH. See PLOUGH.

SYCAMORE. See BUTTONWOOD.

SYTHE. See SCYTHE.

T.

TACAMAHACA. See POPLAR.

TAG. A term applied to a young sheep of the first year. See SHEEP.

TALLOW (*Gerin. talg*). The fat obtained by melting the suet of the ox and sheep, and straining it so as to free it from membrane. When pure, it is white, tasteless, and nearly insipid; but the tallow of commerce has usually a yellow tinge, and is divided, according to the degree of its purity and consistence, into candle and soap tallow. Tallow consists of stearine, eluine, margarin, and traces of hircin. According to Chevreul, its ultimate components are 78.996 of carbon + 11.708 of hydrogen + 0.304 of oxygen in 100 parts. It is used in medicine as an emollient and a demulcent. Tallow is an article of great importance. It is manufactured into candles and soap, and is extensively employed in the dressing of leather and in various processes of the arts. Besides the supplies of native tallow, a very large quantity is annually imported into England, principally from Russia. The exports of tallow from Petersburg amount, at an average, to between 3,500,000 to 4,000,000 poods, of which the largest portion by far is brought to England. (*McCulloch's Com. Diet.*)

TAMARISK (*Tamarix*). This is a genus of very elegant shrubs. The hardy indigenous species, or French tamarisk (*S. Gallica*), is well suited for ornamenting shrubberies: it will grow in any soil or situation, and is freely increased by cuttings planted in the open ground, in spring or autumn. Sheep feed greedily on this species for the sake of its salt taste. The stem is slender, with abundance of long, drooping, smooth, red, shining branches. Leaves minute, lanceolate deciduous, spurred, acute. Lateral cylindrical clusters of numerous, nearly sessile, reddish or white bracted flowers, without scent.

TANK. In gardening, a cistern or reservoir made of stone, timber, or some other material. Tanks are used for collecting and preserving water during a scarcity or drought. They are sometimes built in the ground, and lined with lead or cement. Where wells cannot be sunk, and water is scarce at some seasons, tanks are necessary appendages to a house.

A tank, 12 feet by 7 feet, has been found sufficient to supply with water a large family and 6 horses: this was surrounded by only 4½ inch brick-work, resting solid against the sides, in consequence of being, like a decanter, smaller at the bottom than higher up; and the dome is constructed on the Egyptian plan, by projecting horizontally each row of materials one-third of their length beyond those below, by filling up the back with earth as it proceeded, to balance the weight of this projecting masonry.

At the Eastbourne work-house for 14 parishes, a tank has been made 23 feet deep by 11 wide, of the roughest materials, being only flint stones, and though they require more mortar than if they had been regularly shaped, only 90 bushels of lime were allowed, including 7

coats of plaster, and the workmanship is executed like field walls at 10s. per 100 square feet; the only essential being that no clay be used (which worms in time bore through), and that the lime, or Parker's cement, be good.

A current of air is said to promote the purity of water in tanks, which is easily effected by the earthenware or other pipe which conveys the water from the roof being of 6 or 8 inches in diameter, and an opening left for the surplus water to run away; and where the prevailing winds do not blow soot and leaves on the house, the water remains good, even for drinking, without clearing out the rubbish more than once a year; but, in some cases, filtering by ascension may be found useful, and effected by the water being delivered by the pipe at the bottom of a cask or other vessel, from which it cannot escape till it has risen through the holes in a board covered with pebbles, sand, or powdered charcoal. See RESERVOIRS, PONDS, &c.

TANNER'S BARK. The bark of oak, chestnut, willow, larch, and other trees, which abounds in tannic acid, and is used by tanners for preparing leather. After being exhausted of the tanning principle by being chopped into small pieces, or bruised and steeped in water, it is laid up in heaps to dry, and sold to gardeners for the purpose of producing artificial heat by fermentation in pits or beds, in bark-stoves or other out-houses. See BARK and FARM-YARD MANURE.

TANNIC ACID. This term has been especially applied to a substance obtained by Pelongé, by acting upon bruised galls by common unrectified ether, in a long, narrow funnel or percolater. Tannic acid is a white uncrystalline powder, very astringent, little soluble in water, and reddening litmus. When moistened and exposed to air, it attracts oxygen, is decomposed, and is converted into gallic acid. It is extremely astringent, and appears to be the active principle of tanning substances (tannin) in general. Its ultimate elements are 30 atoms of carbon, 18 of hydrogen, and 24 of oxygen.

TANNIN. A word synonymous with tannic acid, the pure astringent principle upon which their power of converting skin into leather depends. Its leading character is its property of producing a dense whitish precipitate in a strong solution of animal jelly, such, for instance, as isinglass; and on this account it condenses the gelatin of animal hides, and, rendering them impermeable to water, converts them into leather. It may be obtained tolerably pure by infusing bruised grape-seeds in cold water, or more circuitously by adding acetate of copper to filtered infusion of galls, washing the precipitate, and decomposing it (diffused through water) by sulphuretted hydrogen. On evaporating its solution, it is obtained as a pale yellow extract of a strong astringent taste. The action of astringents upon persalts of iron has given rise to its distinction into two varieties, the first changing them to deep blue or black, the second to green. The tan of galls, oak, bark, grape-seeds, &c., possesses the former property; that of catechu and tea, the latter. (*Brande's Dict. of Science.*)

TANNING. The art of preparing leather from raw skins and hides so as to render them

more pliant, durable, and impermeable to water. The processes employed for this purpose are various, every tanner adopting some peculiar or favourite method.

A discovery has recently been made which seems likely to revolutionize the tanning trade. By means of a tanning machine, or pair of horizontal rollers fixed over a tan-pit, between which is fixed a band or belt of hides attached by ligatures to each other, to the number of 50 to 100, and by which the rollers are constantly fed or supplied, the hides are lifted out of the pit on one side of the machine; as they pass between the rollers, the exhausted ooze or tanning liquid is pressed out of them, and they are deposited in folds in the pit on the other side of the machine, where they absorb another supply of fresh tannin. The first hide having been inserted between the rollers, the others follow in succession, and upon arriving at the end of the band the motion of the roller is reversed, and the belt is returned through the machine to receive another squeeze. This alternating motion is constantly repeated, the pit being replenished from time to time with fresh solutions of tan, till the operation is completed. The effects produced by this simple plan, are—
1. The shortening of the time of tanning to one-fourth of that generally required. 2. The production of a considerable increase of weight. 3. The leather tanned by this method resists water longer than that tanned by the old process. 4. The new method is cheaper than the old. 5. It is applicable to the existing tanneries, at a comparatively trifling expense, with a capability of working in rounds or series, and of expending tan or liquor. 6. That it is available for all sorts of leather.

TANSY (*Tanacetum*). The species of tansy are not possessed of much beauty. The hardy kinds succeed in any common soil, and are readily increased by rooted slips of the fibrous creeping root. They increase freely by cuttings. Withering asserts that if meat be rubbed with the leaves of tansy, the flesh-fly will not touch it. In England the only indigenous species is the common tansy (*T. vulgare*). Every part of the herb is bitter, with a strong but not unpleasant scent. The qualities are esteemed of a tonic and cordial nature, expelling intestinal worms, and strengthening the digestive powers. The plant, however, does not agree with every stomach. There are two varieties of this species, the variegated, and the curled or double tansy, which is kept for use in gardens, as being more wholesome or milder than the wild sort; but in England tansy pudding is out of fashion.

TAPE-GRASS or **EEL-GRASS.** See VALESNERIA.

TAPIOCA. A white, edible substance, consisting of very pure starch, obtained from the root of a tropical plant called manioc (*Jatropha manihot*) or cassava.

TAP-ROOT. A root which penetrates deep and perpendicularly into the ground without dividing, and has few lateral fibres. In shape it resembles a spindle; hence it is botanically termed a fusiform root. But the main trunk of any root that penetrates vertically deep into the ground is called the tap.

TAR. A dark brown, viscid liquor, obtained by charring the wood of the fir tree; it consists of resin, empyreumatic oil, and acetic acid. When inspissated by boiling, it is converted into pitch. The manufacture, which is carried on in the pine forests of Northern Europe, is simple. A conical hole, usually in the side of a bank, being made, roots and fillets of pine are let into the cavity, and the whole is covered with turf, which is beat firmly down above the wood. The wood being kindled, a slow combustion takes place. A cast-iron pan at the bottom of the cavity receives the fluid, and has a spout which projects through the bank and carries the tar into barrels. As quickly as the barrels are filled, they are closed with bungs, when the material is ready for exportation. This manner of preparing tar has been derived from the earliest ages. Tar is a very compound substance; it contains modified resin, and oil of turpentine, acetic acid, charcoal, and water. Tar is used in medicine as well as in the arts. It is an excellent topical stimulant, when made into an ointment with lard, in dry skin diseases. These two substances, tar and pitch, are of extensive use in the arts.

Tar may be found useful as an application for cuts in sheep by clipping, and also to the parts affected by the fly. It is also of great use in some cases for applying as a paint to boarding, &c.; but in this use a little tallow or other coarse fat should be melted with it, as by this means it goes farther, and resists the weather more effectually. Large quantities of tar are made from the abundant pine forests of North Carolina. See also **GAS-TAR**.

TARE EVERLASTING. See **LATHYRUS** and **VETCHLING**.

TARES (*Ervum*, from *ervo*, tilled land; some of the species are a pest on cultivated ground). The word tare is frequently applied to what is properly the common vetch (*Vicia sativa*). There are in England two indigenous species of tare, which are troublesome annual weeds.

1. Smooth tare (*E. tetraspermum*, Pl. 10, c), which grows in corn-fields, hedges, and thickets, particularly such as are rather moist. The root is small and tapering. The herbage is besprinkled with fine, soft hairs, especially the flower-stalks and calyx. Stem weak, quadrangular, branched from the bottom, leafy, climbing to the height of 2 or 3 feet. Flowers mostly in pairs, small, drooping, pale gray; the standard streaked, and the keel tipped with a deep blue. Legumes pendulous, oblong, bluntish, smooth. Seeds most generally 4.

2. Hairy tare (*E. hirsutum*), which is in habit much like the foregoing; the flowers are in clusters of 5 or 7, very small, pale blue, or almost white, with two dark spots on the keel. Legumes short, dark brown, besprinkled with hairs, to which the specific name alludes. Seeds two in each legume, large and prominent. See **LATHYRUS**, **SOILING**, **VETCH**, **VETCHLING**, &c.

TARO. A bulbous-rooted plant of the genus *Arum*, a native of the valley of the Columbia river. It is planted on hills, and cultivated in the manner of rice, on ground so situated as to be partially flooded with water. It comes to maturity in 8 or 10 months from the time

of planting. To prepare them for food, they are roasted; they then become a substitute for bread; or they are made into *poi*, by pulverizing and converting them into a paste.

TEAM. A number of horses or oxen drawing at once in the same plough, cart, or other carriage.

It has been long a disputed point among farmers whether horses or oxen form the most economical and advantageous team for the purpose of the cultivator in performing his work. The question remains still undecided, though many intelligent farmers in England now incline to the side of horse teams, except in particular circumstances and situations.

TEASEL, or **TEAZLE** (*Dipsacus*, supposed to be derived from *dipsao*, to thirst; in consequence of the leaves holding water). It is a curious genus of plants: some of the species are pretty flowering plants, especially the small teasel. They grow well in any common soil, and are readily increased by seeds. There are in England three native species, all biennial.

1. The manured or fuller's teasel (*D. fullo-rum*), although growing about hedges, can scarcely be considered wild. This species is extensively cultivated in the west of England, the dried heads of which furnish the teasel used by fullers in dressing cloth. The root is fleshy, branched, and tapering. Stem 5 to 6 feet high, erect, strongly furrowed, prickly, leafy, branched at the top. The leaves sessile, combined, serrated, with prickly ribs. Flowers whitish, with pale purple anthers, very numerous, in a close, obtuse, conical head, the intermediate scales bristly at the edges; rigid and hooked at the points, by which they are rendered serviceable for teasing woollen cloth, being fixed in several rows in wooden frames with handles adapted for that purpose. The scales are just strong enough to raise the wool, giving way before they can injure the cloth. Many mechanical inventions have been attempted to set aside the teasel, but without success, all of them having proved inefficient or injurious. The dressing of a piece of cloth consumes from 1500 to 2000 teasels. They are repeatedly used in different parts of the process. Some esteem this but a luxuriant variety of the following, as it requires a very richly manured soil to preserve its characters and useful properties.

2. Wild teasel (*D. sylvestris*). In England a very common species about moist hedges and by road-sides, less robust than the foregoing; about 4 feet high. Leaves opposite, serrated. Scales of the receptacle straight. Common calyx inflexed, longer than the head.

3. Small teasel, or shepherd's staff (*D. pilosus*). This species grows in moist, shady places, on a chalky or limestone soil. This is a useless weed, but not troublesome to the farmer.

TEATHING. Provincially, the practice of eating turnips off, upon young wheat crops, in the early spring months, by live-stock, as sheep and bullocks. It is often written tathing.

TEETH. See **AGE OF ANIMALS**.

TEMPERATURE. See **ATMOSPHERE**, **ALTITUDE**, **CLIMATE**, **EARTHS**, **ELEVATION**, **METEOROLOGY**.

TENANT (*Tenens*, from the Latin *tenere*, to

hold). In law, one who holds or possesses lands or tenements by any kind of right, either in fee for life, for years, or at will. See LEASE.

TENDRILS. The curling, twining organs of prehension, by which some plants lay hold of others.

TEN-O'CLOCK. A troublesome perennial plant and weed, with a bulbous, fibrous root, difficult to destroy, as it will grow even years after the tops are cut off. Fields must not be ploughed. This foreigner has escaped from the gardens, and has become a grievous nuisance on many farms. Although it rarely perfects its fruit, the bulbs are propagated laterally with great rapidity; and are extremely difficult to extirpate. One native species has been found in the United States, on the Rocky Mountains. (*Flora Cestricea.*)

TETHERING. The practice of confining to precise limits or pasturage any kind of stock, by means of light chains or ropes fastened to iron pins (with swivel rings) driven into the ground. For the small farmer with indifferent fences, or for gentlemen with limited and ornamental lawns, this practice, which secures shrubs and pleasure-grounds from injury, is obviously often an advantageous system; and indeed a rich lawn immediately in view of a house is the fittest situation for tethering, as an impoverished field would disappoint, and demand a too frequent and therefore troublesome change of tether. The practice is almost universal throughout France, even in common farms.

THATCH. Straw, or any other dry vegetable substance, laid on the top of a building, rick, &c., to keep out the wet.

There are many different sorts of materials that may be made use of as thatch, but the straw of wheat and rye, when well laid, forms the neatest and most secure covering for general purposes.

The reed is a highly valuable article for the purpose of thatch, where a lasting roof is required; but is much too expensive at first, although it is cheapest in the end. Reed is also thought to be too stubborn for common purposes. Fern is also occasionally used. See FERN.

THERMOMETER (Gr.). An instrument for measuring variations of heat or temperature, too well known to need description. See ATMOSPHERE, CLIMATE, METEOROLOGY, &c. See also Table in next column.

THISTLE. A well-known prickly weed, common in corn-fields and pastures. Wherever thistles grow naturally it is a sure sign that the land is strong, and of a tolerably good quality; but they are at the same time a great annoyance to every plant intended to be cultivated.

By an excellent regulation in France, a farmer may sue his neighbour who neglects to thistle his land at the proper seasons, or may employ people to do it at the other's expense: and it were to be wished that a similar law was in force here, to prevent the wide-spreading mischief occasioned by the seeding of this pernicious weed; among which may be reckoned, besides its choking the young corn, that of wheat in particular be not well thistled, the

Table exhibiting the degrees of the Centigrade and Fahrenheit's Thermometers corresponding to those of Reaumur's Thermometer.

reapers take up the grip so tenderly, lest they should prick themselves, that, by their loose handling of them, they sometimes leave upon the ground corn enough to sow the whole field. There are no plants over which the economical farmer ought to keep a more watchful eye than the thistle tribe, as they are not only useless, but occupy much ground, and, being furnished with winged downy seeds, are capable of being multiplied and carried almost to any distance: besides, they do much mischief by impeding the work both in handling hay and corn crops. It is, of course, a matter of much consequence to be well acquainted with the qualities of each kind, in order to enable us to judge with certainty how far and by what means their destruction may be effected in the most certain and ready manner.

There are in England many sorts of thistles, but those which chiefly deserve the attention of the farmer are either of the annual, biennial, or perennial kinds.

The annual species of thistle are the musk-thistle (*Carduus nutans*), the milk-thistle (*C. marianus*), the welted or curled thistle (*C. acanthoides*), the slender-flowered thistle (*C. tenuiflorus*), the common sow-thistle (*Sonchus olera-*

zeus). The principal biennial thistles are the spear or bull-thistle (*C. lanceolatus*), the marsh-thistle (*C. palustris*), and the cotton-thistle (*Onopordum acanthium*). The perennial species are two, the common sow-thistle (*Sonchus arvensis*), and the common or field-thistle (*Cnicus arvensis*), or Canada thistle. The dwarf or stemless thistle (*C. acaulis*), the star-thistle (*Centaurea calcitrapa*), and the common carline-thistle (*Carlina vulgaris*), are more frequently found to infest dry sandy pastures and calcareous soils than loamy or damp grass-lands. Where they prevail to a great extent, there is no remedy like breaking up the land and taking a course of crops; for palliative remedies are of little avail. Hand-weeding, when the weeds are confined to local spots, and are only just beginning to spread generally over the soil, will be found effectual; but when once the pasture becomes generally infected with the seeds and roots of these plants, no time should be lost in using the plough, harrow, and horse-hoe, and a judicious course of cleansing crops before returning the land again to permanent pasture.

Among the species of pasture-weeds that generally prevail in loamy soils, and are also prevalent in clayey and damp soils, are the marsh or red plume-thistle (*Cnicus palustris*), the meadow or small purple plume-thistle (*Cnicus pratensis*), and the melancholy plume-thistle (*Cnicus heterophyllus*). In crops of artificial grasses, such as sainfoin, lucern, &c., where the dwarf plume-thistle (*Cnicus acaulis*) prevails, and when it is impracticable, under such circumstances, to draw out this weed without injuring the crops, a good remedy will be found in the use of common salt. Children may be employed to apply the salt by hand to the crown of the weed. If the least part of the root of the thistle be left, it springs up season after season. Besides possessing this principle of vitality in the root, its seeds are so winged with down as to render dissemination, even to a great distance, by means of the wind, almost certain.

It is obvious that the annual and biennial species of thistles may be readily removed by preventing their running to seed and disseminating themselves, which is best effected by carefully eradicating them, or frequently mowing them over close to the surface, and rolling. But in the perennial kinds, from their roots continuing in the earth, increasing and throwing out new shoots or stems every year, there is much difficulty in extirpating them, and they perhaps can be no other way destroyed than by rooting them out of arable land by deep ploughing and frequent harrowings, or by fallowing or laying the land down to pasture; the annual species seldom appear in pasture-lands. But for destroying the common thistles the best method is by weeding-pincers, or the finger and thumb when in loose land, cutting them over in the bleeding season frequently by weeding-knives, and applying salt to the cut stalk.

The most common thistle found in the United States is the *C. lanceolatus*, a biennial. The most troublesome pest, the *C. arvensis*. (See CANADA THISTLE.) Dr. Darlington thinks the yellow thistle a foreigner introduced into the

United States. It is the most prickly of all the tribe, and hence called by botanists *Carduus spinosissimus*, and *Cnicus horridus*. The root of this is considered by some biennial, by others perennial. The tall or tallest thistle (*C. altissimus*), is common along fence-rows, &c., in the Middle and other States. The dwarf *carduus* (*Carduus Pumilus*), is common in Pennsylvania and other Middle States, growing in old fields, &c., from 1 to 2 feet high, with flowers of a pale reddish-purple, and quite fragrant. The heads are handsome, and the largest of any other American species. Several other species of thistle are found in the United States. See CANADA THISTLE.

THISTLE, PLUME (*Cnicus*). This is a separation from the genus *Carduus* made by Sir J. E. Smith. They are prickly, herbaceous plants, and differ chiefly in the down being evidently feathery, not merely rough. The biennial species may be readily destroyed by mowing before the flowers form seed. There are in England nine indigenous species of plume thistle. Some of which are common in waste ground, moist meadows, &c. Those which give most trouble to the farmer are, the

Marsh plume-thistle (*C. palustris*), a biennial, growing plentifully in moist meadows or pastures, and watery spots by road-sides. Stem from 3 to 6 feet high.

Creeping plume-thistle (*C. arvensis*). A very troublesome perennial weed in cultivated fields and by way-sides, from its fleshy root, which is very tenacious of life, creeping deeply into the earth to a great extent. Stems 3 or 4 feet high.

Branching bog plume-thistle (*C. Forsteri*). A perennial, flowering in July and August, with a tapering root.

Woolly-headed plume-thistle (*C. eriophorus*) A large and conspicuous perennial plant, growing in waste mountainous ground, and by road sides, on a limestone or chalky soil.

Melancholy plume-thistle (*C. heterophyllus*). A perennial, growing in moist mountain pastures in the north.

Meadow plume-thistle (*C. pratensis*). A perennial, growing in low, wet meadows and pastures, especially among trees. Root fibrous.

Dwarf plume-thistle (*C. acaulis*). A perennial, growing on chalky and gravelly soils. Root woody, running deep into the ground. Stem entirely wanting. The large bright-green leaves, spreading close to the ground, in a circle near a foot in diameter, choke all other herbage.

THORN (*Cratægus*). A name given to several indigenous shrubs and small trees. See BLACK-THORN, BUCKTHORN, HAWTHORN, WHITE-THORN, &c.

Of this genus of shrubby trees so valuable in an agricultural point of view, there are many species and varieties. Dr. Darlington describes the following as found in Chester county, Pennsylvania: 1. The Newcastle or cockspur thorn (*C. crus galli*). Two varieties of this exist: the most common of which is much employed in making the fine hedges for which Newcastle county, Delaware, is celebrated. Dr. Darlington thinks that, with proper management, this kind will ultimately make a more

durable and effective hedge than the Washington thorn (*C. cordata*), which is now generally used in Chester county. It is a more rugged plant, and seems to be less liable to disease, or to be injured by insects, than the Washington thorn. (*Flora Cestrica*.)

2. The small-leaved thorn (*C. parvifolia*), a rugged little bush abundant in New Jersey.

3. Thorn-bush or dotted cratægus (*C. punctata*), a red-fruited variety. The fruit is large, half to two-thirds of an inch in diameter, mostly three-seeded, red, sometimes yellow when mature, dotted and esculent.

4. Black-thorn (*C. flava*), yellow cratægus, an apparent misnomer. The fruit is pear-shaped, large (about half an inch in diameter), three or four-seeded, greenish-yellow, with a tinge of dark red when mature, esculent, but rather insipid.

5. White-thorn or crimson cratægus (*C. coccinea*). This is the most common species in Chester county, Pennsylvania. The thorns have more resemblance to the cock-spur, than those of the real *crus galli* or Newcastle thorn. The fruit is one-third to half an inch in diameter, and bright purple when mature.

6. The Washington thorn (*C. cordata*). This species, says Dr. Darlington, was introduced into Chester county from the neighbourhood of Washington city, and is now extensively used in hedging. It grows fast in favourable situations, under good management, and will make a handsome hedge in about 10 years from the time of planting. It does not succeed well on dry, rocky banks, and especially in the red shale districts. The young branches are also subject to disease from the puncture of insects. "I have used this thorn," says Dr. Darlington, "to a considerable extent, and have succeeded in obtaining some pretty fair hedges; but I am now strongly inclined to the opinion that the *C. crus galli*, or cock-spur thorn, is entitled to the preference, for that object. One important fact, however, applies to every sort of thorn, and should be remembered by all persons who may undertake hedging, which is, that if they are not carefully attended to, and skilfully managed, the hedges will become a nuisance and a source of vexation, rather than a benefit, and had better never be attempted. With due care and skill, they make a valuable and ornamental enclosure.

7. Hawthorn or English thorn (*C. oxyacantha*), sharp-thorned cratægus. This species (of which there are several varieties in Europe) was introduced many years ago, and is apparently naturalized in a few localities; but does not seem to extend itself much. It is said to be the favourite thorn for hedging in England; but is rarely applied to that use here. Some 10 or 12 additional species have been enumerated in the United States; but the genus stands greatly in need of a careful revision. (*Flora Cestrica*.)

Many species of the thorn genus are highly ornamental. Of these the most beautiful of all thorns when in bloom, is the *C. oxyacantha rosea superba*, with deep crimson flowers and small red fruit. The sweet-scented thorn (*C. odoratissima*) has very large, pale red fruit. The large tansy-leaved thorn (*C. Lecana*), has

large pale red fruit. The small black-fruited thorn (*C. Oliveriana*), bears very profusely, but matures late. The new double-scarlet is a most beautiful variety of the *C. oxyacantha rosea superba*, just mentioned.

THORN-APPLE (*Datura*). An ornamental genus, but chiefly composed of plants possessing very deleterious qualities. One species indigenous to England, is the common thorn-apple (*D. stramonium*), an annual, which grows in waste grounds and dung-hills. It is a bushy, fetid herb, 2 or 3 feet high, of a narcotic quality, and greatly in repute as a remedy for the asthma, being smoked like tobacco. The leaves are ovate, smooth, sinuated. The flowers are axillary, erect, white, sweet-scented, especially at night, about 3 inches long. Fruit as big as a walnut in its outer coat, very prickly. Seeds black. In the United States it goes by the name of Jamestown weed, doubtless from the place where it was first naturalized, in Virginia.

THRASHING, or **THRESHING**. The act of beating out the corn from grain or other crops. The flail was the implement formerly used for thrashing corn, and which separated the grain from the straw and husks very effectually and expeditiously; but as it is now become expensive, and always bruises a great many seeds, it has been attempted to avoid these inconveniences by proper machines provided with a number of flails, or other parts answering the same purpose, made to move by the power of water, wind, or horses. By this means the business of thrashing is found to be performed cheaper, more expeditiously, and with less damage to the health of the thrasher, which is frequently thought to be injured by the dust, &c., which arises in the common way of thrashing, as well as by the extreme laboriousness of the work. Various machines for effecting the purpose of thrashing have been lately invented. See **FLAIL**, and **THRASHING-MACHINE**.

THRASHING-MACHINE. To the farmer on an extensive scale, the thrashing-machine is absolutely necessary. He cannot wait for the tedious operation of the flail to prepare a delivery of corn for a given day, or pressing purpose; nor can he, without the risk of pilfering and imposition, keep his barn constantly open for thrashers. The flail, however, is still the implement in general use among all who farm on a scale not sufficiently extensive to require any of the complex machinery which modern skill has invented. The advantages of the flail are, its simplicity, the power of giving employment to the labourers in the barn during wet days, and the convenience of having fresh straw for fodder every day.

The following description of the thrashing-machine is chiefly derived from the valuable essay *On Agricultural Implements*, by Mr. J. Allen Ransome, of Ipswich, England.

In ancient times various modes of thrashing out grain were resorted to, and we read of "the bruising with the cart-wheel," "the sharp thrashing instrument having teeth," "the trampling under the feet of the unmuzzled ox," or "the rollers plain or fluted" mentioned in the later practice of continental agriculture. But of all these the flail alone remains in use

in England; and it is with this instrument, preserving very nearly its original form, by which till very lately the entire growth of corn and seeds in this kingdom were thrashed.

That the flail may be made thoroughly to effect, though at great cost of labour and time, the purpose of clearing the grain without damage either to the corn or the straw, is a point none will be inclined to dispute. But the disadvantages attending its use are not confined to waste of labour and time; for, though it may be granted that the operation, if properly performed, may be perfect, how difficult it is to secure its proper performance, every agriculturist whose journeys to his barn have from time to time interrupted his surveys of other not less important agricultural operations, can fully testify. It is evident that the latter part of this operation will require much more labour to produce a given quantity than its earlier stages; and hence the straw is frequently passed away partially thrashed, in order to procure a greater bulk in a given time. Nor are these disadvantages all with which we have to contend: constant inspection may, perhaps, to some extent, remedy them; but no attention will altogether suffice to remove the temptation to pilfer, which is continually presented where large quantities of grain are ever under the eye and in the power of those to whom a small portion is of great importance; and hence arises, even when undetected, and often indeed when not committed, a cause of painful temptation on the one hand, and injurious suspicion on the other.

To overcome these evils, prejudicial not only to the true economy of the farm, but to those feelings of confidence which, justly to sustain the social bond, should ever exist in the relation between the labourer and his employer, the attention of our enterprising neighbours in Scotland was first directed to the construction of machinery; and in 1732, Michael Menzies, a gentleman of East Lothian, invented and patented a machine for thrashing grain. We regret that, as nothing but the bare record of this invention is enrolled in the Patent-office, we have not been able to learn more of this, the germ of thrashing-machine invention, than that it was a contrivance by which a series of flails were made to revolve upon a cylinder; but we are pleased to be able in some degree to redeem it from the "condemnation of faint praise," with which we find its memory generally accompanied, by reference to the report of a committee appointed by the Society of Improvers in Scotland, to inspect its operation, and determine upon its merits. This committee, after various trials, reported it to be "their opinion that the machine would be of great use to farmers, both in thrashing the grain clean from the straw and in saving a great deal of labour; for one man would be sufficient to manage a machine which would do the work of six." They further recommended the society "to give all the encouragement they could to so beneficial an invention, which, being simple and plain in the machinery, might be of universal advantage." The society approved of the report, and acted upon the recommendation.

During the next period of twenty years we are not aware of any other attempts to carry out the object of thrashing by machinery; but in 1753-8, Michael Sterling, a farmer in the parish of Dumblane, Perth, applied the principle of the mill in common use for hulling flax to this purpose. This mill had a vertical shaft, with 4 cross arms enclosed in a cylindrical case, 3 feet 6 inches high, and about 8 feet in diameter. The shaft was made to turn at considerable velocity, and the sheaves were gradually let down from an opening at the top; the grain and straw, after being subjected to this beating, were then pressed through an opening in the floor, where rakes and fanners completed the separation of the grain from the straw and chaff. It was, however, found that this machine broke off the ears of barley and wheat instead of clearing them of the grain, and that at best it was only fit for oats.

It is curious to trace the various plans by which the desideratum of thrashing by machinery was attempted to be accomplished; a few of these we shall venture to bring before our readers, and a slight sketch of them will suffice satisfactorily to show that in following out the principles which distinguish Meikle's machine (hereafter to be mentioned), little of value has been lost to the public of those which have fallen into desuetude. In 1772, two gentlemen residing in Northumberland, Alderton and Smart, invented a machine, by which the sheaves were carried round between an indented drum of 6 feet diameter and a number of fluted rollers, which, pressing by means of springs against the fluted concave, rubbed out the corn from the ears; and in 1785, William Winlaw, of Mary-le-bone, patented an invention which he denominated a "mill for separating grain from straw."

This mill was made on a principle similar to the coffee-mill, but was found to exceed the simple object proposed in the specification, by *grinding* the grain as well as separating it from the straw. Other machines upon the plan of rubbing out the corn were also tried, but, on account of the damage done to the grain, were discarded. In addition to the mill invented by Winlaw, a machine was in 1792 patented by Willoughby, of Bedford, Notts, the principle of which appears to have been somewhat similar to that of Menzies; how nearly so, we regret we have not the opportunity of judging. It comprised a series of loose flails made to act upon a grated floor, and turned rapidly round by means of a horse-wheel. The straw was presented by hand to the action of the flails.

In 1795, an individual of the name of Jubb, residing at Lewes, obtained a patent for an invention of which the principal feature was the passing the straw between two rapidly revolving beaters, under which it was held by two feeding rollers, whence the corn fell into a winnowing-machine.

The inventive talent of the Americans was at this time brought to bear upon this important subject. James Wardrop, of Amphyll, Virginia, invented a machine, which was introduced into England about 1796, to be worked by two men; it was made with flails or elastic rods 12 feet in length, of which 12 were attach-

in series, each having a spring requiring a power of 20 pounds to raise it 3 feet high at the point; a wallower shaft, with catches or teeth, in its revolution successively lifted each flail in alternate movements, so that three of the flails were operated upon by the whole power, viz., 20 pounds. The flails beat upon a grating to which the corn is introduced by hand.

In 1785, Andrew Meikle, an ingenious mechanic of Tynningham, East Lothian, first introduced to the public, through the medium of a gentleman of the name of Stein, of Kilbogie, the invention whose principle has been the basis upon which the machines in use in Britain up to the present time have been mainly constructed. It appears that, his attention having been long turned to the subject, he discovered that the plan of rubbing would never be otherwise than attended with the disadvantage before alluded to; and his son George agreed with the gentleman above named to erect a perfect machine, and in 1786 he completed the first that was ever made, adopting the plan of introducing between two rollers the corn, which was then thrashed out by four beaters fixed upon a revolving drum, each striking, as it revolved, the corn held between the rollers. The machine alluded to was erected, and found to work exceedingly well. A patent was accordingly applied for, and, after some opposition from a party not concerned in the invention, obtained.

In the trials between the erection of the original machine and the obtaining the patent, a new principle appears to have suggested itself, viz., that of stripping off the corn from the ear by a comparatively sharp edge, or, as termed by him, "scutching out the grain," instead of beating it by a flat surface. The difference has been partially illustrated by supposing a handful of straw with the corn in the ear to be held in the hand, while with the flat sides of a two-foot rule the ears should be struck or beaten; this is the operation of the common beater. If, instead of striking the ears with the flat side, a sharp blow be given with the thin edge of the rule in the direction of the ear where the rule touches, it will strip the corn from the ear with less labour and with greater certainty. This may be called the scutching principle to which Meikle's beaters in his patent were applied.

It will not be uninteresting to learn, upon the authority of Sir John Sinclair, "that the inventor of this important machine was rendered comfortable in his old age, and enabled to provide for his family after his death, by the voluntary donations of his grateful countrymen." Not less gratifying is the testimony of Professor Low, in his admirable treatise on the *Elements of Practical Agriculture*, that "to Andrew Meikle, beyond a question, belongs the honour of having perfected the thrashing-machine. Changes and improvements have indeed been made on certain parts of the original machine; but in all its essential parts, and in the principle of its construction, it remains as it came from the hands of its inventor."

By the drawings and specification of Meikle's machine, it appears that, at the time of taking out this patent, the plan of shaking the straw by means of circular rakes had not been sug-

gested; and in the report drawn up for the consideration of the "Board of Agriculture" for the county of Northumberland, we find that, in 1789, the first machine having a circular rake attached, and with fanners below, to perfect the cleaning of the grain, was erected. Although it is not there stated, we have good reason to believe that this important improvement, occasioning the addition of but one light wheel to the machine, was the invention of J. Bailey, the enterprising occupier of Chillingham, one of the gentlemen appointed to draw up the report alluded to.

We have thus far traced carefully, and, we trust, correctly, the progress of the invention of the thrashing-machine used in Scotland, till it has arrived at very nearly its present perfection. Various combinations of mechanical powers, and many contrivances, have doubtless been since added to produce particular effects, which have progressively tended to its improvement and ultimate perfection.

It will be difficult, within the limits to which this article must necessarily be confined, to enter minutely into detail, or adequately to set forth the merits of the various inventions and improvements on this machine, for which in the course of the last half-century no fewer than 25 patents have been obtained; besides several awards from the Bath and West of England Society and the Society of Arts. But we should do injustice to the subject, did we not here mention the name of Lester, whose mechanical talent and skill as an engineer have not a little contributed to the establishment of a higher style of excellence in agricultural mechanics than was coincident with the then taste of the age in that much neglected department.

The machines now in general use throughout the eastern counties of England are, with few exceptions, portable. They are frequently the property of individuals who, itinerating from farm to farm, thrash at a certain price per quarter; the farmer finding horses, and, with the exception of the proprietor, who feeds the machine, the necessary complement of men. They are simply *thrashing* instruments, having neither circular rakes nor fanners attached. The beaters, 4, 5, or 6 in number, are so placed round the drum that their beating edge shall radiate from the centre. These strike upon the straw, which is passed along a feeding-board placed at an inclination of about 30°, tending to a point equidistant from the centre and upper part of the circumference of the drum. The concave describes the third part of a circle, and is formed alternately of iron ribs and open wire-work in segments, so placed that its inner surface may be brought into near contact with the edges of the revolving beaters, and susceptible of adjustments by screws to increase or diminish the distance. The usual plan is to place it with about $\frac{3}{4}$ of an inch space at the feeding part, and gradually to increase the distance to 1 $\frac{1}{4}$ or 2 inches at the lower end, where the straw is delivered upon a fixed harp or riddle, through which such part of the grain as is not driven through the wired part of the concave falls, while the straw is removed by forks.

The thrashing part, commonly called the barn work, occupies a space of 6 feet by 4½ feet, and, together with the apparatus by which motion is communicated (which is made either for 2, 3, or 4 horses' power), may at pleasure be elevated upon a pair of wheels and axle, and thus removed by two horses.

Many of these machines are made by persons who possess little claim to any mechanical knowledge, and who, purchasing the unfitted castings, by the help of village artisans, produce an imitation of those which are considered good. As the perfection of these machines must depend upon mathematical accuracy in the adjustment of all their parts, and in the truth and precision of their fittings, it is unreasonable to expect that this can be accomplished where no facilities exist beyond the forge and the work-bench; and hence arises a degree of discredit, which is unfairly thrown upon the principles upon which the machine is constructed.

With these machines, properly constructed, barley may be thoroughly thrashed with as little or less damage than with the flail, and wheat straw need not be so broken as materially to diminish its usefulness even for the purpose of thatching. We cannot, with Sir John Sinclair, reckon the circumstance of breaking the straw one of the *advantages* of thrashing by machinery, as we do not think it desirable that any slovenly performance of the thrashing-machine should trench upon the legitimate occupation of the chaff-engine; and we repeat our opinion that all disadvantages from the above-mentioned causes may, by a well-constructed machine and a competent manager, be entirely remedied.

The latest patent which is at present in operation is one taken out by Joseph Atkinson, of Braham Hall, Yorkshire, which appears to be of American origin. The thrashing or beating-out process is obtained by means differing from any previously mentioned; the drum being surrounded by a series of pegs, so arranged as in its motion to pass similar rows of pegs placed at intervals in a concave, surrounding nearly one-half of the circumference of the drum. This machine is not at present so fully introduced into England as to afford opportunity for fairly testing its comparative merits; and it would be unfair to give, upon slight evidence, an opinion which may have any tendency to increase the difficulty of the introduction of a new article. We can therefore say little more than that while such trials as have fallen under our own inspection have not convinced us of its superiority, we are inclined to the belief that the principle is not so defective as to prevent its being carried out to advantage, under such modifications as may be suggested upon further trials.

We have now to draw the attention of our readers to a machine in operation upon Lord Ducie's example-farm at Whitfield, of which it is probable, in a forthcoming report of that interesting establishment, that a full account, accompanied by the necessary drawings, will be given. Through the kindness of the manager, John Morton, in accordance with whose suggestions it was constructed, we have been

favoured with an opportunity of witnessing its performance, and with the following description, which we give in his own words:—

"This machine is worked by a steam-engine of six horse power. The corn is brought from the stack upon wagons running along a tram-road upon an inclined plane, to the doors of the building, whence, sheaf by sheaf, it is thrown by children into the buckets of an elevator, which, in its rotation, carries them to the feeding-board. This feeding-board is placed at a tangent from the drum parallel with its top; and, as in Lee's machine, and the portable machines in Suffolk and Norfolk, the feeding-rollers are dispensed with, an endless web gradually carries the unthrashed straw to the feeding-mouth, from which the revolving scutches rapidly convey it to the concave.

"The drum and concave, being the part on which the separating of the corn or thrashing principle depends, we shall first describe:—The drum is about 18 inches diameter, formed of sheet-iron strained round a cast-iron skeleton accurately turned; upon this the beaters, or rather scutches, formed of angle-iron with its edges planed, are so placed as to describe an angle with the surface of the drum, pointing forward in the direction of its motion; these project about seven-eighths of an inch. The screen or concave encloses the drum to the extent of about one-third of its circumference, and consists of 4 or 5 arched pieces of grating, 3 inches wide, jointed together. It is made of cast-iron bars, having a square section placed so that every one shall present an edge to the passage of the straw, uniting (as is not uncommon in other machines) the fluted concave of the Scotch machine with the wired grating of the English ones; the screen is supported on iron bolts, so that it approaches to within about one-eighth of an inch of the edge of the scutcher. Spiral springs surround these bolts, which permit the bars of the concave to yield when too much pressure may at any time occur between them and the revolving drum. The grain is thus separated, most of it passing through the screen of the concave; but in order that no grain shall be allowed to pass away with the straw, it is thrown upon the shaker below.

The motion given to the straw by this shaker is the most perfect we can conceive; the blows occasioned as each series of spars strike it from beneath, effectually remove every particle of loose grain, while the shaker rapidly carries forward the straw, and at its termination deposits it in the straw-house, while the corn sifted out by its action falls before the blast of a fanner (the construction of which is peculiar); and all the light grain and short straws thrown out by the first winnowing into the light corn spout is then taken up by another elevator, deposited again upon the feeding-board, and passed a second time through the drum, in order effectually to separate any that may remain. After passing through another winnower, the thoroughly cleaned corn is taken up by a third elevator, and dropped into a hopper, through which it passes into a sack, which is placed on a weighing machine, and it is there weighed and left thoroughly fit for market.

We have introduced at length the description of this machine, or rather series of machines, as being the most complete of any that have fallen within the range of our observation; the most comprehensive in its design, performing every operation, from receiving the sheaf at the barn-door to depositing its grain in a clean state weighed up in the sacks, and excellent in the greater part of its detail, which is carried out, both as regards ingenuity and workmanship, in a style very superior to the general character of agricultural machines.

With regard to the moving power most advantageously connected with the thrashing-machine, it may be observed, that where the locality admits of the use of a water-wheel, this power is most economical and easily managed; but the advantage is limited to peculiar situations.

Where the quantity of work to be performed is sufficient to repay the interest of outlay, expense of wear and tear, &c., a steam-engine would be most advantageously employed on the farm. Of its economy, as compared with either horse or manual labour, there need be no question. But as few farms in England at present have these appendages, the question for consideration is narrowed to the comparison between horses and manual labour. On the authority of Dr. Gregory, the dynamic power of a horse at a dead pull may be calculated in the main as equivalent to that of six men, or to 420 lbs., if exerted in a direct line; but the result of experiments made by Tredgold tend to prove that sustained effort at the rate of three miles per hour must not be calculated at more than equivalent to 120 lbs. drawn over a pulley. This, taking six hours of labour per diem as the utmost he would recommend, would be the maximum of useful effect. Under the circumstance of any deviation from a straight line, this must be materially reduced; and in describing a circle of 18 feet radius, the cramped position of the horse will probably prevent his power from being advantageously exerted to the extent of much more than half. It will, therefore, be seen that a very large proportion of dynamic effort is wasted; and this not only arises from the constrained position of the horse's movement, but from the friction of the mill by means of which motion is communicated to a machine.

It is affirmed by Emerson that a man of ordinary strength, turning a roller by the handle, can act for a whole day against a resistance equal to 30 lbs. weight; and if he works 10 hours a day, he will raise this weight through 3½ feet in a second, or about 2½ miles per hour.

Animal power is, however, so varied by the character of the exertion, that it is difficult to arrive at a correct calculation. The late Robertson Buchanan ascertained that in the action of working a pump, of turning a winch, of ringing a bell, or rowing a boat, the dynamic results were respectively as the numbers 100, 167, 227, and 248. See STRENGTH.

Having caused a machine with beaters to be constructed, worked by 4 men whose force should be exerted as in the manner of rowing a boat, the results, as compared with a machine requiring the force of 4 horses in a circle

of 18 feet radius, we found might be taken on an average as 5 to 12. It was thought the continuous effort might be for an equal length of time exerted by 6 men relieving each other at intervals, as by the same number of horses relieved in the same way.

We have not yet had opportunity to repeat the experiment; and we instance this only to show that, although advantage may be on the side of horse-labour for large quantities, manual force is not so inapplicable to this object as most writers have represented it to be; and we are of opinion that, on small farms, hand-machines may with great advantage be used. A simple and effective hand thrashing-machine, which was exhibited at the Royal Agricultural Society's meeting at Liverpool, obtained the commendation of the judges (vide their report). It is worked by 4 men, and the moving power being obtained by means of a lever on the one side, and by a crank handle on the other, the men working it may relieve each other by change of motion. It requires one man to feed the machine, and the number of hands necessary to bring the sheaves and remove the straw will depend upon the distance it has to be conveyed. When the straw is short, and the wheat of average yield and in good condition, it will thrash at the rate of 12 to 16 bushels per hour.

In England the cost of the thrashing-machines of former days varied considerably, and their performances were very unequal. It may not be uninteresting to compare them with those of the present day. The following are extracted from the *Agricultural Reports* :—

	Thrashing per Day.
In the reports of Roxburgh and Selkirk, in 1796, R. Douglas states that mills by water, or with 4 horses, would do great execution.	} 25 or 30 bolls, or from 150 to 180 bush.
In the report of Norfolk, in 1804, Arthur Young gives an account of machines which belonged to the following parties :	
Droziers, Reedham, built by Wigfull, cost 120 <i>l.</i> , worked by 7 persons and 6 horses.	} 40 co. wheat. 50 co. barley. 60 co. oats or peas.
Farrow, Shibidham, built by Wigfull, worked by 7 persons, and by 4, 5, or 6 horses.	} 20 co. wheat. 30 co. barley. 40 co. oats or peas.
Beck, Castle Rising, built by Wigfull, cost 200 guineas, worked by 6 persons, and 4, 5, or 6 horses.	} 32 co. wheat. 64 co. barley. 80 co. peas.
Whiting, Tring, built by Fordyce, from Scotland, cost 200 <i>l.</i> , worked by 6 persons and 6 horses.	} 24 co. wheat. 55 co. barley. 63 to 84 co. oats.
Bevan, Riddlesworth, engineer from Leith, cost 100 <i>l.</i> , worked by 10 men and 8 horses.	} 40 co. wheat. 40 co. barley. 50 co. oats.
Coke, Holkham, cost 600 <i>l.</i> , worked by 12 men and 8 horses.	} 64 co. wheat.
Reeves, Heverland, built by Assby, Blyboro', cost 100 guineas, worked with 2 or 3 horses.	} 30 co. wheat. 32 co. barley. 40 co. peas.
Styleman, Smithsham, cost 300 <i>l.</i> , worked by 10 persons and 8 horses.	} 80 co. wheat. 120 co. barley, peas, or oats.
In the report of Kent, R. Boys, in 1805, remarks on the only thrashing-mill then in Kent, which, by a number of improvements, and after many alterations, he finds to answer extremely well; and he states that it requires 4 horses and 12 men to work it.	} 24 qrs. wheat. 32 qrs. barley, 40 qrs. oats.
In Sir John Sinclair's <i>System of Husbandry</i> , published in 1812, we find an account of R. Kerr's machine, which, with 6 horses, 4 men, and 4 women, would thrash	} 50 bolls, or about 300 bushels of wheat.

Considerable improvements have since been effected. In the statements of the trials of implements at the Royal English Agricultural Society's meeting at Cambridge, in 1841, the quantity of wheat thrashed by two four-horse portable machines manufactured by J. R. and A. Ransome, of Ipswich, and R. Garrett and Son, Leiston, was respectively 61 bushels and $\frac{3}{4}$ of a peck, and 61 bushels and $\frac{1}{4}$ of a peck per hour; and the corn was clean thrashed and uninjured.

This must not be taken as a criterion on which to found an average, as it was doubtless the result of stimulated exertion; but it is not unusual with machines of this construction, with reaped wheat in fair condition, to thrash 100 co. or 400 bushels in a day of 10 hours, and the same quantity of mown barley.

It should, however, be observed, that these, having neither rakes nor fans, the work of which is done by hand, would require 8 men and 5 boys, and a change of horses in the day.

Thrashing-machines are now very generally used in the United States, to get out the crops of wheat, &c. Before their introduction flails were employed in the Northern and Eastern States, whilst in the Middle and Southern States, treading with horses and cattle was the customary mode of thrashing. The cost by employing the flail was generally estimated at 10 bushels out of every 100, which, when wheat was a good price, proved very expensive. The employment of horses, though expeditious, is very objectionable, the grain being rendered gritty and filthy, so as to lessen its value in the market. The practice, too, of setting horses at such hard and peculiar work in hot weather proved injurious and often destructive to them.

The notice furnished in this article of the successive improvements made in Britain, in contrivances for thrashing out grain, will show the efforts there made and the results obtained. Ingenuity would seem to have been still more actively employed in the same pursuit in the United States, where, within a few years past, more than 100 patents have been obtained for inventions and improvements of the thrashing-machine. These have nearly all involved two main principles: 1st, a beater consisting of bars; and, 2dly, a cylinder furnished with spikes instead of bars. This last may perhaps be called the American principle, *par excellence*. Where bars are used, the machine requires an increased velocity equal to 300 revolutions per minute, over what is requisite where the cylinder is furnished with spikes. It is for this reason chiefly, that the spike machines have been so much more generally used. It must, however, be observed, that where the beater is composed of bars, the force required to work the machine is about one-third less in performing the same amount of work. In Eams's patent, the bars are of wrought or cast-iron, notched on the edges.

Pitts's Thrasher and Separator is considered a machine by which a great saving of labour is effected over the ordinary machines, the operations of thrashing and cleaning being performed at the same time. The bundles are

fed to the machine at one end, and the clean seed, without a kernel being scattered, taken from the other. Its weight is about 700 lbs., and it occupies a space about 8 feet by 2 feet 4 inches. The whole machinery is durable, and easily kept in repair. It thrashes and cleans all kinds of grain in the best manner, performing the work at the rate of from 25 to 50 bushels per hour. Four hands are required to tend the machine when in operation, viz.—one to forward the bundles, one to feed, one to measure and put the grain into bags, and one to pitch the straw away as it comes from the machine. It can be easily moved from place to place, and attached to any horse power, and can be used in the field as well as on the thrashing-floor, there being no loss or scattering of grain after it is once fed into the machine. The late Judge Buel considered this machine as the best adapted to the purpose of any he had ever seen.

Horse Power.—The power almost universally employed to propel thrashing-machines in the United States is that adapted to horses. These are generally of a description which admits of transportation along with the machine from place to place. They are of two kinds, one called the *sweep power*, in which the horses attached pass round in a circle; the other called the *endless chain* or *tread power*, where the horse or horses move as if walking or trotting, but in consequence of the rotation of the endless chain of bars on which they are placed, always remain in the same place. *Mize's cast iron portable sweep power* is generally considered the best now in use, in the Middle States at least. Its weight is from 700 to 1000 lbs., and the price \$80 for a two-horse, and \$90 for a four-horse power.

The *endless chain* or *tread power* is coming into very general use, being specially adapted to farms where there is much barn or shed-room, admitting of the thrashing being done under shelter; whereas, with the sweep power, the operations require the open yard.

The tread power, called Pitts's, is now in high repute. These, as well as all other kinds of machinery used in thrashing, are extensively manufactured in Wilmington, Delaware, by Hollinsworth & Co., and may also be had of Mr. Chandler, manufacturer of agricultural implements, 196 Market street, Philadelphia, as also at most of the numerous depots for agricultural implements in that and other cities in the United States. The price of the one-horse endless chain power is \$75; of the two-horse do., \$85. It is said that a two-horse tread power is equal to a four-horse sweep power.

THREAVE. A quantity of grain, consisting of 24 sheaves. It is sometimes written thrave.

THRIFT (*Statice*, from *statizo*, to stop: in allusion to the powerful astringency of some of the species). The species of thrift ought to be in every garden, on account of their lively little flowers. There are three indigenous species of thrift or sea-lavender, all perennial, viz:—

1. The common thrift, or sea gilliflower (*S. Armeria*), which is a common ornament of rustic gardens, where it serves for edgings of flower-beds; nor does this plant suffer much

from the smoke even of London. The flowers are numerous, rose-coloured, inodorous.

2. Blue spiked thrift, or common sea-lavender (*S. limonium*), which grows plentifully on muddy sea-shores, and about the mouths of large rivers. The root is woody and tough. Leaves leathery, glaucous, usually 2 or 3 inches long. Panicle of spikes of imbricated, upright, fine blue flowers.

3. Matted thrift (*S. reticulata*), growing on muddy sea-shores, chiefly on the eastern coast of England. (*Smith's Eng. Flor.* vol. ii. p. 115.)

A kind of American sea-lavender, *S. Caroliniana* is described by Nuttall as apparently a mere variety of the *S. limonium*. The flowers are of an elegant blue.

THRIPS. *The Thrips*, or vine-fretter, as it is often called, is a very minute, light-coloured or spotted fly, exceedingly active in all its motions, and appearing to leap rather than fly. They live on the buds, leaves, and flowers of plants, being so small as readily to escape notice, unless particular attention is directed to them. They are generally found by observing the effects of their apparently poisonous bites which produce deformities in the leaves or blossoms, causing these often to swell or curl up. The peach tree occasionally suffers severely from their attacks, as well as from those of the plant-lice, to which family of insects they are allied. (*Harris on Destructive Insects.*)

A remedy for thrips will be found, with the mode of using it, under the head of *Aphis*.

A new disease of the plum tree, occasioned by thrips, is described by Dr. Harris, in *Hovey's Horticultural Magazine*.

THYME, GARDEN (*Thymus vulgaris*, from *θυμός*, courage, being considered a reviver of the spirits; or from *θύω*, to sacrifice, being employed as incense). The varieties are,—the broad-leaved green, narrow-leaved green, variegated, and lemon-scented. The variegated is grown almost solely on account of its ornamental foliage. A poor, light, and dry soil is best suited to it. In moist or rich ones, it becomes luxuriant, but deficient in its aromatic qualities, and generally perishes during the winter. The situation cannot be too open.

Thyme is propagated both by seed and rooted slips. Sowing may be performed from the middle of March until about the beginning of May. Slips may be planted from the beginning of February until the close of May.

The seed must be sown neither thin, nor raked in more than half an inch below the surface. It is sometimes sown in drills of a similar depth, six inches apart, or as an edging to a bed or border. The seedlings must be kept clear of weeds, and, if the season is dry, watered moderately twice a week. When of about six weeks' growth, or when 3 or 4 inches high, they require to be thinned to 6 inches apart, unless grown as an edging, when they must be left thick. Those removed may be pricked out to a similar distance, if required. Water is required occasionally until they have taken root. The plants may be left in the situations they are placed in at this season, or be finally planted out in September or October, or in the early spring of the following year. To obtain slips, some old stools may be divided into as

many rooted portions as possible, or layers may be obtained by loosening the soil around them, and pegging the lateral shoots beneath the surface. They must be planted out at distances similar to those raised from seed, water and weeding being similarly required.

In autumn the decayed stalks should be cleared, and a little fresh earth scattered and turned in among the stools.

Although this herb is perennial, yet after 3 or 4 years it becomes stunted and unproductive, consequently requiring to be raised periodically from seed. For the production of seed, some plants should be allowed to run up without being gathered from in early summer. The seed is ripe during July, and must be cut immediately it is so, and laid on a cloth to dry, otherwise the first rain will wash it out of the seed-vessels.

THYME, WILD (*Thymus*). A genus of aromatic, pungent, branched, somewhat shrubby plants, belonging to the natural order *Labiata*. They are often diffuse in England, and of humble growth: in some instances annual. The common wild thyme (*T. serpyllum*) is plentiful almost everywhere, particularly on heaths and dry mountainous ground. The odour of the plant is gratefully aromatic. Bees are fond of the flowers. Whether, as alleged, the quality of mutton is improved by the sheep feeding on this plant, or on fine, short grasses which usually accompany it, is still a matter of great doubt. See **BASIL**, **CALAMINT**, and **THYME**.

TICKS. See **SHEEP**, **DISEASES OF**.

TILLER. A term applied to the branching of the stems of wheat, &c., from the roots.

TILTH. The condition of the earth after ploughing, &c.; or the state of the soil in respect to tillage as relating to manure.

TIMBER (Germ. *zimmer*; Du. *timmerhout*). The term used to express every large tree squared, or capable of being squared, and fit for being employed in house or ship-building.

TIMBER TREES. See **TREES**, **PLANTATIONS**, and the several indigenous trees, under their alphabetical heads.

TIMOTHY GRASS (*Phleum pratense*). See **CAT'S-TAIL GRASS**.

TINE. A tooth or spike placed in any implement, but especially in the harrow kind. See **HARROW**.

TOAD (*Rana bufo*.) A well-known and much dreaded, though perfectly innoxious reptile of the frog genus, which feeds on insects, flies, ants, &c. It is preyed upon by owls, buzzards, snakes, &c.; otherwise the toad attains to a considerable age, some remarkable instances of which have been recorded.

Dr. H. Storer, in some remarks upon reptiles furnished by him to Professor Hitchcock, and published in the *Zoological Survey of Massachusetts*, observes:—Great errors also exist with regard to the order *Batrachia*. The acrid secretion found upon the skin of the *Hyla versicolor*, the toad, and several species of efts and newts, has caused them to be considered venomous—which is incorrect. Every species of this order is inoffensive, and, when better known, will undoubtedly be found beneficial to man.

In some countries, the flesh of the different *Rana*, frogs, is an article of food. With us,

TOAD-FLAX.

the habits of the *Bufo Americanus*, or common toad, are becoming better understood, and the horticulturist, instead of destroying, carefully preserves it on his grounds, for the benefit it affords him, by feeding upon noxious insects. In the same way are our springs and wells rendered the purer by the presence of the carnivorous salamander.

TOAD-FLAX. A name applied to two perennial species of *Antirrhinum*. 1. The creeping, pale blue toad-flax (*A. repens*) is a rare species, growing on chalky banks or rocks near the sea. The herbage is smooth and glaucous, stem paniced, leaves linear, scattered, partly whorled; flowers sweet-scented.

2. Common yellow toad-flax (*A. linaria*), which is common about hedges and the borders of fields. The leaves are linear-lanceolate, crowded; stems erect; spikes terminal; flowers terminal, inodorous. (Pl. 10, x, x.) See FLUELLIN and SNAP-DRAGON.

Common linaria is found in the Middle States, where it bears the names of toad-flax, butter-and-eggs, and Ramstead-weed. It is a foreigner, frequenting fence-rows and pastures, where it is a showy but very obnoxious weed. (*Flora Ces-trica*.)

TOAD-FLAX, BASTARD. See BASTARD TOAD-FLAX.

TOBACCO. Botanists have given this well-known American plant the generic name of *Nicotiana*, from John Nicot, of Nismes, in Languedoc, ambassador from the King of France to Portugal, where he procured the seeds from a Dutchman who had derived them from Florida. The first plant was said to have been presented by Nicot to Catharine de Medicis, whence the former French name, *Herbe à la Reine*, or the queen's plant. The name tobacco, which has superseded all others, is an appellation acquired from the place from whence it was originally most generally derived, namely, the island of Tobago, in the West Indies. According to Linnæus, tobacco was known in Europe as early as 1560. It was taken to England from the West Indies or Mexico by Ralph Lane in 1586, but only the herb for smoking, a practice introduced into England by Sir Walter Raleigh, who acquired it from Captain Lane. In the house in which he lived at Islington are his arms on a shield, with a tobacco plant on the top. Smoking has consequently been common in Europe for upwards of two centuries. It is a powerful narcotic, and also a strong stimulant with respect to the whole system, but especially to the stomach and intestines, to which, in small doses, it proves emetic and purgative. The smoke thrown up the anus acts as a glyster: an infusion of the leaves forms a powerful lotion for obstinate ulcers. The decoction, powder, and smoke of tobacco are used in gardening to destroy insects, and in agriculture for the same purpose, and to cure cutaneous eruptions in domestic animals.

Botanists have identified many different species of tobacco, and Loudon, in his *Encyclopædia of Plants*, makes the following list of those enumerated under the generic head of *Nicotiana*, with the places from which they were derived:—

TOBACCO.

Species.	Common Name.	Origin and Date.
<i>Nicotiana tabacum</i>	Virginian	America 1574
<i>macrophylla</i>	Large-leaved	America "
<i>fruticosa</i>	Shrubby	China 1699
<i>undulata</i>	Sweet-scented	N. S. W. 1800
<i>rustica</i>	Common-green	America 1570
<i>paniculata</i>	Paniced	Peru 1752
<i>glutinosa</i>	Clammy	Peru 1759
<i>plumbaginifolia</i>	Curled-leaved	America 1816
<i>pusilla</i>	Primrose-leaved	Vera Cruz 1733
<i>quadrivalvis</i>	Four-valved	N. America 1811
<i>nana</i>	Dwarf.	N. America 1823
<i>Langsdorffii</i>	Langsdorff's	Chill 1819
<i>cerinthoides</i>	Honeywort	" 1821
<i>repanda</i>	Havannah	Havana 1823

In the 4th plate there are representations of the species known as Virginia tobacco (*Nicotiana tabacum*, f), common green tobacco (*N. rustica*, g), Havana repanda (*h*), of which the fine and fragrant cigars are made; the *Quadrivalvis*, or four-leaved tobacco (*i*), and the *Nana*, or dwarf species (*k*), both of which last are used by the Indians of the Rocky Mountains.

Tobacco is cultivated in Europe as far north as Sweden, and is also grown in China, Japan, and other eastern and hot countries. The sort most generally preferred is the Virginia species, a very beautiful plant. The common green kind (*N. rustica*), is also frequently cultivated, especially in Europe, it being considered harder than the Virginian sort. Parkinson says he has known Sir Walter Raleigh, when prisoner in the Tower, prefer it to make good tobacco, "which he knew so rightly to cure." Tobacco has been successfully cultivated and cured in England, but its growth is prohibited as a crop, and it is now only grown for curiosity as a border flower, or by gardeners for the destruction of insects. In Germany and other northern countries, most families who have gardens grow enough of *N. rustica* for their own use; but as they do not know how to cure it properly, it is not much valued, and is never made into chewing tobacco or snuff, but used for smoking.

Although tobacco, an annual plant, may be brought to maturity in almost every country, even in Russia and Sweden, with their transient summers, still will the plants, under such unfavourable circumstances, be small, and their flavour weak. In long, moist, and not very warm summers, such as those of Ireland, the plants may attain a very large size, but they will not have that superior flavour which can only be derived from abundance of clear sunshine, and free, dry air. The fragrant tobacco of Havana and Luconia may retain pre-eminence for smoking, but for all other purposes the peculiarly high and rich flavour of the tobacco of Maryland, Virginia, and neighbouring states must always give it preference, both at home and abroad.

It will be seen from an estimate furnished Congress by Mr. Ellsworth, Commissioner of Patents, of the agricultural products of the United States in 1842, that tobacco, though cultivated in every State of the Union, constitutes a staple crop in comparatively few, namely, Virginia, Maryland, North Carolina, Kentucky, Tennessee and Missouri. The crop of the year mentioned, was below the average, and in Virginia not over two-thirds of the regular crop, being both light and of bad quality. It was distributed as follows:—

TOBACCO.

States.	No. of pounds gathered.
Maine - - - - -	62
New Hampshire - - - - -	290
Massachusetts - - - - -	97,297
Rhode Island - - - - -	499

Spain - - - - -	5,700	
Portugal - - - - -	363	
Italian States - - - - -	2,000	
Austria - - - - -	4,000	

The remainder of the 100,000 hogsheads is distributed through the German States, Sardinia, Hungary, &c. &c. We have been unable to ascertain the precise duties paid in all cases, but the enormous rates of those ascertained, and the fact that the tobacco import is in most of the countries of Europe farmed out for a stipulated sum, renders it certain, that while none are below what is here named, some of the highest much exceed the almost prohibitory imposts of Great Britain. A duty of 800 per cent., such as England imposes on our tobacco, is an anomaly in the history of trade; and which, under all circumstances, may be deemed positively unjust." This excessive duty, however, is imposed merely for revenue purposes, not for protection to agriculture, like the duty on wheat; as, excepting a few plants for private use, for medicinal purposes, &c., it is prohibited to be grown.

"The culture of tobacco is every year tending itself in the Western States, and promises to become a most important article of export from the rich districts north and south of the Ohio. That tobacco can be grown in Indiana, Ohio, Kentucky, and Tennessee, with a profit greater than that attending the culture of wheat and corn, seems certain; and we doubt not, that as the cultivation progresses, and the better methods of curing are adopted, the tobacco of the new States will rival in quality and celebrity that of the old. The plants on new land grow more luxuriantly than on soils cultivated for any considerable time; but experience proves that the quality is not so fine. The best tobacco in any country is grown on lands in good condition, but not extravagantly rich, or highly manured."

Many facts connected with the history of the first production and exportation of tobacco in America are highly interesting. Some of these were collected by an intelligent investigator a few years ago, from which we extract the following. In a letter still extant, of the Governor and Council of Virginia, dated James' City, January 20, 1622, it is stated, that there was not then above 60,000 lbs. of tobacco made in the colony. In 1639, however, only 17 years afterwards, the Grand Assembly passed a law which recites, that, "Whereas, the excessive quantity of tobacco of late years planted in the colony, has debased the quality," and enacts, "that all the tobacco planted this present year, and the two succeeding years, in the colony of Virginia, be absolutely destroyed and burned, excepting and reserving so much in equal proportion to each planter, as shall make in the whole just the quantity of 120,000 lbs. of tobacco, stripped and smoothed, &c. In consideration whereof, the creditors of the

Increased attention has been latterly paid to the culture of tobacco in Illinois and even in some of the New England States. The following statement would seem to show, that, notwithstanding the vast amount of tobacco raised in the Union for home consumption and exportation, there is yet no reasonable ground for apprehending an over-stock of the market. In a letter of the Secretary of the Treasury relative to the amount of home consumption and exports of tobacco, with a great variety of other particulars, it is stated that the whole amount supplied elsewhere than in the United States, is about 150,000,000 pounds; the amount of possible consumption of American tobacco is put at not less than 1,000,000,000 pounds. So that were only one-half of this quantity actually consumed, it would be four times more than our present export, which, in value, is only second to that of cotton.

In almost every country in Europe the most vexatious restrictions in the forms of excessive duties and imposts are levied upon tobacco. In general, the governments, such as France, Spain, Italy, &c., take possession of all the tobacco imported or raised, and farm or let out to great capitalists for immense sums, the privileges of vending to manufacturers and retailers. In this way the cost of tobacco in Europe is usually extremely high, and governments manage to derive from their subjects vast sums of money by exactions in the shape of imposts upon the tobacco they consume. In France the revenue thus annually derived, is \$10,000,000, and all this from a reduced importation of some 6000 or 7000 hogsheads. It would indeed seem to be a favourite object for excessive taxation in nearly every government. At a great meeting of tobacco planters held in May, 1840, it was shown from authentic documents, that on an export of 100,000 hogsheads, valued here at \$7,000,000, a duty was paid by the consumers in the various countries of Europe, of more than \$30,000,000. "As a matter of interest to many of our readers," says the editor of the *Cultivator*, "we copy or condense

planters were compelled to "accept and receive 40 lbs. of tobacco so stripped and smoothed, in full satisfaction of every 100 lbs. now due them." It is not important to ascertain whether this law was re-enacted at the end of the 3 years named in it; for we find in an official report to the commissioners, that the yearly exports of tobacco for ten years ending in 1709, were 28,868,666 lbs., of which 11,260,659 lbs. were annually consumed in Great Britain, and 17,598,007 lbs. in other countries of Europe. In 1744—1776, the average annual exportation was 40,000,000 lbs., of which 7,000,000 lbs. were consumed in Great Britain, and 33,000,000 lbs. in other European countries. The annual average exportation from 1768 to 1770, both inclusive, was 67,780 hhds. of about 100 lbs. each, or 67,780,000 lbs. As we have now approached the period when the exportation of tobacco arrived at a point from which it has vibrated, (sometimes a little above or below it,) we subjoin a statement of the exportation for the years 1772—1775, inclusive, which will furnish the remarkable fact that (compared with any succeeding four years since that period) the annual exportation of tobacco just before the Revolution, was about the same that it has been at any time since, in our most prosperous periods. For although 1790—1792 were three years of very heavy exportations, they fell off in 1793 nearly one-half, making the annual average exportation not materially different from 1772—1775:

Statement showing the quantity of tobacco exported from the United Colonies from 1772 to 1775, inclusive.

Years.	Pounds exported.	Pounds consumed or remaining on hand in Great Britain.	Pounds consumed or remaining on hand in other countries of Europe.
1772	97,799,263	97,791,805	7,458
1773	100,472,007	3,695,564	96,776,443
1774	97,397,252	18,698,337	78,676,915
1775	101,523,617	27,623,451	74,205,166
	397,497,139	147,509,157	249,665,982

Total exportation for the 4 years, 397,497,139 lbs., or an annual average of 99,374,785 lbs. This brings up to the period of the Revolution. The following will exhibit the exportation of the article during that period.

Statement showing the quantity of tobacco exported from the United Colonies, from 1776 to 1782, inclusive.

Years.	Pounds exported.	Pounds consumed or remaining on hand in Great Britain.	Pounds consumed or remaining on hand in other countries of Europe.
1776	14,498,500	*	14,498,500
1777	2,441,214	†	2,441,214
1778	11,961,533	7,520,550	4,440,783
1779	17,155,907	10,982,899	6,173,008
1780	17,424,267	11,474,791	5,950,176
1781	13,339,168	7,600,296	5,738,872
1782	9,823,244	6,364,813	3,463,431
	86,649,533	43,943,349	42,705,984

* This year Great Britain exported to the Continent nearly 26,000,000 lbs. of old stock.

† Great Britain exported this year to the Continent 6,000,000 lbs. of former stock.

Total exportation for the 7 years, 86,649,533 lbs., or an annual average of 12,378,504 lbs. Of the total 7 years' exportation, 33,974,949 lbs were captured by the British during the war.

The following table exhibits the exports of tobacco from the United States, for the years 1787, 1788, 1789, immediately preceding the adoption of the present Constitution.

Statement showing the quantity of tobacco exported from the United States, from 1787 to 1789, inclusive.

Years.	Pounds exported.	Pounds consumed or remaining on hand in Great Britain.	Pounds consumed or remaining on hand in other countries of Europe.
1787	99,041,000	45,379,795	44,661,205
1788	88,595,000	39,600,404	48,995,156
1789	88,675,000	48,831,232	39,543,768
	267,311,000	133,811,431	133,500,159

It may be proper to remark, that the weight of a hogshead of tobacco is much greater now than formerly. Originally, tobacco being less compactly pressed, the hogsheads averaged only 600 lbs., but they gradually increased, and in 1770, reached 1000 lbs. average. At this time Kentucky averages about 1300 lbs. per hogshead, and the average of all kinds (Kentucky, Virginia, Maryland, and Ohio) we have estimated at 1200 lbs. per hogshead, which we believe to be very nearly right. The annual average exportation for the last 21 years, from 1815 to 1835, inclusive, is within a fraction of 82,760 hogsheads. Taking our estimate of 1200 lbs. per hogshead to be the true weight, we shall thus have 99,313,000 lbs. as the annual average for the last 21 years; and we have seen that the annual average exportation for the four years ending in and including 1775, was 99,374,785 lbs., which establishes the remarkable fact, that the exportation of leaf tobacco has remained stationary for a period of 60 years.

On a careful examination of the foregoing statements, it appears, that when our exports of leaf tobacco, for two or three successive years, much exceed 100,000,000 lbs.; for some succeeding years they are proportionably reduced below that standard. It is also evident that the revolutionary war gave a check to the exportation of leaf tobacco from which it has never recovered; for until that period, as may be seen by reference to the preceding statements, the annual average exportation increased regularly and steadily. It was 37,780,000 lbs. greater for the years 1763 to 1770, than for the years 1744 to 1746; and for the years 1772 to 1775, it was 31,594,785 lbs. more than the annual average for the years 1763 to 1770. In other words, for the 31 years immediately preceding the revolution, our exports of leaf tobacco annually increased very nearly 2,328,000 lbs., and for the 60 years since that period, it has remained stationary, except when interrupted by wars or other commercial embarrassments. The reason is apparent. Before the revolution, all Europe depended on us for supplies of the article; but, being cut off from the supplies by the war, Europeans turned their attention to growing it for themselves, and

Statement exhibiting the number of hogsheads of tobacco exported from the United States from 1790 to 1835, inclusive, and the average price per pound, and gross value from 1802 to 1835, inclusive. Also the number of pounds of manufactured tobacco and snuff exported from 1791 to 1835, inclusive, and gross value from 1817 to 1835, inclusive.

have continued to cultivate it all over the continent.

It will be observed that the exportation of manufactured tobacco and snuff has increased more than 44 fold since 1791, and more than 3 fold since 1817; but the gross value has not proportionably increased, at least since 1817.

From a review of the subject, as above detailed, it will be perceived, that, if it were in our power to furnish a precise statement of the exports of each description of tobacco, and the countries to which it was exported (although very desirable on many accounts), it would not furnish satisfactory evidence that the consumption of tobacco generally, or of any particular description, had increased or diminished in Europe, without knowing *what they grow*, as well as *what we export*. We have devoted much labour and attention to this part of the subject; but, although we can learn generally that the production of it in Europe keeps pace with the increased consumption, yet our researches have not enabled us to lay before you any useful statement, either as to the quantity or the qualities grown, except for 3 years in France, as follows:

Statement showing the quantity of Tobacco grown in France for the years 1818—1820.

Years.	Kilogrammes.	Pounds.	No. of hhd's, estimated at 1,200 lbs. per hhd.
1818	7,418,000	18,545,000	15,454
1819	10,360,000	25,900,000	21,583
1820	13,155,000	32,887,500	27,406

This shows an increased production of nearly double in the 3 years.

It will strike you with surprise, as it did us, that the consumption of tobacco has increased so much in our own country as to carry off the very large surplus grown beyond the foreign demand. Formerly, when all the tobacco was grown in Virginia and Maryland, we exported as much as we do now; and now, in addition to those states, which produce nearly, or quite as much as they did then, Ohio, Kentucky, and Tennessee, together with Connecticut, Pennsylvania, Indiana, and Missouri, produce as much more. We must, therefore, consume more than the quantity required for exportation.

Remarks.—If the preceding statements may be relied on as correct, it appears that there

has been a very surprising increase of the use of tobacco in this country, and that the annual consumption now amounts to upwards of 100,000,000 lbs.:—giving about 7 lbs. to every man, woman, and child. The sum annually paid by the consumers of this quantity of tobacco in its manufactured state, has been computed by a writer in *The Portsmouth Journal*, at \$20,000,000. (*National Gazette*, Philadelphia, Oct. 6, 1836. Republished in *Farmer's Register*, vol. vi. 1838.)

Culture of Tobacco.—The following concise directions for the cultivation and management of tobacco are chiefly taken from a communication drawn up by Mr. J. F. Edmunds, of Mecklenburg, Virginia, and originally published in the *Farmer's Register*.

Raising the Plants.—The land for the *plant-bed* is usually selected in a warm exposure on the south or southeastern side of a hill in a wood, new ground being always preferred. From this the roots should be grubbed, the rubbish cleared away and the old leaves raked off. Brush of pine or other wood is then to be piled on until from 2 to 3 feet thick all over the bed, and this is to be set on fire. As the beds should be prepared for seeding immediately after the frost is out of the ground, the brush should be collected and put in place some time during the winter. Instead of burning over the whole bed at once, a part may be fired for an hour or so at a time, proceeding thus over the entire bed. The place is then to be broken up with hoes, and sometimes with coulter drawn by horses or oxen, and the work repeated until the earth is made perfectly fine, being careful to avoid turning under the surface. All the roots should then be extracted, and the land laid off in beds (slightly elevated if dry, and more if moist or wet) 4 feet wide. And to 16 square yards, a common pipe-bowl of seed is sown. The bed is then trodden or pressed with hoes, and well covered with brush to protect the plants from frosts. When the plants have come fully out, they should be slightly manured with strong manure made fine; this should be repeated frequently, and in larger quantity, as the plants increase in size and are able to bear it.

When the plants have attained a good size, and there is no longer danger of frost, the covering of brush is removed, and the bed weeded with the hand, those employed in this duty taking great care to avoid bruising the tender plants. The beds require frequent picking to keep down the weeds.

Preparation and Planting.—The plants will be generally ready for removal about the last of May or first of June. They are to be drawn out after a rain and transplanted in good ground previously well prepared for their reception.

Soil and Season.—In Virginia and the other states, the best tobacco is grown in rich, light, alluvial, loamy land, or such as has been recently cleared and brought into cultivation. Tobacco requires a mild and warm season, and can never be worth growing in situations elevated much above the level of the sea, in northern exposures, or in wet and springy land.

Field Culture.—The land for tobacco should

be of the best quality, either newly cleared and virgin soil, or old ground highly manured and well pulverized, or good clover fallow, ploughed in the fall, manured and cross-ploughed in the spring, just before planting, well harrowed, and then laid off with a plough in rows 3, 3½, or 4 feet apart each way. Every square thus made is to be scraped with the hoe so as to form a hill in which one plant is to be set. In case the plants die from drought, or are destroyed by worms, a very common occurrence, others must be set in their places.

Cultivation.—The culture is very much like that usually adopted for Indian corn, the plough, cultivator and hand-hoe being freely used to keep down weeds and loosen the earth.

It is important to the early growth of the plant to plough and work deep once or twice, so that when it is ripening, the ground will be broken deep and fine. (The coulter is preferred for this operation.) This should be effected without much interference with the roots, as that would check the growth, and prevent the plant from attaining its proper size. And hence the advantage of greater distance between the rows than the common distance of 3½ feet—because the wide rows can be ploughed, and worked with less damage to the roots. In this, as in all other crops, if we wish a good return, "we must speed the plough" and hoe, before the roots run out. On our high lands we should endeavour, by deep and horizontal ploughing, to counteract the bad effects of drought. On our flats, we should aim to prevent the collection of water by drains discharged at the lowest point.

The bed is best for high land, because it retains more moisture where it is generally needed. The hill, retaining less moisture, is best for flat land, where there is commonly a superabundance.

Priming, Topping, Suckering, and Worming.—As the tobacco plant grows and develops, a blossom-bud puts out from the top, which is termed *buttoning*. This top must be pulled off along with such of the upper leaves as are too small to be of any value. The plants are thus left usually about 2 or 3 feet high. The plants also shoot out suckers from every leaf, which must be broken off, care being taken not to break the leaf from the main stem. This causes the leaves to spread.

The most regular topping is performed by measure. The topper carries in his hand a measure 6 inches long, by occasionally applying which, he can regulate the priming with great accuracy; and as the remaining leaves are numbered, this governs the operation, and gains the object of even topping. The topper should always carry this measure in his hand, as it serves to prevent excuses for negligence and uneven topping. Prime six inches, and top to eight leaves. We have found, by experience, that this is the best average height. We sometimes, but seldom, vary from this general rule. If the land is poorer than common, or if, from the backwardness of the plant, and the advanced state of the season, we apprehend frost, we do not prime as high; (say 4 inches.) If we have an uncommonly rich spot, and there is danger that the top

leaves will come to the ground, we should rise in the same proportion. The crop should be wormed and suckered, at least once a week.

Cutting and Housing.—In about 3 months after setting out, the plants assume a spotted and yellowish appearance, indicating that they have attained sufficient maturity for cutting and housing. This stage of the tobacco culture is generally reckoned the most difficult and delicate part of the whole business, and the planter, if he wishes to be successful, must give it all his attention, as the profit of a whole plantation, for the year, greatly depends upon the diligence and skilful management exercised during the few days of cutting. He should therefore be well prepared for this state of the crop, by having the barns close, carts and wagons in good order, and every thing arranged to despatch business as much as possible, since it is hard work he has to encounter. To save a heavy crop in the best manner requires both energy and activity. The most judicious hands should be selected for cutters. The plants are cut with a knife near the ground, and suffered to lie in the sun for a few hours, to cause them to “fall” or wilt. When the field is a pretty large one, a middling or average hand should count the whole number of plants he cuts, so that, allowing each cutter the same number, we may arrive at nearly the whole quantity cut. We should never cut more nor less than will fill the contemplated barn; otherwise there is labour lost in attending to a barn not full, or the overplus is injured for want of firing. The tobacco, after it has “fallen,” or becomes sufficiently limber, is carried to the barn in carts or wagons, being from 6 to 10 plants on a stick, and stowed away for firing. It is also of great importance to be particular in the arrangement of the sticks. The equal and general circulation of heat throughout the house depends on the manner in which this is done. Our barns commonly have three firing tiers above, and three below the joists. We commence arranging the sticks on the most elevated tier in the roof, to which we give five inches distance; and on each tier, as we descend, we gain one inch; so that on the lowest tier, nearest the fire, the sticks are placed eleven inches apart. This disposition of the sticks, I have ascertained by late experiment, is important. The sticks of tobacco being wider apart, next to the fires, gives a freer circulation, and, consequently, a more equal temperature, than the usual way of equal distance from bottom to top. The heat having more space to ascend, must be more equal and generally diffused, and will give a more uniform house of tobacco. I esteem this a considerable improvement; and if we have house-room, and make a greater difference in the proportionate distance between the sticks, it will be a still better arrangement.

Curing.—We commence our warming or preparing fires, says Mr. Edmunds, the day after housing. We prefer what is commonly called the “bed logs” of green, and the “feeding” of dry or seasoned wood. By this arrangement the fires are rendered more governable. The bed logs should be nicely fitted to

the barn floor, two lengths to reach across, the large ends placed outwards, to guard against the tendency of heat to the centre. We keep up our warming fires from 36 to 48 hours, the mercury ranging from 100° to 115°. This will generally bring the leaf to the drying state; the tail, or end of the leaf, now begins to curl handsomely, and then the planter must be on the alert. If he is careless, and his fires are made too hot, the aromatic oil passes off with the sap and smoke, and he has a house of red or dark inferior tobacco. If his fires are kept too low, his tobacco gets into a clammy sweat, and the oil escapes. There is much more danger of the former than of the latter evil. There is more tobacco injured by too much heat than by the want of a sufficiency. The fires should now be kept steady and regular, with a gradual increase of heat, so that in 48 hours the mercury will stand 150° to 160°. It must be kept at or about that temperature until the tobacco is cured.

Stripping, Prizing, &c.—After the plants become sufficiently dried, known by the stems getting hard, which will be in about 2 months after housing, the leaves are stripped from the stalks. For this operation a moist time in the spring or late in winter is chosen, to prevent the leaves from crumbling. They are divided by select hands into three classes for stripping: 1st, that which is of the best colour and quality; 2dly, that which is somewhat inferior, comprising the balance of the leaf; 3dly, lugs, or ground leaves. Some planters make still more classes, but this requires more attention and discrimination than can be generally bestowed, at least by ordinary hands. After sorting, the leaves are neatly tied up in bundles called “hands,” consisting of 4 leaves in each bundle of the first class, or 6 of the second and third classes. The hands are next “put down to condition,” as the process is commonly termed. This consists in putting it in large bulks and subjecting it to pressure from weights, in which state it undergoes a sweat. It must be watched during this process, and as soon as it is observed beginning to heat, taken out and hung up to dry. After drying thoroughly, it must be again taken down and put into bulk, a damp spell being chosen so as to prevent the leaves from breaking or crumbling. In Mr. Edmunds’ instructions he observes, that, “at the close of each day’s stripping, and oftener if the weather is drying, we bulk down what has been stripped, being careful to pack straight. It is left in this situation until we wish to commence prizing, and then hung, from 12 to 15 bundles on a smooth stick, and hoisted in the barn, the sticks placed 6 inches apart, the hoister carrying a measure in his hand. It is important to measure, as the order will be more uniform. It should remain until the stems are perfectly dry; after which it should be taken down for prizing, as dry as it can be handled without breaking. It remains in this state a few days, until the leaves are pressed together, and we have soft weather for packing. Each bundle is then carefully straightened, repacked, and heavily weighted. It is then ready for prizing. We should prize in weather when the order of the tobacco will

not change. Each bundle should be straight, and closely packed in hogsheads in the usual way."

Some very excellent views upon the culture and subsequent management of tobacco will be found dispersed through the different southern agricultural periodicals, and especially the first volume of the *Farmer's Register*. One of the communications in this last work, signed Frederick Oronoko, is very full of information upon every branch of the subject. The writer states that two great errors are generally committed in *topping and priming*. On rich land the plants are topped too low, which, with planting too far apart, causes the leaves to grow too large, coarse, and curly. On such lands, instead of making 10 leaves, at least 12 should be made by topping to about 16, and not finishing priming with the topping, but commencing again when the four top leaves get about half-grown. If the seasons be favourable to a rapid growth, some of the high top suckers should be indulged a while, which in a wet summer will prevent the leaves from growing coarse. Nothing, he says, is easier than to keep down the size of the leaves, and prevent them from getting too large, if you will only top high and indulge the suckers to a proper extent in the early part of the summer, when the seasons are favourable to rapid growth. Sucker and prime judiciously, as the rains subside and dry weather sets in. By turning out a superabundance of leaves, it enables one to speculate on the weather in this crop with more certainty than can be done with any other. The four top leaves are always the richest, if ripe, and of much the best and most useful shape. In a plant of 10 leaves, he thinks, in general, they are worth more than the other six, although the four are not so large, and do not usually weigh more than half as much as the six. The same rules, he thinks, are also applicable to the culture of tobacco on thin land, such as can just barely produce a crop, although he is opposed to the culture of such poor land. One-third to one-half of the Virginia crop is made upon such land as does not pay for the labour. It is a general impression that much of the fine, high-priced tobacco has been made on poor land. It will, he says, "be well to correct this error, as it has caused much injury, and great loss of labour, and final destruction and death to a great deal of thin land, either poor originally, or in the last stage of consumption by the Virginia-killing mode of cultivation. It is true, however, to a notorious degree, that several poor counties have of late been very conspicuous, and, perhaps, meritoriously celebrated, for making fine, high-priced tobacco; but the fine tobacco was not made on poor land, when the land was actually poor; it was made on the richest, liveliest spots that could be picked out in those poor counties. Many of those who have not rich land, have resorted to the necessity of picking the best spots of thin land with only a meager coat of soil, and that coat nearly all composed of vegetable matter, scraped into hills, which causes them to be tolerably rich, active, and productive for one or two years, as this is generally new ground. In this way a part of the fine, high-priced tobacco has been made,

but much the greater part has been produced by the rich land, with the aid of the art of high curing, with but little or no fire."

Another great error dwelt upon by the same writer is that of cutting before the plant gets *entirely ripe*, which is the chief cause why so much is defective in flavour, colour, and substance; and why so much feels rich and thick without being so. The odoriferous qualities of most aromatic plants are acquired in greatest perfection during the last stages of their growth, and some are never fully developed till they get through the process of curing, which is peculiarly the case with tea, coffee, and tobacco. Much of the substance as well as weight are therefore sacrificed by premature cutting, which also prevents the plant from curing with a good, lively, healthy colour. A dull, dingy hue will inevitably be the aspect of all that is cut green, cure it as you may. Any bright colour given to it artificially by the process of curing will fade away. "I hazard nothing in the declaration that every rich plant cut in perfection, fully ripe, whether on rich or thin land, bottom or high land, may be cured of good colour and flavour, that will be lasting and delicious to the taste and smell. And although good colour and flavour constitute the chief value, yet no more than about one-tenth of the Virginia crop has ever come to market with these great advantages.

"Many incorrect and erroneous opinions have gone into circulation respecting colour. Impressions have been extensively made in the country that yellow is a favourite hue. A bright, lively colour is invariably admired by the purchasers who give the highest prices. But neither brown, red, nor yellow will do. A rich mixture of red and yellow on the under side of the leaf is desirable; such a mixture as is to be found in fat lightwood, and brilliant, rich, bright mahogany. The dull brown and dark, dingy colours are very objectionable. The next best colour to the favourite one just described, is a rich, deep yellowish-green, or rather the fat lightwood colour, with a slight admixture or tinge of green, but it is so much the worse of the green, in the ratio that it contains that shade, which lessens the fine flavour, and detracts from the value.

"A similar colour, in a faint and feeble degree, can be given to the poor, thin tobacco, and is certainly a handsome dressing for it in the new state, and is well calculated to take with superficial judges. But as such a dressing injures the stamina, and increases the fading in going through the sweat, either on land or at sea, it should never be attempted, as it is an injury, and will never take with any competent judge."

The dapple, or pieball, is very much admired by many purchasers who are esteemed good judges, but the writer thinks those variegated colours a disadvantage, and the results of either too rapid curing, or bruising in pressing. A competent judge, he says, had rather have the under side of the leaf, stem, and fibres, all of one colour, of the *fat lightwood appearance*; and this uniformity in colour proves the maximum, and is the best evidence of rich, well-cured tobacco, in its highest perfection.

The same writer thinks that *firing* has been carried to great excess, very much to the injury of tobacco, of late years, both in smoking it too much, and parching and curing it too rapidly. The smoke is a very objectionable flavour, and the excessive parching makes the leaf too crisp, and destroys the valuable elasticity. It should be well cured, with as little fire as possible. *Some cure it very well without fire.*

Several years ago, a great number of planters took up the impression, that the purchasers were fond of hard-fired tobacco, from the erroneous opinion of some of them, who said they liked to smell the effects of fire, because it was an evidence that it was well cured; but they have since discovered their error, and no one is now fond of the smell of smoke, which is a great objection in every market in Europe as well as in America.

The following additional observations relative to curing tobacco, are furnished by the same authority.

Sunning the tobacco is very necessary after cutting; but it should not be kept in the field any longer than to kill and make it sufficiently limber for removal to hang on sticks upon a scaffold at the tobacco-house, where it should hang in open airy order, at first letting in the sun well upon the stalks. In this way the butt-end of the stalks and big ends of the leaves and stems will get a great deal of the sun's heat, which they require in curing. And as fast as the leaves contract and draw up from heat, and in drying, the plants should be moved up nearer to each other, in closer and closer order, to prevent the lower parts of the leaves from being exposed to the sun.

It would be a great advantage to split the stalks, as it facilitates the curing very much. They should be split from the top down within 2 or 3 inches of the cutting point. The plants thus split should straddle the sticks, and the sticks should range north and south, so that the morning's sun will shine on one side of the stalks, and the evening's on the other. In this manner it should take the sun and open air night and day, until it becomes well cured, and until the stalks, and stems, and leaves get dry. Showers of rain, and *even heavy showers*, in this situation, while the leaf continues green, are of little disadvantage; because they only wet a small part, viz.: the under side of the leaves, which are now uppermost. Nearly all of the rich ingredients are concentrated on the upper side of the plants as they stand growing.

But hot, sultry spells of rainy or very damp weather, of many days continuance, will mould, mildew, rot, or wash it to destruction, particularly after a considerable progress in curing. And when the winds come from the eastward, preceded by several damp, cloudy days, you may count upon a long spell, and then you should commence housing before the rain sets in, or much falls; and use fire as the weather may require.

The firing should be in close houses; the closer the better. And the more windows, the better, all with tight shutters, to shut out the damp in long wet spells, and let it in when wanted to bring the tobacco in order. No to-

bacco can be finally well cured without coming and going frequently. You cannot have any command of your tobacco as regards weather, without close, tight houses, which are of very great importance.

Five fires dispersed are enough for a room 20 feet square; and they should not be large, but burn free, steady, and gradual, and would be the better of never going entirely out, if you intend curing by this destructive mode. But why make fires in the house at all? As smoke is now so very objectionable, why not do the little firing that may be necessary in very long wet or damp spells, to prevent mould, mildews, &c., in the manner that plank is steamed and dried at saw-mills?—by stoves, or by running a ditch or two through the house, and covering this with flat slabs of rock, or arching it over with brick, and making the fire at one end, out of doors. The heat and smoke thus procured will be enough in a close house, with the windows all shut, to prevent mould, mildew, &c.

Those who cure without firing, or with as little as possible, let it remain after it turns yellow until the stalks and stems as well as the leaves get dry, in the open air and sun, if the weather permits, or in the house by the aid of fire, if necessary. But if the stalks, stems, and leaves get dry before the leaves get sufficiently yellow, let the tobacco hang until it becomes very high indeed from wet or damp weather, and bulk it in this damp, soft, high order, in very large bulks, in a very close room, and cover well with straw, &c., with heavy weights on the top, and let it remain till it gets warm; examine it every three to four hours night and day, and as soon as it yellows sufficiently, hang it up in the house, if the weather be wet or very damp, and fire it moderately and gradually until dry.

The best kinds of woods to use are those which make the most heat and weakest smoke. The kinds best for smoking bacon are the worst for firing tobacco, since the smoke flavour has become objectionable.

Another correspondent of the *Farmer's Register* shows, by observations of the thermometer, the precise degrees of heat to which the tobacco is subjected in the different stages of *firing*. He has also furnished valuable information in relation to other points connected with the curing process. In warm weather, says this writer, we hang from 8 large plants to 10 small ones on each stick; the sticks should be carried immediately into the house, and placed 8 or 9 inches apart. The sticks having been regularly arranged throughout the house, the process of curing then comes on.

My practice for several years, with but little variation, has been to regulate the sticks, the day after cutting and next morning. Commence with small fires, so as to raise the thermometer to 90°; this heat should be continued from 36 to 48 hours, which we call the warming or preparatory fire: (the small yellow tobacco, when cut, requiring a shorter preparation than large, thick, green tobacco;) the heat should then be raised gradually 10°, and continued 4 or 5 hours—thus continuing to raise

the heat throughout the whole process 16° every 4 or 5 hours, until the thermometer reaches 150°, which is called a curing heat. The continuation of this heat depends much on the state of the atmosphere, as well as on the size of the plant: it should, however be continued until the whole plant is thoroughly cured. As soon, then, as the tobacco comes in order to handle, you may remove it to some other house, hanging it as thick as you can conveniently press the sticks together, where it will remain in perfect security until you are ready for stripping.

In the month of November you may safely begin to strip; and much care should be used in making the different qualities, as well as tying the different bundles; the "tie leaf" should be stemmed, which looks much better than to have one-half of the leaf hanging down the bundle. A good hand will tie from 700 to 1000 bundles in the day. The tobacco stripped during the day, can be easily packed down in bulk at night, on a platform raised 18 or 20 inches from the floor, where it may remain until winter is nearly over, when it must be rehung in order to get it in prizing order.

Much depends on the order for prizing. The stem must be perfectly dry: never strike or take down tobacco for prizing, unless the wind is at some southern point; and it should be taken down as dry as you can possibly handle without very much breaking it. When down, it should be well covered with fodder or leaves; if the "season" continues, you may pack it in bulk as straight as possible for prizing; the hogshead weighing from 16 to 18 cwt. The following are a few extracts from notes taken last summer during the curing season.

"15th Sept. 1833. First barn—tobacco very ripe—weather hot and dry—cut Friday—commenced firing Monday morning—thermometer 90° at 9 o'clock—12 o'clock 106°—process too rapid—half past 3 o'clock, 110°—fired all night—Tuesday 9 o'clock, 120°—3 o'clock 150°—fired all night—Wednesday 150°—fired all night—Thursday 150°—Friday 150°—fires kept up irregularly, and stopped in the evening, High wind each day—thermometer at back side of the house." When this tobacco came in order to be examined, I discovered that a small portion was somewhat injured by the fires being too strong in the commencement, as seen above.

"16th Sept. 1833. Second barn—tobacco ripe—but not very ripe—weather hot and dry—cut Saturday—commenced firing Monday—smoked all day at 90°—Tuesday the same half day—Tuesday evening thermometer 100°—Wednesday morning leaf half cured on the lower tier—heat 140°—fired half night—Thursday 146°—Friday 146°—fired half night—handsomely cured—thermometer 3 feet from the door and 5 feet high—windy each day.

"22d Sept. Third barn—dry weather—cut Saturday—not very ripe—commenced firing Monday morning 90°—continued all night at same—Tuesday 9 o'clock 110°—tails curling—tobacco looks very well—Wednesday 120° at 9 o'clock—lower tier leaf nearly cured—Thursday 150°—fired all night—Friday 160°—fired

till bedtime." This house, on examination, was very well cured.

I forgot to mention in the proper place that my barns are made as tight and close as possible. I do not, however, think that the roof should be very close; my barns are covered with oak boards, and are generally open enough to let off the smoke and vapour as fast as they are formed. Some of my neighbours have windows made just under the comb of the house.

As the essential properties of the tobacco plant are very volatile, the writer maintains that the sooner it is well cured and pressed into hogsheads the better, and the hogshead cannot be too tight. If the crop comes in early, so as to admit of being cured in autumn, it will be all the better. It should not, if possible, be allowed to remain out of the hogsheads all winter. He tells the planters of Virginia not to fear that they will ever overstock the world with fine tobacco, and thereby reduce the price. The finer it is made, the less will be made in Europe and other countries not so favourable to the perfection of its qualities. The low, dull state of the markets for common and inferior tobacco, is not the result of too much, but a consequence of its indifferent quality, which causes it to be little if any better than that which is made on the continent of Europe, with which it comes in competition.

In Maryland and Virginia it is estimated that one good hand can manage 6000 plants, which, allowing a yard to each, would cover about an acre and a quarter. A hogshead weighing 1350 lbs. (some weigh 1800) is considered a good yield for one hand. On the fine rich lands of Kentucky, from 1000 to 1500 lbs. are raised per acre. In Virginia the leaves of 4 good plants are estimated to make 1 lb. of cured tobacco.

Some of the diseases, accidents, and enemies to which tobacco is exposed, are, in the language of the planter, worm-holes, ripe-shot or sun-burnt, moon-burnt, stunted, torn by storms of hail and wind, injured or killed by frost, house-burnt.

TOBACCO, *Chemistry* &c. Under the head of ΑΜΜΟΝΙΑ it has been observed that the juice of fresh tobacco leaves contains ammoniacal salts. The existence of the volatile alkali in cured tobacco, is shown by the action of the smoke of a cigar upon blue vegetable flowers, or vegetable colours, turning the reds to purple, and the purples to green.

When the leaves of the tobacco plant are subjected to distillation with water, a weak ammoniacal liquid is obtained, upon which a white, fatty, crystallizable substance swims, which does not contain nitrogen, and is quite destitute of smell. But when the same plant, after being dried, is moistened with water, tied together in small bundles, and placed in heaps, a peculiar process of decomposition takes place. Fermentation commences, and is accompanied by the absorption of oxygen; the leaves now become warm and emit the characteristic smell of prepared tobacco and snuff. When the fermentation is carefully promoted and too high a heat avoided, this smell increases and becomes more delicate; and after:

the fermentation is completed, an oily, azotized, volatile matter called *nicotine* is found in the leaves. This substance, *nicotine*, which possesses all the properties of a base, was not present before the fermentation. The different kinds of tobacco are distinguished from one another, like wines, by having very different odouriferous substances, which are generated along with the *nicotine*.

On a soil which contains potash, both wheat and tobacco may be reared in succession, because the latter plant does not require so much of the phosphates, salts which are invariably demanded largely in wheat, but requires only alkalies, and food containing nitrogen.

According to the analysis of Posselt and Reimann, 10,000 parts of the leaves of the tobacco plant contain 16 parts of phosphate of lime, 8.8 parts of silica, and no magnesia; whilst an equal quantity of wheat straw contains 47.3 parts, and the same quantity of the grain of wheat 99.45 parts of phosphates.

Now, if we suppose that the grain of wheat is equal to half the weight of its straw, then the quantity of phosphates extracted from a soil by the same weights of wheat and tobacco must be as 97.7 : 16. This difference is very considerable. The roots of tobacco, as well as those of wheat, extract the phosphates contained in the soil, but they restore them again, because they are not essentially necessary to the development of the plant. (*Liebig's Organic Chemistry*.)

Tobacco is a plant that contains much mineral matter. An acre yielding 800 lbs. would contain about 160 lbs. of mineral matter, most or all of which is carried off from the soil. Hence the exhaustion of land from this crop is greater than that from grain crops, *provided their straw be duly returned to the fields*, as in this case the loss would be confined to the phosphates and other mineral matters removed with the grain, which in a four years' rotation would amount to only about 83 lbs. per acre, instead of about 600 lbs. carried off by the tobacco in the same time. The following analysis furnished by Professor J. F. W. Johnston of the ashes of tobacco leaves, gives the mineral constituents, with their proportions per cent :

Potash	12.14
Soda	0.07
Lime	45.90
Magnesia	13.09
Chloride of sodium (common salt)	3.49
Chloride of potassium	3.98
Phosphate of iron	5.48
Phosphate of lime	1.49
Sulphate of lime (gypsum)	6.35
Silica (sand or flint)	8.01

From this view of the mineral constituents of tobacco, the soil most favourable to its growth may be readily recognised. The proportions of the several articles removed by every 100 lbs. is not difficult to estimate, with the additions of the special manures required to prevent the exhaustion of the soil. Among these it will be observed, the largest amounts are lime, magnesia, potash, iron, and silica.

Some successful results are reported in the *Albany Cultivator*, of the culture of tobacco in Massachusetts. The variety produced there is called the "Connecticut Seed-leaf," and it usually brings double the price, and sometimes even more, of Virginia and Kentucky tobacco. For

a profitable crop, rich land is necessary, though sandy soils manured at the rate of 10 or 20 two-horse-loads per acre, will produce well. With good management, the yield is from 1500 to 2000 lbs. per acre, of marketable tobacco, capable of bringing an average price of 8 cts.

The Massachusetts growers believe that, with proper attention, instead of injuring the soil, tobacco may be made an ameliorating or improving crop, the liberal manuring required favouring the after crops; wheat and other grain, and also grass crops, flourishing better when tobacco forms a part of the rotation, than where it does not. Where \$36 worth of manure was put upon 1 acre and 100 rods, a ton of tobacco was raised, worth \$160. The same piece of land, sown immediately afterwards in wheat, yielded 30 bushels. The following crop being grass, produced 4 tons of hay at two cuttings. One farmer in South Hadley had 17 acres planted in tobacco.

A long and instructive account of the mode of cultivating tobacco in Cuba is given in the Report of the Commissioner of Patents for 1847.

TOMATO, or LOVE-APPLE. (*Solanum lycopersicum*; *Lycopersicum esculatum*.) Several varieties of this plant are found in our gardens and fields, some of which are red and others yellow; among the reds are, 1st, the common large; 2d, the small; 3d, the pear-shaped; 4th, the cherry-shaped. Of the yellow there are, 1st, the large yellow; 2d, the small or cherry-yellow.

The tomato is a native of South America. It forms a rich vegetable sauce, and an excellent addition to soups. With sugar it makes a very valuable preserve. In the Middle or Northern States, the seed may be sown in April, in a hot-bed; or in May, in a warm situation, and transplanted as soon as the season will admit. A middling soil produces more fruit and less vines than a very rich soil.

Tomatoes remaining on the vines late in the season, and which, if left out, would be destroyed by frost, may be preserved for many weeks by simply pulling up the vines and hanging them up, with the fruit upon them, in some house or sheltered situation. Those not ripe when the vines are pulled mature afterwards.

Cows are said to thrive well and give an increased quantity of milk of improved quality when fed upon tomatoes. They may not take them kindly at first, but are said to grow fond of them soon.

TOMENTOSE. In botany, means covered with dense, close, white hairs, or down.

TOP-DRESSING. A term applied to such manures as are laid upon land without being turned in: and also to the practice of dressing the surface of grass land, or other crops, with some kinds of highly reduced manure, that can be evenly spread out or sown equally over them by the hand.

A great variety of substances are in use for this purpose, such as soot, ashes, guano, and the dung of pigeons and other birds, rape dust, lime, gypsum, &c., the benefits of which are noticed under their respective heads.

TORMENTIL (*Tormentilla*, alluding to a supposed efficacy in toothache, as well as to a belief that it could cure diseases of the bowels). The British species are two; both perennial. They are now regarded as belonging to the genus *Potentilla*, and the natural order *Rosaceæ*.

1. In England common tormentil or sept-foil (*P. officinalis* or *tormentilla*) grows in barren pas-

tures, heaths, and bushy places. The stem is slender, ascending, branched. The woody red roots are so astringent as to be used in the western isles of Scotland for tanning leather, for which purpose they are superior even to oak bark. The root is likewise one of the most efficacious of English indigenous aromatic astringents, and may be used with great effect in cases where medicines of this class are proper; namely, in chronic purgings. It is usually given in decoction, but is best administered in powder.

2. Trailing tormentil (*T. reptans*). This species grows sparingly about the borders of fields and hedges. The stems are 2 feet long, hairy, prostrate, but not creeping; the leaves composed of 5 leaflets, obovate, strongly serrated, bright green, on long hairy footstalks. Flower of a full yellow, twice the size of the foregoing. Stipules undivided. It is also astringent, but less so than its congener.

TOUCH-ME-NOT. See **BALSAM.**

TOWER-MUSTARD (*Turritis*, from *turris*, a tower; the foliage is so disposed on the stems as to give them a pyramidal form, and for the same reason the plants are called tower-mustard). The species are hardy annuals: one, the smooth tower-mustard (*T. glabra*), is indigenous, and grows wild on banks and by roadsides, in a dry gravelly soil. The flowers are numerous, closely corymbose, pale sulphur-coloured. Pods very long and slender, on short stalks. Seeds about 60 in each cell, very small.

TRACTION. See **CARTS, HORSE, ROAD, STRENGTH, &c.** The reader may also consult a very able essay "On Draught" in Professor Youatt's work on *The Horse*, of which our space will not allow us to give even an outline.

TRANSPLANTING. The act of removing either cuttings, layers, roots, or entire plants, from one soil into another. See **PLANTING** and **PROPAGATION.**

TRAPA NATANS. This plant grows in ponds, and is eaten like the chestnut. The canal of Versailles is covered with the plant, and the root is sometimes served up at table.

TRAVELLER'S JOY. See **CLEMATIS.**

TREACLE-MUSTARD (*Erysimum*, from *erion*, to draw and cure: it is popularly reckoned a cure for a sore throat, and is also said to draw and produce blisters). An extensive genus of plants, possessing warm and pungent qualities. The leaves are simple, often lanceolate, and nearly entire. Flowers corymbose, yellow, sulphur-coloured, or white. Pods in very long upright clusters. There are in England three indigenous annual species. 1. The worm-seed treacle-mustard (*E. cheiranthoides*): 2. The garlic treacle-mustard (*E. alliaria*), known also under the local names of Jack-by-the-hedge, or sauce-alone. 3. Hare's-ear treacle-mustard (*E. orientale*). The second is the most common. The whole herb is smooth, shining, deep green, and exhales, when bruised, the smell of garlic; and the seeds are stronger than the other parts of the plant. The stem is a foot high, somewhat branched. The leaves stalked, cordate, acute, veiny, and broadly serrated. The flowers are white. The pods erect, smooth, on a spreading stalk. The peasantry

eat the young leaves with bread and butter. See **HEDGE MUSTARD.**

TREES are divided naturally into two principal classes, namely, fruit and timber trees: the former includes all such as are raised chiefly, or entirely, for their edible fruit, an account of which, together with their modes of cultivation, the reader will find in alphabetical order, and also in the articles **FRUIT, ORCHARD, PRUNING, &c.**

The second division comprehends those trees, the wood of which is employed in ship-building, machinery, or for other useful purposes, such as the oak, elm, larch, &c., the culture of which has been discussed under those respective heads. For the diseases of trees, see **AMERICAN BLIGHT, CANKER, MILDEW, &c.**

By timber, in English law, is intended only such trees as are considered fit and proper by the custom of the country to be employed in building or repairing houses; and timber trees are those which are of 20 years' growth. The custom of the country naturally varies with regard to the kind of trees which are considered to be timber. The oak, the elm, and the ash are universally deemed to be such: beech is considered so in Buckinghamshire, birch in Yorkshire, because it is generally used for buildings of an inferior kind. Thus the chestnut, walnut, lime, and others may, under similar customs, be considered timber. If pollards are sound, it seems that they must be considered as timber: this was the opinion of Chancellor King.

According to English common law, the property of the tree is in the owner of the soil on which it grows; and though its roots may extend into two estates, yet it belongs to the owner of the land on which it was originally planted or sown. Nurseries of young fruit trees, raised for filling up orchards, cannot be removed by the tenant, but a nurseryman may do so.

The tenant for life, without impeachment of waste, of an estate, may cut down timber in a husbandlike manner. But the Court of Chancery will restrain such tenant from cutting down underwood of an insufficient growth, or ornamental or sheltering trees. But this shelter or ornament is not to be construed to mean extensive woods.

By custom, but not by common law, the trees growing on a copyhold estate may belong to the lord. The copyholder is not guilty of waste if he cut timber merely for necessary repairs. Timber trees growing on the estates of ecclesiastical corporations are to be devoted to the repair of the church. And consequently neither they nor their lessee can fell timber for their own use. Neither can a mortgagor cut down timber if the land without it is a scanty security. But the Court of Chancery will not restrain a mortgagor from cutting timber, unless the security is insufficient without it. Though the timber of the estate belongs to the landlord, and also such trees as are likely to become timber, yet the general property in bushes and trees not timber is in the tenant, and, therefore, the landlord cannot maintain an action of trespass against a stranger, for cut-

ting bushes and thorns growing in a hedge, if the tenant afterwards assented. The tenant or lessee has no right to cut timber; and in an action for waste the defendant cannot give in evidence, even in mitigation of damages, that the timber was cut for the purpose of necessary repairs; or, that after it was cut the timber was exchanged with the lessor's consent for timber more fit for the purpose intended. But he may cut timber without waste which has been cut within 20 years; and in Kent they are in the habit of cutting trees of 26 or 28 years' growth. Windfalls belong to the lord, and the Court of Chancery will, if necessary, order it to be preserved for him who has the first estate of inheritance in the land. See BARK, FORESTS, NURSERY, TIMBER, &c.

TREFALLOW. A local term, signifying to plough land the third time before sowing.

TREFOIL (*Trifolium*, from *tres*, three, and *folium*, a leaf. All the species have trifoliate leaves. The French call it *trèfle*, and the English *trefoil*, or clover). An extensive and well-known genus of herbaceous plants, natives of cold or temperate climates, either perennial or annual. Many of the species are highly important as food for cattle, either fresh or in the state of hay, often acquiring a fragrant scent in drying. The white, red, and yellow clover are amongst the most valuable herbage plants adopted in European agriculture.

Lucern has been recommended as superior to clover and sainfoin, and various other leguminous plants have been highly extolled; yet the red clover for mowing, and the white for pasturage, far excel all other plants in these respects. All the species thrive in common garden soil, and many of them being very showy are well suited for ornamenting the flower border. The perennial kinds are readily increased by dividing the plants at the roots in spring, or by seeds. See BIRD'S-FOOT TREFOIL, CLOVER, and MELILOT.

TREFOIL, THE MARSH. See BUCK-BEAN.

TRENCH PLOUGH. See PLOUGH.

TRENCHING. See SUBSOIL PLOUGHING.

TRIFOLIUM INCARNATUM. A well-known and much esteemed species of trefoil. See CLOVER and TREFOIL.

TRITICUM. See WHEAT-GRASS.

TRUFFLE (*Tuber cibarium*). A round fungus growing under ground in many parts of Southern Europe, destitute of roots and leafy appendages. It absorbs nutriment at every point on its surface. The truffle is composed of globular vesicles, destined for the reproduction of the vegetable, and short, barren filaments, called by Turpin *tigellules*; and the reproductive bodies, *trufinelles*. Each globular vesicle is fitted to give origin to a multitude of reproductive bodies, but a few of them only perfect the young vegetable. The parent dies; the trufinelles are nourished by its dissolving substance, and the cavity it originally filled becomes the abode of a multitude of young truffles; but many of them die, the stronger starving the weaker. As truffles spread over a large space, it is difficult to say by what means they progress. The truffle is one of the most wholesome and nutritive of the esculent fungi, and is generally discovered by means of

dogs, which are taught to scent it; so that, on smelling the truffle, they bark and scratch it up. Truffles are highly esteemed at the tables of the luxurious, where they are served up, either roasted in a fresh state like potatoes, or they are dried, shred, and dressed as ingredients in soups and ragouts. See TUCKAHOE.

TRUSS. A bundle of hay, straw, &c. It may be observed that in England a truss of hay must contain 56 lbs. or half a cwt.; a truss of straw 36 lbs.: 36 trusses make a load. In June, July, and August, a truss of new hay must weigh 60 lbs. See HAY and STRAW.

TUCKAHOE. This curious vegetable is sometimes known by the name of *Indian bread*, or *Indian loaf*. It is found in the Southern States on the Atlantic, and even as far north as Kent county, Del. It is a natural production, the origin of which has greatly perplexed naturalists, as it is commonly found several feet under the surface, and, like the truffle of Europe, has apparently no stem or leafy appendage connecting it with the external atmosphere. They are generally found through the instrumentality of hogs, whose acute sense of smelling enables them to fix upon the spot where they lie buried. They are usually of a globular or flattened oval shape, and rather regular surface, the large ones resembling somewhat a brown loaf of coarse bread. The size varies from that of an acorn to the bigness of a man's head. Clayton, the celebrated botanist, was the first naturalist who has mentioned the Tuckahoe. He gave it the Latin name of *Lycoperdon solidu*. (See his *Flora Virginica*.) In May, 1817, Dr. Macbride, of Charleston, S. C., communicated a memoir on the subject to the New York Philosophical Society. Although the tuckahoe is quite common in the Southern and one or two of the Middle States, its natural history is still involved in much obscurity. Its name in the Indian language is said to designate bread, and is applied to certain edible roots. Though sometimes found emerging from the earth and exposing a small part of the surface, it is generally met with 2 or 3 feet below the soil. When first dug up, it is soft enough to be easily cut with a knife, and of an acrid taste. Its colour internally is white, like that of the meat of the cocoa-nut, and its texture compact and homogeneous. It is covered with a tough substance, strongly adhering to the white *parenchyma*, of a dark brown colour, and somewhat wrinkled. When dried, the internal substance becomes hard and loses its acrimony, possessing very little taste or smell, and capable of being reduced to powder without difficulty. When examined by the microscope, the tuckahoe exhibits no fibres or pores or any other indications of organization, so easily detected in roots and other vegetable productions of ordinary growth. Its substance breaks as easily in one way as another, like a lump of starch or chalk. From these characteristics, together with the peculiar nature of the bark or external covering, it has been classed among the fungus tribe. In those parts of the country, however, where the tuckahoe most abounds, it is generally supposed to be the root of a species of *Convolvulus* (*Panduratus*), called "the man of the earth." But both

Dr. Macbride and Mr. La Conte, after much attentive examination in its native state, are decidedly of the contrary opinion, the roots of the *Convolvulus* being unlike those of the tuckahoe. Most of the southern botanists regard it as a fungus. (See *Medical Repository*, vol. vi.) See TRUFFLE.

TULIP (*Tulipa*). A genus of celebrated and much-prized florists' flowers. They succeed well in rich loam and sand, and are increased by offsets; new varieties are obtained from seed. The choicer kinds require to be taken up and dried after they have ceased flowering, and planted again in the autumn. They should be slightly protected in very rainy or frosty weather, as they are very liable to rot. One species, the wild tulip (*T. sylvestris*), is indigenous to England, growing about old chalk-pits. It bears sweet-scented, bright-yellow, somewhat drooping flowers in April. Although the *Tulipomania*, which rose to such an absurd height in Holland in the 17th century, is long since extinct, yet the rage for producing fine tulips still exists. The finest tulips are reared at Haarlem. The principal florists have their favourite breeders. A breeder is a seeding tulip, 8 or 9 years from the seed, but still vigorous. If the stem be tall; the petals of the flower blunt at the apex; if the flower be self-coloured, or of an equal, uniform colour on both surfaces of the petals; if the base be pure white or bright yellow; and the anthers and stigmas dark or black, it is highly esteemed as a breeder. The bulb is planted deep in a sheltered, sunny place, and care is taken to prevent the leaves being injured by wind or hail; the stem is propped, and the flower carefully secured from the hot rays of the sun, as well as from wind and violent rain. The seed is carefully collected, and from it many fine tulips are anticipated. The varieties at Haarlem are very numerous; they are chiefly varieties of the *Tulipa Gesneriana* and *T. Suaveolens*.

TULIP POPLAR (*Liriodendron tulipifera*). This tree, the only one of its genus, is found in great abundance in the Middle United States, where, on the rich woodlands in the alluvials bordering the Delaware and other bays, it attains a growth which makes it the most majestic tree of the American forest. Trees are frequently found from 100 to 140 or 150 feet in height, and 6 or 8 feet in diameter, the trunk being sometimes 60 or 80 feet perfectly straight and without a knot or branch. This stately tree, when its wide-spreading branches extend from the ground to the summit, loaded in May with its tulip flowers, has been referred to in the article on the BEE, as the most magnificent of floral productions. The wood, which is very soft, is highly valued for building, and also for many purposes to which it is applied by the cabinet-maker and other mechanic artists. The variety called *yellow poplar* is generally preferred. It is known by its thicker and more deeply furrowed bark. The bark, which is very thick and spongy, is also a valuable aromatic bitter; and has been successfully used in intermittents.

TULL, JETHRO. The science of agriculture, although the first in importance to mankind, is yet remarkable for the few great names

whose discoveries or general abilities adorn its history. For an explanation of this fact, we must in some measure be contented with the common observation that its advances, its improvements, are so slow, as to be almost imperceptible; are dependent upon much more tedious experiments than any other science: for instance, it is true that many, very many of the processes, daily witnessed and carried on by the cultivator, are based upon chemical principles, and may be illustrated, and very materially assisted, by chemical experiments: but those who have studied the science the most carefully are fully aware that no experiments upon the laws of dead matter even nearly equal in difficulty those upon living substances, for these last, in many instances, seem endowed with powers which completely neutralize and overcome the very principle of chemical attraction and repulsion. Such experiments, too, are not, like those made in the philosopher's laboratory, secure from interruption, and carefully and readily guarded from every source of error; on the contrary, those of even the most scientific, the most careful cultivators, are of necessity liable to many accidents, are ever the sport of the winds and the weather, require months to complete, and often the duration of a life to repeat and firmly establish. Then, again, to add to the difficulty of such investigations, there are hardly two soils to be found, in England or elsewhere, whose composition and conditions are even nearly the same. All differ either in the proportion of some ingredient, in climate, in declination, or in the nature of their substrata; the variations in their treatment, therefore, must often be as different as their numerous varieties. Thus, encircled with difficulties, requiring for the attainment of considerable eminence the union of both practical experience, patient and long-continued research, and scientific knowledge, we need hardly feel surprised that those who have made important improvements in agriculture have been but few in number, and that these illustrious exceptions to the general rule have appeared at very distant intervals. The farmer, too, however skilful and successful in his business, however industrious and talented, is but rarely induced to describe the improvements he has caused, or the implements he has improved or invented; he is too often content with the profit derived from his own ingenuity, and too frequently lets others reap all the honours of discoveries to which he is more justly entitled.

In the list, however, of distinguished English farmers, Jethro Tull presents us with a highly honourable exception to the general rule; for, utterly regardless of all selfish considerations, he not only made great and successful efforts for the promotion of agriculture, but he made those valuable researches, publicly known in a work entitled the *Horse-hoeing Husbandry*, which will hand him down to all after-ages as one of the chief of English farmers; as a patriot who, undaunted by the natural difficulties of the attempt, attained great and important advances in the cultivating and increasing the fertility of the land, and in enlarging the resources of the followers of a business to which he was not originally bred; for, as we shall

presently see, Tull became a farmer not from inclination, but from the effects of a sickly constitution and diseased frame.

The life of Jethro Tull will, indeed, well repay the careful and often-repeated study of the English farmer in more ways than one; will afford not only instruction, but encouragement to him who has to contend against the poorest soils, the most adverse of circumstances; for, if such a cultivator holds a poor, thin, hungry soil, so did Jethro Tull;—if he farms in a remote and desolate district; if he has ignorant and obstinate labourers; if he is visited by sickness; if he is almost driven from his profession by even incurable diseases, so, let him be assured, was that great farmer whose labours are the subject of this memoir. The dauntless intrepidity and perseverance, too, of Tull, should always be remembered to his honour. Knowing, as he did, the correctness of the principles for which he so nobly contended, he never relaxed in his endeavours to induce their general adoption; and if it was only after the lapse of many years, when Tull had long been in his grave, that those principles and those mechanical inventions for which he so energetically contended were commonly adopted, the fault was not Tull's, but must be attributed to the ignorance and the apathy of the age in which he made his important, his ill-requited discoveries.

The debt of gratitude which all modern farmers owe to Tull is, indeed, a large one; he was the first who boldly and zealously contended for the adoption of improved machinery in all agricultural operations; the ploughs which he depicts in the engravings which accompany his *Horse-hoe Husbandry*, have not been very materially improved in the last century. He invented several varieties of hand and horse-hoes. He was very nearly, if not quite, the first who produced a practically useful drill. He shared the fate of all those who, as discoverers, have the temerity to disturb old systems. He was regarded by the bulk of his contemporaries as an idle, restless innovator. He was ridiculed, thwarted, and opposed in every way, not, as might have been reasonably expected, by the most ignorant, but by those who either did know, or ought to have known, better things. His neighbours regarded him as almost a lunatic; and the tradition of the neighbourhood of Shalborn still is, that he was even wicked enough to attempt to banish the flail from his farm, and that he had a machine in his barn at Prosperous, which worked a set of sticks so readily as to thrash out his corn without the assistance of the labourer. This, there is little doubt, was an attempt to construct a thrashing-machine; and that it was, in those quiet days for agriculture, regarded as a wonder, is proved by the existence of the tradition. When thus located in a remote rural parish, on the borders of the counties of Berks, Hants, and Wilts, Tull wrote his *Husbandry*, a book which is not nearly so well known as it ought to be; for, though the progress of science has rendered a considerable portion of Tull's writings obsolete, yet much, very much, remains unaltered by the progress of discovery,

to amply repay the farmer for a careful and often repeated perusal.

Tull wrote with all the modesty and diffidence of genius: he tells us, in the preface to his *Husbandry*, that he knew that he had undertaken a task of which he was incapable, and that it was produced during a long confinement within the limits of a lonely farm, in a country where he was a stranger. And when we remember that he was, through life, an invalid,—obliged to abandon his sedentary profession of the law, and seek for health by foreign travel and by country pursuits,—when we think of these things, we cannot but still more admire the energy of mind he betrayed, and the difficulties he overcame. He feelingly alludes to some of these, when he says, with regard to his great work—"Tis no wonder that the style is low as the author, or as the dust that is here treated of, since the whole was written in pains of the stone, and other diseases as incurable and almost as cruel; but fine language will not fill a farmer's barn." Every thing connected with the history of this great benefactor of agriculture must be interesting to the cultivators of this and all other countries. I regret that, with some industry, I have not been able to obtain for the farmer more information with regard to him. He was born in Oxfordshire, on his paternal estate. He was educated for the legal profession, became a member of Staple Inn, and was called to the bar on the 11th December, 1693, by the benchers of Gray's Inn, and not at the Temple, as is commonly asserted in the biographical dictionaries. He was afflicted soon after his call to the bar with a pulmonary disorder, and, in consequence, abandoned his Oxfordshire farm, and for some time travelled on the Continent. He was for a considerable period at Montpellier, in the south of France. Returning to England, he took into his own hands the farm called Prosperous, at Shalborn, in Berkshire, where, again resuming those agricultural efforts which he had commenced in Berkshire, he wrote his *Horse-hoe Husbandry*.

During his tour on the Continent, Tull carefully compared the agriculture of France and Italy with that of his own country, and omitted no occasion to observe and note every thing which supported his own views and discoveries. He particularly, on more than one occasion, in his work, alludes to the similarity of the practice followed by the vine-dressers of the south of Europe, in constantly hoeing or otherwise stirring their ground, and his own horse-hoe husbandry. Finding that they did not approve of dunging their vineyards, Tull readily adduced the fact in favour of his own favourite theory, that manuring a soil is an unnecessary operation.

After Tull's decease, his lands in Berkshire found their way into Chancery, and were sold, by order of the court, in 1784, to Mr. Blandy, the father of the present owner. It consists of about 70 acres of freehold land, but Tull held about 130 acres in addition, by a different tenure. The house in which he dwelt has been modernized, but the old-fashioned brew-house yet remains as Tull had it; and when I visited

Prosperous, in July, 1840, was still in very good condition. Of the out-houses, Tull's granary and his stables are yet in existence, though fast verging to destruction; and at the end of this granary, which Tull built, is an old well in which, when cleared out some years since, was found, deeply buried in the accumulated mud of nearly a century, a three-pronged hoe, which there is no doubt belonged to Tull, and is now in the museum of the Royal Agricultural Society of England. Into this well it was most likely thrown by his men, who, adopting the use of his new tools with the utmost reluctance, annoyed him in many ways. Against these he declaims with much bitterness: "Tis," he says, "the most formidable objection against our agriculture, that the defection of servants and labourers is such, that few gentlemen can keep their lands in their own hands, but, rather than make nothing of them, they let them for a little to tenants who can bear to be insulted, assaulted, kicked, cuffed, and bridewelled, with more patience than gentlemen are endowed with." This burst of feeling would very clearly intimate the probable truth of the case—that Tull was energetic and irritable—that his servants pillaged and annoyed him, and that he did not submit to their impositions without struggling against them in a way which his legal education should have taught him to avoid.

Such was the spirit of enterprise, and such was the genius of Tull, that no difficulties, however formidable, stopped him in his researches. His experiments, carried on in his garden and in his house, with regard to the food and the habits of plants, some of which he gives in the first pages of his work, betray the thirst for knowledge, the industry, and tact, which he possessed.

The tradition of his neighbours is, that, when confined to his room and to his couch by his incurable maladies, he yet managed to carry on his experiments on vegetation, by having large boxes and garden-pots of earth placed in his room, and before his windows, where he sowed his seeds, and watched their progress under different modes of cultivation, with all the zeal of a martyr, and the enthusiasm of an inventor. He is still spoken of by the old labourers of that district, as being a man whom it was impossible to oppose, in any of his plans, with eventual success. He was evidently the wonder of his neighbours, who would, perhaps, have regarded him as a magician, if the age of witchcraft had not then been nearly, if not quite, over. It would seem, from what Tull says (p. 50), that it was in 1701 that he constructed his first drill for planting sainfoin. And the occasion of his doing so he thus describes in his preface: "It was very difficult to find a man that could sow clover tolerably; they had a habit (from which they could not be driven) to throw it once with the hand to two large strides, and go twice on each cast; thus, with 9 or 10 pounds of seed to the acre, two-thirds of the ground was unplanted, and on the rest it was so thick that it did not prosper. To remedy this, I made a hopper, to be drawn by a boy, that planted an acre sufficiently with 6 pounds of seed; but

when I added to this hopper an exceedingly light plough, that made 6 channels 8 inches asunder, into which 2 pounds of seed to an acre being drilled, the ground was as well planted. This drill was easily drawn by a man, and sometimes by a boy."

Jethro Tull's great improvements in tillage consisted in the use of his drill, and in the adoption of such wide intervals between his rows of turnips (several feet, 3 to 6), that the horse-hoe could be easily and constantly employed. He ridiculed, very justly, the delusions under which the farmers then laboured with regard to the unvaried advantages of thick sowing. He told them that they "did not grudge to bestow three or four pounds in the buying and carriage of dung for an acre, but that they thought themselves undone if they afforded an extraordinary eighteen-pennyworth of earth to the wide intervals of an acre, not considering that earth is not only the best, but also the cheapest entertainment that can be given to plants." And again, in another place (p. 32), he told the thick-sowing, broadcast cultivators of those days, what must have not a little astonished them, "that every row of vegetables to be horse-hoed ought to have an empty space or interval of 30 inches on one side of it at least, and of nearly 5 feet in all sorts of corn;" and he was very justly suspicious that what he was going to advance "would seem shocking to them before they have made trials."

Tull was the first English farmer who advocated to its fullest extent the decided advantages of constantly pulverizing and stirring the soil, to illustrate which almost all his experiments were directed. His explanations, however, of his own discoveries were not always so good as the object he had in view, although there is little to find fault with in his theory of the advantages of tillage. "I have had," he says (p. 24), "the experience of a multitude of instances, which confirm it so far, that I am in no doubt that any soil, be it rich or poor, can ever be made too fine by tillage; for one cubical foot of this minute powder may have more internal superficies than a thousand cubical feet of the same or any other earth tilled in the common manner; and I believe no two arable earths in the world do exceed one another in their natural riches twenty times; that is, one cubical foot of the richest is not able to produce an equal quantity of vegetables, *ceteris paribus*, to 20 cubical feet of the poorest; therefore, it is not strange that the poorest, where, by pulverizing, it has obtained 100 times the internal superficies of the rich, untilled land, should exceed it in fertility; or, if a foot of the poorest was made to have 20 times the superficies of such rich land, the poorest might produce an equal quantity of vegetables with the rich. Besides, there is another extraordinary advantage when a soil has a large internal superficies in a very little compass; for then the roots of the plants in it are better supplied with nourishment, being nearer to them on all sides within reach than it can be when the soil is less fine, as in common tillage, and the roots in the one must extend much farther than in the other to reach an equal quantity of nourishment; they must range and fill perhaps

above 20 times more space to collect the same quantity of food. But, in this fine soil, the most weak and tender roots have a free passage to the utmost of their extent, and have also an easy, due, and equal pressure everywhere, as in water."

He did not confine his attention to the advantages of thoroughly pulverizing the land: he was also an advocate for much deeper ploughing than was usual in his time, and in one or two places laments the supineness of the farmers in this respect, and the idleness of the ploughmen, in only half-penetrating the soil, for fear of injuring the appearance of their horses; and he illustrated the advantages of his proposed mode of ploughing by the best means in his power, not only by general observation, but by also appealing to several very ingeniously-contrived little experiments upon the habits of plants.

Tull saw very clearly that this theory of the advantages of pulverizing and deepening soils would be strongly supported if it could be shown that the roots of the commonly cultivated grasses would, under favourable circumstances, penetrate to more considerable depths than the ordinary shallow soils of the farmer allowed them. He paid, therefore, considerable attention to the roots of plants, not only in his small experimental glasses and pots, but in his fields. He found, by some observations on the roots of some wheat plants growing in a deeply loosened soil, that their roots had penetrated to more than double the depth of the commonly ploughed land of the farmer; and all this I can support from my own observations on the roots of the crops growing on the edge of chalk and loam pits, and in other situations where the soil has been loosened to great depths. Tull, too, noticed the very considerable and rapid extension of the roots of trees growing near to old dunghills, sewers, &c., and he hence adduced another argument in favour of the advantages which are derived from assisting, in the best ordinary way then known, the roots of plants to penetrate deeper into the soil. Had Tull lived in our days, he would have been an ardent advocate for the subsoil and subsoil ploughs: he would not then have confined his efforts to the increased use of the common plough and the trenching-spade.

A century has now elapsed since Jethro Tull thus earnestly endeavoured to draw the attention of the farmers of England to the importance of deepening, pulverizing, and mixing their soils. Tull, unfortunately for himself, lived an age or two too soon: had to encounter the ignorance and the obstinacy of his workmen, the apathy of his neighbours, the ridicule of those who understood him not, and the anger of the indolent. The principles, however, which he inculcated have survived and overcome all these obstacles; are yearly more prized, because better understood. Tull thought that the earth, and the earth alone, did every thing for vegetation; astonished at the effects which were produced by merely deepening and pulverizing, he allowed his enthusiasm to carry him too far. "Every plant," he tells us, "is earth, and the growth and true increase of a plant is the addition of more earth;" and in

another place he adds, "too much nitre corrodes a plant, too much water drowns it, too much air dries the roots of it, too much heat burns it; but too much earth a plant never can have." Thus impressed with the value and the all-sufficient powers of earth to support vegetation, it need hardly surprise us that Tull soon came to the conclusion that, under a proper management of the plough and the scarifier (for a rude instrument of this kind was known in Tull's days), the land might be so pulverized and deepened as to bear its crops without the addition of any decomposing manures.

Tull deceived himself, in this instance, by not attending to the quantity of finely-divided, slowly decomposing substances, which all cultivated soils contain in some shape or other. By ploughing and pulverizing, the progress of the putrefaction of these organic matters was accelerated, they were rendered more soluble, and then the succeeding crop was, by their decomposition, sufficiently nourished. But these operations could not be long continued; at each repetition of the experiment the amount of the stubborn, slowly decomposing matters of the soil became reduced, and, in consequence, the crops produced under the system became less. Tull's farm at Shalborn was well adapted to try the effect of this theory; it is situated on the crown of a rising ground, whose thin-skinned soil is a light loam mixed with gravel, resting on chalk; of such a soil the organic matters, of necessity, are speedily exhausted by cropping and pulverizing. Tull soon found this out; he struggled hard against the necessity, but he finally had recourse to the employment of manures; he found at last, that, however valuable good tillage is to the application of fertilizers, it is utterly incapable of supplying their place. The failure of Jethro Tull, therefore, in this great effort was complete; but it was the failure of a man of genius. He tardily admitted the value of dunging the land; but he still explained its operation in such a way as to refer all the benefit to the earth, when he told the farmers of those days, "its use is not to nourish, but to dissolve, that is, divide the terrestrial matter which affords nutriment to the mouths of vegetable roots." To a very considerable extent Tull was correct in this explanation of the mode in which common manure operates in rendering the soil more fertile; for it renders the land more pervious to the atmospheric gases and vapour, and, in consequence, all vegetation growing upon the land is better nourished. But the benefit, as Tull imagined, does not end here; the organic matters of the compost, as they slowly dissolve in the soil, gradually give out a considerable proportion of various gases, such as carburetted hydrogen and carbonic acid gas, all of which are absorbed by the plant at the moment of their extrication, enter into new combinations, and promote its vigorous growth. That this is not a merely mechanical advantage is proved in several ways; for instance, the benefit of the application of the decomposing compost is proved to be just as advantageous in some instances to the crop where it is not even mixed with the soil. This is shown by the effect (known to every gar-

denier) which is produced by placing the manure in a chamber beneath the soil, so that the roots of the plants neither mix with, nor does the soil even touch the compost. The gases of putrefaction, however, arise and mix with the soil, and the most luxuriant effects are produced without any division of "the terrestrial matter," which Tull imagined to be so essential to the explanation of the phenomenon. We need not search in the works of Tull for any attempts to use the drill for the application of fertilizers, for all Tull's efforts were directed to cultivate the earth without manure of any kind. He admitted the necessity of using it at all only with extreme reluctance; he told his readers, 7 years before his death, that "the particular scheme of raising constant annual crops of wheat without dung or fallow is as yet only upon probation; but, by six crops I have had in that manner, I see nothing against their being continued. This, it is true, requires greater care in their management than any other branch of the husbandry; but he who can do this without dung or fallow, may easily do it with one or both of them; and there may be such wet, clayey land which the plough cannot well pulverize without help of the ferment or dung."

Tull, in fact, let no opportunity escape him to decry the ill effects of employing manure. Modern gardeners would be astonished at his zeal when he contends for its banishment from the kitchen garden. "There is," he says (p. 18), "much more reason to prohibit the use of dung in the kitchen garden, on account of the ill taste it gives to esculent roots and plants, especially such dung as is made in great towns. It is a wonder how delicate palates can dispense with eating their own and their beasts' ordure, but a little more putrefied and evaporated, together with all sorts of filth and nastiness, a tincture of which those roots must unavoidably receive that grow amongst it. Indeed, I do not admire, that learned palates, accustomed to the gout of silphium, garlic, and mortified venison, equalling the stench and rankness of this sort of city muck, should relish and approve of plants that are fed and fattened by its immediate contact. People who are so vulgarly nice as to nauseate the modish dainties, and whose squeamish stomachs even abhor to receive the food of nobles, so little different from that wherewith they regale their richest gardens, say, that even the very water wherein a rich garden cabbage is boiled stinks; but that the water wherein a cabbage from a poor undunged field is boiled has no manner of unpleasant savour; and that a carrot bred in a dunghill has none of that sweet relish which a field carrot affords. Dung not only spoils the fine flavour of these our eatables, but it spoils good liquor. The dunged vineyards in Languedoc produce nauseous wine; from whence there is a proverb in that country, that poor people's wine is best, because they carry no dung to their vineyards." Our author, however, had a better opinion of vegetable manures than those of animals, for he says, "Vegetable dung, unless the vegetable be buried alive in the soil, makes a much less ferment in it, and, consequently, divides it less than animal dung does. But the dung of vege-

tables is much more wholesome for the use of edible roots and plants than that of animals."

Jethro Tull, according to Chalmers, died at his house at Prosperous, January 3, 1740. Of his works and inventions of agricultural machinery I have already spoken. Five chapters of his only work that I am acquainted with, *The Horse-hoe Husbandry*, were published in folio in 1731, the chief volume in 1733; and in the same year some additions were printed which are not found in many of the copies of that year, or even in that of 1751. Cobbett, however, was careful to add it to an octavo edition which he printed in 1829. In this, he omitted only the plates of the ploughs and other agricultural implements; but he added an introduction, in which he did little except laud Tull, and vituperate those who had adopted Tull's plans, without acknowledging the source of their obligation; not remembering that many a Tullian improvement has been often made since our author's time, by plain, practical farmers, who never even heard the name of Tull mentioned.

Tull, as I have before remarked, published his "addenda" to his *Husbandry* in the same year that the first edition appeared; in these he takes more notice than was perhaps necessary of certain attacks which had been made upon his book, by the members of a certain "equivocal society," amongst whom was the celebrated Stephen Switzer, the most talented seedsman, gardener, and horticultural author of his day. It appears, too, that a society of gentlemen in Dublin had, without his leave, reprinted for distribution his five "specimen chapters," all of which annoying circumstances evidently irritated him; besides these controversial notices, and certain corrections of the errors made by the printer, the long addenda do not contain any thing very valuable. Time has settled pretty well the respective merits of the contending parties; the fame of Tull is steadily increasing, while the name and works of even the classical, the elegant Switzer, are much too little known amongst modern cultivators.

Twenty-four years after the death of Jethro Tull, a paper appeared in the *Gentleman's Magazine*, vol. xxxiv. p. 522, dated at Hungerford, about 4 miles from the farm where he lived and died, and signed with the initials D. Y., which details almost all that is known of the life of the great introducer of the drill system. It was written by one of his neighbours, who had known and associated with him, and valued very properly his services in the cause of agriculture. He describes in that essay the sensation produced by the unheard-of attempts of Tull. He says, "Novelty always excites curiosity—many gentlemen came from different parts on the fame of this new method of farming, some of whom were persuaded by the weight of Mr. Tull's arguments, to go hand in hand with him in the course of his experiments, while others, who thought themselves more wise and more discerning, took every occasion of ridiculing the practice, and of representing it as a fanciful project, that, after a great expense, would end in nothing but the ruin of the proprietor. In general, the whole

body of farmers and husbandmen pronounced the man as a conjuror, who, by sowing a third part of his land, would make it produce a quantity equal to that of sowing the whole."

The farm of Jethro Tull will ever be an object of interest to the lover of agriculture. Arthur Young made a pilgrimage to Prosperous (*Annals of Agr.* vol. xxiii. p. 173), and William Cobbett did the same. More persons would visit it if they knew where it was to be found. To such it will be interesting to know that the rural parish of Shalborn is situated under the Coomb Hills, about 4 miles south of Hungerford; that the roads are tolerable, and the present holder of the farm obliging, and not insensible of Tull's great merits. If Tull was deceived in his belief of the powers of the plough to render the soil fertile without the assistance of manure, he was yet fully justified in almost every thing that he predicted, with regard to the advantages of thoroughly pulverizing and increasing the depth of the soil.

"The difference betwixt the operation of the spade and that of the common plough," he observes, "is only this, that the former commonly divides the soil into smaller pieces, and goes deeper;" and he adds, "how easy and natural it is to contrive a plough that may equal the spade, if not exceed it, by going deeper, and cutting the soil into smaller pieces than the spade commonly does." The explanation, too, which Jethro Tull gave to the advantages or theory of deep ploughing was excellent, considering the chemical knowledge of his days; for the modern cultivator must remember, that, in his time, the composition of the atmosphere was almost entirely unknown. Tull could not have known any thing of the three gases,—nitrogen, oxygen, and carbonic acid,—of which it is now found to be constituted; and of the existence of its insensible aqueous vapour he was equally unacquainted; he did not know how important these are to the roots of plants, and how the access of them all is naturally promoted by pulverizing the land on which they vegetate. But though Tull did not know these things, yet it is certain that he had carefully observed many facts which proved that vapour was absorbed by the soil, and that this absorption was promoted by pulverization. "To demonstrate," he says (pp. 27, 28), "that dews moisten the land when fine, dig a hole in the hard, dry ground, in the driest weather, as deep as the plough ought to reach; beat the earth very fine, and fill the hole therewith; and after a few nights' dews, you will this fine earth become moist at the bottom, and the hard ground all round will become dry. Till a field in lands: make one land very fine by frequent deep ploughing, and let another be rough by insufficient tillage alternately; then plough the whole field crosswise in the driest weather, which has continued long, and you will perceive, by the colour of the earth, that every fine land will be turned up moist, but every rough land will be dry as powder from top to bottom. In the driest weather, good hoeing procures moisture to roots; though the ignorant and incurious fancy it lets in the drought, and therefore are afraid to hoe their plants at such times."

These enlightened observations of Tull have been verified and illustrated by the progress of agricultural discovery, by the improved modes of practice adopted by modern farmers, and by the march of chemical philosophy. Evelyn had observed the advantages of continually keeping the ground of fruit orchards hoed or dug. Sir Henry Steuart attests, with Sir Walter Scott, Withers, and a hundred others, the same fact, as applicable to timber plantations. The farmers of even the most sandy soils of Norfolk, on the very same principle, keep the ground between their rows of turnips constantly stirred, just as Tull proposed and practised a century since. And when, long after Tull was in his grave, Dr. Priestley discovered the oxygen gas of the atmosphere, it was soon found that its presence was essential to the growth of plants; that it was highly grateful to the roots of plants, either when applied to them in its simple state, or when combined with the aqueous matters of the atmosphere; and that this application was very sensibly indeed promoted, in either form, by increasing the finely divided state of the soil; and, further, that without this division of its particles, the earth was totally incapable of absorbing either the necessary gases or the watery vapour.

The subsoil-plough of Mr. Smith of Deanston, and the suburf-plough of Sir Edward Stracey, which have both proved so successful in our days, only illustrate the truth of Tull's principles and Tull's sagacious observations. Tull was an advocate for deep ploughing, and for internal pulverizations: he did not, it is true, see the necessary limits, on ordinary soils, and with common ploughs, to the realization of this theory: he forgot that the inert nature of many substrata would render it impossible to bring them at once to the surface; but though he omitted to take this into his calculation, yet still he argued correctly enough, when he so strenuously urged his brother farmers to increase the depth of their soils by every practicable means, to let in the air to the roots of their crops, and to give every facility possible to the growth of the roots of the plants; for, by so doing, he very plainly told them they derived benefits which exclusively belong to the vegetable world. "There is yet," he said (p. 28), "one more benefit hoeing gives to plants, which by no art can possibly be given to animals; for all that can be done in feeding an animal is, to give it sufficient food at the time it has occasion for it; if you give an animal any more, it is to no manner of purpose, unless you could give it more mouths, which is impossible; but, in hoeing a plant, the additional nourishment thereby given enables it to send out innumerable additional fibres and roots; so that hoeing, by the new pasture it raises, furnishes both food and mouths to plants."

To every agricultural operation, in fact, of a mechanical nature, Tull's genius was admirably adapted; his ploughs, his hoes, his drills, were all of a description far superior to those of the rest of the farmers of those days. It was only where he attempted to reason upon the habits and food of plants, involving chemical truths, that Tull made great blunders. Thus,

believing, as he did, that earth, and earth alone, was the sole food of plants of all kinds, he ridiculed the opinion of Dr. Woodward, that all the constituents of plants were conveyed to them through the agency of water. Woodward thought, very justly, "that water is only the agent that conveys the vegetable matter to the bodies of plants, that introduces and distributes it to their several parts for their nourishment." This theory seemed absurd to Jethro Tull, who believed that all plants fed upon the same kind of food, and that that food was earth, and only earth. It is true that Tull had a very indistinct idea that something else was requisite for the food of plants, and that "certain materials contribute in some manner to the increase of plants." And he then specifies five substances, at the head of which it is not a little singular that he places saltpetre or nitre. But how this salt operated as a fertilizer was not at all more clear to Tull than to any who have succeeded him in the investigation. "Nitre," he says, (p. 10), "is useful to divide and prepare the food, and may be said to nourish vegetables, in much the same manner as my knife nourishes me, by cutting and dividing my meat; but when nitre is applied to the root of a plant, it will kill it as certainly as a knife misapplied will kill a man. Nitre is, in respect of nourishment, just as much the food of plants as white arsenic is the food of rats." Tull, however, had a high opinion of the powers of common salt, when used as a steep for seed-corn, to prevent the smut in wheat; and he gives (p. 66) this account of the origin of the practice. "Brining of wheat, to cure or prevent smuttiness, was accidentally discovered about 70 years since, in the following manner: A ship-load of wheat was sunk near Bristol in autumn, and afterwards at the ebb-tide all taken up, after it had been soaked in sea-water; but it being unfit for making of bread, a farmer sowed some of it in a field, and when it was found to grow very well, the whole cargo was bought at a low price by many farmers, and all of it sown in different places. At the following harvest, all the wheat in that part of England happened to be smutty, except the produce of the brined seed, and that was all clean from smuttiness." He then gives the farmer directions for drying the brined seed, by rolling it in quicklime, just as is now commonly practised by the farmer.

Water, Tull thought, was not a food for plants, because it commonly contains earth, to which he attributed the origin of the common opinion that water is a *food* of plants. And as to air being their food, which it certainly is, Tull considered this as a complete "phantasie,"—quite an "airy hypothesis." In common with many of the learned of his days, Tull here strangely confused himself, by not attending to observations and experiments with regard to plants, and to these only. The merit, however, of Tull, amid his occasional mistakes, was enhanced by his modesty; and it is impossible for us, when we reflect upon the difficulties he had to encounter in the prosecution of his researches, and in the production of his book, to be insensible to his appeal, where he tells us, at the conclusion of his preface, "One cause

that made the three parts of this book (that is to say, the theory, or speculative part, the practical part, and the description of the tools), the more defective was, that all three were too many for me to make perfect at once, and two would have been useless without the third: therefore, it was better to give but a sketch of all than to have made any two of them never so full and perfect, leaving out the other."

Such was the modesty, such were the merits of this great father of the drill and the horse-hoe husbandry, to whose memory something, I hope, will one day be erected—some memorial to indicate the agriculturist's gratitude, worthy of the English farmer. Tull lies buried without even a stone to indicate that such a benefactor of agriculture reposes beneath it. His grave is even doubtfully placed. If Tull died at Shalborn, as Chalmers asserts, he was not buried there. There is no trace of him in the parish register; the tradition of the old people of the neighbourhood is, that he died and was buried in Italy. His deeds, his triumphs, it is true, were of the quiet, peaceable kind, with which the world in general is little enamoured; but their results, their value to the land of his birth, were of no mean order. His drill, his horse-hoe, have saved his country, in seed alone, the food of millions; and when used as a distributor of manure, it has done, and it will hereafter accomplish, still greater things. It has brought into cultivation thousands of acres of the barren craig, the wolds of Lincolnshire, of the deep sands of Norfolk; and its powers are not yet nearly exhausted, for, as fresh fertilizers are discovered, the drill evenly and economically distributes them; and as improvements in its construction are continually taking place, there is evidently much yet to be achieved by its use. The same remarks apply, in a great measure, to his hoe, and to his system of attempted cultivation without manure; for, although the last was a complete failure, yet even this bold attempt was not unattended with benefit to agriculture; for the farmer was hence taught, that, although by deep ploughing and complete pulverization of the soil the use of manure could not be entirely avoided, yet that by these means a much smaller quantity was sufficient than under the old and indolent mode of tilling the land. The efforts, too, of Tull were productive of advantage in other and in indirect ways;—his researches, his successes, his example, excited a spirit of inquiry, which since his days has hardly ever entirely slumbered. He was certainly the first who dared to boldly quit the beaten track, which had been used by the farmer for ages, and follow a way of his own. And although he has been well followed and imitated by succeeding cultivators, who have availed themselves of new discoveries and machinery of which Tull had not the assistance, yet there have been none who have since excelled, or perhaps equalled him, in the boldness and originality of his conceptions, or in the energy with which he realized them. (*Quart. Journ. of Agr.* vol. xi. p. 342.)

TUMBREL. A sort of dung-cart, convenient for many purposes.

TUMBRIL. A machine employed chiefly in the county of Lincoln, for the purpose of giving

hay to sheep during the winter. It resembles the basket fish-pots used by fishermen, and consists of a circular cage or crib, which may be made of osiers, willows, or other pliant brush-wood of any kind. The whole is about 10 feet in circumference, and closely wattled to the height of about one foot, above which it is left open for the space of 18 inches; it is then wattled again to the height of 8 or 10 inches, and an opening, about 18 inches in breadth, is left at the top, for putting in the roots or other food, whether green or dry. The staves which form the skeleton of it are 10 inches asunder, so that 12 sheep may feed at the same time in each tumbrel.

TUPELO. Under this name Michaux describes three species of the genus *Nyssa* found in the United States. One of these, the *Nyssa aquatica*, has already been described with the Black gum, with which it is commonly confounded where both grow together. (*Michaux*, vol. iii. p. 40.)

TURF. A term often applied to the green surface or sward of grass lands. Also the name given to peat, which is used in several parts as fuel. It varies much in its nature in different places, being sometimes hard and of a dark or black colour, while in others it is soft and spongy. It is a substance very useful in burning calcareous stones into lime. See **LIME, MOSS, PEAT.**

TURKEY (*Meleagris gallo-pavo*). A wild fowl, originally introduced into Europe from America. They require care in their infancy. The black turkey is the best sort, both for size and delicacy. Turkeys are particularly clean birds, loving sweet food and delighting in air. They prefer roosting in trees, for which reason an evergreen, such as a yew tree, spruce fir, &c., is a great advantage, planted in the centre of a poultry-yard. Turkeys and pea-fowl hop up gradually from the low branches, and are sheltered from frost. But where this is not the case, the turkey-house must be dry and warm in winter, and cool in summer; it must be kept free from vermin, and the dung and litter of feathers, &c., should be often swept away. The perches must be large for their talons to grasp; and there should be plenty of ventilation, by gratings or holes bored in the floor.

Turkeys seek quiet places to lay in, and often stray far from home. Their nest must be watched, and the newly laid egg exchanged for one made out of chalk every day. The turkey-hen lays from 12 to 20 eggs; and when she desires to sit, place her in the turkey-house on her eggs, and coop her up with them, if she is unwilling to remain, till she becomes settled. Do not disturb the hen while sitting, or attempt to assist the chick in piercing the shell. When the young ones are born, keep them in the nest for some time, as they love warmth, but do not handle them. Keep them warm and dry. When the red colour of the head appears, they are considered safe from the diseases of their infancy. Do not allow a turkey to sit twice in a season; the young ones never succeed unless they are full feathered before Michaelmas. Feed young turkeys three or four times a day, and let the food be a thickish paste, made of

fine barley-meal, mixed with finely chopped onions, nettles, and pot-herbs. The French give their turkeys plentiful supplies of nettles, of which they are very fond; it is a warming and nutritious herb. Let the food be given fresh every day, and place it on a board with a shallow pan of water. Coop the hen while the young ones feed, or she will eat it herself. When the chicks begin to follow the turkey into the poultry-yard, do not let them out till the dew is off the ground. Vetch and marrow-fat peas are poisonous to young turkeys; lettuce brings on looseness; and hemlock and henbane should be destroyed near all poultry-yards.

Turkeys love oats, boiled potatoes mashed with the meal of buckwheat, barley, or beans; or plain barley, like other fowls. Let the water always be sweet and clean. A turkey is six weeks fattening; if possible, feed two or three together, as they do not love solitary confinement. Let them eat as much as they like, but let the food be fresh every day, and let it be the paste above mentioned, softened by melted lard. Cramming turkeys is a cruel practice, and is not often done. They will feed well enough and fast enough if plenty of sweet food is placed before them, and if they are allowed some little space to move about in. It is a curious fact, that turkeys in America feed on the caterpillars that are found on the tobacco plant with impunity.

Turkey eggs are very good in pastry, and mixed with hen eggs they improve omelets. Turkey's dung, properly mixed with other composts, makes a valuable manure.

TURNIP (*Brassica rapa*). No vegetable has had such influence in advancing the husbandry of Great Britain as the turnip. By whom and at what period turnips were first used in England as the food of cattle, however, does not appear; but from various accounts, their culture and uses were known in the Low Countries as far back as there are any records. The ancients appear to have been well acquainted with the value of this root; Columella, speaking of the several kinds of vegetables adapted for the farm, recommends the cultivating of rapa in plenty, because, says he, those roots that are not wanted for the table will be eaten by the cattle. Worledge, in his *Mystery of Husbandry*, &c., printed in 1669-81, says, that "although turnips be usually nourished in gardens, and be properly a garden plant, yet are they, to the very great advantage of the husbandman, sown in his fields in several places in England, not only for culinary uses, as about London and other great cities, but also for the food of cattle." Again, he says, "that in Holland they slice their turnips with the tops, and rape-seed cakes and grains, &c., and therewith make mashes for the cows and give it them warm, which the cows eat like hogs." He likewise complains of the very great neglect and deficiency of English husbandry in this particular. Some time since, a very excellent paper "On the Cultivation of the Turnip Crop on Light Soil, by Mr. M. Milburn," appeared in the *Transactions of the Yorkshire Agricultural Society*, from which this paper is chiefly extracted.

It is generally supposed that the cultivation

of turnips as a field crop was introduced into Norfolk by Lord Townshend; but there is still further evidence that they were known as such some time before the date assigned for their introduction. They are mentioned in *Houghton's Collection of Papers*, vol. i. p. 213, as food for sheep, in 1684. Since that period considerable improvements in their cultivation have taken place, and a great variety of very inferior soils have been made capable of growing considerable crops of them, by judicious management and proper selection of manure.

On the value and importance of the turnip crop to England, it is unnecessary to expatiate. Not only does it enable the farmer to supply the consumer with fresh meat during the winter, instead of the salted food upon which our ancestors had almost exclusively to depend, but also partially supplies the place of a fallow; it imparts to the land a degree of fertility which ensures, under proper management, a succession of crops for the following years of the rotation. It is indeed the sheet-anchor of light soil cultivation, and the basis of the alternate system of English husbandry, to which every class of the community is so much indebted.

Preparation of the Soil.—Turnips generally succeed a crop of wheat. In some cases, on very poor soils, the clover leys are broken up for turnips; and, on others, a crop of winter tares, either mown or depastured, are taken off between the wheat crop and ploughing for turnips. As a regular system, the former cannot be pursued; for the frequent recurrence of the turnip and clover crops would operate injuriously, and defeat the object of the cultivator; and the latter is only applicable to soils quite free from root weeds, of a superior staple, or in a very high state of cultivation.

As soon as the grain crop is secured, and the stock have passed over the stubble, it is desirable to have it ploughed, to subject the soil to the ameliorating influence of the frosts of winter. In all cases the plough should be below the couch-grass, which is usually most abundant on inferior soils, but seldom below the mould. In ordinary cases, nothing is more necessary than to prevent the water from standing in any part during the winter; where the land is intended for Swedes, an effort should be made to have it partly or entirely cleared of weeds before the winter.

When the land is free from weeds, the cross-ploughing may be begun as soon as the dryness will admit of it. It may take place in February with advantage; inasmuch as it exposes a new and more extensive surface to the action of the frosts which generally succeed. If allowed to remain a month or two longer, it may advantageously be crossed with Finlayson's harrow. Where the couch-grass, however, is abundant, it is positively injurious to cross-plough early, as the operation breaks the roots, and renders the clearing of the land afterwards tedious and difficult. Where very abundant, the operation should be delayed until the soil is dry, even if it should be the latter end of April or the beginning of May; more will be effected by one ploughing in this case than by two under different circumstances.

When the dryness admits of it, usually in

two or three days, the land should be harrowed across; first with the patent or hinge harrows, and subsequently with the loose harrows, which separate the rubbish more effectually from the soil; and then the weeds should be raked off, which is generally performed by women.

As soon as the couch-roots, &c., are cleared off, either by carting into large, or burning in small heaps, the land may be dragged with Finlayson's or any approved drag; and the same course followed alternately, so long as any roots remain. When they are unable to rake them off, they should be hand-gathered, and no dependance whatever should be placed on the destruction of any by the sun's rays, until the 25th of June, a time when, on most soils, the sowing should be concluded. It is desirable that the land should lie a week or ten days before the last ploughing is given to it, as it admits of the germination of such seeds of weeds as may be lying dormant in the soil, and is likewise favourable to the accumulation of moisture in a dry season. The turnip-seed should be sown immediately, however, after the last ploughing.

Manure.—In treating of the manures with which the turnips should be dressed, farm-yard manure stands the foremost, because it is what every farmer possesses, and, with the exception of the calcareous soils in the East Riding of Yorkshire, is almost invariably employed in the cultivation of turnips. In general, it never will, and never can be superseded; and, though every deference is due to the practical knowledge of the East Riding farmers, there can be no doubt that, if their straw were *more carefully made into manure*, and applied to the turnip crop in conjunction with bones, it would be decidedly advantageous. It is unnecessary to say that house-made manure, and by fattening cattle, especially such as are consuming artificial food, is the best; and that of horses, cows, pigs, &c., should be mixed as intimately as possible, the hot character of horses' dung neutralizing the coldness of that of the cow, and *vice versa*. It is desirable to cart this mixture to the fields intended for turnips in January and February, during the frost, or at such other times as convenience may dictate; but the earlier the better. About three weeks before used it should be turned over, the sides of the mixen being carefully turned into the middle. Without entering in particular into the much disputed question of the fermentation of dung being useful or otherwise, thus much every farmer will know well the truth of, that on *light soils*, and *for turnips*, well rotted dung is indispensable, where it is used at all. When fermentation is progressing so fast as to induce destructive heat, or mouldiness, it may be checked by treading the mixen and covering it with soil; and when it is sluggish, it may be excited by turning and watering.

For sandy or gravelly soils, farm-yard manure is an almost necessary ingredient in producing a crop of turnips. The rapid decomposition of vegetable matter which takes place on such soils requires that there should be a supply for that succulent crop; and, as before stated, there can be no doubt of its utility to calcareous soils; but for peaty descriptions

where there is abundance of vegetable matter, it is less useful.

The time for laying on the manure depends on the method of sowing adopted, and clearness of the land from weeds. If the plough-drill be used, it is desirable to immediately precede the plough; if the Norfolk, or large drill, it is better to lay it on a week or two before sowing, to allow it to mix intimately with the soil, especially if other manure is intended to be used, and the soil pretty free from weeds. The quantity to be applied will vary with circumstances: 12 to 14 tons per acre may be stated as an average, and more if the soil be poor and no other manure intended; while less may be used in proportion as other manures are applied.

Lime stands next in importance, as a dressing. The object of all manure is to supply some deficiency, remedy some mechanical inconvenience, or correct some detrimental agent in the soil. When dung, for instance, has been applied for several successive crops, a quantity of undecomposed vegetable matter accumulates, which the natural soluble properties of the soil cannot dissolve, and it remains inert. A dose of lime will correct this, and bring every particle of such inert matter, with which it comes in contact, available as food to the plants. It also assists in the intimate pulverization of the soil, as well as corrects any acidity which may exist in it, from causes which the agriculturist can seldom foresee, nor correct, except by its use. It is also destructive to weeds in the soil, and hence exceedingly valuable; for every farmer knows that weeds, being indigenous, are much more ready to grow in the soil than his crops, which are artificial, and often exotic. For peaty soils, an occasional dressing of *quick lime* is invaluable, especially if there is an addition of clay, road scrapings, &c., to give the requisite firmness to the soil. It should be laid on as soon as convenient after bringing from the kiln, and in as hot a state as possible. The time for laying on lime is a few weeks before the sowing, in order that the subsequent ploughings may mix it thoroughly with the soil, and thus its effects be more immediate after the sowing. The quantity per acre entirely depends upon the character of the lime in the locality. Two to four chaldrons per acre are used; but as it is applied for turnips generally in conjunction with other fertilizers, the former may be stated as the better quantity. If dung is also applied, they should be used at as great a distance of time between each other as circumstances will admit of, and the latter not long before the sowing.

Bones form one of the most valuable manures for turnips on all light soils, on account of their portable and stimulating character; they are least useful on a gravelly or loamy soil. They have converted barren moor lands into rich, fertile, and productive farms, luxuriating in every valuable product of the earth. Their value is beyond all praise. The East Riding of Yorkshire affords a specimen of what they have effected; and they require only to be known to be extensively applied. In

many cases they are used alone; in others, in conjunction with farm-yard manure, with ashes, and with lime. Ashes are sometimes drilled with them as a substitute, by diminishing the quantity of the bones. Lime is a valuable auxiliary, on "old going land," or soil which has been long under cultivation. On peaty soils, having a substratum of sand, they have produced wonderful crops, by supplying them with the necessary animal matter. The quantity varies from 12 to 30 bushels per acre. Sixteen bushels per acre will produce a fair crop, on average soils; and some farmers say that more than that quantity is waste. It is desirable to mix them with a quantity of ashes, when they are drilled in the above quantity. This facilitates the early progress of the plants, and supports them until the bones become available. English bones are generally preferred to foreign; but from experiments made by the writer, he prefers foreign to English, and also to recent bones; for, although the latter have more of their juices than the former, the former sooner decompose; and the fat and animal juices require considerable chemical changes before they are available as food for the plants. A mixture might be judicious, but he has not tried it, nor is he aware of the trial having been made.

Other manures of a miscellaneous character are used for turnips. Pigeon's dung is most valuable; rape dust has been used successfully; and animalized carbon has also been advantageously employed. Sixteen bushels per acre, when drilled, is the quantity generally applied. Malt culms are useful as a top-dressing. (*Trans. York. Agr. Soc.*)

A machine for sowing turnip-seed with bone-dust is described in the second volume of *Trans. High. Soc.* p. 205; and the results of some experiments with different manures is given, *Trans. High. Soc.* vol. i. p. 66, 72, vol. iv. p. 233.

Weir's Manuring one-row Turnip Drill, is described and figured by Loudon, and said to be a remarkable improvement on the Northumberland implement. It has a manure hopper, and a seed hopper, the same as the others; but the manure, in place of being dropped along with the seed, is deposited in a deep gutter made by the coulter which goes before; this manure is covered by a pronged coulter which follows the other: next comes the coulter which forms the gutter for the seed, which are deposited 1 inch above the manure. (See *Loud. Ency. of Agr.*)

Varieties.—There are numberless varieties and sub-varieties of turnips, which arrange themselves under four heads:—1. Swedish turnips, or *Ruta baga*; 2. Yellow and white turnips; 3. Yellow turnips; and 4. White turnips. Professor Low has divided them into three classes, distinguished by their form:—1. The round, or globular; 2. The depressed; and 3. The fusiform. These may be considered as types, to which the different cultivated kinds more or less approach. Many varieties are cultivated which are more fanciful than useful. For the main particulars of the following list I am chiefly indebted to an interesting *Essay on*

Turnips published by Dr. William Ellis of Caistor, Lincolnshire, and to Messrs. Lawson's excellent *Agriculturist's Manual*.

SWEDISH TURNIPS.—The *Ruta Baga*, or Swedish turnip is hardier and more nutritious than any of the common sorts, and in addition to its being more esteemed as food for horses throughout the turnip season, is better adapted for spring feeding generally. It, however, requires a somewhat deeper and superior class of soils, together with a greater allowance of manure. Swedish turnips are generally sown from about the middle to the end of May, and 2 to 2½ lbs. of seed per imperial acre are, under ordinary circumstances, considered sufficient. They possess an advantage over the others in being easily transplanted, so that the blanks in the rows, either of the Swedes or other sorts (when they occur), are by that means easily filled up.

Skirving's new improved Purple-topped Swede.—Mr. William Skirving of Walton Nursery, near Liverpool, who has for many years directed his attention to the improvement of agricultural roots and plants, introduced last season for the first time the above variety. From comparison with every known variety of turnip, which Mr. Skirving has been at pains to collect from all quarters, both in England and on the continent, it appears to have shown itself to possess all the good qualities of a turnip, and gives a greater weight per acre of sound nutritive bulb: it is also hardier, and keeps longer than any other variety. The leaves of Mr. Skirving's Swede appear to partake considerably of the character of those of the common turnips, being less smooth and more serrated at the edges, and deficient in that glaucous bloom which distinguishes the leaves of the genuine Swedish turnip, which leads me to suspect that he has attained the size by hybridizing with some of the larger varieties of yellow turnips.

Ballantyne's new improved Purple-topped Swede.—This improved variety for symmetry of shape, equality of size, and for the uniform deep purple colour of its top, is unsurpassed by any other variety which has come under our notice.

Scott's Prize Purple-topped Swede.—This is ox-heart shaped, purple above ground, and yellow fleshed, with a small top.

Laing's new Purple-topped Swede is a decidedly distinct variety. It has a leaf something like that of a lettuce. The leaves are so inserted in the top of the turnip as to give it much the appearance of that of a pine-apple. It grows to a good size, keeps well, and bears a very high character among the agriculturists of Berwickshire and Northumberland, where it is extensively cultivated. The crop has a most beautiful appearance when in full leaf.

Green-topped Yellow Swede.—This variety is of longer standing than the purple-topped, since the introduction of which less attention has been bestowed by cultivators in procuring improved stocks of the green-topped Swede, which has on that account fallen somewhat in the estimation of growers; but, where the same care is taken in selecting the roots grown for seed, the green-topped may be considered as being equal in merit to the purple.

Scott's Prize Green-topped Yellow Swede is an improved variety of the above. The purple-

topped Swedes are at present more popular, as we before mentioned; but where, as is the case with Mr. Scott's, equal care has been bestowed on the selection of stocks, and in the subsequent management, the green is in no way inferior to the purple-topped variety.

Hillyard's Thorpe Land Swede.—This has the appearance of a true Swedish turnip, and is said to be more nutritive, bulk for bulk, than some of the larger varieties, which may or may not be the case. Its dwarfish size, and the impossibility of raising any great weight of food per acre from it, must, notwithstanding its other merits, be a great obstacle to its making its way among the larger sorts which now invite the attention of cultivators.

Cox's new Imperial Swede.—This variety may be considered as intermediate in colour between the purple and green-topped sorts; its roots often attain a large size, but are rather irregular, and of a somewhat coarse-like quality.

White Swede.—The roots of this turnip are very irregularly shaped, with numberless fangs: they are white under the surface of the ground, and greenish above. It is impossible to say what improvement may do for even this kind, but at present we are acquainted with no variety of white Swede worthy of cultivation.

YELLOW AND WHITE TURNIPS.—Common turnips are divided into two important classes, viz. the white and yellow-rooted; the former comprehending those which are most tender and arrive soonest at maturity, and which are best fitted for using during the earlier part of the season; and the latter, with trifling exceptions, such as from their hardness and period of arriving at perfection, are intermediate between the white sorts and the Swedes, and, like the latter, require a somewhat superior soil and an additional allowance of manure. The period of sowing common turnips should be regulated according to the length of time that the variety to be grown requires to arrive at maturity; for when allowed to remain in the ground in what may be termed growing weather, or before winter sets in, after they attain to a full size, they become soft, spongy, and of inferior quality. A general rule, however, is, to commence with the yellow sorts about a fortnight after the Swedes, or about the beginning of June, and to follow with the white sorts from the middle till towards the end of that month.

YELLOW TURNIPS.—*Altringham Yellow.*—This turnip—although from its being rather below the medium size attained by yellow turnips in general, it is more particularly suited for garden culture—is also in good repute in some quarters as a field turnip. It is recommended for its fine globular shape, and the superior solidity of its flesh. It has a light greenish top, very small neck, and tap-root.

Aberdeenshire Sugar Yellow.—This is a very hardy turnip; it buries itself considerably in the ground, is highly nutritious, and one of the most approved of the varieties lately introduced.

Border Imperial Purple-topped Yellow.—The following particulars, respecting this variety, are given by Mr. Hogg:—"This turnip possesses all the qualities of the Swedish, with the advantage of being a much freer grower

It produces a larger crop than the white globe, is a good feeder, and stands the winter better than any of the common yellows. It is in full perfection for using in February, and continues for as long a period as the Swedes; and should the latter fail, the border imperial being sown as late as the month of June, will yield a crop equal, if not superior, to what might have been expected from the Swedes, had they succeeded."

Green-topped Bullock Yellow.—This turnip attains a medium size. Its shape is globular, or somewhat flattened, with a very small tap-root; it is an old variety, and is held in deserved estimation.

Purple-topped Bullock Yellow.—This variety differs from the former chiefly in the colour of the top; the size, shape, and quality of the roots being pretty nearly the same. It is also highly esteemed, and is considered by some to come nearest to the Swedes in hardness and solidity of texture.

Skirving's Improved Purple-topped Bullock Yellow.—This improved variety of the above obtained for its introducer—Mr. Willaim Skirving, of Liverpool—the medal of the Highland Society of Scotland. It has been generally grown for a number of years by the first agriculturists in Lancashire and the northwestern counties.

Green and Purple-topped Yellow Scotch differ but little in any of their essential properties from green and purple-topped bullock yellow. The roots are flatter, and grow more in the ground.

Ox-heart Yellow is an excellent turnip; although it comes early to maturity, and attains a considerable size, it is by no means deficient in hardness.

Yellow Globe.—This is a superior turnip, both for field and garden culture. Its roots are of medium size, globular, and always nearly under the surface of the ground; top greenish, leaves rather small and spreading.

Yellow Sone.—This variety differs from the last in growing more out of the ground, and having a greener top; in other respects it is pretty similar.

Brown-topped Tankard Yellow.—Root bright yellow, with a purple or brownish top, of a somewhat irregular long or tankard shape. This variety is in great repute in Aberdeenshire. A sub-variety, of not so very long a shape, is preferred by some growers. They are both excellent turnips.

Green-topped Tankard Yellow differs from the above chiefly in the colour of the top. Of this there is also a sub-variety, of a flatter shape.

Large Laurencekirk Yellow Tankard, introduced by Mr. Robert Scott, of Laurencekirk, resembles Dale's hybrid in many particulars, like which it grows a good deal out of the ground, but is distinguished by its more oblong and more uniformly shaped roots. It arrives early at maturity, but is generally considered as rather less hardy, although it yields an equally bulky crop.

Dale's Hybrid.—This highly esteemed variety is a cross between the green-topped Swede and white globe, procured by repeated impregnations. Its most distinguishing characteristics

are as follow:—foliage strong and luxuriant, roots of a large size, oblong shape, and of a lightish yellow colour, with light green top, having also a small neck and tap-root. The form of the root, however, although generally oblong, is rather apt to vary, being sometimes almost globular; but its more material characteristics, of large size and luxuriance of growth, are always the same. Compared with any other of the yellow field sorts, it is found to arrive sooner at maturity, and consequently may be sown at a later period of the season; while at the same time it is equally hardy, or at least has been found sufficiently so, to withstand the severest winters which have occurred since its introduction.

Gordon's Yellow.—This very superior variety is of a rather oblong shape, deep green colour on the top, which is generally very slightly tinged with red. It is very nearly allied to Dale's hybrid, being a cross between the Aberdeenshire bullock yellow and the Swede. Sir F. A. Mackenzie, Bart., upon whose extreme accuracy as an experimentalist the utmost reliance may be placed, grew last year a considerable number of the most approved kinds of turnips, on his farm at Conan Mains, near Dingwall, in Ross-shire, with the view of selecting such as might be found most worthy of being kept in cultivation as best suited to the soil and climate of Ross-shire. The result of his experiments was, that of Swedes, Skirving's is decidedly the best, Gordon's yellow the best of the yellow-fleshed, and Scott's purple-topped hybrid and the old white globe, of the white-fleshed kinds.

Hood's New Large Yellow is a very superior, large, globular-shaped, hardy turnip, remarkably perfect in symmetry, with rather a lightish green top.

Pollexfen Yellow.—This turnip derives its name from its introducer, Thomas Pollexfen, Esq., of Cairston. From his peculiar method of selecting and transplanting the bulbs, as well as of stacking and preserving the seed, the turnip-seed of Mr. Pollexfen's growth has long been held in deserved estimation in Scotland, and has commanded the highest prices. The insular situation of Orkney, although in latitude 59° north, renders its climate less exposed to the extremes of heat and cold than in more continental situations farther south, the winters being mild, and the frost so gentle that the ice is seldom sufficiently strong to sustain the weight of a man. Its climate is on that account peculiarly favourable to the growth of turnips, and turnip-seed grown in Orkney is accordingly highly prized by the Scotch farmers. The Pollexfen yellow is a green-topped turnip of a large size, rather flattish in shape, skin very smooth and thin; the flesh is firm and nutritious, being slightly impregnated with the green topped Swedish. It is adapted for winter and spring feeding, and is not liable to injury from frost. This turnip obtained the prize at the meeting of the Highland and Agricultural Society of Scotland, held at Inverness in 1836, in the report of which it is highly commended.

WHITE TURNIPS.—*White Globe.*—Roots globular; skin smooth, and perfectly white; neck

and tap-root small. Although the above description embraces the principal characteristics of the white globe turnip, yet there is a considerable variety in those to which the name is applied, arising from the degree of care and attention bestowed by growers in selecting their seed-roots; and the shape is often not a little affected by the kind and state of the soil in which they are grown. Thus globes of any kind, and particularly the variety here mentioned, when grown on a very superior rich soil, may be said to be forced beyond their natural size, and thereby acquire somewhat of a monstrous or overgrown appearance, losing in a great measure their natural symmetry of shape.

Pomeranian Globe.—This variety was introduced some years since from Pomerania, and may be considered the most perfect globe turnip in shape, as well as the most regular or uniform grower. Its skin is of a smooth white, and somewhat shining or transparent-like in appearance; leaves smoothish, of a dark green colour, with whitish nerves.

Green Globe.—Roots of a fine globular shape, with a small neck and tap-root; very white beneath, and green above the surface of the ground, of medium size, hardy and firm of texture, but scarcely so much so as the green round, although it arrives at maturity rather earlier.

Stone Globe.—This is considered to be the hardiest of all the entire white globe turnips. It grows naturally deeper in the soil than the others, and has stronger and darker green foliage.

Red Globe.—Roots medium-sized, globularly shaped, and firm in texture. This is an old, and, in some districts, a pretty extensively cultivated variety. It is medium early, and generally allowed to be particularly well suited for light soils and exposed elevated situations.

White Round is known in Lincoln by the name of spring white. It is the largest of the round turnips, and, at the same time, the softest and most irregular in shape. It is generally hollowed towards the neck, and, being so, is apt to be injured by retaining moisture, which renders it unfit for using, except in the beginning of the winter season.

Green Round.—The round turnips are all of a peculiar flattish shape, rather hollowed towards their neck, as also on their under side; and, when grown to a large size, they become more or less of an irregular round, or somewhat cornered shape. The green-topped variety possesses these characters in a less degree than the former, and is generally of a pretty, regular, round shape, flattened, but not much hollowed, on the upper and under surface, the former of which is of a green colour, and the latter white. It is also the hardiest of the round turnips.

Red Round.—This sort is inferior in size to the two former, but rather firmer in texture, and more regular in shape. It should also be used in the early part of the season.

White Tankard.—The tankards, like the three preceding kinds, are unsuitable for winter feeding, not so much on account of their softness, as from their standing mostly above ground, and being thereby much exposed to

frost. They are generally earlier in arriving at maturity than the others. The white tankard has its roots more than half out of the ground, oblong, or tankard-shaped, but often bent or crooked. It is the largest of the tankards, but is also softer in texture than either red or green; its leaves are large and luxuriant: it is the earliest in maturing of any, but will not stand the frost.

Green Tankard.—The roots of this species are also more than half above ground; of a greenish colour, except on the under surface, which is white.

Red Tankard.—In size, form, and texture, this variety may be considered as occupying an intermediate place between the white and green tankard. It is of a bright red colour on the upper surface, and white on the under.

Lawton Hybrid.—Hardy, and possessed of more solidity and firmness than most of the white sorts.

Scott's improved Purple-topped Hybrid.—For a white-fleshed turnip is remarkably solid, and attaining a great size.

Lewisham Green-topped Ox-heart.—An excellent variety, grown in some of the southern districts of England and Scotland.

The short seasons of growth allowed the turnip in the American climate, renders most of the preceding varieties unfit for culture. Mr. Buist of Philadelphia, recommends the two following preferable to the most superior of the European sorts.

Red or Purple-topped. (American,) shape flat and round, with purple top; very hardy and keeps well. Sow about the end of August, or not later than the 8th of September.

White or Flat Dutch; often called *strap-leaved White*, is in form, size and qualities, very similar to the preceding; it is more generally cultivated in the United States than any other kind of turnip.

Lewisham Green-topped Ox-heart.—This is an excellent variety, grown in some of the southern districts of England, and in Scotland. It acquired this name from having been first introduced by Messrs. Willmot & Co. of Lewisham.

Autumn, Stubble, or Six Weeks.—Roots much above ground, rather large, of an irregular globular shape, or in form between the white globe and white round, and rather soft. This sort arrives sooner at maturity than any of the others, the tankard turnips perhaps excepted; and from its natural softness of texture should always be sown late, and used before the severe frosts set in. As descriptive of its forwardness, it has received the above names, being suited for sowing in early situations in autumn after the corn crop has been removed, and it is also valuable for making up blanks in turnip fields, where the first sowing may have partially failed.

The comparative nutritive powers of the different varieties of turnips appear to be as follow:—

	Grains of Nutritive Matter
64 drachms of the Swedish turnip afford	110
Stone or garden turnip	85
Norfolk white turnip	83
Common or white loaf	80
Tankard or long-rooted	76

(Sinclair's Hort. Gram. p 406.)

Methods of sowing.—The modes of sowing are various; but the general principle to be attended to is, to get the seed into the nearest possible connection with the manure used, so that it may have all the advantage of its fertilizing influence in the earliest stage. This is forestalling, because, it decides the drill method to be the most valuable, before we describe the others; but it is a principle so necessary and obvious as to strike every reflecting person at the outset. The old broadcast plan was, to spread on the manure, plough it in, and then very carefully sow the seed with the hand. This practice is almost everywhere abandoned, nor can it be justified or recommended in any case.

The plough drill is used where farm-yard manure only is employed. The manure is spread on the ground, and the plough follows with the drill, being fixed to the right-hand side of the plough, and thus deposits the seed immediately in the seam made by the plough, and directly upon the manure just covered by the plough. The plough-drill is only useful where very bulky manure alone is applied. See **DRILL**.

The ridge or Scotch method is used with success, especially on inferior and thin soils, and has its decided advantages. The ridges are made either with a single cast of the double mould-board plough, or a double one of the common or ribbing plough, and from 20 to 28 inches apart. A cart with manure follows, and women are generally employed to drop the manure into the seams made by the plough. The plough again follows, and closes the ridges, covering the manure; and the drill succeeds, drawn by one horse, and sows one ridge at a time. A light roller goes over the sown ridges to cover the seed, and sometimes the ridges are rolled before the sowing. This plan takes more time and labour to effect it, but the turnips generally succeed; and if they should be destroyed by the flea-beetle, they can be resown with more probability of success than by any other method.

The general and most expeditious way is by the large drill. This is constructed to deposit the bones, ashes, &c., with the seed, upon the level surface, drilling 6 or 7 rows at once. It is drawn by 3 horses, and will drill 12 acres per day. The seed does not run down the same funnel as the bones, but has a separate apparatus immediately behind the latter, and the coulters of the drill generally cover the whole. A pair of light harrows are usually passed over once after the sowing; and should much heavy rain succeed, it is desirable to give it another turn with the harrows immediately before it is dry, to prevent it from scarping. The quantity of seed sown by each of these methods, is from 2 to 3 pounds per acre.

After Culture.—When the turnip plants are of about 3 weeks' growth, they require to be thinned, and the weeds destroyed. This is usually performed by hand-hoeing; but in some cases Swedes are hand-thinned by women, and subsequently horse-hoed, which can be done in all cases where they are sown in ridges, and is a considerable saving of labour.

No two plants should be left together at the first hoeing, but they should be thoroughly singled; and a second hoeing must take place about 2 or 3 weeks afterwards, to destroy the weeds. For ordinary crops, they should be left 7 to 12 inches distant, according to the richness or poverty of the soil; if the latter is the case, they should be at shorter distances, as they will grow to a smaller size. The whole of the ground should be gone over, as it loosens the earth, and promotes the growth of the plants. The double operation is usually performed for from 6s. to 7s. per acre. Sometimes the crop requires hand-weeding in the autumn, especially if the soil is infested with charlock.

Diseases.—The extensive and repeated culture of the turnip has fostered the rapid increase of its natural enemies; and after all the pains, labour, and expense of the cultivator, he often sees his crop entirely destroyed, or seriously injured. The remedies he can apply for many of these can only be termed palliative; but still he has much in his power; and as the knowledge of natural history and field-entomology advances, he may expect more and more assistance. See **INSECTS**.

The turnip flea-beetle (*Haltica nemorum*) is one of the worst enemies which attack the turnip plant, which it does when in its seed-leaf state, and often destroys a crop, and even the second and third sowings. Various steps have been taken in order to prevent its attacks, and several steepes for the seed used, but without success; top-dressings of a saline and astringent character have been applied, but have failed; machines have been invented, but none of these have succeeded. The only directions which can be given are: sow plenty of seed; use stimulating manure, to excite the plants to vigorous growth in their first stages, and secure a sufficiency of moisture in the soil at the time of sowing; especially keeping seedlings in turnip fields clear of charlock, which nurses the flea. See **FLY IN TURNIPS**.

The black caterpillar, larva of the *Athalia centifolia*, also preys upon the leaves in a more advanced stage, appearing on the plants when they are about 3 weeks old. See **SAW-FLY**.

Another disease to which the turnip is liable, is vulgarly called "fingers and toes." See **ANBURY**.

The wire-worm is a sad enemy. (See **WIRE-WORM**.) The swarms of aphides, or plant lice, severely injure the turnips; and, from the smallness of their size, are often unobserved. In 1836 they committed terrific ravages. They suck the juices of the plant, and appear in countless numbers. They are both oviparous and viviparous, and increase with amazing rapidity. Happily they are always followed by swarms of lady-cows, which feed on them, as well as insectivorous birds, which destroy vast numbers. No remedy can be applied with any probability of success. Every farmer should carefully protect swallows, red-breasts, &c., which are great destroyers of the aphides.

Slugs are, especially on newly ploughed soils, great devourers of the turnip plant in all its stages. Ducks will devour them, but always injure the plants. Three bushels of quick

lime per acre, scattered over the plants early in the morning, when the slugs are active, is a certain method of destroying them. Perhaps the very best preservative from all the above diseases may be stated to be—liberal manuring, adapted to the soil; thorough clearing of the land from weeds; and, in short, pursuing the steps above detailed for securing a full crop. The vigour of the plants in such cases, and their rapid vegetation, often enable them to overcome many serious attacks.

Storing.—There are different modes of performing this useful practice. The common way is to take up the turnips, choosing dry weather, cutting off the leaves and taproots (provincially called topping and tailing), which operation should be performed with as much exactness as possible, so as not to wound the bulb, as this would cause the turnip to rot; nor yet to leave much of the leaves, as this would make the turnip vegetate on receiving a slight degree of heat; after this the turnips are placed in a well-aired situation, adjoining to the feeding byre, in a narrow tapering ridge, similar to potato pits, and this is covered with straw and secured with ropes. The situation chosen for the store should be as dry as possible. The heaps must not be covered with earth, like potatoes; for this would cause the turnips to heat and completely destroy them.

But as this practice of storing is only adapted for the Swedish and yellow varieties, the white globe variety possessing too much water to be preserved for any length of time, another method is often practised by what is called *placing*. The tap-roots being taken off, the bulbs, with the leaves, are placed close together in the position they grew, upon some dry place near to where they are to be consumed. In this way they will keep longer than if they had been left in the field, as they are not so apt to run to seed.

But even the *placing system* has its objections; for if a tract of dry weather set in, the turnips, from being merely on the surface, become soft and shrivelled, and not so palatable to the cattle, and will even continue so for a considerable time, although the weather should be rainy, until the fibres begin to take hold of the soil; and another objection is, that if the turnips are not placed near the steading, the destruction from game, hares, wood-pigeons, &c. is very great, particularly if the turnip be Swedish.

In order, therefore, to remedy these objections, another method has been adopted, which has been found to answer every purpose intended. The turnips are brought from the field, without either "topping or tailing," to a piece of dry ground near the straw-yard; then a man with one horse in a plough makes a straight furrow; the turnips are then placed in the furrow quite close together, till the whole is filled from end to end; then the man with the plough moves round to where he commenced, drawing another furrow just as close to the turnips as to enable him to cover them, and so on alternately, the men making the furrow and covering the turnips, while the women and girls lay in the turnips. By this method the turnips keep as fresh, preserving all their natural juice and are as well relished by the

cattle as though they were taken from the field; thus allowing the land to be sown with wheat.

The *report of the Harleston Farmers' Club* for 1839, affirms that the best method of preserving roots during the winter, is by clamping them, both as regards protection from frost and maintaining their quality; and that the following is a very effectual method of making the clamps:—Select a convenient and dry situation, and pack the roots carefully, with their crowns outside, in a row about 6 feet wide at the bottom, and terminating in a narrow ridge at the top; then dig a trench, commencing immediately at the edge of the roots, 2 feet wide and 1 deep, turning the mould from the heap; thatch the latter carefully with straw, commencing in the trench, so that all the rain may drain off the heap into it. The clamp may be left two or three weeks in this state, that the evaporation from the roots may escape; the mould already taken out of the trench is then to be laid on the straw, commencing at the bottom of the thatch, and covering the heap 12 inches thick throughout, finishing with a sharp edge. Half the trench originally made will, of course, by this plan be filled up with straw and mould; the other half will remain as a channel for the water falling off the heap; and, as sufficient mould will not have been raised from the original excavation, it will be advisable, in procuring more, to make the channel left round the heap a few inches deeper, as well as wider. If the roots are stored late in the season, and the probability of frost setting in renders it necessary to cover the heap with mould as soon as it is made, it would be better to leave the top uncovered for a week or ten days longer, that the heat may escape. There is no objection to the roots being wet and dirty when they are clamped: the tops should be cut off, but not too close to the crown; the roots and fibres should be left on.

In England, the turnip crops cultivated with so much care and at so much cost, yield a most abundant supply of vegetable matter, most of which, owing to the comparatively mild winters, is left on and in the ground to be eaten off by sheep. This adds great fertility to the soil and prepares it for producing those astonishingly luxuriant crops of wheat of 40, 50 and 60 bushels to the acre. The profits of the turnip crop, either direct or indirect, must be very great, to authorize a tenant on land loaded with taxes, to go to an expense of nearly \$50 per acre in putting in his root crop, as may be seen in the article APPRAISEMENT, where the details of expenditures in putting in only 17 acres of Swedish turnips are estimated at £117 15s. sterling, equal to nearly \$900, of federal money, a sum actually paid for the crop in the ground by an incoming tenant. The root crops of Britain which form the basis of her agricultural prosperity, can only be partially carried on in the United States, owing to the severity of the winter, by which every thing on or near the surface of the ground is bound in early and enduring frost. But then, where cold thus opposes a barrier, a high summer heat opens a new resource, and where nature obstructs the way in one direction, she opens others to agricultural thrift. One of these is

the Indian corn crop, denied to Europe, except in a small space on or near the Mediterranean. The value of this crop, far transcending that of any other staple, is referred to under the head of MAIZE. In reference to the agricultural value of the turnip and other roots, Mr. Nicholas Biddle in an address before the Philadelphia Agricultural Society in 1842, made the following interesting observations:—

“It is strange how things so lowly acquire national importance. The best farming is that which will give the greatest mass of sustenance to animals—since the less land required for animals, the more can be given for the maintenance of human beings. That fine farming region, England, had reached the limit of its power of supporting animals—since it turned to the root culture it more than doubled or quadrupled its power—and now, odd as the mingling of such dissimilar notions may seem, it is scarcely an exaggeration to say, that England’s power is based upon its iron, its coal, and its turnips. Then, that beet, which the commercial jealousy of Napoleon endeavoured to raise to the dignity of the sugar-cane, which at this moment yields to France more than 60 millions of pounds of good sugar, and has now become so incorporated into the French agriculture as to divide the government of France between the encouragement of the foreign sugar-cane and the domestic sugar beet. To us the question is unimportant, since sugar is so cheap in this country as to leave to us the sugar beet as an excellent food for our cattle.”

Although the excessive frosts in the United States interfere with the English plan of feeding the turnips from the ground during winter, still there is no question that great advantages may be derived by the American farmer from the cultivation of the turnip, the Swedish especially, to lay up as green and succulent food for stock, to be used conjointly with hay and other kinds of provender. Very satisfactory experiments have demonstrated the value of turnips appropriated in this way, for an account of which the reader may consult *Buel’s Farmer’s Instructor*, *Coleman’s Reports*, the *Cultivator*, and other Am. agricultural periodicals.

The insects which attack turnips in America will be found described under the heads CATERPIL-LAR, FLEA-BEETLE, FLY IN TURNIPS, &c.

TURNIP CART. This is an ingenious adaptation of the disc turnip cutter to the turnip cart. The disc is put in motion by a face-wheel fixed upon the nave of the cart-wheel, which, as it revolves communicates by means of cog-wheels with the axis of the cutting-plate. It offers a very convenient mode of feeding sheep on pastures or lawns, and was introduced about the year 1834, by Arthur Biddell, farmer, of Playford, the inventor of the well-known scarifier, which bears his name.

TURNIP CUTTERS. Although there are several kinds of turnip cutters, the principles upon which they are constructed do not embrace much variety: setting aside the simple application of the knife with a lever handle, the others may be divided into two classes; first, those which have their knives placed on a disc; and secondly, those with their cutting edges arranged on a cylinder.

As the object to be effected is simple, and involves little mechanical contrivance, a short description will suffice.

Gardner’s Patent Turnip Cutter, is pronounced the best known in England. In *Ransome’s Barrow Turnip Cutter*, Gardner’s machine is used, the disc of which is attached to the side of a barrow, which serves as a hopper; the knife is nearly the length of the radius, and when required to cut the turnip in slices is alone used; if it be necessary to cut small slices for sheep, the small cross-knives are, by a simple contrivance, adjusted to dissect the slice; and in this case the barrow is useful, as it is easily moved from trough to trough, into which the small slices may be made to fall.

It is intended to cut into small slices for sheep, and is generally acknowledged to be the best implement for the purpose that is at present in use in England.

TURPENTINE. A transparent, oleo-resinous substance, which exudes naturally, but is chiefly obtained by incision, from various species of pine. There are several kinds of turpentine, namely, common, Bordeaux, Canadian, Strasburg, Venice, and American white. The Chian turpentine is the production of the *Pistachia terebinthus*; but all of them possess the same general and chemical properties.

TUSSER, THOMAS, a celebrated agricultural writer. Five-and-twenty years after the publication of the first English work upon agriculture (*Fitzherbert’s Boke of Husbandry*), appeared (in 1557) the *One Hundred Points of Good Husbandry*, by Thomas Tusser. This celebrated work must be regarded more as a series of poetical good farming, and domestic directions and axioms, than as a regular treatise upon agriculture. All that is known of the author of this curious production has been collected by Dr. Mavor, in his able edition of Tusser’s book, and by my brother, Mr. George W. Johnson, in his *History of English Gardening*; and both these authors have been obliged to content themselves chiefly with Tusser’s own account of himself; for Tusser did what few men ever attempt—he wrote his own life, and in a manner still more rare, in verse. His life was full of adventure; for he evidently had all the restlessness of genius, with the unsettled habits too commonly confirmed by continued change of occupation.

He was born about the year 1515, at Rivenhall, a village on the high-road between the towns of Witnam and Keldevon, in Essex, of a family allied by marriage to the higher ranks of society.

He was buried in the church of St. Mildred in the Poultry, according to Stowe, with this epitaph:

“Here, Thomas Tusser, clad in earth, doth lie,
That sometime made the Points of Husbandry:
By him then learn thou may’st; here learn we must,
When all is done, we sleep, and turn to dust:
And yet, through Christ, to heaven we hope to go;
Who reads his books, shall find his faith was so.”

In whatever capacity he at various times lived he acted with ability, yet never so as to benefit his fortune. That he excelled as a chorister,—to which he was originally educated, though strongly against his inclination,

—is certain; for none but those of more than ordinary powers are admitted into the royal choir. As a courtier he was unfrowned upon till the disgrace of his patron. As a farmer it is evident that he possessed a correct knowledge, from his work upon the subject. The same book testifies that, as an author and a poet, he was far above mediocrity. Fuller, in his *Worthies of Essex*, describes him, in his usual quaint manner, as "a musician, school-master, serving-man, husbandman, grazier, poet; more skilful in all than thriving in any vocation. He spread," he adds, "his bread with all sorts of butter, yet none would stick thereon." The testimony of Fuller to the excellent private character of Tusser is valuable as coming from one who must have been the contemporary of many persons who well remembered our author. "I hear," says Fuller, "no man to charge him with any vicious extravagancy or visible carelessness." The true reason of his ill success in life is to be found, perhaps, in the verses of a poet almost his contemporary. Peacham, in his *Minerva*, a book of emblems, published in 1612, has a device of a whetstone and a scythe, with this beneath:

"They tell me, Tusser, when thou wert alive,
And hadst for profit turned every stone,
Where'er thou camest thou couldst never thrive,
Though hereto best couldst counsel every one;
As it may in thy *Husbandry* appear,
Wherein afresh thou livest among us here.
So, like thyself, a number more are wont
To sharpen others with advice of wit,
When they themselves are like the whetstone blunt."

Tusser's work first appeared in 1557, entitled "*A Hundreth Good Pointes of Husbandrie*:"

"A hundreth good points of husbandry
Maintaineth good household, with huswifry.
Housekeeping and husbandry, if it be good,
Must love one another like cousinnes in blood.
The wife, too, must husband as well as the man,
Or farewell thy husbandry do what thou can."

Imprinted in London, in Flete strete, within Temple barre, at the sygne of the hand and starre, by Richard Totell, the third day of February, An. 1557. Cum privilegio ad imprimendum solum."

A copy of this edition, which Dr. Mavor considers to be unique, is in the British Museum. It consists of only 13 quarto leaves.

The *Book of Huswifry*, it is supposed, was at first printed by itself; it was afterwards added to the editions of the *Husbandry*.

Editions of this work appeared in 1561, 1562; and another, "newly corrected and amplified," 1570, 1571 (Watts). To these succeeded an enlarged edition and several reprints, the last of which is that edited by Dr. W. Mavor in 1812, 4to and 8vo, with many notes and additions.

To this *Book of Husbandry*, says Weston, is often joined *The Booke of Regarde, containing the Castle of Delight, the Garden of Unthriftinesse, the Arbour of Virtue, and the Castle of Repentance*. Another work is ascribed by Haller to the pen of Tusser, viz. *Tractatus de Agricultura Versibus Anglicis*. London, 1638-72. Both these last-mentioned works are extremely rare.

Tusser dedicated his book first to Lord William Paget, in an acrostic, and after his death to "the Lord Paget of Beaudesert," his son and

heir. From this we find that Tusser shared an author's very common fate, for he tells us—

"By practice and ill speeding,
These lessons had their breeding,
And not by hearsay or reading,
As some abroad have blown;
Who will not thus believe me,
So much the more they grieve me,
Because they grudge to give me,
What is of right mine own."

Its price, when first published, as described in his prefatory address to the reader, was only 4*d.* or 8*d.* He says,

"What is a goat
Or twain to note,
Once in the life,
For man or wife?"

The style in which Tusser wrote his book is plain, and sometimes rather hobbling; but at the same time it is a metre easily remembered; and verse is well adapted to impress upon the memory the mass of useful truths and rural directions contained in the work. In the rhyming preface, "to the buyer of this book" (for Tusser seemed to do every thing in verse), he says,—

"What look ye, I pray you shew what?
Terms pointed with rhetorick fine?
Good husbandry seeketh not that,
Nor is't any meaning of mine."

His tenth chapter consists of a series of 63 excellent "Good Husbandry Lessons, worthy to be followed of such as will thrive." He omitted no opportunity to give occasion for seasonable reflections:

"As hnd, by appearing, betok'neth the spring,
And leaf, by her falling, the contrary thing;
So youth bids us labour to get as we can,
For age is a burden to labouring man."

He comments the system of moderate corn-rents, and was evidently no enemy to the sports of the field:

"To hunters and hawkers take heed what ye say,
Mild answer with courtesy, drives them away;
So where a man's better will open a gap,
Resist not with rudeness, for fear of mishap."

He begins his monthly husbandry with September, for that was then the period, as now in England, when arable land was commonly entered upon by the farmer. He says, in his opening stanza,—

"At Michaelmas lightly, new farmer comes in,
New husbandry forceth him; new to begin;
Old farmer, still taking, the time to him given,
Makes August to last untill Michaelmas even."

In furtherance of his object, that of giving some very minute directions to the incoming tenant, he even gives a catalogue of farming implements in verse, in which he manages with some adroitness to include several apparently impracticable names, such as,—

"A hand-barrow, wheel-barrow, shovel, and spade,
A curry-comb, mane-comb, and whip for a jade."

It was the approved practice in Tusser's days to "sow timely thy white wheat, sow rye in the dust." They were used also to put rye-meal into their wheat-flour:

"But sow it not mixed to grow so on land,
Lest rye larry wheat till it shed as it stand."

Thick and thin sowing had even then their respective advocates:

"Though beans be in sowing; but scattered in,
Yet wheat, rye, and peason, I love not too thin:
Sow barley and dredge with a plentiful hand,
Lest weed, stead of seed, overgroweth thy land.

It is evident that in those days the farmers were not able to grow their grain on many soils where the modern holders find no obstacles. Thus he speaks of the difficulty they found in producing barley in the parish of Brantham, in Essex, where he farmed some land; and, again, he tells us, what will surprise the modern skilful Suffolk farmers,—

"In Suffolk, again, whereas wheat never grew,
Good husbandry, used, good wheat land I knew."

And he adds,—

"As gravel and sand is for rye and not wheat."

He mentions several varieties of wheat then grown by the farmers of the reign of good Queen Bess, such as white and red rivet, white and red pollard, Turkey and gray. But of this last he says,—

"Oats, rye, or else barley, and wheat that is grey,
Brings land out of comfort, and soon to decay."

The land, however, was evidently farmed with little skill:

"Two crops of a fallow, enricheth the plough,
Though 'one be of pease, it is land good enough:
One crop and a fallow some soil will abide,
Where, if ye go further, lay profit aside."

He warns the farmers to beware of corn-stealers, and to keep their soil in good heart; to manure their land with the earth from headlands and old banks; he commends the use of night-soil for gardens; and recommends the manure of the farm-yard to be laid up "round on a hill." And he had the wisdom to perceive the advantages of shed-feeding live-stock:

"The houseing of cattle, while winter doth hold,
It is good for all such as are feeble and old;
It saveth much compass and many a sleep,
And spareth the pasture for walk of thy sheep."

Grazing has, since Tusser's days, been more and more on the decline, as soiling has been better appreciated. A distinguished modern, witty divine, in a letter to a friend, thus zealously denounces the grazing system: "Grazing is an absolute barbarism; it is just the same as if you desired your servants to trample and roll over your bread and butter."

For faint cattle he recommends the use of bay-salt; and in his February's husbandry gives some directions for the management of their dung, which betrays a deplorable want of knowledge in its economy:

"Who layeth on dung, ere he layeth on plow,
Such husbandry useth, as thrift doth allow:
One month ere ye spread it, so still let it stand,
Ere ever to plow it, ye take it in hand.

Place dung-heap alow, by the furrow along,
Where water, all winter-time did it such wrong:
So make ye the land to be lusty and fat,
And corn thereon sown, to be better for that."

In another place, however, he recommends the farmer to use the mud from ditches and ponds as a dressing for their land.

They harvested their corn, it seems, then, much after the same manner as at the present day. They reaped their wheat and mowed their stubbles; and this they carried as we do now, as soon as possible after harvest:

"For fear of destroying with cattle or rain,
The sooner ye load it more profit ye gain."

And as to barley, Tusser says,—

"The mowing of barley, if barley do stand,
Is cheapest and best, for to rid out of hand:
Some mow it, and rake it, and set it on cocks;
Some mow it, and bind it, and set it on shocks."

They let out, at the period when Tusser wrote, it seems, the harvest-work either by the acre or by the day; of which modes of getting in the corn he seems to prefer the latter:

"By great will deceive thee, with ling'ring it out,
By day will despatch, and put all out of doubt."

His directions to the farmer with regard to the treatment of his harvestmen and the poor gleaners, and his warm hopes for the farmer's success, betray the excellent benevolent spirit with which he was actuated. He says,—

"Corn carried, let such as be poor go and glean,
And after thy cattle, to mouth it up clean;
Then spare it for rowen till Michel be past,
To lengthen thy dairy, no better thou hast.

In harvest-time, harvest-folk, servants and all,
Should make altogether, good cheer in the hall;
And fill out the black bowl of blythe to their song,
And let them be merry all harvest-time long.

Once ended thy harvest, let none be beguil'd;
Please such as did help thee—man, woman, and child.
Thus doing, with alway, such help as they can;
Thou winnest the praise of the labouring man.

Now look up to God-ward, let tongue never cease
In thanking of Him for his mighty increase,
Accept my good will,—for a proof go and try;
The better thou thriveest the gladder am I."

Having commenced his directions with the outgoing tenant, his last stanza concludes with a reference to the incoming:

"New farmer he thinketh each hour a day,
Until the old farmer be packing away."

"Thus endeth and holdeth out
August's Husbandry till
Michaelmas Eve. Tho. Tusser."

The *Book of Husbandry* of Tusser is also interesting from the information it gives us with regard to the customs and habits of the farmers of more than two centuries and a half since. It is evident that they then lived very much upon salt fish, for in his directions for the farmer's diet, he mentions for Lent herrings and salt fish—at Easter they had veal and bacon—at Martinmas, beef—before the feast of St. John, mackerel—fresh herrings at Michaelmas—at Hallowtide, sprats and spurlings—for Christmas fare they seemed to have all the modern standing dishes,—

"Good bread and good drink, a good fire in the hall,
Brawn-pudding and souse, and good mustard withal;
Beef, mutton, and pork, shred pies of the best,
Pig, veal, goose, and capon, and turkey well drest."

They evidently, however, lived generally very frugally:

"Where fish is scant, and fruit of trees,
Supply that want with butter and cheese,
Quoth Tusser."

They bought, in Tusser's time, such stocks of salt fish as would amaze a modern farmer in these protestant days, when, by the increase of green winter food, cattle and sheep are kept easily through the winter, and fresh meat is always to be had. Few farmers would now think of undertaking a journey to buy fish; yet he directed the farmer of the sixteenth century,—

"When harvest is ended, take shipping or ride,
Ling, salt fish, and herring for Lent to provide;
Get home that is bought, and go stack it up dry,
With pease-straw between it, the safer to lie."

They had a rude way of measuring time, it seems:

"As huswives are teached, instead of a clock,
How winter nights passeth by crowing of cock."

The care of the garden evidently fell to the wife's share, who had also to see to the feeding of the household. It seems that the labourers had then a great fondness for porridge, for Tusser tells us,—

"No spoon-meat, no bellyfull, labourers think."

In other days, too, it is evident that spinning was no mean part of the mistress's avocation, for it is here said,—

"Wife, pluck fro thy seed hemp the fible hemp clean;
This looketh more yellow, the other more green.
Use t' one for thy spinning, Michell the t' other,
For shoe-thread and halter, for rope and such other:
Now pluck up thy flax for the maidens to spin."

Tusser never seems to have forgotten, on any occasion, to recommend to the landholder the payment of his just dues; even the question of the tithes, once so obnoxious to the farmer, was not overlooked by him. He advised his farming brethren to

"Tithe duly and truly, with hearty good will,
That God and his blessing may dwell with thee still;
Though parson neglecteth his duty for this,
Thank thou thy Lord God, and give ev'ry man his."

The Points of Huswifery, united to the Comfort of Husbandry, by Thomas Tusser, Gentleman, was, it is concluded, first published with *The Husbandry* in 1561 or 1562. It is written in rather a more lively style than the former, and has an epistle dedicatory, "to the right honourable, and my especiall good lady and mistress, the Lady Paget," which he thus commences:

"Though danger be mickle,
And favour so fickle;
Yet duty doth tickle
My fancy to write:
Concerning how pretty,
How fine and how netty,
Good huswife should jetty
From morning to night."

This work contains an abundance of directions, in his usual style of versification, for the conduct of household duties. He directs the servants, before breakfast, to be set to work:

"Let some to peel hemp, or else rushes to twine,
To spin, or to card, or to seething of brine."

At breakfast time the wife was, in those days, the carver for the farm servants:

"Let huswife be carver, let pottage be heat,
A mess to each one with a morsell of meat."

In the cookery department the now nearly extinct race of turnspits were indispensable attendants upon the cook:

"Good diligent turnbroche, and trusty withal."

In his washing section he is rather more terse than gentle in his conclusion:

"Maids, wash well, and wring well, but beat, ye wot
how,
If any lack beating, I fear it be you."

In his directions for malt-making he alludes to the use of straw and wood, but does not mention the modern fuel, coke, or cinders. They used, it seems to dine at noon:

"By noon, see your dinner be ready and neat;
Let meat tarry servant, not servant his meat."

The mistress of the house then made, as now in some parts of England, her own candles, it seems:

"Provide for thy tallow, ere frost cometh in,
And make thine own candle, ere winter begin."

Twice a week, Sundays and Thursdays, the ploughmen were entitled to roast meat for supper; and to a harvest goose when the corn was gathered in. At harvest-home the mistress was enjoined,—

"Remember thou, therefore, though I do it not,
The seed-cake and pasties, and furnety pot."

In Tusser's time a very unwholesome custom prevailed, in the absence of carpets, of strewing the citizens' houses with rushes, and those of the country with flowers. He gives, therefore, a list of "strewing flowers of all sorts," in which we find only the common sorts of flowers now cultivated, such as cowslips, daisies, lavender, roses, sage, tansy, violets, &c.

Such were the works of Tusser, writings which were long in the hand-book of the English country gentleman. That they were popular is evidenced by the rapid succession of copious editions which fell to their lot; that they were read with delight is shown by the way in which he is commonly quoted by the farmer of all grades. If he had spoken in prose, as has been sometimes suggested, he might certainly have been more instructive to the few, but he would not have been read by the many.

The popular details and histories of all nations escaping from rudeness are commonly written in verse; and multitudes can learn these by heart who never were taught to read. Tusser, therefore, is deserving of the gratitude of the English farmer, for his labours tended to improve, to refine, to elevate the profession he celebrated in his verses. The attempt at any thing like a systematic treatise on farming had not, when Tusser died, been deemed possible. (*Quart. Journ. Agr.* vol. xii. p. 69.)

TWAYBLADE (*Listera*; named in honour of Martin Lister, M.D., a famous English physician and naturalist; best known as a conchologist and entomologist). A genus of curious little native plants, growing wild in shady places. They may be grown in a mixture of peat and loam, and are increased by divisions of the roots.

TWIG-RUSH (*Cladium*, from *klados*, a branch or twig, referring to the appearance of the plant). This is a genus of hard, harsh, rushy, often prickly-edged plants, whose stems, whether round or triangular, are more or less clothed with alternate sheathing leaves or scales.

TWITCH. See **CORCH.**

U.

UDDER. The glandular organ of a cow, mare, ewe, or other animal which is destined for the secretion of milk. There are four teats, each of which consists of two granular lobated glands, comprehending bloodvessels, nerves

and milk ducts, all of which first unite into eight or ten principal ducts, and these again into one, which perforates the skin of the teat at its apex. The granular part is the secreting organ.

UMBEL. In botany, a particular arrangement of the flowers in certain plants, of which the carrot is a familiar example; the peduncles and pedicles spring from a common centre, and rise till they form a somewhat flat tuft. The umbel is a loose inflorescence, the primary axis of which is short, and the secondary long; and the umbel becomes compound when the secondary axes are developed, in the same manner as the primary. Both the primary and the secondary umbel is generally furnished with bractes at the point of its divergence. The secondary umbel is termed *umbellule*. The difference between an umbel and a corymb is, that in the latter the flowers form a flat head, the secondary axes arising alternately from different points of the primary, not, as in the former, springing from a common centre. See **INFLORESCENCE**.

UMBELLIFEROUS PLANTS (*Umbelliferae*). An extensive group of useful plants, including those well-known garden vegetables parsley, celery, carrots, fennel, caraway, coriander, dills, anise, lovage, angelica, eryngo, samphire, hemlock. The name of the class was given from a fanciful resemblance to some parts of an umbrella or parasol. The flower-stem divides at the top into a number of short, slender branches, which all run from a common point or centre like the rays of an umbrella from the ring sliding up and down the stick. The class, though containing so many useful plants, has many possessed of extremely poisonous qualities, such as hemlock, the fool's parsley (*Æthusa cynapium*, Pl. 10, g), dropwort, &c. The blossom of the elder resembles at first sight those of umbelliferous plants, to which, however, the elder does not belong, because the rays of the flower do not proceed from a common point, some being higher and some lower.

UNDERWOOD. A term applied to coppice, or any wood not accounted timber. See **COPPICE**, **FOREST**, and **PLANTATION**.

URINE. A saline fluid secreted from the blood of animals by the kidneys, collected in the urinary bladder, and emitted by the canal of the urethra. Urine differs in different animals, and varies in its characters, according to the kind of food employed. The usual salts contained in it are, sulphates, phosphates, and chlorides, all of which are fertilizing substances. The urine also of oxen and horses is alkaline; it undergoes decomposition less rapidly than that of carnivorous animals: it contains hippurates, but no lithic acid, that substance which forms red gravel in man. Hippuric acid contains 7 per cent. of nitrogen. Urine, therefore, is of much use as a manure, improving most kinds of soil. Columella has asserted that, stale, it is excellent for the roots of trees. And Hartlib commends the Dutch for preserving the urine of cows as carefully as they do the dung, to enrich their lands.

It is a fluid capable of being employed with great benefit both on meadows and on arable land. See **LIQUID MANURE** and **NIGHT-SOIL**.

URITH. Provincially the etherings or bindings of hedges.

USTILAGO (from *ustus*, scorched appearance). A genus of fungi, parasitical, which are found preying upon the cereal and other grasses. See **SMUT**.

V.

VALLESNERIA (*Spiralis*). This plant grows very abundantly from the bottoms of fresh water rivers and lakes over the whole United States, where the flow of water is not very rapid. It goes by the different names of eelgrass, tapegrass, and channelweed. It is upon the roots of this grass, or a native species of *vallesneria*, that the canvass-back duck feeds, and to which its peculiarly delicate flavour is ascribed, by Wilson, the ornithologist.

VALUATION. See **APPRAISEMENT**.

VEGETABLE CHEMISTRY is that branch of the science of chemistry which relates to vegetable substances. Under the heads **ANALYSIS**, **CHEMISTRY**, **ORGANIC CHEMISTRY**, **GASES**, **EARTHS**, **WATER**, **SALTS**, &c., I have endeavoured to include all the facts supplied by this important science for the assistance of the farmer with which I am acquainted; I shall, therefore, merely insert in this place the chemical analysis of the inorganic substances found in several of the commonly cultivated crops of the farmer; and this I take from p. 318, of the valuable *Lectures on Agricultural Chemistry and Geology*, by J. F. Johnston; see also *Liebig's Organic Chemistry*.

Besides the elements of the organs of plants, other substances, obtained from inorganic nature, are necessary for certain organs destined to special functions peculiar to each family of plants. In the ashes of the plants left after burning them, these substances are found. Almost all plants contain acids, in combination with soda, potassa, lime, alumina, or magnesia. The quantity of these salts varies at different periods of the growth of the plant: thus unripe grasses contain more bitartrate of potassa than the ripe, and the potato more potassa before it blossoms than afterwards. The nature of a soil, as has already been detailed, alters the quantity of salts found in plants. The *Salsola kali*, raised from seeds of plants near the sea, in an inland garden, contains both potassa and soda; but the plants from the seed of this contain potassa only. But these facts are detailed under the head **SALTS**, &c.

In examining the results of these analyses, the farmer must remember, that the acids and their bases do not exist in plants in an uncombined state, but in combination with each other; that is, as salts.

1. *Of the Ash of Wheat.*—According to the analysis of Sprengel, 1000 lbs. of wheat leave 11·77 lbs. and of wheat straw 35·18 lbs. of ash, consisting of—

VEGETABLE CHEMISTRY.

	Grain of Wheat.	Straw of Wheat.
Potash - - - -	2.25 lbs.	0.20 lbs.
Soda - - - -	2.40	0.29
Lime - - - -	0.96	2.40
Magnesia - - - -	0.90	0.32
Alumina, with a trace of iron	0.36	0.90

	63.3	180.9	66.19	41.80	82.83	308.4

7. *Of the Ash of the Grasses and Clovers.*—The following table might have been much enlarged. I have thought it necessary, however, to introduce in this place only those species of grass and clover which are in most extensive use. I have also calculated the weights given below for these plants in the state of hay only, as the succulency of the grasses—that is, the quantity of water contained in the green crop—varies so much that no correct estimate

could be made of the quantity of inorganic matter present in hay or grass, from a knowledge of its weight in the green state only. The

annexed quantities are contained in 1000 lbs of the dry hay of each plant:

	Rye-grass. Hay.	Red Clover.	White Clover.	Lucern.	Sainfoin.
Potash - - - - -	8.81	19.95	31.5	13.40	20.57
Soda - - - - -	3.94	5.29	5.79	6.15	4.37

	52.86	74.78	91.32	95.53	69.57

VEGETABLE PHYSIOLOGY is that science which treats of the vegetable kingdom, its habits, properties, and organization, in the most comprehensive manner. Its objects have been clearly stated by Mrs. Marcet, in her excellent *Conversations on Vegetable Physiology*, when describing the lectures of M. Decandolle on this science; and what she has so well described, it is needless for me to give in other words. "So far from confining himself to the classification of plants, the physiologist examines the vegetable kingdom in its most comprehensive and philosophical point of view. In describing the structure, he investigates the habits and properties of plants, and shows, not only how wonderfully they have been formed to fulfil the purposes of their own multiplication and preservation, but how admirably they answer the high purpose which nature has assigned to them, of ministering to the welfare of the animal creation, and more especially to that of man. He turns his attention particularly to point out the means by which the science of botany can promote that with which it is most intimately and importantly connected—agriculture. He makes ready the soil and sows the seed for the husbandman; he extracts the healing juices and the salutary poisons for the physician; he prepares materials for the weaver, colours for the dyer: in a word, as he proceeds, there is scarcely an art on which he does not confer some benefit, either by pointing out a new truth, or warning against an old-established error." From this description of the objects of the science of vegetable physiology, the reader will see that almost all its different branches are treated of separately in articles which are dispersed through this volume. It is only, therefore, a few scattered fragments which I propose to gather together in this place. See ACCLIMATION, BOTANY, EARTHS, GASES, LIGHT, PUTREFACTION, SALTS, TEMPERATURE, WATER, &c.

The description of the cambium for the descending sap of plants was omitted in its proper place, and the effect of gravity or attraction upon plants was referred to this head. The sap having ascended into the leaves, and being in its course gradually altered into a fluid suitable for the nourishment of the plant, descends principally through the liber, or inner layer of bark, but a small portion also descends through the young wood, or alburnum. This movement, especially through the plants with

pendent branches, is materially facilitated by motion, as by the action of the wind. "Mr. Knight," adds Mrs. Marcet, "has made a variety of interesting experiments on this subject. He confined both the stem and branches of a tree in such a manner that it could not be moved by the wind. The plant became feeble, and its growth much inferior to that of a similar tree growing in its natural state. He confined another tree so that it could be moved only by the north and south winds, and obtained the singular result of an oval stem, the sides accessible to the wind growing more vigorously than those sheltered from its influence. Every species of restraint, and especially such as tend to render plants motionless, impedes their growth. Stakes by which young trees are propped, nailing them to walls or trellises, green-houses, or confined situations where the air has not free access, check and injure the vigour of vegetation, and render plants diminutive and weakly. The cambium descends almost entirely through the liber or most internal and youngest layer of the bark; if, therefore, a ring is cut completely through the bark, this fluid is arrested in its course, and, accumulating around the upper edge of the intersected bark, will cause an annular protuberance. The descent of the cambium thus being obstructed, it will accumulate in that part of the tree above the intersection, afford it a superabundance of nourishment, creating a proportional vigour of vegetation, and a corresponding excellence and profusion of produce." This operation, or *ringing*, is often performed on the non-productive branches of fruit trees.

The effect of gravitation or attraction upon plants is of the highest importance to their germination and their growth. From the very nature, however, of this essentially present power, a principle known only to us by its effects, the research is surrounded with difficulties. Mr. Knight, the late excellent president of the Horticultural Society, described some of the effects of gravity upon plants in his usual happy manner, when, in addressing the fellows of the Royal Society, he observed, "It can scarcely have escaped the notice of the most inattentive observer of vegetation, that in whatever position a seed is placed to germinate, its radicle invariably makes an effort to descend towards the centre of the earth, while the elongated germen takes precisely the oppo-

site direction; and it has been proved by Duhamel, that if a seed during its germination be frequently inverted, the points both of the radicle and germen will return to the first direction. Some naturalists have supposed these opposite effects to be produced by gravitation; and it is not difficult to conceive that the same agent, by operating on bodies so differently organized as the radicle and germen of plants are, may occasion the one to descend and the other to ascend." The hypothesis of these naturalists it was the intention of Knight to examine by certain experiments, which he thus proceeds to describe: "I conceived that if gravitation were the cause of the descent of the radicle and the ascent of the germen, it must act either by its immediate influence on the vegetable fibres and vessels during their formation, or on the motion and consequent distribution of the true sap afforded by the cotyledons; and as gravitation could produce these effects only while the seed remained at rest, and in the same position relative to the attraction of the earth, I imagined that its operation would become suspended by constant and rapid change of the position of the germinating seed, and that it might be counteracted by the agency of centrifugal force. Having a strong rill of water passing through my garden, I constructed a small wheel, similar to those used for grinding corn, adapting a wheel of a different construction, and formed of very slender pieces of wood, to the same axis.

"Round the circumference of the latter, which was 11 inches in diameter, numerous seeds of the garden bean, which had been soaked in water to produce the greatest degree of expansion, were bound at short distances from each other. The radicles of these seeds were made to point in every direction, some towards the centre of the wheel, and others in the opposite direction; others at tangents to its curve; some pointing backwards and others forwards, relative to its motion, and others pointing in opposite directions in lines parallel with the axis of the wheels. The whole was enclosed in a box and secured by a lock, and a wire-grate was placed to prevent the ingress of any body capable of impeding the motion of the wheels. The water being then admitted, the wheels performed something more than 150 revolutions in a minute, and the position of the seeds relative to the earth was as often perfectly inverted within the same period of time, by which I conceive that the influence of gravitation must have been wholly suspended. In a few days the seeds began to germinate; I soon perceived that the radicles, in whatever direction they were protruded from the position of the seed, turned their points outward from the circumference of the wheel, and in their subsequent growth receded nearly at right angles from its axis. The germens, on the contrary, took the opposite direction, and in a few days their points all met in the centre of the wheel. Three of these plants were suffered to remain on the wheel, and were secured to its spokes to prevent their being shaken off by its motion. The stems of these plants soon extended beyond the centre; but the same cause which first occasioned them to approach its axis still

operating, their points returned and met again at its centre. The motion of the wheel being in this experiment vertical, the radicle and germen of every seed occupied during a minute portion of time in each revolution precisely the same position they would have assumed had the plants vegetated at rest; and as gravitation and centrifugal force also acted in lines parallel with the vertical motion and surface of the wheel, I conceived that some slight objections might be urged against the conclusions I felt inclined to draw. I therefore added to the machinery I have described another wheel, which moved horizontally over the vertical wheels; and to this, by means of multiplying wheels of different powers, I was enabled to give many different degrees of velocity. Round the circumference of the horizontal wheel, whose diameter was also 11 inches, seeds of the bean were bound as in the experiment which I have already described, and it was then made to perform 250 revolutions in a minute. By the rapid motion of the water-wheel, much water was thrown upwards on the horizontal wheel, part of which supplied the seeds upon it with moisture, and the remainder was dispersed in a light and constant shower over the seeds in the vertical wheel, and on others placed to vegetate at rest in different parts of the box.

"Every seed on the horizontal wheel, though moving with great rapidity, necessarily retained the same position relative to the attraction of the earth, and therefore the operation of gravity could not be suspended, though it might be counteracted in a very considerable degree by centrifugal force, and the difference I had anticipated between the effects of rapid vertical and horizontal motion soon became sufficiently obvious. The radicles pointed downwards about 10 degrees below, and the germens as many degrees above, the horizontal line of the wheel's motion, centrifugal force having made both to deviate 80 degrees from the perpendicular direction each would have taken had they vegetated at rest. Gradually diminishing the rapidity of the horizontal wheel, the radicles descended more perpendicularly, and the germens grew more upright, and, when it did not perform more than 80 revolutions in a minute, the radicle pointed about 45 degrees below, and the germens as much above, the horizontal line; the one always receding from, and the other approaching to, the axis of the wheel.

"I would not, however, be understood to assert that the velocity of 250 or 80 horizontal revolutions in a minute will always give accurately the degrees of depression and elevation of the radicle and germen which I have mentioned; for the rapidity of the motion of my wheels was somewhat diminished by the collection of fibres of conserræ against the wire grate, which obstructed in some degree the passage of the water; and the machinery having been the workmanship of myself and my gardener, cannot be supposed to have moved with all the regularity it might have done, had it been the work of a professed mechanic. But I conceive myself to have fully proved that the radicles of germinating seeds are made to descend, and their germens to ascend, by some

external cause, and not by any power inherent in vegetable life; and I see little reason to doubt that gravitation is the principal, if not the only, agent employed in this case by nature." Mr. Knight has endeavoured to point out the means by which he conceives the same agent may produce effects so diametrically opposite to each other.

It has, however, been objected by Duhamel (and the greatest deference is always due to his opinions) that gravitation could have little influence on the direction of the germen, were it, in the first instance, protruded, or were it subsequently inverted, and made to point perpendicularly downwards. To enable myself, says Mr. Knight, to answer this objection, I made many experiments on trees of the horse-chestnut and of the bean, in the box I have already described; and as the seeds there were suspended out of the earth, I could regularly watch the progress of every effort made by the radicle and germen to change their positions. The extremity of the radicle of the bean, when made to point perpendicularly upwards, generally formed a considerable curvature within 3 or 4 hours when the weather was warm. The germen was more sluggish; but it rarely or never failed to change its direction in the course of 24 hours; and all my efforts to make it grow downwards by slightly changing its direction were invariably abortive.

As trees possess the power of turning the upper surfaces of their leaves and the points of their shoots to the light, and their tendrils in any direction to attach themselves to contiguous objects, it may be suspected that their lateral roots are by some means directed to any soil in their vicinity which is best calculated to nourish the plant to which they belong; and it is well known that much the greater part of the roots of an aquatic plant which has grown in a dry soil, on the margin of a lake or river, have been found to point to the water, whilst those of another species of tree which thrives best in a dry soil have been ascertained to take an opposite direction: but the result of some experiments I have made is not favourable to this hypothesis; and I am inclined to believe that the roots disperse themselves in every direction, and only become more numerous where they find most employment, and a soil best adapted to the species of plant.

A tree growing upon a wall at some distance from the ground, and consequently ill supplied with food and water, has also been observed to adapt its habits to its situation, and to make very singular and well-directed efforts to reach the soil beneath by means of its roots. During the period in which it is making such efforts, little addition is made to its branches, and almost the whole powers of the plant appear to be directed to the growth of one or more of its principal roots. To these much in consequence is annually added, and they proceed perpendicularly towards the earth, unless made to deviate by some opposing body; and as soon as the roots have attached themselves to the soil, the branches grow with vigour and rapidity, and the plant assumes the ordinary habits of its species.

In some other experiments of Knight to illus-

trate these highly interesting habits of plants, pieces of alum, and of the sulphate of iron (green vitriol), blue vitriol (sulphate of copper), were placed at small distances perpendicularly beneath the radicles of germinating seeds of different species, to afford an opportunity of observing whether any efforts could be made by them to avoid poisons; but they did not appear to be at all influenced except by actual contact of the injurious substances. The growth of their fibrous lateral roots was, however, obviously accelerated when their points approached any considerable quantity of decomposing vegetable or animal matter; and when the growth of the roots was retarded by want of moisture, the contiguity of water in the adjoining mould, though not apparently in actual contact with them, operated beneficially: but I had reason to suspect that the growth of roots was, under these circumstances, promoted by actual contact with the detached and fugitive particles of the decomposing body and the evaporating water.

The way in which plants establish themselves in opposition to the various obstacles they have to encounter, as, for instance, in withstanding violent winds, is very remarkable. The growth and forms assumed by the roots of trees of every species are, to a great extent, dependent upon the quantity of motion which their stems and branches receive from winds; for the effects of motion upon the growth of the root and of the trunk and branches are perfectly similar. Whatever part of a root is moved and bent by winds or other causes, an increased deposition of alburnous matter upon that part soon takes place, and consequently the roots which immediately adjoin the trunk of an insulated tree in an exposed situation become strong and rigid, whilst they diminish rapidly in bulk as they recede from the trunk, and descend into the ground; by this sudden diminution of the bulk of the roots the passage of the descending sap through their bark is obstructed, and it, in consequence, generates, and passes into many lateral roots, and these, if the tree be still much agitated by winds, assume a similar form, and consequently divide into many others. A kind of net-work, composed of thick and strong roots, is thus formed, and the tree is secured from the danger to which its situation would otherwise expose it. In a sheltered valley, on the contrary, where a tree is surrounded and protected by others, and is rarely agitated by winds, the roots grow long and slender, like the stem and branches, and comparatively much less of the circulating fluid is expended in the deposition of alburnum beneath the ground; and hence it not unfrequently happens that a tree in the most sheltered part of a valley is uprooted, whilst the exposed and insulated tree upon the adjoining mountain remains uninjured by the fury of the storm.

All such investigations as these are fraught with instruction to the cultivator of the earth. They not only illustrate the every-day operations of the farmer, but they guard him against the adoption of specious novelties and unscientific efforts to increase the fertility of the soil. Such researches, too, will hardly fail to

instruct and elevate the character of the tiller of the earth in more ways than one. They will teach him, as M. Mirbel long since well remarked, that every operation "is connected in the vast system of the globe, and that order emanates from the equipoise of conflicting phenomena. Animals carry off the oxygen of the atmosphere, replacing it by carbonic acid gas; and are thus at work to adulterate the constitution of the air and render it unfit for respiration. Vegetables take up carbonic acid gas, retain the carbon, and give out oxygen; and are thus purifying the air tainted by animals, and re-establishing the necessary proportions between its elements. In Europe, while our vegetables, stripped by the severity of the season of their foliage, no longer yield the air contributing to life, the salutary gas is borne to us by trade winds from the southernmost regions of America. Breezes from all quarters of the world intermingle thus the various strata of the atmosphere, and keep its constitution uniform in all seasons and at all elevations. The substances which are produced by the dissolution of animal and vegetable matter are absorbed by plants, and constitute a portion of the nourishment by which they are maintained; plants, in their turn, become the food of animals, and these again the prey of others which subsist on flesh. Yet, in spite of this perpetual state of war and destruction, nothing perishes, for all is regenerated. Nature has ordained that the two great divisions of organized beings should depend the one upon the other for support, and that both the life and death of individuals should be equally serviceable in preserving the harmony of the universe."

If we come to consider vegetation as it regards ourselves, we shall find that this great agent of nature, subjected in a certain degree to the control of man in a state of society, is the main source of his prosperity or of his misery. How many countries have the greedy ambition of princes, and the degradation and ignorance of the people, made barren! Recollect what Asia Minor, Judea, Egypt, the provinces at the foot of Mount Atlas, have been, and behold what they are at this day. Recollect Greece, once the country of science and of liberty, now that of ignorance and slavery; she can be only recognised in her ruins, and her monuments of the dead. Man had denied his labour to the earth, and the earth her treasures to man: all vanished with agriculture. The traveller who passes that country of so great renown, finds, in the place of the fine forests that crowned its mountains, of the rich harvests reaped by twenty busy nations, of the numerous flocks that enriched its fields, only naked rocks and sterile sands, with here and there a miserable village. He seeks in vain for several rivers recorded in history; they are gone! Thus the rage of conquest and of rule not only overturns cities, depopulates whole countries, and brings back barbarism, but it dries up the very springs from which the natural riches of the earth have flowed. To these melancholy results of our passions we might oppose the more cheerful ones of our industry; but they are more properly within the province

of the arts of cultivation than of vegetable physiology.

VEGETABLE MARROW (*Cucurbita ovifera*). This fruit of the succada gourd is uniformly of a pale yellow colour, and of an elliptic-oblong shape, the surface having irregular, longitudinal ribs, uniting into a projecting apex. When full grown it is about 9 inches in length and 4 in diameter, and is by far the best adapted for culinary purposes of any species of the gourd tribe. It is of recent introduction into Europe, having been brought from Persia. It is useful for culinary purposes in every stage of its growth; when very young, it is good if fried with butter; when large, or about half-grown, it is excellent either when plain, boiled, or stewed with rich sauce; for either of these purposes it should be cut in slices. The flesh has a peculiar tenderness and softness, from which circumstance it has received its name, much resembling the buttery quality of the *beurré pear*, and this property remains with it till it is full-grown, when it is used for pies. It is in its intermediate state of growth that it is likely to be most approved. Compared with all the other vegetables of the same family, its superiority is decided. I consider the vegetable marrow without a rival.

"We have grown the true vegetable marrow two seasons," says the editor of the Cultivator, "and although we have not used it in the intermediate state of its growth, as recommended by Mr. Sabine, we esteem it among the best varieties of the cucurbita for boiling and for pies. It is cultivated like the common pumpkin or squash, and will ripen in the U. S. in a high latitude."

VEGETABLES. The observations of vegetable physiologists and the researches of chemists have mutually contributed to establish the fact, that the growth and development of vegetables depend on the rejection of oxygen, which is separated from the other component parts of their nourishment.

In contradistinction to vegetable life, the life of animals exhibits itself in the continual absorption of the oxygen of the air, and its combination with certain component parts of the animal body.

While no part of an organized being can serve as food to vegetables, until, by the processes of putrefaction and decay, it has assumed the form of inorganic matter, the animal organism requires, for its support and development, highly organized atoms. The food of all animals, in all circumstances, consists of parts of organisms.

Assimilation, or the process of formation and growth,—in other words, the passage of matter from a state of motion to that of rest,—goes on in the same way in animals and in vegetables. In both, the same cause determines the increase of mass. This constitutes the true vegetable life, which is carried on without consciousness. (*Liebig's Animal Chemistry.*)

VENTILATION. The injurious effects of close and dirty stables, and other places where stock are often kept, and the great advantages derived from securing a proper ventilation or continual supply of fresh unbreathed air to

animals, are matters which have received, of late, a great deal of merited attention. The owner of horses or other stock, intent upon protecting these from the wet and cold, and placing them in the most favourable position to take on fat, often exposes them to the most injurious effects induced by the breathing of impure air. "We generally find," says an able writer upon this subject, "that the unhealthiness of the atmosphere in which stabled horses and cattle are placed, increases with the value of the animal; this is especially the case with the horse. The groom finding no mode so easy in his endeavours to procure for his horses a fine coat, as that of keeping them in a high temperature, is pretty sure, if not restrained, to effect this by excluding from his stable every breath of air by which its temperature may be lowered, or its purity preserved. It results then (often, it is true, by slow degrees) that the animal, from the breathing an atmosphere surcharged as a certain consequence with the carbonic acid gas emitted from the lungs of the horses in the stable, and with fumes of ammonia from the decomposing urine with which the floor is saturated (a decomposition accelerated by the warmth of the place), becomes tender and diseased. That to this source must be attributed the majority of those diseases of the lungs by which so many valuable horses are annually carried off, there is no reason to doubt. 'The temperature of the stable,' says Professor Youatt, in his excellent treatise on the horse, 'should never in winter exceed ten degrees above that of the external air, and during the rest of the year should be as similar to it as possible.' And he adds a fact which is far too little known to the owners of live stock: 'The return to a hot stable is quite as dangerous as the change from a heated atmosphere to a cold and biting air. Many a horse that has travelled without injury over a bleak country, has been suddenly seized with inflammation and fever when he has immediately at the end of his journey been surrounded with heated and foul air.' 'And,' he adds in another place, 'of nothing are we more certain, than that in the majority of the maladies of the horse, those of the worst and most fatal character, directly or indirectly are to be attributed to the unnatural heat of the stable.' The evil, then, being certain, the remedy merely consisting in the better and more *regular* ventilation of the stable, can I urge upon the horse's owner a more reasonable or a more profitable improvement than this? My own experience tells me that a warm box, well ventilated and constantly kept clean, is by far the best and the most healthy medium in which a horse can be placed. Both *cleanliness* and ventilation must, of course, go together; for it is easy to lose the advantages of ventilation by a disregard to the cleanliness of the stable.

"With regard to the stall-fed cow and the ox, the same erroneous mode of treatment is too constantly adopted: *warmth* and *quiet*, and an absence of light, it is true, have all been determined to be highly conducive to the rapid progress of the animal to maturity, but no sensible farmer ever yet concluded that the purity or the foulness of the air in which the animal is placed, is a matter of perfect indifference: and yet in now many instances are such cows, such fattening oxen, stall-fed, in an atmosphere in which the lungs of the animals *must* be weakened, their

health endangered? How commonly do we see them placed in low close stables, into which a breath of fresh air rarely enters? It is idle to contend that to confine them in such an atmosphere does them no injury. It has been found that the same kind of impure air which these animals are too often made to endure, is *certain death* to the *smaller animals*; and, that the mortality increases as the size of the animal decreases, has been well shown by many curious and valuable inquiries. I will give a few only of these, being quite sure that to many of my readers they will afford matter of grave and useful reflection, when they are considering the ventilation not only of the stables of their live stock, but of the cottages of their labourers, and the rooms which the farmer is himself inhabiting. Let us commence our inquiries, then, with the effects of bad air upon the smaller tribes of birds, and proceed afterwards to the larger animals. 'It is well known,' says Dr. Arnott (*Report of Commissioners upon the Health of Towns*, p. 61), 'that a canary bird suspended near the top of a curtained bedstead in which people have slept, will generally, owing to the impurity of the air, be found dead in the morning; and small, close rooms, in the habitations of the poor, are sometimes as ill-ventilated as the curtained bedstead.'

"Mr. Edwin Chadwick, the excellent Secretary to the Poor-Law Commissioners, in his able supplementary report upon the sanitary condition of the labouring classes, gives some striking facts in illustration of the ill effects of bad smells upon the health of small birds. He says (p. 10), 'In the course of some inquiries which I made with Professor Owen, when examining a slaughterman as to the effects of the effluvia of animal remains on himself and family, some other facts were elicited illustrative of the effects of such effluvia on still more delicate life. The man had lived in Bear Yard, near Clare Market, which was exposed to the combined effluvia from a slaughter-house and a tripe factory. He was a bird fancier, but he found that he could not rear his birds in this place. He had known a bird, fresh caught in the summer time, die there in a week. He particularly noted, as having a fatal influence on the birds, the stench raised by boiling down the fat from the tripe offal. He said, 'You may hang the cage out of the garret window, in any house round Bear Yard, and if it be a fresh bird it will be dead in a week.' He had previously lived for a time in the same neighbourhood, in a room over a crowded burial-ground in Portugal Street. At times, in the morning, he had seen a mist rise from the ground, and the smell was offensive. That place was equally fatal to his birds: He had removed to another dwelling-house in Vere Street, Clare Market, which is beyond the smell from this particular place, and he was now enabled to keep his birds. In town, however, the ordinary singing birds did not actually live more than about eighteen months. In cages, in the country, such birds were known to live as long as nine years or more, on the same food. When he particularly wished to preserve a pet bird, he sent it for a time into the country; and by repeating this removal he preserved them much longer. The fact of the pernicious effect of offensive smells on the small graminivorous birds, and the short duration of their life in close rooms and districts,

was attested by a bird-dealer. In respect to cattle, the slaughterman gave decided reasons for the conclusion, that, whilst in the slaughter-house, they lost their appetites and refused food, from the effect of the effluvia of the place, and not, as was popularly supposed, from any presentiment of their impending fate.' 'The spread of the knowledge of the fact that animals are subject to typhus, consumption, and the chief of the train of disorders supposed to be peculiarly human,' remark the Commissioners in another place, 'will, it may be expected, more powerfully direct attention to the common means of prevention.' (*Report*, p. 103.)

Epizootic diseases, are such as prevail among a large number of animals at the same time, just as *epidemics* do in the human species. 'The *epizootic* are, in many respects, less serious than the epidemics: nevertheless, as they often affect the animals which serve for the nutriment of man, and that, apart from this consideration, they may have grave consequences for the public health, they have constantly engaged the care of the Council. In 1834 an *epizootic* was reported to the Administration, which prevailed amongst the cows of the communes round Paris, and which caused a great mortality. The researches of the Council established that this *epizootic* was only a chronic disease, a true pulmonary phthisis, to which has been given the name of *pommelière*, and by which the greater part of the cows had been attacked which fill the stables of the milkmen of Paris and its environs. According to the Council, the principal cause of the evil was to be attributed to the vicious regimen to which this animal is subjected. It is known that they pass a part of the year in stables perfectly closed, in which the space is not proportioned to the number of inmates, in which the vitiated air renews itself with extreme difficulty, and in which the heat is sometimes suffocating. It is known, also, that they pass suddenly from the food of the stable to pasture, and that in this change they go from the hot and humid atmosphere of the stable to a sudden exposure to the continued variations of the external air. This alternation of food, and of heat and cold, operates as a powerful cause of disease. But as the evil does not announce itself in a violent manner, as its progress is not very rapid, as there is even a period in the disease in which the animal is disposed to get flesh, the cow-feeder, who knows to what point to keep her, sells her when she is ready to calve. It is in a radius of thirty leagues from the capital that cows of this kind are purchased by the jobbers, who supply the milkmen of Paris. With these last they still hold out a certain number of years, if they are properly cared for; but in general they are kept in stables which are neither sufficiently large nor sufficiently airy, where they are exposed to the same causes which gave birth to the malady. The phthisis arrives insensibly at its last stage, and carries off every year, from Paris and its neighbourhood, a great number of these cows.'

'A similar discovery was only lately made as to the effect of defective ventilation on the cavalry horses in some of the government barracks in England; and it is stated a saving of several thousand pounds per annum was effected by an easy improvement of the ventilation of the barracks near the metropolis. An agriculturist had a large number of sheep housed to feed them on mangel wurzel, but a great number of them

sickened and died, and he supposed that it was the food which had killed them. A veterinary surgeon, however, who happened to be aware of the consequences of defective ventilation, pointed out the remedy—a better ventilation for the over-crowded sheep. The defect was remedied; the sheep thrived well.'

In adopting means for the *removal or extraction of foul air*, in dwellings for man, as well as in stables, dairies, and even sheep-cots and pig-pens, when these are made close, the ventilator, or holes for its escape, should always be placed at the highest part of the ceiling. Withdrawing the foul air from the bottom of buildings, on the supposition that, as carbonic acid gas is heavier than common air, it must necessarily subside to the lowest portion of the interior, though plausible in *theory*, is found to be altogether erroneous in practice. For it has been ascertained that this heavy gas, as it comes from the lungs combined with heat and moisture, is lighter than common air, as we see by the rising of the breath in frosty weather. In the ventilation of stables, cow-houses, &c., the supply of air will require to be of larger amount than for buildings intended for human beings. About 400 cubic inches per minute is the usual allowance of air breathed by an adult person; but for horses and cows, three times as much is required.

The one or more openings for the escape of the foul air, have their sizes or areas calculated according to the following rule. Multiply the number of horses the stable is to contain by 12, and divide the product by 43 times the square root of the height in feet from the ceiling to the floor, and the quotient is the area of the ventilation tube or tubes in feet. (*Burn on Practical Ventilation.*)

No foul air can by any possibility be extracted from the interior of a building, however well arranged it may be, unless an ample supply of pure air is admitted, because it is the force of the entering air that causes the vitiated to be expelled.

The *fresh air* should be admitted by apertures in the walls, made close to the floor under each window. Where this can be done, and supposing there were six windows, and the fresh-air ducts required to be 6 square feet, six openings should be made, each equal to one square foot. All the openings should have valves fixed on the outside, to regulate the admission of air. In stables, &c., well supplied with the means of admitting fresh air and withdrawing the foul air, the doors and windows may be made as tight as possible, yet the interior will smell sweet and clean.

Dairies cannot be too well supplied with pure fresh air; to secure which, they should not be situated in the vicinity of any source of contamination. (See *Burn's Treatise on Practical Ventilation*, for further details.) See SOILING.

Animal Heat.—Recent researches made by chemists have developed many wonderful phenomena of life hitherto regarded as inexplicable mysteries. Among these is that relating to the source of animal heat, and the kinds and proportions of food necessary to maintain it. This being a subject intimately connected with the practices of sheltering and feeding cattle and other stock, it of course demands the close consideration of the intelligent farmer, to whom we present the results recently obtained through the investigations of Dr. Playfair:—

'The average temperature of the bodies of

our cattle is about 100°, or more than 40° higher than the ordinary temperature of the climate of England. Hence there must be some provision in the animal body to sustain the heat, which is absolutely necessary for the performance of the organic functions. The air, being so much colder than the body, must constantly withdraw from it heat, and tend to lower its temperature. Whence, then, comes the fuel for the production of the heat?

“The fuel consists of those ingredients of food from which nitrogen is absent; they all contain carbon and the elements of water. We know that oxygen is continually inhaled in the air we breathe, and that it is never again expired as such. Expired air consists of carbonic acid, a gas composed of carbon and oxygen. In the body, therefore, the oxygen has united with carbon; or it has produced the very gas which is obtained by burning a piece of charcoal in the open air. Now the heat generated by the combustion of the carbon in the body must be exactly equivalent to that produced by burning the same amount in the atmosphere.”

Experiments have taught us, that the average quantity of carbon in the food of an adult man amounts to 14 ounces daily. By the combustion of this quantity 197,477° of heat are produced, and this is amply sufficient to account for the heat of the human body.

The experiments of Boussingault show, that a cow breathes out about 70 ounces of carbon daily, and from this we calculate that 987,385° of heat must be produced in the body of a cow in the space of twenty-four hours. These calculations will at once prove that there is little difficulty in accounting for the heat of the animal body.

But, as the heat of the animal body is the same in all regions, it is obvious that the quantity of fuel (food) necessary to sustain the constant temperature of the body must vary according to the nature of the climate. Thus less food is required for this purpose in India, where the temperature of the external air equals that of the body, than in the polar regions, in which it is very many degrees lower. But a beneficent Providence has arranged the produce of different countries so as to meet the exigencies of the climate. The fruits, upon which the inhabitants of warm countries love to feed, contain only 12 per cent. of carbon, while the train-oil enjoyed by the inhabitants of arctic regions contains above 70 per cent. of the same element.

It has been shown that the food of various countries is more or less combustible, according to the temperature of the climate; and proofs were adduced that the amount of the food consumed varied also according to the temperature. The animal body is a furnace which must be kept up to a certain heat in all climates. This furnace must, therefore, be supplied with more or less fuel according to the temperature of the external air. If then in winter we wish to retain the vital functions of our cattle in a proper degree of activity, we must keep up the heat of their bodies. This we may do in two ways. We may either add more fuel (food) to the furnace, or we may protect their bodies from the cold. Warmth is an equivalent for food, which may thus be economized. As a proof of the view I have now given, I will cite the following experiment, which was made by the Earl of Ducie at Whitfield farm.

One hundred sheep were folded by tens in pens, each of which was 22 feet in length by 10 feet in breadth, and possessed a covered shed attached to it of 12 feet in length by 10 feet in breadth. They were kept in these from the 10th of October to the 10th of March. Each sheep consumed on an average 20 lbs. of swedes daily. Another hundred were folded in pens of a similar size, but without sheds attached. They were kept during the same time, and their daily consumption of swedes amounted to 25 lbs. each. Here the circumstances were precisely similar with respect to exercise, the only difference being that the first hundred sheep had sheds into which they might retire, and thus be partially protected from the cold.

This partial protection was equivalent to a certain amount of food, and consequently we find that the sheep enjoying this protection consumed one-fifth less food than those sheep which were left entirely exposed to the cold. In the last case the consumption of the additional food arose wholly from the necessity of adding more fuel (food to the furnace of the body,) in order to keep up its normal temperature. This was proved from the circumstance, that those sheep which enjoyed the protection had increased 3 lbs. each more than those left unprotected, although the latter had consumed one-fifth more food.

The influence of warmth in reducing the consumption of food has been examined experimentally by other farmers, who pretty well agree in the conclusion, that warmth is, to a considerable extent, a substitute for food. It is true, that in the experiments with sheep the results have been somewhat discordant, but, as I have elsewhere had occasion to remark, this has arisen in many cases from inattention to other injurious influences to which these animals were exposed. Warmth is not only essential to their health and fattening progress, but this must be a dry and a wholesome warmth. To confine the sheep, as is sometimes done, over putrefying masses of fold, shed, or farm-yard dung, in an atmosphere saturated with fumes of ammonia and the gases of putrefaction, is to substitute one drawback upon the health and comfort of the animal for another, which produces a greater evil than cold. The sheep, in a state of nature, carefully avoids all these things; it leaves to the ox the deep rank-growing grasses of the damp lowland pastures. It carefully seeks its food and its habitation on the highest elevations, amid dry rocks and heath-producing soils, far away from all great masses of decomposing organic matter. The domestic sheep of our enclosed lands, by always occupying the most elevated portions of the field, clearly indicates that its natural instinct in this respect is still unchanged by all the efforts of the breeder. Follow, then, the sheep from his upland pastures, in the clear, dry, warm climate of Asia, and view him placed in our cold temperature, in a warm shed it is true, but with the floor of that shed covered for a depth of many inches with a mass of putrefying dung, and then let us ask ourselves, “Is this the way fairly to test the advantages of shelter and of warmth to the domestic sheep? Is this the way to fairly try the economy of raising the temperature of the atmosphere in which it is placed?” The Rev. A. Huxtable saw this in its true light, when he commenced his trials. He tells us, in his valua-

ble little paper *Jour. R. A. S.* vol. vi. p. 242.) "Having observed that sheep in wet weather on our downs always select the most beaten roads for their bed, it occurred to me that not only when under sheds should they lie on boards, according to your own experiment, but also that the courts to which they have daily access whilst their houses are being cleaned should be covered, not with soft litter, but with hard chalk or sand, or other materials to form a solid bottom. My little yards attached to the sheds are floored with a sort of asphalte made of chalk beaten small, covered with gas-tar and sand. In constructing sheds for my sheep I have kept in view the strictest economy; and I venture to send these minute details, which I hope will serve to prove that the protection of sheep from the inclemency of the weather is within the reach of every tenant farmer. Each of these sheds contains about 50 sheep. They are erected on a very simple plan: a couple of fir poles, 12 feet long, are nailed together at the top; their extremities, at a distance of 15 feet, are driven into the ground; another couple, 10 feet distant, are united with this, and held firm by a ridge-pole nailed into and lying between the tops of the fir poles. Side pieces are nailed parallel to the ridge-pole, and small hazel-wood is interlaced so as to support the thatch, which a labourer ties on with tar-twine. The thatch in front and behind reaches to about 3 feet from the ground; behind, a bank of turf is raised to meet the thatch; the front is guarded by a hurdle, moveable at pleasure, to allow the sheep to go into the court, which is of the same size as the shed. It is important that both ends of the shed should be protected with bavins only, which will secure a free ventilation, yet keep out rain. My sheds, about 50 feet long (not charging the straw), cost about 41s. each.

"These sheds are floored with 1-inch boards, separated (each strip from the other) by $\frac{3}{4}$ inch intervals. The cost of the timber and mode of preparing the floor were as follows:—White pine timber was used for its cheapness, being 1s. 3d. the cube foot, which would therefore give eleven 1-inch boards. On account of the particular width of the logs which I bought, the board was sawn into pieces 7 inches broad and 1 inch thick. These, for economy, are hand-sawn into three parts, and are nailed upon joists at a distance of $\frac{3}{4}$ inch. By this plan nearly one-third of timber is saved; so that each sheep, requiring 9 feet of space, lies actually on 6 feet of 1-inch board. The cost of timber for joists, nails, and carpenters' work, raises the total expense of placing the sheep on boards to 1s. 4d. per head. Instead of sleepers I used small blocks, 6 inches thick, to keep the rafters from direct contact with the manure. The boards are put together into frames about 10 feet by 4, so that they may easily be taken up by one man. Beneath the boards the floor, excavated 8 or 9 inches, is puddled and made water-tight, and covered with 6 inches of sawdust, burnt clay, or good dry mould. This receives and absorbs the manure which falls, or is swept below twice a day. The boards, after sweeping, are watered with a solution of 3 lbs. of sulphate of iron (copperas), which instantaneously removes the odour not only of the ammonia, but of the more offensive sulphuretted hydrogen. The boards should be laid perfectly flat, to prevent the sheep slipping about. The sheep are fed under the sheds, not

in the courts. The results of this arrangement have been most successful, both in the health and *well-doing* of the sheep.

"It is true that I have lost four head, which seem to have died from apoplexy; but I lost the same number in the flock which were at large, and treated in the usual manner. Though I have had more than 300 Southdowns so sheded, some of them longer than five months, yet I have never seen any instance of lameness, even in the least degree.

"Their food consists of turnips, for the last fortnight only of swedes; half a pint per day (never more) of oats or peas; with straw cut into chaff, over which ground linseed has been poured, mixed with boiling water.

"I regret that I cannot send the important statistics of weight and improvement under this regimen. During one month the sheep were weighed, and found to have increased about 3 lbs. per week on an average; that is, ten were selected and weighed which seemed fairly to represent the flock, and they had made this improvement. The illness of my bailiff stopped these calculations; but the general issue will be allowed to be satisfactory, as more than half have been sold which in twelve weeks have paid 13s. a head.

"Leaving out of the account both the injury which in bad seasons my clay-lands would have sustained by the treading of the sheep, and the value of the rich manure saved under shelter (its gases fixed by the sulphate of iron and gypsum strewed daily over the boards), I consider that the whole expense of boards and sheds was saved in the first month."

In the stall feeding of cattle, the application of these just principles can hardly be too systematically regarded. Of this opinion, too, is Mr. George Dobito, who, in his prize "Essay on fattening Cattle," (*Jour. R. A. S.* vol. vi. p. 78), remarks, "Cleanliness, warmth, and quiet, are the great points I insist upon, of course coupled with good feeding; but many tons of oil-cake are annually wasted, because the comfort of the animals is not more attended to."

The subjects of air and food are so closely allied as to be viewed to most advantage together. That vegetable substances contain animal matters ready formed, was a suspicion which was entertained in a confused shape by more than one of even the early Greek philosophers, but it was reserved for the modern chemist to prove the truth of the supposition. This has been thus explained by Dr. Lyon Playfair (*Jour. R. A. S.* vol. iv. p. 216):—

"All vegetable food has been found to contain a peculiar substance, which, though it differs in appearance and in form, according to the source from whence it is obtained, is in reality the same body. It has received the name of gluten or albumen, and is precisely identical, in chemical composition, with the albumen obtained from the white of an egg. This substance is invariably present in all nutritious food. Chemists were surprised to discover that this body never varies in composition; that it is exactly the same in corn, beans, or from whatever plant it is extracted. But their surprise was much increased when they remarked that it is quite identical with the flesh and blood of animals. It consists, like the latter, of carbon, hydrogen, nitrogen, and oxygen, and in the very same proportion in 100 parts. By identity in composition

is not meant a mere similarity, but an absolute identity; so much so, that if you were to place in a chemist's hand some gluten obtained from wheat flour, some dry albumen procured from the white of an egg, a fragment of the flesh of an ox or of a man, or some of their dried blood, and request him to examine their difference, he would tell you, strange as it may appear, that they are precisely the same, and that with all the refinements of his science he was unable to detect any essential difference between them. There is much difference, indeed, in external appearance and in structure, but in their ultimate composition there is none." To render this more obvious, I subjoin the composition of these various substances, as obtained by different chemists, who executed their analyses without any knowledge of the results obtained by the others:—

	Gluten from Flour. Boussingault.	Casein from Pease. Scherer.	Albumen from Eggs. Jones.	Ox Blood. Playfair.	Ox Flesh. Playfair.
Carbon.....	54.2	54.138	55.000	54.35	54.12
Hydrogen....	7.5	7.156	7.073	7.50	7.89
Nitrogen....	13.9	15.672	15.920	15.76	15.67
Oxygen.....	24.4	23.034	22.007	22.39	22.32
	100.0	100.00	100.00	100.00	100.00

These analyses do not differ from each other more than the analyses of the same substance usually do. Thus we are led to the startling conclusion, that plants contain within them the flesh of animals ready formed, and that the only duty of animals subsisting upon them is to give this flesh a place and form in their organism. When an animal subsists upon flesh, we find no difficulty in explaining its nutrition; for the flesh being of the same composition as its own body, the animal, in a chemical point of view, may be said to be eating itself; nor, with a knowledge of this identity of vegetable albumen with flesh, is there any difficulty in comprehending the nutrition of vegetable feeders.

Plants, then, in reality, form the *flesh* of animals; and the latter merely appropriate it a place in their organism.

It follows, then, as a conclusion, that the analysis of any vegetable substance pretty accurately indicates its nutritious powers. "It has been shown by many laborious chemical researches," to use the words of Dr. Playfair, "that there are two kinds of food. The first, which contains nitrogen, is exactly of the same composition as the principal tissues of the human body, and is the only substance which can supply the waste of these tissues. The second kind of food is that destitute of nitrogen, such as starch, gum, and sugar, all of which are destined for the support of respiration and consequent heat of the animal. The latter kind of food, when in excess, is converted into fat, but never into muscle. The increase of flesh in an animal consists in two changes of the matter of the food, without any alteration in its composition. The albumen or nitrogenous constituent of the food is first converted into blood, without decomposition, and the blood is afterwards converted into flesh. In order to show that the transformation is actually effected without change, we have only to refer to the following results of the analysis of vegetable albumen, of ox blood, and of flesh:—

	Vegetable Albumen.	Ox Blood.	Flesh.
Carbon.....	55.160	54.35	54.12
Hydrogen.....	7.055	7.50	7.89
Nitrogen.....	15.996	15.76	15.67
Oxygen.....	21.18	22.39	22.32

"As muscle then is formed only by the albumen or gluten of the food, which albumen is in reality flesh itself, we can ascertain the comparative value of food, as far as the production of muscle is concerned, by estimating the exact quantity of the nitrogenous constituent of the food. The following table," continues Dr. Playfair, "contains the approximative, though not perfectly accurate, information relative to the value of food for the support of respiration and production of fat:—

100 lbs.	Albumen. lbs.	Unazotized Matter. lbs.	100 lbs.	Albumen. lbs.	Unazotized Matter. lbs.
Flesh . . .	25	0	Oats . . .	11	68
Blood . . .	20	0	Barleymeal	14	68½
Beans . . .	31	51½	Hay . . .	8	68½
Peas . . .	29	51½	Turnips . .	1	9
Lentils . .	33	48	Carrot . . .	2	10
Potatoes .	2	25	Red-beet . .	1½	8½

That *fat* exists ready formed in various vegetable substances, has been proved by careful chemical examination. Thus, according to Liebig, hay contains 1.56 per cent., and maize 4.67 per cent. of fat. Braconnot found 1.20 per cent. in peas, while Fresenius got 2.1 per cent.; and in lentils 1.3 per cent. Vogel obtained 2.00 per cent. of fat in oats; Liebig 0.3 per cent. in dry potatoes; and Braconnot 0.13 per cent. in rice, although, in another variety, Vogel states that he detected 1.05 per cent. The substance here called fat is in reality a waxy or resinous body, and not tallow, except in a few instances.

[FOOD.] An animal requires, to sustain its body in good condition, supply heat, and make up for daily waste, about 1-60th part of its own weight. If the object be to increase the size, enable it to work, or give milk, a still larger proportion of food must be given. Thus, to feed for milk twice the quantity of food named will be required. If muscle for labour be needed, food containing gluten must be given, and as peas and beans contain gluten in the largest quantity, they constitute exceedingly valuable food for working horses. Wheat contains 35 to 40 per cent. of the gluten out of which muscle is formed. Cabbage is rich in gluten, and the flower of the cauliflower contains more gluten than any other garden vegetable we raise for food. When fat is required, or a good coat, give substances containing oil, such as Indian corn, oats, linseed-cake, as well as rape-cake and poppy-seed cake. Farmers generally prefer those substances which unite the muscle and fat-giving qualities. The milkman desirous of quantity and little regarding quality, gives his cattle grains from the brewery—and various kinds of watery slops. But where the dairyman wants butter or cheese, then quality is to be considered. In order to make butter, the milk must be rich, and he has it in his power to add largely to the ordinary produce of the dairy, by the selection of food rich in oil. In England oil-cake is given, but not much at a time, as it gives an undesirable taste to the butter. A skilful dairyman can, however, often manage, by giving a large quantity of oil-cake, to get a far better quality of milk than by giving any other kind of food. If the object be to make cheese, food is given rich in the material to produce curd—which is precisely that furnishing the flesh or muscle, already referred to. To feed with cabbage would produce a poor cheese, which contains little fat, but a large proportion of the curd or muscle-forming material. Where milk to make butter or rich cheese is

required, more fatty food must be furnished; and of all substances for effecting this object, linseed-cake, and maize are perhaps the best.

It is of great importance to attend to the state in which food is introduced into the stomach of animals. Indian corn, for example, given without mixing with other food, will not be so readily digested. The proper preparation of food for animals is a branch of agricultural knowledge which has been found highly profitable to the farmer. By mixing different kinds of food, the requirements of the animal are best met. Cut straw or chaff is an admirable substance with which to mix other more nutritious materials, rendering these more readily digested and nourishing, besides making the food go further. Malt is often employed with great advantage, mixed with other food. Other influences, such as warmth, shelter, ventilation, and quiet, exert a great effect in promoting the thrift and welfare of animals.

The amount of nutriment found in different varieties of the food consumed by the farmer's live stock, has been referred to under the head Food, where some interesting facts will be found, chiefly derived from the researches of Davy. It is a subject to which still more recent investigations have given additional interest. The proportions in which the several elementary substances exist in 100 parts of some of the most commonly cultivated grains and products of the farm, are represented in the following table from Prof. J. F. W. Johnston's Lectures.

	Water.	Husks or woody fibre.	Starch, gum and sugar.	Gluten, albumen, &c.	Fatty matter.	Saline matter.
Wheat . . .	15	15	55	10to19	2to4	2
Barley . . .	15	15	60	12to15	2to3	3
Oats . . .	16	20	60	14to19	5to7	4
Rye . . .	12	10to20	60	10to15	3to4	2
Indian corn .	14	6	70	12	5to9	1½
Buckwheat .	15	25	50	8	0·4	4
Rice . . .	13	3	75	7	0·7	0½
Beans . . .	14	8-11	40	24-28	2·3	3
Peas . . .	14	9	50	24	2·1	3
Potatoes . .	75	4	18	2	0·3	1
Turnips . .	88	2	9	1·5	0·3	½to4-5
Carrots . .	85	3	10	1·5	0·4	1½to2
Mangel-Wurzel . . .	85	2	11	2·0	?	½to1½
Meadow hay .	14	30	40	7·1	2to5	5to10
Clover hay .	14	25	40	9·3	3to5	9
Pea straw .	10to15	25	45	12·3	1·5	4to6
Oat straw .	12	45	35	1·3	0·8?	6
Wheat straw .	12to15	50	30	1·3	2to3½	5
Barley straw .	12to15	50	30	1·3	?	5
Rye straw .	12to15	45	38	1·3	?	4
Indian corn stalks . .	12	25	52	3·0	1·7	3to7

Some of the numbers in the above table are given as mere approximations, especially those referring to buckwheat and fatty matter, which last is very uncertain.

It hence appears that water enters into the composition of every vegetable product, wheat containing 15 per cent., the turnip 88 to 90 per cent., exhibiting the strong contrast between grains and roots. The second column represents woody fibre, straw and husks, parts of plants which animals cannot digest, and from which they consequently derive no nourishment. In wheat and other grains, the proportion of this varies from 10 to 20 per cent. In the column designating the proportions of starch, gum, and sugar, the grain of wheat exhibits about 55 per cent., Indian corn 70 per cent., Indian corn stalks 52 per cent., rice 75 per cent., &c. All grains

likewise contain a substance called gluten, but in quantities varying very much, as may be seen by running the eye down the 4th column of the table; the greatest proportion of this and albumen being found in beans, which explains their highly nutritious qualities. Even pea-straw is very rich in these materials, which makes them valuable provender, where other kinds of straw are almost worthless. Of oil or fatty matter, wheat and barley have very little, whilst in oats and Indian corn, oil abounds. The root crops and straws have very little. Plants take in, through their leaves and roots, the carbonic acid and other materials, the changes in which produce the starch, gluten, and fat to be found in them all, and which go to nourish animals.

It forms, says Mr. Karkeek, in his "Essay on Fat and Muscle" (*Jour. R. A. S.* vol. v. p. 249), a curious and interesting subject for the feeder to ascertain the respective quantities of the fleshing and fattening properties contained in an acre of the different crops commonly used in the rearing and feeding of stock. The following *acreable table of nutrition* has been constructed chiefly from Professor Johnston's calculations; the proportions of gluten, &c., from Boussingault's analysis, which indicate the *fleshing properties*; and the proportions of starch, gum, and sugar, the *fattening properties* :—

One Acre of	Produce per Acre.	Weight of Grain per Bushel.	Wt. of Gluten, Albumen, & Caseine.	Wt. of Starch, Gum, Sugar, and Fat.	Weight of Water per Acre.
Field beans .	25 bush.	64	450	672	256
Peas . . .	25 "	66	380	845	208
Oats . . .	50 "	42	290	1,168	336
Hay . . .	3 tons	..	480	2,790	752
Potatoes . .	12 "	..	600	3,330	20,250
Carrots . .	25 "	..	1,120	5,800	47,600
Turnips . .	30 "	..	800	6,700	56,950
Wheat straw	3,000 lbs.	..	40	940	450
Oat straw .	2,700 "	..	36	970	324
Barley straw	2,100 "	..	28	646	252

Another table showing the nutritive properties per acre of the ordinary crops of the farmer has been given by Mr. Hyett, and will be found at the head of the next page.

The tables just given from analyses made by Prof. J. F. W. Johnston, and other eminent chemists, show the proportions of water, with those of the several dry organic constituents, as well as the ashes or saline matters contained in many of the articles of food with which the farmer is most familiar. From these it may be seen that it is very important for the economical management of live-stock to know the amount of water as well as of the organic and nutritive ingredients which each kind of food contains. Thus we find that in giving a pig 100 lbs. of potatoes, we actually give it about 75 lbs. of water. But in giving it 100 lbs. of Indian corn, we contribute only about 14 lbs. of water, nearly all the remaining 86 lbs. being nutritious matter. As already observed, the table just given from Professor J. F. W. Johnston shows the proportion of woody fibre freed from the nutritious substances, well known to be contained in greater or less proportion in husks, straw, &c. This woody fibre, as it cannot be digested by animals, must therefore be deducted from the amount of nourishment. It constitutes half the amount of wheat and rye straw, whilst it makes but 30 per cent. of ordinary meadow grass hay, and only 23 per cent. of clover hay.

	Assumed Average per Acre.	Taken at	Average per acre in lbs.	Equivalents of Nourishment.	Relative Nourishment per Acre.
Wheat	32 bush.	60 lbs. per bushel =	1,920	÷ 41	46.8
“ straw	30 cwt.	“ “ =	3,360	÷ 450	7.46
Peas	20 bush.	“ “ =	1,200	÷ 45	26.6
“ straw	“	“ “ =	“	÷ 125	“
Barley	40 bush.	48 “ “ =	1,920	÷ 54.5	35.2
“ straw	20 cwt.	“ “ =	2,240	÷ 300	7.4
Oats	50 bush.	40 “ “ =	2,000	÷ 55	36.3
“ straw	40 cwt.	“ “ =	4,480	÷ 300	14.9
Beans	32 bush.	60 “ “ =	1,920	÷ 61.5	31.2
“ straw	40 cwt.	“ “ =	4,480	÷ 450	9.97
Clover hay	30 cwt.	“ “ =	3,360	÷ 90	37.3
Ordinary hay	20 cwt.	“ “ =	2,240	÷ 100	22.4
Potatoes	100 bags	280 lbs. per bag =	28,000	÷ 200	140
Cabbage	20 tons	“ “ =	44,800	÷ 250	179.2
Carrots	25 tons	“ “ =	55,000	÷ 275	200
Beet	25 tons	“ “ =	55,000	÷ 397	138.5
Green clover	6 tons	“ “ =	13,440	÷ 475	28.29
Turnips	25 tons	“ “ =	55,000	÷ 500	110

And in the same economical point of view, it becomes an important question to ascertain, provided the result of modern experiments relating to the formation of flesh and the generation of heat is correct, and calculating from the data which they furnish, the relative value of each description of food. This has been attempted by Dr. Playfair, with a result which he thus describes (*Jour R. A. S.* vol. vi. p. 560: “ All food then has two distinct purposes, the formation of flesh, and the sustenance of animal heat. The substances in vegetables destined for the formation of flesh are perfectly identical with it in composition, and are known by the names of gluten, albumen, fibrin, or casein; those which are suited for the support of animal heat are not at all similarly composed to flesh, and consist of starch, gum, sugar, &c. Knowing these facts, it becomes a money question as to the value of particular kinds of food for the support of the frame. We know how much of flesh-giving principle each variety of food contains, and therefore we can at once estimate how much of each it will be necessary to consume to obtain one pound of real nutriment, and what the cost of that pound will be to the consumer. The following table is constructed on this principle, but as prices vary in different localities, these may be altered to suit the peculiar case: in the table, they are given at the rate at which the respective substances might be purchased in London under favourable circumstances.

Quantity of Food necessary to produce 1 lb. of flesh, and the Money-Cost of its production.

25 lbs. of milk furnish 1 lb. of flesh, £. s. d.

and cost	0	3	1
100 “ turnips	0	2	9
50 “ potatoes	0	2	0
50 “ carrots	0	2	1
4 “ butcher’s meat, free from fat and bone, furnish 1 lb. of flesh, and cost,	0	2	0
9 “ oatmeal	0	1	10
7 ¹ / ₀ “ barleymeal	0	1	2
7 ⁴ / ₀ “ bread	0	1	2
7 ⁴ / ₀ “ flour	0	1	2
3 ¹ / ₂ “ peas	0	0	7
3 ² / ₁₀ “ beans	0	0	6 ¹ / ₂

Let us look at the various kinds of food with reference to their value as fuel, and we shall

perceive the potato takes its proper rank. 1 lb. of carbonaceous fuel to sustain animal heat would be furnished by different weights of the following articles at the English prices named: 4 lbs. of potatoes, 2 ¹/₂d.; 10 lbs. carrots, 2d.; 1 ¹/₂ lb. flour, 2 8-10d.; 1 ¹/₂ lb. barleymeal, 2d.; 11 1-10 lb. turnips, 2d.; 1 ¹/₂ lb. oatmeal, 3 ³/₄d.; 1 9-10 lb. beans, 3 ³/₄d.; 1 9-10 lb. peas, 3 8-10d.; 2 lb. bread, 4d.; 11 9-10 lb. milk, 1s. 5d. These estimates must, however, be considered as rough approximations.

It will not be unattended with benefit if we contrast these valuable scientific researches upon the cost of production with the results of the trials of a practical Scotch farmer.

From some careful experiments of Mr. Bruce, of Waughton, in East Lothian (*Trans. High. Soc.* 1846, p. 375), with linseed cake and other substances in sheep feeding, he concludes that “ mutton can be produced at a lower rate per lb. upon liberal use of foreign keep along with turnips, than upon turnips alone, taking of course the increased value of the manure into account;” that of this foreign keep “ linseed is the most valuable, and beans the least so; but that the mixture of both forms a useful and nutritious article of food. In his trials 95 Cheviot ewes were divided into five lots, and enclosed, and fed with turnip tops and the following substances, upon portions of equally sheltered grass land. Lot A consisted of 15 ewes, B, C, D, and E, of 20 each.

Lot.	Weight.		Average Consumption of each Sheep per Week.	Cost of Production per lb.
	Oct. 21. lbs.	Dec. 23. lbs.		
A	1839	2008	56 ¹ / ₂ Linseed. 4 ¹ / ₂ Beans.	46 ¹ / ₂ Linseed.
B	2401	2603	113 ¹ / ₂ Lins’d cake.	101 Lins’d cake.
C	2382	..	95 ¹ / ₂ Beans and Linseed.	59 Beans and Linseed.
D	..	2657	157 ¹ / ₂ Poppy cake.	106 Poppy cake.
E	2104	2557	113 ¹ / ₂ Beans.	133 ¹ / ₂ Beans.
	2417	2736	100 Beans and Linseed.	56 ¹ / ₂ Beans and Linseed.

See ORGANIC CHEMISTRY, FOOD, GELATIN, VEGETABLE CHEMISTRY, and other heads relating to these subjects.

VERBENA. See VERVAIN.
 VERJUICE. An acid liquor, prepared from the twigs of the vine, or from grapes or apples that are unfit to be converted into wine or cider. It is also made from the wild crab apples.

VERMIN. A general name for all birds, animals, insects, &c., which prey upon or prove injurious to the cultivator's crops, and to his live-stock.

The insects, &c., comprise the most extensive and fearful class of depredators. Among these are the aphides, caterpillars, ants, beetles, and their grubs, wire-worms, slugs, earth-worms, &c.

VERNAL GRASS. See **ANTHOXANTHUM.**

VERSATILE. In botany, signifies swinging lightly on the stalk, so as to be continually changing direction. It is illustrated in the leaves of the aspen.

VERTICILLATE. Disposed in a whorl.

VERVAIN (*Verbena*; said to be derived from its Celtic name *Ferfaen*). This is a genus of extremely beautiful ornamental plants while in flower, either when grown in pots in the green-house or when planted out in the flower garden; and they will all succeed well in the open ground during the summer months. The flowers of *V. teucrioides* have a delightful jasminelike odour. They all flourish well in a light loamy soil, with careful drainage when kept in pots. The herbaceous perennial kinds increase rapidly by cuttings, planted in sand under a glass; the green-house kinds in a little heat. The annuals and biennials should be raised on a gentle hot-bed.

One species is indigenous to England, the common vervain (*V. officinalis*), a perennial which grows by road-sides and in dry waste grounds, or pastures about villages. The root is woody, somewhat creeping. Stem ascending, 1½ foot high, leafy, roughish, with minute prickles or bristles. Leaves deeply cut. Spikes slender, several composing a sort of panicle of small, bluish, inodorous flowers. This species has scarcely any aromatic or other sensible quality. The root worn about the neck with a string is an old superstitious remedy or charm for the king's evil.

A great many species of vervain or verbenas are found in various parts of the United States. Nuttall enumerates 10 in this country, and altogether 20 American species in the two hemispheres.

VESICLES. In botany, inflated, hollow excrescences, like bladders or blisters.

VETCH (*Vicia*, from *vincio*, to bind together, because the species have tendrils by which they encircle other plants). Some of the species of this genus are well worth cultivating in the flower-border for the beauty of their flowers. They are of the easiest culture in any common garden soil. The perennial kinds may be readily increased by dividing the root or by seeds. The seeds of the annual kinds only require to be sown in the open border in spring. *V. sativa* and its varieties are extensively cultivated, and well known by the common name of vetch or tares; they are used in England as early fodder for all kinds of cattle, and are allowed to be more nutritive and profitable than hay or any other herbage. The seeds also form the food of pigeons. There are in Britain 10 indigenous species of vetch, the principal of which are the tufted vetch, wood vetch, common vetch, and bush vetch. Of all the different vetches (says Sinclair) that were submitted to experiment

the winter tare or common vetch (*V. sativa*, var.) afforded the most nutritive matter: 64 drachms of the herbage, cut at the time of flowering, afforded 4 drachms 4 grains of nutritive matter; while spring tares only yielded 3 drachms 3 grains, which confirms the justice of that preference which practice has given to the former.

1. The tufted vetch (*V. cracca*), is a perennial, very common in England in a wild state in hedges, thickets, osier grounds, and bushy, low meadows. The stems are 2 or 3 feet high, furrowed, rather downy, climbing by means of their long, many-branched tendrils, by which they choke and overtop other herbs. Flowers numerous, in dense clusters, beautifully variegated with tints of bright violet-blue, and some purple. Legume scarcely an inch long, smooth, with 4 or 5 dark, globular seeds, the size of a lentil. This vetch is said to be nutritious food for cattle, but it has not come into use, probably from the difficulty of gathering, or of cultivating, so pertinacious a climber. Dr. Plot, in his *History of Staffordshire*, says that this and the *Vicia sylvatica* advance starved or weak cattle above any thing yet known; and Dr. Anderson, in his *Essays*, speaks highly of this plant. It is inferior to the wood vetch, or common tare (*V. sylvatica*), in the quantity of nutritive matter it affords, but contains much less superfluous moisture. This must give it a superiority, in regard to nutrient properties, over tares which contain an excess. But it has a strong, creeping root, that will always prevent its admission to arable lands. It might be best cultivated on tenacious soils, and used after the manner of lucern, to which it is much superior in nutritive qualities, though greatly deficient in the weight of crop. Forty-three grains of nutritive matter consisted of—

	Grains.
Saccharine matter, or sugar - - -	20
Mucilage - - - - -	12
Insoluble and saline matter - - -	11

The tufted vetch flowers about the middle of July or the beginning of August, and the seed is ripe at the beginning of September.

2. The wood vetch (*V. sylvatica*) grows in woods and hedges, chiefly in the more mountainous parts of Britain, and is one of our most elegant wild plants, well worthy to decorate shrubberies, or to be trained over a trellis or bower. The habits of this vetch are similar to those of the species last described, but it seems more impatient of exposure, and thrives best where it has the support of bushes. The root is creeping, perennial; herbage smooth. Stems numerous, much branched, climbing to the height of 6 or 7 feet, and spreading widely, decorating the bushes which support them with a profusion of delicate flowers, elegantly variegated with blue and white, streaked with gray. Legume the size of the last, bright brown, minutely dotted. When transplanted to open situations, the produce is inconsiderable compared with that of the tufted vetch or the bush vetch, though in its natural place of growth the produce is six times that of either of these species; it is likewise superior in the quantity of nutritive matter it affords. Horses, cows, sheep, and the South American llamas, ate this vetch

with more eagerness than they did the other vetches or natural grasses that were on several trials offered to them. The wood vetch flowers in July and August, and the seed is ripe in September.

3. The common vetch or tare (*V. sativa*, Pl. 7, r) is an annual plant, which is in general cultivation, and therefore too well known to need description; 3000 grains of the green herbage of the common vetch consist of—

	Grains.
Woody or indigestible substance - - -	557
Water - - - - -	2250
Nutritive matter - - - - -	193

Hence 1,135 grains of the woody fibre of tares are combined with 27½ grains of saline matter.

In England vetches are very commonly sown upon a wheat stubble, and no crop better repays the addition of any organic fertilizers.

The bush vetch (*V. sepium*) has been already noticed. See BUSH VETCH.

The other British species of vetch or tare are the narrow-leaved crimson vetch (*V. angustifolia*), spring vetch (*V. lathyroides*), rough-podded yellow vetch (*V. lutea*), hairy-flowered yellow vetch (*V. hybrida*), smooth-podded sea-vetch (*V. lavigata*), and rough-podded purple vetch (*V. bithyrca*). These call for no detailed description. A few species of the vetch family are found in the United States and Territories. The species called tufted vetch (*V. cracca*), is common on the borders of woods and meadows, and troublesome in some gardens in the southern parts of Pennsylvania and other Middle States. Mr. Nuttall says it is smaller than the European plant described under the same name, but Dr. Darlington does not feel satisfied of its being a native of the United States.

The species enumerated by Mr. Nuttall are, 1. *V. pusilla*. 2. *Sativa*. 3. *Americana*. 4. *Sylvatica*, inhabiting the alluvial banks of the Missouri as far north as Fort Mandan. Leaflets a little more obtuse than usual. 5. *Cracca*. 6. *Caroliniana*. See TARE and VETCHLING.

VETCH, THE BITTER (*Orobus*, from *oro*, to excite, and *bous*, an ox; the *orobos* of Theophrastus was the name of a plant used for fattening oxen). The plants of this genus deserve to have a place in every flower-border, on account of their very elegant papilionaceous blossoms. Any soil suits them, and they are readily increased by dividing the plants at the roots in spring, or raised by seeds. There are in England two native species, both perennials.

1. The common bitter vetch, or heath pea (*O. tuberosus*), grows in elevated or mountainous pastures, thickets, and woods. The root is creeping, externally blackish, swelling here and there into oblong knobs. Herbage smooth, darkish green. Stems simple, erect, a foot high, compressed and winged. Leaves alternate. Flowers in loose, long-stalked, axillary clusters, elegantly variegated and veined, with purple, crimson, and shades of blue and flesh colour. Legumes pendulous, long, cylindrical, black when ripe. The roots have a sweetish taste, and afford some luxuries and refreshments to the hardy independent Highlander. There is considerable elegance in the flowers, and in the plant altogether.

2. Wood bitter vetch (*O. sylvaticus*). In this

species the root is woody and tough, deeply fixed in the ground. The stems are numerous, spreading or recumbent, 1 to 2 feet long, hairy, more or less branched. Clusters of numerous flowers, which have a hairy calyx, are cream coloured, streaked, and tipped with purple. The legumes are ovate-oblong, smooth, compressed, and shorter than usual in the genus.

VETCH, KIDNEY. See KIDNEY-VETCH.

VETCH, MILK. See MILK-VETCH.

VETCHLING (*Lathyrus*.) A numerous herbaceous genus of annual or perennial plants. The flowers are stalked, axillary, either solitary, in pairs, or in clusters; either crimson, purplish, blue, or yellow. The herbage commonly affords good fodder; the seeds are scarcely used for any purpose. There are seven indigenous species of vetchling, or everlasting pea; the yellow vetchling (*L. aphaca*), the crimson vetchling or grass-vetch (*L. nissolia*), the rough-podded vetchling (*L. hirsutus*), the yellow meadow vetchling, or tare everlasting (*L. pratensis*), narrow-leaved everlasting pea (*L. sylvestris*), broad-leaved everlasting pea (*L. latifolius*), and the blue marsh vetchling (*L. palustris*): most of these species have been already noticed under the heads EVERLASTING PEA and LATHYRUS. The *latifolius* is that species usually cultivated in gardens on account of the beauty of the flowers. It has been recommended for field cultivation, but the advice has not been followed. Bees procure much honey from the flowers.

VETERINARY COLLEGE. The Highland Society of Scotland have instituted a veterinary school in connection with their establishment, which is under the management of Professor Dick. By diffusing generally a practical knowledge of veterinary medicine, it cannot fail to be attended with the happiest consequences to the community at large. A veterinary college has long been established in London; and that useful periodical, the *Veterinarian*, edited by Professor Youatt, has added much valuable information to our stock of knowledge on the diseases of animals. See FARRIERY and HIPPO-PATHOLOGY.

The London Veterinary College was first established in the year 1792, at St. Pancras. Mr. Boardman, in his *Dictionary of the Veterinary Art*, remarks, that "the public are indebted for this national foundation to the exertions of the Agricultural Society of Odiham, in Hampshire. The first professor was M. St. Bel, a Frenchman, who had previously signalized himself in this country as a veterinary anatomist, by dissecting the famous race-horse Eclipse. This college is supported by public subscription. The annual contribution is 2 guineas, but payment of 20 guineas at once constitutes a subscriber for life.

"The views and objects of the college appear in the following statement, printed by the authority of the governors. The grand object, they observe, is the improvement of veterinary knowledge, in order to remedy the ignorance and incompetency of farriers, so long universally complained of. For this end, a range of stables, a forge, a theatre for dissections and lectures, with other buildings, have been erected: a gentleman of superior abilities has

been appointed professor, with other requisite officers.

“The anatomical structure of quadrupeds, as horses, cattle, sheep, dogs, &c., the diseases to which they are subject, and the remedies proper to be applied, are investigated and regularly taught; by which means enlightened practitioners of liberal education, whose whole study has been devoted to the veterinary art in all its branches, may be gradually dispersed over the kingdom, in whose skill and experience confidence may be securely placed.

“Subscribers have the privilege of sending their diseased animals to the college, without further expense than that of their daily food, and these in general form a sufficient number of patients for the practice of the professor and pupils. On fixed days, the professor prescribes for animals belonging to subscribers who find it inconvenient to spare them from home, provided the necessary medicines be furnished and compounded at the college; subscribers' horses are also there shod at the ordinary prices.”

VILLOUS. A term in botany, signifying covered with soft, close, long, loose hairs, resembling shag.

VINE (*Vitis*, from the Celtic *gwid*, signifying the best of trees. Wine is derived from the Celtic word *gwin*). A valuable genus of plants. The common grape vine (*V. vinifera*), with its very numerous garden varieties, is in general cultivation for its much-esteemed fruit. None of the other species are worth cultivating. The acids of grapes are chiefly the tartaric and acetic; but malic acid is also present in them. Mr. Loudon, in his *Encyclopædia of Gardening*, thus botanically describes the vine:—“The grape vine is a trailing, deciduous, hardy shrub, with a twisted irregular stem, and long flexible branches, decumbent, like those of the bramble; or supporting themselves, when near other trees, by means of tendrils, like the pea. The leaves are large, lobed, entire, or serrated and downy, or smooth; green in summer, but when mature, those varieties in which the predominating colour is red constantly change to, or are tinged with, some shade of that colour; and those of white, green, or yellow grapes as constantly change to a yellow, and are never in the least tinged with purple, red, or scarlet. The breadth of the leaves varies from 5 to 7 or 10 inches, and the length of the footstalks from 4 to 8 inches. The flowers are produced on the shoots of the same year, which shoots generally proceed from those of the year preceding; they are in the form of a raceme, of a greenish-white colour, appearing in the open air in England in June; and the fruit, which is of the berry kind, attains such maturity as the season and situation admit by the middle or end of September. The berry or grape is generally globular, but often ovate, oval, oblong, or finger-shaped; the colours are green, white, red, yellow, amber, or black, or a variegation of two or more of these colours. The skin is smooth; the pulp and juice of a dulcet, poignant, elevated, generous flavour. Every berry ought to enclose five small heart or pear-shaped stones; but as they are partially abortive, they have seldom more than

three; and some varieties, as they attain a certain age, as the Ascalon or Sultana raisin, have none. The weight of a berry depends not only on its size, but on the thickness of its skin, and texture of the flesh, the lightest being the thin-skinned and juicy sorts, as the sweet-water or Muscadine.”

Although we presume the excellent treatise of Mr. Clement Hoare on the *Culture of the Vine* is in the hands of most of our readers, yet, as there is no other standard work of reference on this subject, we must necessarily draw upon this for our extracts.

Of all the productions of the vegetable world (observes this experienced cultivator) which the skill and ingenuity of man have rendered conducive to his comfort and to the enlargement of the sphere of his enjoyments, and the increase of his pleasurable gratifications, the vine stands forward as the most pre-eminently conspicuous. Its quickness of growth, the great age to which it will live,—so great, indeed, as to be unknown; its almost total exemption from all those adverse contingencies which blight and diminish the produce of other fruit-bearing trees; its astonishing vegetative power; its wonderful fertility, and its delicious fruit, applicable to so many purposes, and agreeable to all palates, in all its varied shapes,—combine to mark it out as one of the greatest blessings bestowed by Providence to promote the comfort and enjoyments of the human race.

From the remotest records of antiquity, the vine has been celebrated in all ages as the type of plenty and the symbol of happiness. The pages of Scripture abound with allusions to the fertility of the vine as emblematic of prosperity; and it is emphatically declared, in describing the peaceful and flourishing state of the kingdom of Israel during the reign of Solomon, that “Judah and Israel dwelt safely, every man under his vine and under his fig tree, from Dan even to Beersheba.” The source of enjoyment thus mentioned to record the happy state of the Jewish nation may be, with reference to the vine, literally possessed by the greater portion of the inhabitants of Great Britain.

The native country of the vine is generally considered to be Persia. The finest grapes in the world are those of Shiraz and of Casvin. The latter city, says M. Morier, is environed by vineyards and orchards, and the former yield a grape which is celebrated throughout Persia. It is along the line of mountains that stretch from the Persian Gulf to the Caspian Sea, that the best vine districts are situated; but the grape vine has been found wild in America, and has now become naturalized in all the temperate regions of the world. In the northern hemisphere it forms an important branch of rural economy, from the 21st to the 51st parallel of latitude; and by an improved method of culture very fine grapes may be annually grown on the surface of walls, in the open air, as far north as the 54th parallel, and even beyond that in favourable seasons. The vine is supposed to have been introduced into Britain at the commencement of the Christian era. It certainly did not exist before the

man invasion, as neither Cesar, Pliny, nor Tacitus notice it in the description of Great Britain. Bede informs us, that in the commencement of the eighth century the cultivation of the vine had made some progress in Great Britain: vines are mentioned in the laws of Alfred. History, indeed, amply proves, that for a long series of ages vineyards were common in the southern parts of England, and that the quantity of wine produced from them was so great as to be considered one of the staple products of the land. Lambarde (*Topographical Dictionary of England*) informs us, that at Halling, near Rochester, the bishop's vineyard yielded such excellent wine, that a present of it was sent to Edward II. when he was at Bakingfield. There was a royal vineyard at Rockingham, in the fifth year of King Stephen; and William of Malmsbury, speaking of the vale of Gloucester, says, "this district, too, exhibits a greater number of vineyards than any other county in England, yielding abundant crops, and of superior quality." The same author also says, that in the isle of Ely the soil is "covered with vines, which either trail along the ground or are trained on high, and supported on poles." In the time of Richard II., also, the vine grew so plentifully in Windsor Little Park, that part of the wine made there was sold for the king's profit. From some cause or other, however, the cultivation of the vine has fallen into general neglect, although good grapes might be grown on vines trained as espaliers, or in the same manner as in the vineyards abroad, from which excellent wine could be made, at a cost that would not exceed that of moderately strong beer. Why vineyards should have so completely disappeared, it is difficult to say, since there are many thousands of acres of poor land that are of little value in an agricultural point of view, but on which vines would flourish, and produce abundant crops of grapes, and yield thereby a most profitable return.

Fruit-bearing Powers of the Vine.—From a long course of experiments, Mr. Hoare has computed the following scale of the greatest quantity of grapes which any vine can perfectly mature, in proportion to the circumference of its stem measured just above the ground.

Circum.	lb.	Circum.	lb.
3 inches	5	7 inches	45
3½	10	7½	50
4	15	8	55
4½	20	8½	60
5	25	9	65
5½	30	9½	70
6	35	10	75
6½	40		

No vine should be suffered to ripen fruit until its stem measures 3 inches in girth. In general, vines are allowed to bear a much greater quantity of grapes than the above scale represents, but in all such cases it will be found that they are not perfectly ripened; and moreover, by producing a superabundance of fruit, the plants are crippled for many years.

Aspect.—The warmer the aspect, the greater perfection does the grape attain in the climate of England, provided all other circumstances are alike; and if the greatest quantity of the sun's rays shining on the surface of a wall

were alone to be considered as constituting the best aspect, there would, of course, be no difficulty in naming a due southern one as better than any other. But *warmth* alone is not sufficient; *shelter* from the withering influence of the wind is equally necessary. The best aspects are those that range from the eastern to the southeastern, both inclusive. The next best are those from southeast to south.

Soil.—The natural soil which is most congenial to the growth of the vine, and to the perfection of its fruit in this country, is a light, porous, rich, sandy loam, not more than 18 inches in depth, on a dry bottom of gravel, stones, or rocks. A strong argillaceous soil is injurious to the vine: it checks the expansion of the roots, and retains too much moisture. In calcareous soils the vine always flourishes, especially if the bottom be stony or gravelly. No subsoil can possess too great a quantity of these materials for the roots of the vine, which run with eagerness into all the clefts, crevices, and openings in which such subsoils abound. In these dry and warm situations, the fibrous extremities, pushing themselves with the greatest avidity, and continually branching out in every possible direction, lie secure from that excess of moisture which frequently accumulates in more compact soils; and, clinging like ivy round the porous surfaces of their retreats, extract therefrom a species of food, more nourishing than that obtained by them under any other circumstances whatever. All borders, therefore, made expressly for the reception of vines, ought to be composed of a sufficient quantity of dry materials, such as stones and brickbats, broken moderately small, lumps of old mortar, broken pottery, oyster shells, &c., to enable the roots to extend themselves freely in their search after food and nourishment; to keep them dry and warm by the free admission of air and solar heat, and to admit of heavy rains passing quickly through, without being retained sufficiently long to saturate the roots and thereby injure their tender extremities. The sweepings obtained from a turnpike road, or from any other high road kept in a good state of repair by the frequent addition of stones, and on which there is a considerable traffic of horses or other cattle, is the very best compost that can be added to any border intended for the reception of vines. Its component parts, consisting chiefly of sand, gravel, pulverized stones, and the residuum of dung and urine, afford a greater quantity of food, and of a richer and more lasting nature, than can be found in any other description of compost that I have ever seen or heard of being used for that purpose. Borders in which vines are planted should never be cropped nor digged.

Manure.—The best species of manure for the vine are those which afford a considerable degree of nourishment, but at the same time slowly decompose in the soil. Such are bones, whole or crushed, the horns and hoofs of cattle, the entire carcasses of animals, cuttings of leather, woollen rags, feathers, and hair, and the leaves of the vines themselves. Liquid manures are also valuable, and forcing in their effect; of this class the most powerful are urine, soot-water, blood, the drainings of dung

heaps, and soap-suds. It should, however, always be recollected, that the more manure is used, the poorer the wine procured from the grapes. As a top-dressing, and to be forked into the border, night-soil, refuse fish, stable manure, and the excrements of all birds and animals, will be found highly enriching substances as fertilizers, and their nutritive and stimulating properties have been frequently alluded to in the progress of this work; but if rich manures are used, they should be mixed with turf and sand. In the Alto Douro is a law which prohibits the vine being "littered;" as this operation, though it considerably augments the produce, tends to deteriorate the quality of the wine.

On the Construction of Walls.—No general rule can be laid down as to the height of the wall, which must necessarily vary under different situations and circumstances. Mr. Hoare states, that in unsheltered situations and exposed aspects he has never seen fine grapes produced much higher than 8 feet from the ground.

But, in favourable situations, height is no consequence. If built for the express purpose of rearing grapes, low walls of not more than 6 feet are to be preferred, as more convenient for pruning and training the vines. Brick walls are undoubtedly the best, the surface being smooth and even. A considerable heat is obtained by blackening the wall.

Propagation.—Vines are propagated in the open ground by layers and by cuttings. The former is the most expeditious mode, provided the shoots be laid down in pots, and planted out the same summer. The latter mode is much the best. To provide cuttings to be planted at the proper season, select at the autumnal pruning a sufficient number of shoots of the preceding summer's growth. Choose such as are well ripened, of a medium size, and moderately short-jointed. Cut them into convenient lengths of 6 or 8 buds each, leaving at the ends not less than a couple of inches of the blank wood for the protection of the terminal buds. Stick these temporary cuttings about 9 inches in the ground, in a warm and sheltered situation, where they will be effectually protected from the severity of the winter. The best time to plant them out is about the middle of March, but any time from the 1st of that month to the 10th of April will do very well.

Pruning and training are so closely connected together, and so mutually dependent on each other, that they almost constitute one operation. The judicious pruning of a vine is one of the most important points of culture throughout the whole routine of its management. The object is to get rid of all the useless and superabundant wood, for those shoots of a vine which bear fruit one year never bear any afterwards. There are three methods of pruning vines in practice amongst gardeners; namely, the long-pruning, spur-pruning, and the fan or fruit tree method. The first is considered to be the most eligible method, and is that which is practised and recommended by Mr. Hoare. As the sole object in view in pruning a vine is to increase its fertility, the best method to accomplish this is to leave a sufficient supply of bearing shoots

on the least possible proportionate quantity of old wood.

Long-pruning appears to recommend itself by its simplicity; by the old wood of the vine being annually got rid of; by the small number of wounds inflicted in the pruning; by the clean and handsome appearance of the vine; and by the great ease with which it is managed, in consequence of its occupying but a small portion of the surface of the wall.

Mr. Hoare lays down the following practical general rules for the guidance of the pruner:—

1st. In pruning, always cut upwards, and in a sloping direction.

2d. Always leave an inch of blank wood beyond the terminal bud, and let the cut be on the opposite side of the bud.

3d. Prune so as to leave as few wounds as possible, and let the surface of every cut be perfectly smooth.

4th. In cutting out an old branch, prune it even with the parent limb, that the wound may quickly heal.

5th. Prune so as to obtain the quantity of fruit desired on the smallest number of shoots possible.

6th. Never prune in frosty weather, nor when a frost is expected.

7th. Never prune in the months of March, April, or May. Pruning in either of these months causes bleeding, and occasions thereby a wasteful and an injurious expenditure of sap.

8th. Let the general autumnal pruning take place as soon after the 1st of October as the gathering of the fruit will permit.

Lastly, use a pruning-knife of the best description, and let it be, if possible, as sharp as a razor.

Training.—To train a vine (Mr. Hoare goes on to observe) on the surface of a wall is to regulate the position of its branches, the principal objects of which are, to protect them from the influence of the wind; to bring them into close contact with the wall, for the purpose of receiving the benefit of its warmth; to spread them at proper distances from each other, that the foliage and fruit may receive the full effect of the sun's rays, and to retard the motion of the sap, for the purpose of inducing the formation of fruit-buds. The flow of sap, it must be remembered, is always strongest in a vertical direction, and weakest in a downward one. For this reason, the method of serpentine training may be considered preferable to every other, being calculated in a greater degree to check the too rapid ascent of the sap, and to make it flow more equally into the fruiting shoots, and those intended for future bearers. On walls that are much less than 5 feet high, a portion of the shoots must be trained horizontally.

Varieties of Grapes.—The following 12 sorts of grapes are those best adapted for culture on open walls in England:—

1. Black Hamburgh. As a splendid table-fruit, this is, in every respect, one of the most valuable grapes that can be grown on open walls. It is a prolific bearer, hardy in its nature, and under judicious culture will ripen with as small a portion of direct solar heat as any grape we have.

2. **Black Prince.** This is a very fine grape, and nearly if not quite equal to the black Hamburg; both of these sorts ripen in a southeastern aspect, about the middle of October.

3. **Esperione.** The Esperione vine is very hardy, extremely prolific, and ripens its fruit perfectly in any season, however unfavourable.

4. **Black Muscadine.** This is also a prolific bearer, but it requires a good aspect to ripen it perfectly.

5. **Miller's Burgundy.** This is a very hardy and prolific grape, and ripens perfectly in any season. Its leaves, which are very thick, distinguish it from every other sort, being covered on both sides with a hoary down, which, when they are young, is nearly white; hence it is called the "miller's" grape.

6. **Claret grape.** This is a very fine wine grape. It requires a good aspect. Early in the summer its leaves change to a russet red, and die in the autumn of a deep purple blood colour.

7, 8, 9. **Black, grizzly, and white Frontignan.** The flavour of these three sorts is so extremely delicious, that no good vine wall should be without them. They ripen well in favourable aspects, and where the soil is very dry; but, being thin-skinned, and constitutionally disposed to decay after they become fully ripe, they cannot be kept long on the vine, particularly if the wall against which they are growing be destitute of a projecting coping.

10. **White Muscadine.** This is an exceedingly fine grape, and a prolific bearer; and from its hardy nature, and the certainty with which it ripens in any season, it may be considered as the best white grape that can be grown on open walls.

11. **Malmsey Muscadine.** This resembles the preceding, except that the berries are smaller, and the branches not so regularly formed; but the juice is sweeter, and possesses a higher flavour.

12. **White sweetwater.** This is a delicious grape; but, owing to its tenderness when in blossom, the berries sit very unevenly on the branches.

If it be desired to have a very early sort, to the preceding may be added the early black July; which, though the branches and berries are smaller, and the latter in general unevenly set, is a very sweet and also a well-flavoured grape. (*Hoare on the Cultivation of the Grape-Vine on open Walls*, 3d edition; *Phillips's Hist. of Fruits*, p. 177.)

The work of Mr. Hoare is so full of details that it is scarcely necessary to add any thing to the directions contained in his work; and we shall therefore confine ourselves to a statement of a few general truths in regard to the cultivation of the vine in the United States, the results of much observation and some experience.

1. The vine is a native of America, as it is of Asia, while it was an exotic in Europe. There is nothing, therefore, in the soil or climate of America uncongenial to the vine, and, in fact, there are few parts of the United States where the forests are not filled with grape-vines growing with the greatest exuberance. If,

therefore, the cultivation of the vine has made comparatively little progress, it is mainly because other fruits and other crops have offered greater attractions. But as the country has advanced, and the population is concentrated in large towns, the grape has become an object of more interest, and we think it would now reward the industry of our farmers.

2. This cultivation would have two objects, the making of wine, and the supply of grapes for the table. As to the first, we have no doubt that wine can be made of an excellent quality and at not unreasonable prices in the United States. In fact, we know that cultivators on a large scale, such as Mr. Rapp, at Harmony, Mr. Longworth, in Ohio, Mr. Geo. Sheaff, and Mr. N. Biddle, both of Pennsylvania, have succeeded in making wine—good, sound, palatable wine, which would require only the wine-dealers' arts to place it on a footing of equality with some of the best wines of Europe. But so long as the wines of France and of the old-established wine countries of Europe can be produced so cheaply, and imported with scarcely any duty, the competition of the foreign wine-makers is difficult to withstand, and it is mainly, therefore, when raised for the table that grapes will repay the labour of the farmer; and this, we think, they certainly would do. The importation of grapes and raisins into the United States will afford the best evidence of the consumption of those articles, and their cost to us.

We happen to have before us two returns of importations for different years, from which we make the following extracts.

In the year 1834 the importation stood thus—

	Quantity.	Value.
Raisins in jars -	6,897,517 lbs.	\$177,318
All other raisins -	7,423,567	306,516
	14,321,084	\$783,834

The importation of 1837 was—

	Quantity.	Value.
Raisins in boxes -	12,331,762 lbs.	\$980,201
All other raisins -	6,805,316	340,629
	19,137,099	\$1,320,830

We have not at hand any more recent statements, and therefore do not know how these importations have been sustained. But these tables show an efficient demand for grapes, fresh and dried, of no less than 1,320,000 dollars in a single year. Such an object is worth contending for. These imported grapes are generally not of the best kind, even in their own country, being selected mainly on account of their hard skins and their ability to bear the long voyage. They are gathered before they are fully ripe, and, being packed in sawdust, they retain too much of the flavour of that material. Now, if these grapes were met on their arrival by grapes grown here, and plucked from the vines within a few hours instead of a few months before they are brought on the table, the preference could not fail to be given to the native fruits.

Such fruits might be furnished from vineries covered with glass, or raised in the open fields.

For raising grapes under glass, we do not think it necessary to give any directions, since whoever proposes it will find ample instruc-

tions in the works of M'Intosh and other gardeners. Of the kinds of grapes best adapted for culture under glass we may speak with some confidence. These kinds are very numerous—great varieties of Chasselas—great varieties of Muskats—many of Frontignac. But we think that the labour and time are best rewarded by the black Hamburgh, which, for its excellence and its abundant bearing, may perhaps be placed at the head of all the grape family; by the Muscat of Alexandria, the flavour of which is of surpassing richness, though an uncertain and scanty bearer, and by one or two varieties of the Frontignac. These are at the head of their respective kinds, and none of the imported grapes can be placed in any sort of comparison with them.

The cultivation of grapes in the open air is of course cheaper and easier to farmers.

The best kind of foreign grapes, such as are above enumerated, may be successfully grown in city gardens with much shelter and care, and there are few gardens in which they would not prosper. But as yet the foreign grape has not succeeded in field cultivation, and accordingly for this purpose we must employ other varieties, which, though of inferior quality, are either natives, civilized by cultivation, or foreigners gradually acclimated. The sorts which are most considered are the Scuppernon, a vine of doubtful origin, which thrives well and bears abundantly in North Carolina, but as yet has made little progress to the north, though worthy, we believe, of more extensive experiments. Those most known to field cultivation in the Middle States are the Alexander, the Isabella, and the Catawba; and on these our markets will probably rely for some time. They may be cultivated in rows exactly like Indian corn, with the plough and the hoe-harrow; they do not require even as much trouble as a field of Indian corn, and, instead of being renewed and replanted every year, the plants will last for many generations of men. They require no covering in winter, but will stand unharmed the severest frosts and snows.

On the whole, what we think should come next in the progress of American farming is, that every farm-house should have its patch of grapes as well as of peas or beans, of the improved native grapes, and that by degrees the highest kinds of foreign grapes should be acclimated, so as to form a part of field cultivation. This we believe entirely practicable, and to this we invite the attention of farmers.

Of foreign grapes two kinds are well known in Virginia and other Southern as well as Middle States, namely, the Summer sweetwater and the White sweetwater. Highly interesting communications upon the subject of the vine culture in the United States will be found in the *American Farmer*, *Farmer's Register*, and many other valuable periodicals.

Among the various species of grape-vines found wild in the forests of the United States, the following have been described by botanists.

1. **Fox-grape** (*Vitis labruska* or *Vitis vulpina*). The berries of this luxuriant vine grow in short clusters, and are about half an inch and often more in diameter, varying at maturity from near-

ly black to dark amber or copper colour and greenish-white. The flavour is musty and strong. "All kinds of this grape," says Bartram, "possess a strong, rancid smell and taste, have a thick coriaceous skin, and a tough, jelly-like pulp or tegument which encloses the seeds. Between this nucleus and the skin is a sweet, lively juice, but a little acerb or stinging to the mouth if pressed hard in eating them. There is another property of this grape which alone is sufficient to prove it to be the *V. vulpina*, that is, the strong, rancid smell of its ripe fruit, very like the effluvia arising from the body of the fox, which gave rise to the specific name of this vine, and not, as many have imagined, from its being the favourite food of the animal for the fox (at least the American species) seldom eats grapes or other fruit if he can get animal food." "In the wild state," says Dr. Darlington, "we find varieties in the fruit, and in our gardens and vineyards we have grapes under several names, which appear to be nothing more than varieties of this—(or possibly some of them may be hybrids)—such as the *Isabella grape*, the *Schuylkill* (called also *Alexander's* and *Tasker's grape*), the *Catawba grape*, and *Bland's grape*. The two former of these are nearly black, the two latter copper or amber coloured—with less of the musky flavour than the others. The *Schuylkill* and *Catawba* varieties have been cultivated with the most success in Chester county." (*Flora Cestrica*.)

2. **Little summer grape** (*V. astivalis*), called also the Common blue grape and Bunch grape. In this most common of all American wild grapes the berries are round and small, generally about one-fourth of an inch in diameter, of a deep blue or nearly black colour, covered when ripe with a thick bloom or powder. Their flavour when mature, which is generally after the first frost, is of an agreeable sprightly acid. "This species," says Dr. Darlington, "presents several varieties; some of them with a larger fruit, which is much esteemed, and well worthy of culture. It sometimes attains to a great height in rich woodlands; the upper branches sustaining it by clinging to the limbs of tall trees, and gradually ascending, whilst the older branches below die and drop off, leaving the stem naked and suspended, somewhat resembling a topgallant halyard, belayed at the root."

3. **Chicken grape** (*V. cordifolia* and *V. labrusca* of Marsh, and *V. serotina* of Bartram), also called Winter grape and Bermudian grape. This kind has very small berries, not so large as currants. They are very late in ripening, and, when mature, are nearly black, and possessed of so much acerbity, that even birds will not eat them until they have undergone melioration from autumnal frosts. This vine is remarkable for its sweet flowers. It mounts to the top of trees, and its stems and twigs are more hard and woody than those of the preceding variety, or Summer grape.

4. **Bull or Bullet grape** (*V. taurina* of Bartram, and *V. vulpina* of Linnæus and Walter). This excellent grape is a native of the Southern States, and in the Carolinas, Georgia, and the Floridas is called the Bull grape. It is pronounced by Bartram and others a distinct variety from that which it resembles in external

appearance, called Fox grapes from Pennsylvania to Florida. The Bullet or Bull grape is described by Bartram as having "A stiff, ligneous, smooth stem, of pale ash colour, and mounts to a great height by climbing up trees. The leaves are cordated and serrated, thin, and both surfaces naked or smooth. The racemes or fruit bunches short, containing 15 or 20 grapes at a medium. The berries or *acini* are large, near the size of a rifle ball; of a black colour when ripe; having a bluish nebule over them, which being rubbed off they appear of a deep blood colour. In figure they approach to an ellipsis or prolate spheroid; however, at a little distance they appear black and round. This species is deservedly esteemed the best native grape in America, and would make a rich and delicious wine. The juice is sweet, rich, and lively, and there is but little of the tough, jelly-like substance enclosing the seed. The skin of the grape is rather thick, yet there is a sweet, melting pulp within, which mixes with the saccharine juice when eaten. This undoubtedly is the first American grape which merits attention and cultivation for wine. It thrives in every soil and situation, from the sea-coast to the mountains; it even thrives and is fruitful when growing in the barren sandhills of Carolina and Florida."

After describing these distinct varieties of grapes found in the United States, Mr. Bartram mentions several others which he considers derived from a commixture of those described, as *Alexander's* or *Tasker's* grape; *Bland's* grape; *Raccoon* grape. Other varieties, possessing still superior properties, have since been added, such as the *Isabella*, *Powell*, *Catawba*, *Scuppernon*, &c., already mentioned.

Although so short a time has elapsed since the previous observations relative to the grapes and their culture in the United States were written, vineyards have become an important branch of husbandry in various parts of the United States, especially in the valley of the Ohio.

An interesting publication, made in 1850 by R. Buchanan, Esq., of Cincinnati, furnishes in a small space, a very great amount of instructive information relative to this culture and wine making, as carried on in the vicinity of Cincinnati, where the general intelligence and capital of the Americans is seconded by the practical experience of the very numerous German settlers.

The soil where these vineyards are mostly planted gives, on analysis, from 3 to 4 per cent. of carbonate of lime, with oxide of iron from 2 per cent. to 0.30; vegetable matter, 10 to 13 per cent.; sand and clay, about 80 per cent.

Mr. B. gives, from his own experience, the following estimate of the cost of a vineyard of 6 acres, containing 14,400 vines; the details are highly interesting, as showing the several operations to be performed, and cost of each.

Trenching, two feet deep, \$65 per acre.....	\$390.00
Sodding avenues.....	60.00
Cost of 30,000 cuttings, at \$2.50 per thousand.....	75.00
Planting.....	70.00
14,500 locust stakes, at \$3 per hundred.....	435.00
Setting 14,500 stakes.....	55.00
	1,085.00
Cost of attending the first year—vine dresser, \$216, and a hand for one month, \$15, (and board themselves).....	\$231.00
Second year—vine dresser, \$216, and a hand for two months, at \$15 per month.....	256.00
Cuttings, after first year, to replace failures, say, 20,000.....	500.00

Hauling, carting, &c.....	68.00
Contingencies, &c.....	150.00

Average cost, say, \$300 per acre.....1,800.00

In this instance the vineyard was on a gentle declivity, not requiring terracing or *benching*; nor was there much stone to remove, both of which would have added much to the expense. "By proper economy," Mr. B. says, "a man may have a vineyard of several acres in a few years, without feeling the expense to be burthensome. Commence by trenching with the spade 2 or 2½ feet in the fall or winter, and planting out in spring. Next year another acre, and so on for five or six years. After the third year he will have his own cuttings from the first acre, and also grapes enough to pay the cost of planting the succeeding additions to his vineyards. The stakes can be got out in winter at little cost in money, and in this way a vineyard of six acres might be established at one half the cost of the estimate just given."

Mr. B. estimates the cost of vineyards in *trenched* ground at \$200 to \$350 per acre—according to situation and condition of the soil, and the judicious economy displayed in the management.

The expenses of attending a vineyard will be comparatively small where there are workers in the family. But where hired hands have to be employed, in Ohio a vineyard of 6 acres will cost for a vine dresser, who boards himself, \$240 per annum; assistants in pruning, \$25; assistance in the spring culture, \$40, and summer culture, \$55; in all \$360, or at the rate of \$60 per acre. Where the cuttings can be sold for \$2 to 2.50 per 1000, it will reduce the sum about \$100.

The vineyard should be laid off with a line, so as to make rows 5½ to 7 feet apart, with the vines 3 to 4 feet asunder. The more level the ground, the farther apart should be the vines, so as to give freer access to the sun and air. Mark with a stick about 15 inches long, every place where a vine is to grow, digging a hole a foot deep in which two cuttings are to be placed in a slanting position, separated 6 or 8 inches at the bottom, and one inch at the top of the hole. Cover with a shovelful of rich vegetable mould from the woods, leaving the top eye of each cutting even with the surface, or, if the weather be dry, covered with the light mould half an inch or an inch. If both cuttings grow, one should be removed or cut off the following spring, leaving but one to each stake. To preserve and prepare the cuttings, the trimmings pruned from the vines should be buried in the earth; about the last of March or first of April, the proper time for planting, cuttings may be made, having each 4 eyes or joints, taken from ripe wood; and if some of the old wood is left on, so much the better. Cut them off close below the lower joint, and about an inch above the upper. Some have recommended planting with roots 2 years old, but experience seems to be in favour of planting cuttings, as the most thrifty vines are those which have never been transplanted or disturbed.

Treatment of the Young Vineyard.—The first year, keep the ground clean and free from weeds, with the hoe; many use the plough as being more expeditious and economical, but the more careful vine dressers who can afford it, never cultivate with the plough, using only the two-pronged German hoe, made especially for the purpose.

The earth should be stirred around the young vines, two or three times during the season, to promote their growth; superfluous shoots must be pulled off, leaving but one or two to grow, at first, and but *one* eventually.

In the spring, cut the young vine down to a single eye, or bud; at first, if two are left for greater safety, take off one, afterwards; drive a stake 6 or 7 feet long firmly to each plant. Locust or cedar is preferred, but oak or black walnut, charred at the end, driven into the earth, or coated with coal tar, will, it is said, last nearly as long. Keep the young vine tied neatly to the stake, with rye or wheat straw—pick off all suckers, and let but one stalk or cane grow. The vineyard must be kept clean of weeds, and the young vines hoed as before.

The *second spring* after planting, cut down to two or three eyes, or joints, and the *third year* to four or five; suckering, tying up, and hoeing the vines as recommended above.

Re-plant from the nursery, where the cuttings have failed to strike root in the vineyard.

The *third year*, the vines will produce a few grapes, sometimes enough to pay the expenses of attending them.

Train *two* canes to the stake this year, take off suckers, and keep well hoed.

The vineyard having now commenced to bear, may be considered as *fairly established*; and for the *fourth* and successive years, the following treatment is generally adopted.

Spring Pruning.—This is usually done from the middle of February to the first week in March. Some prune in January, and Mr. Schuman has recommended November and December, as the proper time.

No serious injury to the vines, by winter pruning, has yet been discovered.

Pruning, *the fourth year*, requires good judgment, as the *standard stem, or stalk*, has to be established.

Select the best shoot or cane of last year, and cut it down to 6 or 8 joints, and fasten it to the adjoining stake in a horizontal position, or bend it over in the form of a hoop or bow, and tie it to its own stake. The ties should be of willow. This is the bearing wood. The other cane, cut down to a spur of two or three eyes, to make bearing wood for the next season.

Mr. Schuman remarks in his treatise, "There are various methods of training adopted. Some tie the shoot up to the stake with two or three ties at proportionate distances.

"The greater part of the German vine-planters make circular bows with three ties, and another mode is to make half-circle bows. I recommend the latter as the best, and proceed to describe it.

"Give the shoot the first tie on the stake 9 inches from the ground, and the second 9 inches above it; then bow it over to the neighbouring stake in a horizontal position, and give it the third tie to that stake, at the top of the vine."

In the succeeding, and all subsequent years, cut away the old bearing wood, and form the new bow, or arch, from the best branch of the new wood of the last year, leaving a spur as before, to produce bearing wood for the coming year, thus keeping the old stalk of the vine down to within 18 to 24 inches, from the ground. The vine is then always within reach and control.

Should a vine be lost after the vineyard is in

bearing, it can be replaced by a layer from the adjoining vine, which is a much better mode than planting a young vine. The layers may be put down late in summer, but spring is preferred.

Cultivate the yellow, and the osier willow, to make ties for the spring pruning. They will grow in any wet place.

Summer Pruning consists in removing suckers, and *pinching* off all lateral shoots, leaving but two stalks or canes to be trained for bearing wood the ensuing year, and *pinching* off the ends of the bearing branches, about the time of blossoming, some two or three joints beyond, or above the last blossom bunch; pull no leaves off the bearing branches, and but very few from any other. As the vines grow, tie them neatly to the stakes, with rye straw, (some use grass), and when they reach the top, train them from one stake to the other, until the fruit has nearly matured; the green ends may then be broken off. If this is done too early, there is danger of forcing out the fruit-bearing buds for the next year, and of injuring the grapes in ripening.

Mr. Longworth cautions American vine growers against a common European practice of shortening the leading branches intended to produce the next year's crop, heading in the short branches and thinning out the leaves for the purpose of exposing the fruit to the sun and air to promote its ripening. This method, though sometimes advantageous where there are cold summers, he says will, in the hot American climate, where some shade is necessary, prove highly injurious, if not entirely destructive to the grapes. No more lateral branches should be taken from the main shoots intended for next year's fruit, then to give them the necessary length. A large crop is often occasioned by leaving too much bearing wood. This should always be avoided; for even if the crop ripens thoroughly, too much of the sap is taken by the fruit, and too little left to produce good young wood for the next season's crop.

Culture.—The vineyard must be kept perfectly clean from weeds and grass, and should be hoed twice during the spring and summer.

The cultivator or the plough is less expensive, but the vines and roots are in danger of being injured by that mode of culture; therefore the hoe is preferred by those who can afford it. It has been recommended by some writers, to cut off the roots of the vines near the *surface* of the ground, and 4 or 5 inches under, that the roots, when the vines are young, may be well established at a proper depth below.

By others, this plan is thought to be injurious. The majority, however, prefer cutting off the surface roots for the first three or four years.

About every third year, put in manure, by opening a trench the width of a spade, and four or five inches deep. Above and near each row, throw in two or three inches of well rotted manure, and cover up with the earth.

Another plan adopted, is to run a furrow with the plough, put in manure, and cover over, either with the plough or hoe.

Others, again, scatter manure over the surface, and dig it in.

An intelligent cultivator, J. A. Corneau, remarks: "High manuring is generally admitted to be injurious to the vinous quality of the grape; or, in other words, it accelerates a larger growth of wood, and a more attractive-looking fruit

while the more essential qualities of the grape for wine making, are very much deteriorated. No substance should ever be used which has a tendency to ferment, or which, in undergoing a chemical change in the soil, would form an acid or a salt of a highly stimulating nature. Vegetable manures, bones, &c., may be used to advantage." *Well rotted* stable-yard manure has been used *moderately*, by the writer, with good effects to the plants and the fruit, and without any perceptible injury to the "vinous quality of the grape."

Diseases, Insects, and Frosts.—The "rot," as it is termed, is the great evil, especially in cultivating the Catawba.

This takes place usually in the latter end of June or early in July, Dr. Warder says, "about the period of stoning," or "hardening of the seed," after continued heavy rains, and hot sweltering suns.—It strikes, something like the rust in wheat, suddenly, and with the same disastrous effect to the crop. Various modes of prevention have been recommended, but none yet tried have proved always effectual.

The cause is supposed to be an excess of water about the roots of the vine, in any clay subsoil retentive of moisture; sandy soils with a gravelly substratum, are generally exempt from this disease.

The opinions of Mr. Elliott, Mr. Longworth, and the Fruit Committee of the Cincinnati Horticultural Society, on this subject, are quoted.

Mr. Elliott, in the *Horticulturist*, Vol. 2, p. 314, says the rot for the past three years has followed excessive rains in July and August. Dr. Flagg, two years since, found a small part of a vineyard where the rot was very slight. This had not been worked after the spring, and the ground was in such a state, that most of the rains passed off on the surface. Vines planted in rows eight feet apart, in one instance were found to be affected with rot, but very slightly.

In the same article, Mr. Longworth says: "It is of late years only, that the rot has been so destructive among our grapes; one thing is certain, if we had little or no rain after the grapes are fairly forward, we should see but little of the rot; certain it is, that continued rains followed by a hot sun, cause us to look out for the appearance of the rot."

He also refers to instances where, in seasons when the rot prevailed extensively, crops escaped although raised upon a stiff clay sub-soil. In such cases the ground had been left without hoeing, and become so hard baked on the surface as to prevent the rain-water from penetrating to the roots. Under draining will doubtless be found of the greatest advantage to vineyards on soils retentive of moisture. See DRAINING.

In the able report of Dr. Mosher, Mr. Ernst, and Mr. Kidd, the Fruit Committee of the Society for 1848, it is remarked, "some vineyards were injured by the wet weather in July, causing the grapes to rot and fall off; this however, seems to have been confined to situations where the air had not a free circulation, allowing fogs and vapours to remain too long upon the vines in hot weather, as well as to a tenacious clayey soil; on dry and more airy situations, and where the ground was thoroughly drained, the crop has been fine and fair."

H. W. S. Cleveland, of Burlington, N. J., who has a vineyard of two to three acres, and who, Mr. Downing says, is one of the most reli-

able horticulturists in the State, recommends covering the whole surface of the vineyard with shavings, leaves, or coarse grass, to prevent the ravages of insects, and diseases of the fruit—see *Horticulturist*, Vol. 3, p. 113.—In the same Vol. p. 121, "A Jerseyman," in summer pruning, put the leaves and young stems in a trench at the root of the vines—sprinkled gypsum on them, and covered over with earth. This was done at the suggestion of Mr. Downing, who strongly recommends it to the vine dressers on the Ohio, with a request that upon trial they "report progress."

And at page 161, of the same Vol., "B.," "of Chester Co. Pa." recommends "special manures," as a certain specific—having tried with success, a mixture of guano, gypsum, and wood ashes.

Mr. Downing says to "J. D. Legare, Aiken, S. C." in the same Vol. p. 255, "We note your experiment with ashes to prevent rot, but you must not decide against it with one year's trial.—It has been found effectual here at the north, when used along with gypsum."

Two years ago, the writer of this treatise tried ashes on a small scale, *but without gypsum*; a trench was dug above two rows, the width of a spade, some four inches deep, and two or three inches of leached ashes put in and covered over with earth. No beneficial effect was perceived. The two rows were slightly affected by the rot, as were those adjoining.

Hoeing in autumn, and not stirring the ground at all in the spring and summer, but keeping the weeds cut down, and the surface smooth, that the water may not sink, but pass off rapidly, has also been spoken of as a probable remedy against rot.

Some persons even recommend letting the weeds grow; to say the least of it, this would be slovenly culture.

With a view to test the advantages of wide planting and high training, in preventing the rot, Mr. Werk has planted on his farm near Cheviot, eleven acres in the Catawba grape, twenty feet apart in the rows each way, and the vines are trained to locust stakes twelve feet high. Last year they produced fruit for the first time, and were entirely free from rot. But here it must be remarked, that the *first crop* from young vines, is generally but little affected by that disease. Mr. Werk also cultivated the ground between the rows, for other purposes.

The "mildew" comes earlier in the season, when the grapes are about one fourth grown, blighting occasionally a few bunches, and sometimes only the lower end. It is neither common nor destructive.

The "speck," by some persons mistaken for the rot, and by others called the bitter rot, is a large circular spot on the side of the grape, looking as if caused by the sting of an insect, and extending to the seed on one side of the berry, whilst the other is uninjured; but owing to this wound, or speck, the juice will be bitter. This has been attributed to the action of the sun on the fruit when covered with rain or dew-drops.

The vine is so remarkably healthy, and of such luxuriant growth in almost any proper soil, that *diseases at the root* are almost unknown here. Mr. Schuman states that a white worm resembling the peach tree worm, is sometimes found eating off the young roots of the vine, and

Mr. Mottier has also found and destroyed it—but it is rarely met with in vineyards.

The *Insects* found most annoying, are a *green worm* that feeds on the vines just as the fruit buds appear, and before they blossom, eating off the tender bunches, and doing great mischief if not promptly destroyed. The *Canker, or Measuring Worm* (of which the above may be a variety) is sometimes found on the leaves and young shoots. The *Curculio*, so destructive to the plum, has occasionally been found on the grapes; they can be readily shaken down on a sheet, by a sudden blow on the stake, and destroyed. If ever permitted to get domesticated in a vineyard, this insect would be immensely destructive.

The *Rose-bug*, Dr. Shaler says, has been observed in some vineyards in Kentucky, but it is rarely met with here.

A *large brown beetle*, or bug, will frequently sting the young tender branches of the vine in summer, making a wound that subjects the branch to be broken off by strong winds. They can be watched and picked off, late in the evening, or early in the morning. All horticulturists are familiar with the spring and the early fall *caterpillar*, and of course, would not permit either to get a foothold in the vineyard.

Frost.—Late spring frosts have some years, but not often, been highly injurious, especially to vineyards near *small* streams of water, damp woods, or in cold situations. The most severe within the memory of Mr. Buchanan, occurred on the 9th of May, 7th of May, and 15th of April, of three successive years, when the buds had so far put out, that their loss was not replaced by the pushing out subsequently of the latent, or twin bud, which partially overcame the loss of the first bud in the latter year, 1849.

In warm and sandy lands, with a gravelly substratum, the buds are in some years pushed forward prematurely by warm autumns, so as to be killed by the severe frosts in winter. See WINE.

VINEGAR is the acetous and acetic acids of the chemist, containing a variety of foreign admixtures, some colouring matter, and an ethereal substance or spirit, which gives it a grateful aroma. Vinegar has been known from a very early age. It was by far the earliest known acid of commerce. That it was drunk in remote periods, diluted with water, by the labourers and soldiers, is very certain. It is repeatedly mentioned in the Old Testament. But then they had several descriptions, one of which, a kind of small wine, which they called *pesca* or *sera*, is supposed to be that offered to Ruth (*Ruth*, ii. 14), and to our Saviour by the Roman soldiers (*Matt*. xxvii. 48). The stronger variety of vinegar is alluded to in another place (*Prov*. x. 26). They mixed it also with nitre, or, properly speaking, natron, which was an alkali that, by neutralizing, destroyed its sharpness. "As vinegar upon nitre, so is he that singeth songs to a heavy heart." (*Prov*. xxv. 20.) They made it in those days from wine. (*Numb*. vi. 3.) It is known to every one, that when wine or beer is exposed to the influence of the atmosphere, it becomes sour or acid; now this acid is the acetic. In the wine countries it is chiefly made from the produce of the vine, weak or low wines; the shoots of the vine, &c., being also employed for that purpose. It may be readily made from merely sugar and water.

That of commerce in England is usually made from wort from malt liquor or cider. Vinegar is of a yellowish or reddish colour, an acid taste, and pleasant odour. Its specific gravity is commonly between 1.0135 and 1.0251. It usually holds in solution various foreign substances, such as colouring matters, sulphate of lime, mucilage, sulphuric acid, and the ethereal spirit already mentioned. Vinegars differ greatly in strength and in purity. The best known in England for domestic purposes is the French white wine vinegar; but the *Vinaigre d'Orleans*, made from the red wine of the Orleans, is that most esteemed in France; and that imported from Bourdeaux, although named Champagne vinegar, is often made from red wine. The density of French vinegars varies from 10.14 to 10.22. The free sulphuric acid in British vinegar is permitted by the English excise laws to the amount of one part in one thousand, but it is often added to four times that amount.

Vinegar is readily purified from its impurities by distillation, and in this form is the transparent distilled vinegar of commerce. But even then it is united with a considerable portion of water.

The specific gravity determines this point. Thus, at 10.14 it contains 10 per cent. of real acetic acid, at 10.22 15 per cent., at 10.25 18 per cent., at 10.35 26 per cent., at 10.60 50 per cent., and so on, until it reaches 10.635, which is the strongest liquid acetic acid.

When deprived of all impurities and water, by chemical means, pure acetic acid is composed, according to the analysis of M. Berzelius, of—

	Parts.
Carbon	46.83
Oxygen	40.82
Hydrogen	6.35
	100.

Some plants contain acetic acid naturally. M. Vauquelin found it in the sap of various trees, and in the chick-pea. Scheele detected it in the elderberry. It has been found also in the date palm tree, and in several others; and few plants exist in which acetic acid in the form of salts, such as the acetates of lime or potassa, is not found.

In England, for domestic purposes, it is prepared in several very considerable manufactories from a mixture of barley or malt with water, by keeping the wash exposed in open vessels to the influence of the atmosphere, in rooms heated to a particular temperature. The formation of the acetic acid in this manner is in these works promoted by the addition of a certain small proportion of acetic acid.

An excellent vinegar for domestic purposes may be readily made by exposing a mixture of one part of brown sugar by weight with seven parts of water and some yeast, in a cask whose bung-hole is only slightly covered over (as by a piece of gauze pasted down to keep out insects), for some weeks to the action of the atmosphere and the sun. The acetic fermentation and the goodness of the vinegar are promoted by the addition of vine leaves.

Although vinegar is familiarly used in small quantity as an agreeable and useful addition to food, yet in large quantities it interrupts digestion, and induces emaciation. In combination

with water, it is an excellent cooling and invigorating substance when employed for sponging the body, especially in febrile conditions of it: its vapour inhaled with the vapour of hot water relieves hoarseness; and, when moderately diluted, it forms an excellent gargle in inflamed or sore throats. See **ACIDS** and **PYROLIGNEOUS ACID**.

VIOLET (*Viola*). All the species of this genus deserve to be cultivated, either for the beauty or the scent of their flowers. The species natives of America thrive best in vegetable mould or peat, and are readily increased by parting the roots or by seeds. There are 8 native species of violet in England, and, according to Schweinitz, 29 in the United States.

VIOLET, AMERICAN (*Erythronium Americanum*). Sometimes called Dog's-tooth violet. This very pretty plant is found throughout the Atlantic States on the lowest alluvial banks of streams, and in most moist places, where it puts forth its beautiful violet flowers in April and May. It has a perennial bulbous root, rather deep in the ground. Among other American species of the violet enumerated by botanists, is the white violet (*E. albidum*), found throughout the Western States and Territories, in Upper Louisiana, and on the banks of the Missouri, where no other species appears to exist. There appears to be a yellow-flowered species confounded with this white species, and nearly allied to it.

VIPER'S BUGLOSS. See **HONEY**, *Ciniak*.

W.

WAGES. The price or hire paid to labourers or servants for performing different sorts of farm work.

These differ greatly in different districts and situations, and according to the character and employment of the workmen, but in all they are considerably increased within the last 15 or 20 years. They may perhaps be stated as varying, in England, under different circumstances, from 9s. to 18s. by the week, and from 9l. to 15l. or 18l. by the year.

WAGON. A wheel-carriage, of which there are several varieties, accommodated to the different uses which they are intended to serve.

In the business of husbandry, wagons constructed in different forms, and of various dimensions, are made use of in different districts or parts of the kingdom; and mostly without much attention to the nature of the roads, or the articles which are to be conveyed by them; being in general heavy, clumsy, and inconvenient. There is, however, a wagon much employed in Berkshire, England, which is constructed on a more simple and convenient principle than those mostly met with in the other southern parts of the island, not having the height or weight of them, while it possesses sufficient strength, and is easy in the draught.

Wagons require more power in the draught than carts, which is certainly an objection, though they carry a much greater load, and are far from being so handy and convenient; and Mr Parkinson is of opinion, that more work

may be done in any particular time, with the same number of horses, by carts than by wagons, in the general run of husbandry business, especially where the distance is small between loading and unloading; a fact which has long been known and attended to in Scotland.

Where wagons are used for husbandry, they should be made wide and low. Manures may be carried in this sort of wagon almost as well as in carts. Broad wheels are improper for passing and repassing upon tillage lands; for, if in fallow, they press the land too much, and make it so hard as to prevent its being ploughed till wet comes; but on grass land broad wheels are proper for all uses, as there they operate as rollers.

Wagons are probably the best conveyances for different sorts of heavy loads to a distance; but for home business, especially harvest and other work, which requires to be speedily performed in the field, carts with proper shelving will be found preferable. See **CART** and **HIGHWAY**.

WAIN. A name applied to an ox cart, without any side rails, or ladders, in some districts in England; but in others shelvings are added, and the body is large and open. They are rarely met with at present. In Gloucestershire they adapt them to harvest work by fixing ladders and rathes on them. In the lower part of the vale they are called *dungpots*; but in the forest districts, where drawn by oxen, wains.

WALNUT TREE (*Juglans*, from *Jovis glans*; literally the nut of Jove). All the species of the ornamental genus to which the well-known walnut tree belongs are tall, stately-growing trees, well adapted for parks and lawns. They grow freely in any rich loamy soil, and are raised from seeds. This deciduous tree was formerly held in great esteem in England for its wood, which is often very finely veined; but, on account of its aptness to be worm-eaten, it has long since given place to the mahogany. As a fruit tree, independent of its timber, which is still of much value, it merits attention, and it is also useful as an ornamental tree. There are several species capable of being cultivated with advantage both for their wood and fruit; as the common walnut, the white walnut, and the black walnut tree.

The common walnut (*J. regia*) is a very large and lofty tree, which has strong spreading boughs. The leaves are pinnate, with a very strong but not unpleasant smell; the leaflets 3 pairs (sometimes 2 or 4), nearly equal, except that the odd one is largest; they are entire, smooth, and shining. The male flowers are in close, pendulous, subterminating filaments; the females scattered, frequently 2 or 3 together. Fruit an ovate, coriaceous, smooth drupe, inclosing an irregularly grooved nut, which contains a four-lobed, oily, eatable kernel, with an irregular knobbed surface, and covered with a yellow skin. This tree is a native of Persia.

It has been noticed by Martyn, "that as they all vary again when raised from the seed, and that as nuts from the same tree will produce different fruit, those who plant the walnut for its fruit should make choice of the trees in the

nurseries, when they have their fruit upon them."

The common walnut has several varieties, as the oval walnut, the round walnut, the large walnut, the small-fruited walnut, the double walnut, the early walnut, the late walnut, the tender thin-shelled walnut, and the hard thick-shelled walnut.

There are two other species, the hickory-nut, or white walnut (*J. alba*), and the black walnut (*J. nigra*). Both these are natives of Virginia; but they are seldom cultivated in Britain, except as timber trees.

The best manure for the walnut is ashes, spread in the beginning of winter, the land having been first ploughed or trenched over in an effectual manner.

The length of time in which the English walnut bears well from the nut is about 20 years.

Mr. Knight has suggested that this tree will bear much sooner when raised by grafting, with bearing branches, by approach. But where the trees are intended for timber, it is a good practice to plant them out at once where they are to grow, as they thrive faster, and form better trees, by that method of raising them.

These trees should not be planted nearer together than 40 feet, and even more distant, if they are designed for fruit. They delight in a firm, rich, loamy soil, or such as is inclinable to chalk or marl; and will thrive very well in stony ground, or on chalk hills, as is evident from those large plantations near Leatherhead, Godstone, and Carshalton in Surrey, where great numbers of these trees planted upon the downs produce annually large quantities of fruit, to the no small advantage of their owners.

In order to preserve this fruit, it should be left upon the tree till it is thoroughly ripe, and then, as it would be exceedingly troublesome to gather it by hand, it may be beaten off, but not with such violence as is commonly used, from a mistaken notion that the tree is improved thereby; for most certainly it cannot be benefited by that rough way of forcing off the young wood upon which this fruit grows.

The fruit is used in two different stages of its growth: as when green, to pickle; and when ripe, to eat the kernel. For the first purpose, the young green walnut, when about half or near three parts grown, before the outer coat and internal shell shall become hard, is most excellent, for which they are generally ready in July or the following month, and should be gathered by the hand, choosing such as are as free from specks as possible. But the fruit is discovered to be fully ripe by the outer husk easily separating from the nut, or by the husks sometimes opening at the valve, and the nuts dropping out, which occurs usually about the latter end of September. In trees of considerable growth, it is commonly beaten down with long poles; for, as the walnuts grow mostly at the extremity of the branches, it would, in very large spreading trees, be troublesome and tedious work to gather them by hand. As soon as gathered, they should be laid in heaps a few days to heat and sweat, to cause their outer husks, which closely adhere, to separate from

the shell of the nuts; after which they should be cleaned from the rubbish, and deposited in a dry room for use, covering them over close with dry straw, a foot thick, where they will keep 3 or 4 months. They always command a ready sale at market in large towns, where, at their first coming in, they are bought with their husks on, and sold by the sack, or bushel, but afterwards cleaned, and sold both by measure and by the thousand.

Plantations of these trees in England are therefore profitable, in their annual crops of fruit, while growing, and in their timber when felled or cut down.

It is stated in the *Gloucestershire Report*, that "it will grow almost in any soil, wants no pruning nor care, and in less time than the oak it will make a large tree. The wood is too valuable to apply to the usual purposes of timber trees, but is always used either in cabinet work or for gun-stocks; for the latter, indeed, so great has been the demand for a few years past, from the Birmingham gun-makers, that the county has been ransacked for this wood, and high prices have been held out to tempt the sale of it. In consequence of this, the stock has been much diminished, and, with very few exceptions, only here and there is a solitary walnut tree seen growing. In the parish of Arlingham there are more, perhaps, than in many other parishes combined."

Were it only for the oil that these nuts afford, the trees which produce them would be worth some care. It has been observed by Evelyn, that one bushel of them will yield 15 lbs. of peeled kernels, and that these will yield half that weight of oil, which, the sooner it is drawn, is the more in quantity, though the drier the nut, the better is its quality. He adds, that the lee, or marc of the pressing, is excellent for fattening hogs. Certainly it would be good manure for land; as are the cakes of linseed, rape, &c., after the oil has been squeezed out of them. The green husks boiled, without any mixture, make a good colour to dye a dark yellow-brown. The kernel being rubbed upon any crack or chink of a leaking vessel, stops it better than either clay, pitch, or wax. (*Philips's Fruits*, p. 342.)

In the variety of trees which compose the vast forests of North America east of the Mississippi, the walnut, says Michaux the younger, ranks after the oak, among the genera whose species are most multiplied. In this particular, the soil of the United States is more favoured than that of Europe, to no part of which is any species of this tree indigenous. This ardent student of nature has designated 10 species of walnut in the United States, including the hickories, and thinks others may yet be discovered in Louisiana. There is, he adds, room to think that species may be discovered, susceptible, like the pacanenuit hickory, of speedy melioration, by the aid of grafting and attentive cultivation. Some weight is given this consideration, by an observation of Michaux the father, that the fruit of the common European walnut, in its natural state, is harder than that of the American species just mentioned, and inferior to it in size and quality. To the members of agricultural societies in

the United States it belongs to extend their observations and experiments on this subject, after the example of our ancestors, to whom we are indebted for a rich variety of fruits, equally salutary and beautiful.

The walnuts of North America appear to present characters so distinct as to require their division into two sections. These characters consist principally in the form of the barren aments or catkins, and in the greater or less rapidity of vegetation in the trees. The first section is composed of walnuts with single aments, and includes two species, the black walnut and the butternut; to which section is added the European walnut. The second section consists of such as have compound aments, and comprises the 8 species already described under the name of HICKORY.

The black walnut (*Juglans nigra*), is known by no other name in all parts of the United States where it grows. East of the Alleghany mountains, the most northern point at which it appears, is, says Michaux, about Goshen in the state of New Jersey, in the latitude of 40° 50'. West of the mountains, it exists abundantly 2° farther north, in that portion of Genesee which is comprised between the 77th and 79th degrees of longitude. This observation, as I shall have occasion to remark, is applicable to several other vegetables, the northern limit of whose appearance varies with the climate, and this becomes milder in advancing towards the west.

This last observation of Michaux in respect to the amelioration of climate in going west, has been ascertained, from exact thermometrical observations, to be applicable only to those sections of country situated sufficiently near the Lakes, and to the eastward of them to be influenced by the greater equality of temperature maintained by bodies of water than by land. The proximity of those great internal seas have a similar effect in modifying climate to that manifested on the Atlantic border, where many trees and plants creep up several degrees higher than they can be found further in the interior. (See CLIMATE OF THE UNITED STATES.)

The black walnut is multiplied in the forests about Philadelphia, and, with the exception of the lower parts of the Southern States, where the soil is sandy, or too wet, it is met with to the banks of the Mississippi, throughout an extent of 2000 miles. East of the Alleghany mountains in Virginia, and in the upper part of the Carolinas and of Georgia, it is chiefly confined to the valleys, where the soil is deep and fertile, and which are watered by creeks and rivers: in the western country, in Genesee, and in the states of Ohio and Kentucky, where the soil in general is very rich, it grows in the forests, with the coffee tree, honey-locust, red mulberry, locust, shellbark-hickory, black sugar maple, hackberry, and red elm; all which trees prove the goodness of the soil in which they are found.

It is in these countries, says Michaux, that the black walnut displays its full proportions. On the banks of the Ohio, and on the islands of that beautiful river, I have often seen trees of 3 or 4 feet in diameter and 60 or 70 feet in height. It is not rare to find them of the thick-

ness of 6 or 7 feet. Its powerful vegetation clearly points out this as one of the largest trees of America. When it stands insulated, its branches, extending themselves horizontally to a great distance, spread into a spacious head, which gives it a very majestic appearance.

The leaves of the black walnut when bruised emit a strong aromatic odor. They are about 18 inches in length, pinnate, and composed in general of 6, 7, or 8 pair of leaflets, surmounted by an odd one. The leaflets are opposite and fixed on short petioles; they are acuminate, serrate, and somewhat downy. The barren flowers are disposed in pendulous and cylindrical aments, of which the peduncles are simple, unlike those of the hickories. The fruit is round, odoriferous, of rather an uneven surface, and always appears at the extremity of the branches: on young and vigorous trees, it is sometimes 7 or 8 inches in circumference. The husk is thick, and is not, as in the hickories, divided into sections; but when ripe it softens and gradually decays. The nut is hard, somewhat compressed at the sides, and sulcated. The kernel, which is divided by firm ligneous partitions, is of a sweet and agreeable taste, though inferior to that of the European walnut. These nuts are sold in the markets of New York, Philadelphia, and Baltimore, and served upon the tables. The size of the fruit varies considerably, and depends upon the vigour of the tree, and upon the nature of the soil and of the climate. On the banks of the Ohio, and in Kentucky, the fruit with the husk is 7 or 8 inches in compass, with the nut proportionally large: in Genesee, on the contrary, where the cold is intense, and in fields exhausted by cultivation, where these trees have been preserved since the first clearing of the land, it is not of more than half this bigness. Some variations are observed in the form of the fruit, and in the moulding of the shell; but these I consider as merely accidental differences. Indeed, there is no genus of trees in America, in which the fruit of a given species exhibits such various forms as in the walnut; and doubtless this circumstance has misled observers, who, being acquainted only with the small number of trees existing in European gardens, have described them as distinct species.

The bark of the black walnut is thick, blackish, and on old trees deeply furrowed. When the timber is freshly cut, the sap is white and the heart of a violet colour, which after a short exposure to the air assumes an intenser shade, and becomes nearly black: hence probably is derived the name of black walnut. There are several qualities for which its wood is principally esteemed; it remains sound during a long time, even when exposed to the influences of heat and moisture; but this observation is applicable only to the heart; the sap speedily decays. It is very strong and very tenacious: when thoroughly seasoned it is not liable to warp and split; and its grain is sufficiently fine and compact to admit of a beautiful polish. It possesses, in addition to these advantages, that of being secure from worms. On account of these excellencies, it is preferred and suc-

cessfully employed in many kinds of work, chiefly in cabinet-making.

The husk of the fruit yields a colour similar to that which is obtained from the European walnut. It is used in the country for dyeing woollen stuffs.

This tree has been long since introduced, in England and France, into the gardens of the lovers of foreign culture. It succeeds perfectly and yields fruit abundantly. Though differing widely from the European species, it bears a nearer resemblance to it than any other American walnut. By comparing the two species as to their utility in the arts and in commerce, it will appear that the wood of the black walnut is more compact, heavier, and much stronger; that it is susceptible of a finer polish, and that it is not injured by worms; qualities which, as has been seen, render it fit not only for the same uses with the European, but also for the larger works of architecture. These considerations sufficiently evince that it is a valuable tree, and that it is with great reason that many proprietors in America have spared it, in clearing their new lands. On high-roads, I am of opinion that it might be chosen to succeed the elm; for experience has proved, that to insure success in the continued cultivation of trees or herbaceous plants on the same soil, the practice must be varied with species of different genera.

Nuts of the European walnut and of the black walnut have been planted at the same time in the same soil; those of the black walnut are observed to shoot more vigorously, and to grow in a given time to a greater height. By grafting the European upon the American species at the height of 8 or 10 feet, their advantages, with respect to the quality both of wood and of fruit, might be united. (*Michaux.*)

The second species of walnut, properly so called, has been described under the head of BUTTERNUT.

WARBLE. See BACK-SORE, GALLS, and SITFAST.

WARP. A slimy deposit or ooze left upon land by the receding sea tides in particular situations. See ALLUVIUM and WARPING.

WARPING OF LAND. A mode of fertilizing and improving tillage lands practised in particular situations on the borders of large rivers and waters into which the sea tides flow, and where the level of the ground is such as to admit of their being flooded with great facility. The practice is, for the most part, confined to the districts situate on the coasts of Lincolnshire and Yorkshire. The water of the tides that come up the Trent, Ouzé, Dun, and other rivers which empty themselves into the great estuary of the Humber, is muddy to an excess; insomuch that in summer, if a cylindrical glass, 12 or 15 inches long, be filled with it, it will presently deposit an inch, and sometimes more, of what is called warp: a circumstance which renders them so fertile.

The fertility of Egypt, of the land bordering on the shores of the Ganges, and some of the large American rivers, I have already shown to be attributable to the periodical overflowing of the waters which are surcharged with a

large quantity of earthy substances which they hold in solution.

"The effect of warping is very different from that of irrigation; for it is not the water that works the effect, but the deposition of the mud, so that in floods the business ceases, as also in winter; and the object of this practice is not to manure the soil, but to create it. The quality of the land intended to be warped is not of the smallest consequence; a bog, clay, sand, peat, or a barn floor, are all one; as the warp raises it in one summer from 6 to 16 inches thick, and in the hollows, or low places, 2, 3, or 4 feet, so as to leave the whole piece level. Thus a soil of any depth you please is formed, which consists of mud of a vast fertility, though containing not much besides sand."

This is a practice which is begun in the month of July, and is proceeded with during the summer season; and as it can only be performed at that period, every occasion of having it executed should be embraced, by having the work in perfect repair, that every tide may be made to produce its full effect. With regard to the advantage of doing this work in the summer months, it may be remarked that at these times the lands not only become the soonest dry, a circumstance which must always fully take place before the process of cultivation can be carried on, but the tides are less mixed with fresh water, in which situation they are constantly found the most effectual.

The method of executing the work is thus described, in the *Agricultural Survey of the West Riding of Yorkshire*, by Lord Hawke:—

"The land to be warped must be banked round against the river. The banks are made of the earth taken on the spot from the land: they must slope 6 feet, that is, 3 feet on each side of the top or crown of the bank, for every foot perpendicular of rise: their top or crown is broader or narrower, according to the impetuosity of the tide and the weight and quantity of water; and it extends from 2 to 12 feet: their height is regulated by the height to which the spring tides flow, so as to exclude or let them in at pleasure. In these banks there are more or fewer openings, according to the size of the ground to be warped, and to the choice of the occupier; but in general they have only two sluices, one called the flood-gate, to admit, the other called the *clough*, to let off the water gently; these are enough for 10 or 15 acres. When the spring tide begins to ebb, the flood-gate is opened to admit the tide, the *clough* having been previously shut by the weight of the water brought up the river by the flow of the tide. As the tide ebbs down the river, the weight or pressure of water being taken from the outside of the *clough* next the river, the tide water that has been previously admitted by the flood-gate opens the *clough* again, and discharges itself slowly but completely through it. The *cloughs* are walled on each side, and so constructed as to let the water run off between the ebb of the tide admitted and the flow of the next; and to this point particular attention is paid. The flood-gates are placed so high as only to let in the spring tides when

opened. They are placed above the level of the common tides.

“Willows are also occasionally planted on the front of the banks, to break the force of the tides, and defend the banks by raising the front of them with warp thus collected and accumulated; but these willows must never be planted on the banks, as they would destroy them by giving the winds power to shake them.”

It is stated that in England the first cost of a sluice by warping, that is, 5 feet in height and 7 feet in width, may be estimated at from 400*l.* to 500*l.*; and that such a sluice will in general be adequate to the warping of 50 acres annually, and, where the soil is contiguous to the river, for 70 or more.

The following is given as the substance of a note by a commissioner employed in warping:—“Warp leaves one-eighth of an inch every tide on an average; and these layers do not mix in a uniform mass, but remain in distinct layers.

“If only one sluice, then only every other tide can be used, as the water must run perfectly off, that the surface may incrust; and if the canal be not empty, the tide has not the effect.

“As a new soil is created by this practice, it is of little consequence what the original nature of the land may be, almost all kinds being improved by it. But at the same time it may be the most beneficial in such light soils as are very open and porous, and such stiff ones as are defective in calcareous matter, and which require substances of this kind to render them less tenacious. Land, when once well warped, will continue for a vast length of time in a good state of fertility; but still it is suggested by some experienced warpers as a better practice to apply a small portion of warp whenever the land is in the state of fallow, which will be about every 5 or 6 years, as by this means the farmer will be more secure of having good crops. The depth to which the lands are covered by the tides must be regulated according to their levels, and the height of the tide in the rivers from which they proceed. It may be admitted to the height of 3, or 4, or more feet; but the deposit of sediment is in some measure proportionate to the height of the water, though the same effects may be obtained from much smaller quantities of water by continuing the process a great number of tides.”

The expense of this mode of improving lands must necessarily differ much in different cases, according as the circumstances of situation and distance vary; but, according to Mr. Young, it can seldom exceed 12*l.* or 15*l.* the acre, and in most instances it must be greatly below such estimates.

Warped lands are found capable of growing most kinds of crops in great plenty, but particularly oats, beans, wheat, flax, potatoes, and grass-seeds.

WARRANTY. In horsemanship, &c., a term applied to the assurance of the animal's being sound when purchased. See **BUYING** and **SELLING**.

WARREN. A franchise, or place privileged, either by prescription or grant from the king, to keep beasts and fowls of warren in; as rabbits, hares, partridges, pheasants, &c.

By statute 21 Edw. 3, a warren may lie open, and there is no need of closing it in, as there is a park.

In the forming a warren, great caution is to be used for the fixing upon a proper place and a right situation. It should always be upon a small ascent, if possible, and exposed to the east or the south. The soil that is most suitable is that which is sandy; for when the soil is clayey or tough, the rabbits find great difficulty in making their burrows, and never do it so well; and if the soil be boggy or moorish, there would be very little advantage from the warren; for wet is very destructive to these animals. See **RABBIT**.

WASP (*Vespa*). An extensive genus of insects, of which three species are common to Britain. The hornet, or *V. crabro*, already mentioned; common wasp, or *V. vulgaris*, which makes its nest in the ground; the small wasp, or *V. coarctata*, the nest of which is a kind of paper made of woody fibre and suspended to the boughs of trees.

Of the wasps most commonly known in the United States there are two species, namely, the large, fierce, stinging insect which builds its flat paper nest in bushes, &c., and the more harmless blue-winged mud-wasp, commonly called the mason, from its plastering its nest with mud against the walls of houses, &c. These nests are composed of cells, each one of which contains a single egg, together with a considerable number of living spiders, caught and imprisoned therein solely for the purpose of affording the little mason's young a ready supply of fresh provisions. In noticing this characteristic of the mud-wasp, Dr. Harris also refers to the habits and nests of some other tribes of the same family, such as the holes of the stump-wasp, stored with hundreds of horse-flies for the same purpose; the skill of the leaf-cutter bee in cutting out the semicircular pieces of leaves for her patchwork nest; the thimble-shaped cells of the ground-bee, hidden in clusters under some loose stone in the fields, made of little fragments of tempered clay, and stored with bee-bread, the work of many weeks for the industrious labourer; the waxen cells made by the honey-bee, without any teaching, upon purely mathematical principles, measured only with her antennæ, and wrought with her jaws and tongue; the water-tight nests of the hornet and wasp, natural paper-makers from the beginning of time, who are not obliged to use rags or ropes in the formation of their durable paper combs, but have applied to this purpose fibres of wood, a material that the art of man has not yet been able to manufacture into paper. These are only a few of the objects deserving of notice among the insects of this order; many others might be mentioned, that would lead us to observe with what consummate skill these little creatures have been fashioned, and how richly they have been endowed with instincts, that never fail them in providing for their own welfare, and that of their future progeny. (*Treatise on Des. Insects.*)

Wasps are not only destructive to grapes, peaches, and the more delicate kinds of fruit, but also to bees, the hives of which they attack and plunder, frequently compelling these in-

dustrious insects to change their habitation. The nests of those wasps which build in the earth may be destroyed with hot water or oil; those on trees are best suffocated by lighted brimstone. (*Kollar on Insects*, p. 79.)

Wasps are much affected by cold; so that when winter begins to set in they become less bold and savage, and they all perish, except a few females, as soon as the frost begins. This is a wise provision of nature; for, did they survive the winter, they would soon rival the locust in their destructive depredations.

WASTE LAND. The following is an account of the quantity of land uncultivated and waste in the British dominions, including Scotland, Ireland, and the British islands, according to the evidence of Mr. Cowling before the Emigration Committee in 1827:—

	Uncultivated Acres.	Unprofitable Acres.
England - - -	3,454,000	3,256,000
Wales - - -	530,000	1,105,000
Scotland - - -	5,950,000	8,523,930
Ireland - - -	4,900,000	2,416,664
British Islands - -	166,000	569,469
	15,000,000	15,871,463

WATER. A well-known, universally diffused substance, which in ordinary temperatures is fluid, but is solid when cooled down to 32° of Fahrenheit's thermometer. It rises into vapour at all temperatures, even below the freezing point, and at 212° expands suddenly into steam. It is composed, by weight, of oxygen 8 parts, and hydrogen 1 part.

Water is one of the most useful elements in the arts and manufactures, as well as in rural and domestic economy. The extensive utility of water for imparting motion to machinery, and for domestic purposes, is too well known to require explanation; and as we have already treated of its beneficial properties for irrigating land, under this head we shall have principally to confine ourselves to its uses to plants.

Its Uses to Vegetation.—The value of water to vegetation very early attracted the attention of mankind. In the most ancient of all books, *Genesis* ii. 10, we are told that "a river went out of Eden to water the garden." And the earliest of the Greek and Egyptian philosophers, astonished and confused by the magic effects which water produced upon the rank and luxuriant lands of the warm eastern climates, were loud in their praises of the unaided powers of water to support vegetation. They not only regarded it as one of the four elements of which the world was composed, but Hippocrates considered it to be the substance which nourishes and supports plants and animals. Theophrastus even considered that all metals were produced from water. The opinion that pure water, and water only, was able to support vegetation, was in succeeding ages long the opinion of many philosophers distinguished for their laborious investigations and their ardent love of truth. Amongst these may be named Van Helmont, Bonnet, Duhamel, Tillet, and the illustrious Boyle. These great men deceived themselves, however, by not sufficiently attending to the purity of the water

with which they experimented, or guarding with rigid accuracy against other sources of error. Of the many researches which they instituted to determine this point, none was more apparently conclusive than that of the well-known willow tree experiment of Van Helmont, which long deceived, from its apparent accuracy, the philosophers of that age. This celebrated experimentalist planted a willow which weighed 5 lbs. in a common earthen vessel filled with 200 lbs. of soil, which had been previously thoroughly dried in an oven, and then moistened with only rain-water. This earthen vessel he placed in the earth in a garden, covering it over in such a manner that all access of dust, &c., was prevented. For five years this willow continued to grow, although moistened only with either rain or distilled water. At the end of that period, it was found to weigh 169½ lbs., although the earth in which it was planted, when again dried and weighed, was found to have lost only two ounces of its original weight. Here, then, said the contemporaries of Van Helmont, is an increase of 164 lbs., and yet the only food the willow had was water; it is evident, therefore, that pure water, and water only, is quite sufficient to support vegetation.

Various sources of error were, however speedily discerned to prove that this experiment was totally insufficient to decide this question. The illustrious Bergman, in 1773, showed that the rain-water employed by Van Helmont, so far from being chemically pure, contained sufficient earthy matters to supply the whole of that found in the willow tree. And, in addition to this, it was afterwards shown that unglazed earthen vessels readily imbibe and transmit the moisture of the soil in which they are placed: now this moisture abounds with a variety of solid matters, both organic, earthy, and saline. (*Thomson*, vol. iv. p. 313.)

Still more accurate experiments have been since instituted with water *chemically pure*, with very different results. In this way all attempts to raise plants have in every instance totally failed, although, as I have in another place had occasion to remark, I have fruitlessly varied the attempt in several ways. See LIQUID MANURE.

Although, however, it is, from the result of these laborious researches, pretty clearly proved that water is not the sole food of plants, yet it must be evident to the most casual observer what an indispensable food this universal fluid is to vegetation. To all vegetation, in fact, it is an indispensable necessary of life, although almost every species of plant requires to be supplied with it in varying proportions: some, such as the aerial epidendron, and other Oriental plants, being able to supply themselves from merely the aqueous portion of it which always exists in the atmosphere; while some, such as the rice plant, and the aquatics, cannot prosper without being supplied with it in such copious quantities as would be destructive to the ordinary crops of the farmer. In some proportion or other, however, they all require it, and all attempts have been in vain made to cause plants to grow in situations where moisture was absolutely

removed both from the earth and their surrounding atmosphere.

M. Berthollet was of opinion that the leaves of plants have the power of decomposing water when exposed to the light of the sun. The oxygen gas, according to this distinguished philosopher, which is always emitted under these circumstances, is derived partly from the decomposition of the water. "Indeed," adds Dr. Thomson, "If we consider the great quantity of hydrogen contained in plants, it is difficult to conceive how they should obtain it, provided the water they absorb does not contribute to furnish it." (*System of Chem.* vol. iv. p. 349.) These views open a field for future and highly interesting researches, which will probably lead to the establishing of new facts highly important to the cultivator. And as Davy, the chief of chemists, well said, "We can only reason from facts. We cannot imitate the powers of composition belonging to vegetable structures, but at least we can understand them; and as far as our researches have gone, it appears that in vegetation compound forms are uniformly produced from simpler ones; and the elements in the soil, the atmosphere, and the earth, absorbed and made parts of beautiful and diversified structures." (*Lectures*, p. 314.)

Pure water, therefore, is certainly not capable of entirely supporting vegetation. Yet, although it cannot produce effects so extensive as these, yet its uses are many and important, and it is more than probable that it is decomposed by plants, its oxygen partially evolved, and its hydrogen assimilated with carbon and oxygen into a variety of vegetable substances, most of which contain hydrogen in some form or other: thus

Sugar is composed of—

Hydrogen	-	-	-	-	-	6.18
Oxygen	-	-	-	-	-	49.38
Carbon	-	-	-	-	-	44.44
						100

Gum, of—

Hydrogen	-	-	-	-	-	6.43
Oxygen	-	-	-	-	-	51.46
Carbon	-	-	-	-	-	42.11
						100

Starch, of—

Hydrogen	-	-	-	-	-	6.22
Oxygen	-	-	-	-	-	49.78
Carbon	-	-	-	-	-	44.
						100

It would be difficult indeed to account for the large proportion of hydrogen present in vegetable substances, without we allow that in some instances water is decomposed by the plant. "All the hydrogen," says Professor Liebig, rather too sweepingly, "necessary for the formation of an organic compound is supplied to a plant by the decomposition of water." (*Organ. Chem.* p. 66.)

That plants have a strong attraction for water is evident from a variety of circumstances; thus by their leaves and roots they separate the aqueous vapour of the atmosphere from the gases in which it is contained, and that too

in all ordinary temperatures. This unvaried presence of aqueous vapour in the atmosphere is not less remarkable by the immense importance it is to vegetation; for without the assistance which the farmer's crops derive from it in dry weather, the warmth of the sun would too often in the summer months wither and destroy them. This beautiful arrangement of creative wisdom did not escape the attention of Davy, who noted too the variations in its quantity according to the changing demands of vegetation. The quantity of water, he remarked (*Elements of Agr. Chem.* p. 207), which exists in air as vapour, varies with the temperature. In proportion as the weather is hotter the quantity is greater. At 50° of Fahrenheit's thermometer, air contains about one-fiftieth of its volume of vapour; and as the specific gravity of vapour is to that of air nearly as 10 to 15, this is about one seventy-fifth of its weight. At 100°, supposing that it has a free communication with water, it contains about one-fourteenth part in volume, or one twenty-first in weight. It is the condensation of vapour by the diminution in the temperature of the atmosphere which is probably the principal cause of the formation of clouds, and of the deposition of dew, mist, snow, or hail. The leaves of living plants appear to act upon the vapour likewise in its elastic form, and to absorb it. Some vegetables increase in weight from this cause when suspended in the atmosphere, and unconnected with the soil; such are the house-leek, and different species of the aloe. In very intense heats, adds Davy, and when the soil is dry, the life of plants seems to be preserved by the absorbent power of their leaves; and it is a beautiful circumstance in the economy of nature, that aqueous vapour is most abundant in the atmosphere when it is most needed for the purposes of life, and that when other sources of its supply are cut off, this is most copious.

And, again, when water is combined with saline substances, the roots of plants separate it from them in a very remarkable manner. Some curious experiments of this kind were made by M. Saussure. See SALTS, *their Uses to Vegetation.*

That plants have the power, when nourished only with pure water, of decomposing the carbonic acid gas of the atmosphere, has been shown by some very careful experiments of M. Saussure. He found that some sprigs of peppermint, when supplied with pure water only, and allowed to vegetate for some time in the light, nearly doubled the portion of carbon which they originally contained. The quantity of water which, under ordinary circumstances, plants absorb, is very considerable; thus, Dr. Hales ascertained that a cabbage transmits into the atmosphere, by insensible vapour, about half its weight of water daily; and that a sunflower, 3 feet in height, transpired in the same period nearly 2 lbs. weight. (*Veg. Statics*, vol. i. p. 5, 15.) Dr. Woodward found that a sprig of mint, weighing 27 grains, in 77 days emitted 2543 grains of water. A sprig of spearmint, weighing 27 grains, emitted in the same time 2558 grains. A sprig of common nightshade, weighing 49 grains, evolved

3708 grains, and a lathyrus of 98 grains emitted 2501 grains.

In a previous page of this Encyclopædia, I have endeavoured to show the various uses of the carths to vegetation. (See **EARTH**.) The cultivator will observe how many of their chief fertile properties are connected with their attraction for the aqueous vapour of the atmosphere, their powers of absorption, their capability of retaining it. It is in vain, indeed, by any contrivance to attempt to make plants of any description vegetate in absolutely dry earth, or in air from which the aqueous vapour is entirely withdrawn. It is true that some of the flowering roots of the East, and some of the mosses of our own country, almost appear to do so; but such plants support themselves by absorbing a certain degree of moisture, even when suspended, as in oriental countries, by a silken cord from the ceiling of the room, or from apparently dry brick walls; for when by chemical means the moisture is entirely removed from them, even these hardy plants cease to vegetate.

Various foreign substances have been supposed to exist in minute proportions in rain-water, to which its fertilizing effects have been chiefly ascribed: thus ammonia is believed by Professor Liebig to exist in rain-water. Nothing, however, is more likely to lead to erroneous general conclusions than the detection of minute foreign substances in water. Such hasty generalizations have often deceived the most excellent philosophers: thus the great Boyle, by digesting pure water for a lengthened period in glass vessels hermetically sealed, found that it deposited a minute quantity of flint in powder; and hence he was led to conclude that water was in this way converted by long boiling into silica, an error which several other philosophers adopted, until the celebrated Lavoisier and Dr. Priestley proved that the flint deposited arose from the water having, by long boiling, partially dissolved the glass. In the same way even Davy, the most cautious of experimentalists, once thought that chlorine and soda might, by the influence of the voltaic pile, be obtained from water absolutely pure; but more careful and rigid experiments soon convinced him of the extreme difficulty of procuring entirely pure water, the vessels in which the water was procured communicating, with every apparent caution, sundry impurities; and this difficulty, I think it very likely, the skilful chemists of Germany have not successfully escaped.

Water exists in all cultivated land in some proportion or other. The quantity, however, necessary to be present in the farmer's soils to obtain the maximum advantage varies with their nature, the climate, and the crop. For instance, the rice-fields of India require a degree of moisture which would be utterly destructive to the grain crops of the English farmer. The most porous, sandy land in a rainy climate will be prolific, when the same soil in a dry, warm country will be absolutely barren. Even the drifting sands of Arabia, for instance, if placed under the incessant rains of the American Andes, would certainly be speedily covered with vegetation. Some of the richest water-

meadows of the south of England and of Scotland are formed on subsoils of broken flints, gravels, and the roughest shingle. And, again, the meadow-lands often need such copious supplies of moisture as would be the means of destroying the grain crops. The surface water which tenants many uncultivated soils is generally surcharged with a variety of foreign substances, very commonly with vegetable matters. That in the gravelly soils is usually surcharged with oxide of iron; that resting on calcareous soils, with sulphate of lime (gypsum); whilst those from peat lands commonly abound with sulphate of iron, or the red oxide of the same metal.

In most of the soils which the farmer has to bring into cultivation, the removal of these waters is his first care; for such an abundance of moisture is not only pernicious, from the usual bad quality of the land water, but from the quantity being far too great for the habits of the plants which the farmer intends to cultivate; such waters, too, dissolve, and sometimes carry off from the soil, in their imperceptible drainage, all the soluble richest portion of the soil. For many reasons, therefore, draining has been long very justly held to be the foundation of all agricultural improvements; since its good effects are not confined to the low marsh land, but its beneficial influence is extended to the most upland soils. It removes the land springs, and dries the surface of thousands of acres of even the most elevated of the English gravels.

Almost to an equally beneficial extent has the addition of water to plants for a lengthened period been carried on by the cultivator in a variety of modes; by the gardener, either in steam in his conservatories, or by the watering-pot in the open ground. Almost endless, indeed, are the varieties of artificial irrigation, from the minor applications of the gardener to the more gigantic efforts of the managers of the water-meads. It is this branch of the investigation of the uses of water to vegetation which is the most interesting to the farmer, and to the head **IRRIGATION** I must refer the reader. In regarding the uses of water to vegetation in this manner, however, the cultivator must remember that it is not *pure* water that he is thus using for his crops, but, as I have before remarked, water surcharged with a variety of earthy, saline, and organic matters, to whose presence a chief portion of the fertilizing effect of such streams must be attributed; for it is found that the most foul and impure waters are much the best for the purposes of irrigation: thus the water of a river below a town is found to be much more fertilizing than the same water before it has been mixed with the contents of the sewers. These are facts well known, for instance, to the owners of the fine water meadows of the valleys of the Itchen, the Kennet, and the Avon. That of the Thames above the influence of the tide is not nearly so valuable to the grazier as it is after it has had mixed with its waters the huge mass of impure matters from the London sewers. Then, again, by far the richest irrigating waters, because the very foulest of all, are those of the sewers of the city of Edinburgh, which produce such singu-

larly luxuriant crops of grass on the Craigin-tinny meadows. This observation is not confined to the English graziers: those of the duchy of Milan long since made the same remark. Half a century since, Mr. Songa, when describing the meads of the banks of the Brembo, says, "That water is found excellent which passes through the fosses of the town of Treviglio, and discharges itself from them by forming a canal of 8 or 10 feet broad, and 1 foot or 1½ foot deep. The lands irrigated with this water seem to receive every time the advantage of a dunging, and on this account sell from a third to a half dearer than any other of an equal quality of soil." (*Young's Annals*, 1793, p. 182.) Watering the land to add to its fertility is a very ancient practice.

Such, then, are a few of the well-ascertained facts with regard to the application of water to vegetation, uses which are so valuable when well understood by the farmer. In all his operations this universal fluid will be found to influence his arrangements; and in a due and regular supply of it to his crops consists, in fact, the success of most of his efforts. If, for instance, a farmer would judge of the value of a particular field from merely a specimen of its soil, the attraction of the previously dried earth for the moisture of the atmosphere will afford a very tolerable indication of its comparative value; those soils which attract the most water being commonly those which obtain the highest rents.

All researches like these, in many obvious and indirect ways, are attended with considerable advantage to the cultivator. For, the more he becomes acquainted with the uses and properties of water, the more readily will he be able to avail himself of every opportunity which may present itself for extending its sphere of usefulness. It is idle to conclude that every thing possible has been effected with regard to the agricultural uses of water; for, saying nothing of the inferior extent of our water meads to those of even the banks of the Italian rivers, much still remains to be accomplished in rendering available, not only the liquid drainage of our large towns, but in the use of the steam-engine for the purposes of irrigation; an agent to which I have in this work already alluded, and for obtaining whose magic assistance the farmers of no other country are so well situated as those of our own island. To the cultivator, therefore, an examination of the powers and properties of water will in many ways be attended with benefit; for if the farmer once seriously contemplates the powerfully invigorating and enriching qualities of the waters near to which he is very often placed, the abundance of organic matters which they contain, and the advantages to be derived from their judicious application, he will speedily devise some means or other by which he may avail himself of this too often neglected agent. The finely divided earthy and organic matters which now so copiously pollute the waters of our rivers are in fact the only great drawbacks upon the otherwise gradually increasing productiveness of the land. (See **AL-LUVIUM** and **WARFING**.) These, be it remembered, are ever quietly yet incessantly acting

as drains upon the fertility of the land; they never cease the work of impoverishment; and it is only by the efforts of the merchant, the fisherman, and the irrigator, that any portion of these finely divided matters ever return again to the cultivated soils of our country. See **IRRIGATION** and **RAIN**.

WATER-ALOE, or **WATER SOLDIER** (*Stratiotes aloides*; from *stratos*, an army, in allusion to its long sword-like leaves). In England, an ornamental native aquatic, which fills the ditches in summer with a close phalanx of sword-like leaves, and increases so fast in the ponds where it is planted as to become almost a troublesome weed. In its wild state it inhabits deep ditches and pools, and is a stoloniferous, smooth, floating herb, with numerous radical leaves, and a solitary central flower-stalk, but no stem. The parent plant sinks to the bottom after flowering, and sends out long simple runners, each terminating in a leaf, bud, or young plant, which first takes root in the mud, by several long fibres, and in the following summer rises to the surface of the water, blossoms and then again subsides to ripen its seeds and throw out fresh runners, each tuft of leaves flowering but once. The leaves are a span long or more, acute, highly vascular, fringed with very sharp saw-like teeth. Flowers white, large and handsome, the stalk firm, stout, two-edged, much shorter than the leaves.

WATER-MELON. The following directions for cultivating water-melons for an early market, are given in the *Southern Agriculturist*.

Select a high and dry soil for the purpose. Plough it up well, and harrow it. Check off the spot thus treated at distances of 10 feet each way. Dig out each check with a hoe or spade, and into the same place 5 or 6 quarts of cotton seed; or if this cannot be procured, fill the place with stable manure, partly decomposed. Haul over this the earth before dug from the hole, and mix it well with the manure. If you have used cotton seed, in the spring, it will have sprouted a week or two after being put into the hole; and must now be killed by chopping up the same well, and mixing it with the soil. This being done, you may now haul up the manure and earth as before directed, into hills, on the top of which you must place about a peck of sand, taken from some street or well-travelled road. Your hills will be now ready for planting. I should, however, state that the hills must, instead of being made high, be made flat and broad.

Soak your seed over night in milk-warm water, and plant them out the next morning, placing from 5 to 6 seed to each hill. The

seed must not be covered more than 1 or 2 inches under ground. Water the hills for a few days until the seed has sprouted, and then leave the plants to run.

As soon as the plant has got 6 leaves, take off the centre plant with a sharp penknife, and when the lateral shoots are 6 inches or a foot long, take off all but three. When the shoots, thus left, begin to run to the ground between the hills, stake them down with a small cross-stick.

As the vines begin to branch, at every 3 or 4 feet, where the vine branches, put a shovelful of rich earth over the same, and press it down lightly with the foot. Wet weather should be selected for this operation, and by so doing the vines will never fail to take where they have been set. The spaces between the hills should be kept free of grass—and by following the above directions, large melons will be produced.

From a quarter acre of land thus treated, more melons will be made than from four times the amount as usually cultivated. See MELON, WATER.

WATER-PEPPER (*Polygonum punctatum*). A plant found in the Middle and other States, possessing very acrid qualities, causing obstinate ulcerative inflammation when applied to the skin.

WATER-PLANTAIN (*Alisma*, from the Celtic *alis*, water). A genus of pretty little, aquatic, perennial, smooth plants, with simple, entire leaves, and numerous, stalked, white, yellowish or purplish, paniced or umbellate inodorous flowers. In England, there are four native species; viz.:

1. The greater water-plantain, or thrumwort (*A. plantago*), which is very common in pools, ditches, and about the margins of rivers. The root is fibrous. Leaves all radical, on long stalks, erect, ovate, acute, ribbed, in deep or running water lengthened out more or less. It has been recommended in hydrophobia; but, like many other wonder-working remedies, it is worthless.

2. Star-headed water-plantain (*A. damasonium*), found in ditches and pools on a gravelly soil, but not common. The root consists of many long pale fibres. The leaves all radical, floating, bluntnish or oblong, heart-shaped at the base. Footstalks very broad, with many ribs, and a membranous border, tapering upwards. Flower-stalks scarcely a span high, bearing 1 or 2 whorls of white flowers, yellow in the middle. Capsules six, spreading in the form of a star, half-ovate.

3. Floating water-plantain (*A. natans*). This species frequents the lakes of North Wales and Cumberland.

4. Lesser water-plantain (*A. ranunculoides*). This grows in swamps and turfy bogs, but is not a very common species.

5. Creeping water-plantain (*A. repens*). This has only been found on the margins of some of the lakes in North Wales.

WAX (Germ. *wachs*). A solid concrete abounding in the vegetable kingdom, whence it is erroneously supposed that it is collected by bees. Bees' wax is a secretion in the body of the bee, and is accumulated in what are

called the wax-pockets. Bees confined to a hive, and fed merely on sugar, form wax. It constitutes the partitions of the cells in which they store their honey. It is obtained by melting the comb. Wax, when pure, is of a whitish colour; it is destitute of taste, and has scarcely any smell. Bees' wax, indeed, has a pretty strong aromatic odour; but this seems chiefly owing to some substance with which it is mixed; for it disappears almost completely by exposing the wax, drawn out into thin ribands, for some time to the atmosphere to blanch, frequently changing the surface thus exposed, by remelting it, and reducing it again to thin flakes. By this process, which is called *bleaching*, the yellow colour of the wax disappears. White wax is principally used in making candles, and in white ointments, for the sake of its colour. Wax is insoluble in water; nor are its properties altered though kept under that liquid. When heat is applied to wax, it becomes soft; and at the temperature of 142°, if unbleached, or of 155°, if bleached, it melts into a colourless transparent fluid, which concretes again, and resumes its former appearance, as the temperature diminishes. If the heat be still further increased, the wax boils and evaporates; and if a red heat be applied to the vapour, it takes fire and burns with a bright flame. It is this property which renders wax so useful for making candles. Wax combines readily with fixed oils when assisted by heat, and forms with them a substance of greater or less consistency, according to the quantity of oil. This composition, which is known by the name of cerate, is much employed by surgeons.

According to the experiments of Gay-Lussac and Thenard (*Rech. Physico-Chim.* vol. ii. p. 316), 100 parts of wax are composed of—

						Parts.
Oxygen	-	-	-	-	-	5.54
Hydrogen	-	-	-	-	-	12.67
Carbon	-	-	-	-	-	81.78
						100

Wax is sometimes adulterated with the white oxide of lead to increase its weight, with white tallow, and with potato starch. The first is detected by melting the wax in hot water, when the oxide falls to the bottom undissolved; the presence of tallow is indicated by the wax being of a dull opaque white, and wanting the transparency which distinguishes pure wax; and starch may be detected by applying strong sulphuric acid to the suspected wax, as the acid carbonizes the starch without acting on the wax.

Notwithstanding the large supply of wax produced in England, a considerable quantity is imported from abroad; but it is subject to the high duty of 1*l.* 10*s.* per cwt. The price varies, duty included, from 5*l.* to 10*l.* per cwt (*Thomson's Chem.* vol. iv. p. 103; *Thomson's Dispensatory*; *McCulloch's Com. Dict.*)

WAX-MOTH. See BEE-MOTH, and Pl. 16, g.
WAY-BREAD. One of the common names of the Common or Great Plantain.

WAYFARING TREE. See GUELDER ROSE

WAY-GOING CROP. That which is taken from the land the year the tenant leaves a farm

WAY, PRIVATE RIGHT OF. This may arise either from grant or by prescription and usage from time immemorial, for this is in law supposed to arise from a grant. According to English common law, a right of way may be to a particular person to go over the grantor's land to church, to market, or to any particular close. Such a special permission is, however, to be construed strictly: the grantee cannot, under such a grant, justify going beyond the place specified in the grant; nor can he take any other person with him; neither can he assign over this right,—it dies with him. And a grant for agricultural purposes does not authorize the grantee to use the road for commercial or general purposes; neither does a prescriptive right of way for all kind of carriages, prove a right of way for all manner of cattle. If a grantor convey a piece of ground in the middle of his own land, the law will presume that he also granted a way to it. "When," said Lord Kenyon, in this case, "they made the conveyance, it must be taken for granted that they intended to convey some beneficial interest; but he can derive no benefit whatever from the grant unless he has a right of way to the land." But if by purchasing other land, or new circumstances afterwards arise by which he can approach the public road, then the right of way ceases with the necessity. And if a private way is granted, that does not justify a person for going over the land by the side of it, even if the road is overflowed with water from an adjoining river. Lord Ellenborough, C. J., said, in this case, "It is a thing founded in grant, and the grantor of a private way does not grant a liberty to break out of it at random over the whole surface of his close."

By the 2 & 3 W. 4, c. 71, it is enacted, that in all claims for right of way by prescription, where it has been enjoyed for 20 years, such right shall only be defeated or destroyed by showing that such right was first expired at any time previous to such 20 years; and where it has been enjoyed for full 40 years, the right shall be absolute and indefeasible, unless it shall appear that the same was enjoyed by some consent or agreement by deed or writing.

WEANING. The means employed to reconcile a young animal to the loss of its mother's milk, and habituate it to take common food. Under the head FOAL we have already given directions for their management during and after weaning. The process of weaning calves is variously managed by different farmers. When not let run with the cow, the most advisable mode, as it regards the calf, is to place it loose in a crib, and to suckle it by hand with the mother's new milk, of which it will consume for some time not more than about four quarts per day: the quantity, however, must then be gradually increased, as it will, in the course of a few weeks, require as much as three gallons. If the weather be fine, it should be, within a fortnight or three weeks, turned out daily in the orchard, or some well-sheltered enclosure of sweet herbage; and, as it will in the course of 10 or 12 weeks have acquired some relish for the pasture, it may be regularly weaned by gradually diminishing the

quantity of milk, and then substituting the skimmed for the new. Calves may, however, be reared with skimmed milk and meal, without any portion of new milk, except the first few days' biestings, and many persons give them nothing but water-gruel and hay-tea within a fortnight after they have been removed from the cow. Sago and linseed jelly are also very nutritious, and calves may be weaned on them without any other food. (*British Husb.* vol. ii. p. 441.)

The time of weaning lambs differs materially, according to the locality of the farms and the quality of the pasture. Four months old is about the period usually selected.

The lambs should be turned into somewhat better pasture than that to which they had been accustomed, in order to compensate for the loss of the mother's milk. Many farmers are very fanciful as to the provision for the weaned lambs. The clover or the sainfoin, or the aftermath, are selected by some; others put their smaller and more weakly lambs to weed the turnip crops; but there can be nothing more desirable than a fresh pasture, not too luxuriant, and yet sufficient to maintain and increase their condition. (*Youatt on Sheep*, p. 516.) For directions as to weaning pigs, see SWINE.

WEASEL-SNOUT (*Galeobdolon luteum*). The weasel-snout, yellow archangel, or dead nettle, is a pretty, indigenous, perennial plant, found abundantly in most parts of England, in marshy, shady places. The root is somewhat tuberous, moderately creeping. The stems are 18 inches high, simple, leafy, covered with close deflexed hairs. Leaves stalked, ovate, acute, serrated, slightly hairy, bright green, various in breadth. Whorls numerous, each composed of many large, handsome, inodorous yellow flowers, whose lower lip is spotted with red, the middle segment stained with orange-colour. The flowers afford to bees an abundant supply of honey.

WEATHER (Sax.). A term applied to denote the state or disposition of the atmosphere, with regard to heat and cold, drought and moisture, fog, fair or foul, wind, rain, hail, frost, snow, &c.

A knowledge of this is of vast importance to the farmer, as the securing of his produce in a perfect manner greatly depends upon it; and as it is in and by means of the atmosphere that plants are nourished, and animals live and breathe, any alteration in its density, heat, purity, &c., must, of course, necessarily be attended with proportionable effects on organization.

The great but regular alterations a little change of weather makes in many parts of inanimate matter is fully shown in the common instances of barometers, thermometers, hygrometers, &c.; and it is owing partly to our inattention, and partly to other causes, that man, like other animals, does not feel as great and as regular ones in the tubes, chords, and fibres of his own body.

In order fully to establish a proper theory of the weather, it would be necessary to have registers carefully kept in different parts of the globe for a long series of years, whence we

might be enabled to determine the directions, breadth, and bounds of the winds, and of the weather they bring with them; with the correspondence between the weather of divers places, and the difference between one sort and another at the same place; and thus, in time, learn to foretell many great emergencies; as extraordinary heats, rains, frosts, droughts, &c. But hitherto very few, and only partial, registers or accounts of the weather have been kept. The Meteorological Society of Great Britain, and the British Association for the Advancement of Science, have latterly done much towards increasing our stock of meteoric knowledge, and have collected an immense body of facts and registers, from which many useful inferences have been drawn, and some important theories deduced. The general conclusions that have been drawn from the experiments that have been made on this subject are—that barometers generally rise and fall together, even at very distant places, and a consequent conformity and similarity of weather; but this is the more uniformly so, as the places are nearer together, as might be expected;—that the variations of the barometer are greater as the places are nearer to the pole: thus, for instance, the mercury at London has a greater range by 2 or 3 lines than at Paris; and at Paris, a greater than at Zurich; and at some places near the equator there is scarcely any variation at all;—that the rain in Switzerland and Italy is much greater in quantity for the whole year than in Essex; and yet the rains are more frequent, or there are more rainy days, in Essex than at either of these places;—that cold contributes greatly to rain, apparently by condensing the suspended vapours, and so leading to their precipitation; thus, very cold months or seasons are commonly followed immediately by very rainy ones, and cold summers are always wet ones. High ridges of mountains, and the snows with which they are covered, not only affect the neighbouring places, but even distant countries often partake of their effects.

The science of meteorology, or the study of the changing phenomena of the atmosphere, &c., has from the earliest periods occupied a greater or less share of attention from the tiller of the soil, the gardener, and those engaged in the pasturage of animals. To no individual (the mariner, perhaps, excepted) is a foreknowledge of the probable future state of the weather of more consequence and importance than the agriculturist; for on this must mainly depend the progress and success of his field operations, his seedtime and his harvest, and the greater or less return afforded by his crops.

It may not comport with the dignity of the man of science, or the elevated learning of the erudite philosopher, to have his eyes and ears open to the plain and simple rules and guides which nature lays out before him. Perhaps he has little of leisure to note the every-day phenomena which the atmosphere and all animate and inanimate nature hold up to observation, as in a glass, where all who use their eyes may read as they run. The companions of his study are the more costly and elaborately pre-

pared philosophical instruments: how much, however, might their value be enhanced by a careful and comparative observation of the "skye influences," as the poet terms them! But to these closet companions, the husbandman, the shepherd, the traveller, the fisherman, and the mariner have rarely access, while engaged in the busy out-of-door occupations of their several avocations. Those who till the land, or who go down to the sea in ships, of all others, are they who become, by habits of observation and reflection, most conversant with the signs and changes of the heavens; the sun, the moon, and the stars are to them monitors and instructors, whose warning voices meet a prompt and ready response. The ripple of the wave, the curl of the smoke, the passing shadow of the cloud, the budding of the tree, the arrival and departure of the migratory birds, the frolicsome gambols of animals, every leaf that quivers in the sunbeam, every plant that drinks the dew of heaven, the myriads of insects, and creeping things innumerable, that inhabit each leaf and opening flower, are all fraught with instruction and information to the experienced and watchful observer.

Around, above, beneath, all animate and inanimate creation, animals, vegetables, the elements, a thousand objects in a thousand directions, in every recurring season, furnish their quota of information towards our stock of meteoric knowledge, and foretell the approaching variations of atmospheric phenomena. The experienced fisherman and the watchful and wary mariner will predict the coming storm, by the tiny cloud and other unerring criteria which frequent and attentive observance of the sky has rendered familiar, long before its approach is visible to the ken of the ordinary and inattentive observer.

It has been well remarked, that "the shepherd, whose sole business it is to observe what has a reference to the flock under his care, who spends all his days and many of his nights in the open air, under the wide-spread canopy of heaven, is obliged to take particular notice of the alterations of the weather; and when he cares to take a pleasure in making such observations, it is amazing how much progress he makes in them, and to how great a certainty he arrives at last, by mere dint of comparing signs and events, and connecting one observation with another. Every thing in time becomes to him a weather-gauge: the sun, the moon, the stars, the clouds, the winds, the mists, the trees, the flowers, the herbs, and almost every insect, animal, and reptile with which he is acquainted—all these become, to such a person, instruments of real knowledge."

To the farmer, a careful study of the weather, and of the inferences to be drawn from precedent, and from natural and artificial data, come fraught with numerous and important considerations. Like the angler, the husbandman "must observe the wind, sun, and clouds by day; the moon, stars, and wanes of the air by night." Few are so entirely dependent on the caprice of the weather, for the commonest routine operations of the farm, as the agricul-

turist. And how soon may his fairest crops be blighted by adverse and unfavourable seasons, or by the baneful effects of scorching and arid winds, of severe frosts, of heavy rains. Some winds come fraught with disease and death; murrain, malaria, and epidemics, in hot, dry seasons, commit fearful ravages among his live-stock; and these are frequently to be attributed to some mysterious atmospheric agency: other winds bring swarms of noxious insects and predatory birds to our shores; the lightning and the whirlwind level his plantations or fire his ricks; the hail-storm, and the frost, and excess of rain, damage and destroy his growing crop, or that to which he has looked for reward and profit for all his toil and outlay.

The various casualties and diseases to which his crops are liable are frequently attributable to, and certainly much aided by, the state of the weather and conditions of the atmosphere. Information relative to many of the important phenomena connected with the atmospheric states and changes, will be found dispersed through this work under various heads, such as **ATMOSPHERE, ALTITUDE, BAROMETER, CLIMATE, DEW, FOGS, FROST, HOAR FROST, LIGHTNING, RAIN, SNOW, MOON, Influence of, &c.**

As means of prognosticating the future states of the weather, data, either natural, artificial, or both combined, are usually referred to. In the natural data are included those of—

1. The vegetable kingdom; many plants shutting or opening their flowers, contracting or expanding their parts, &c., on approaching changes in the humidity or temperature of the atmosphere.

2. The animal kingdom; most of those familiar to us exhibiting signs on approaching changes, of which those by cattle and sheep are more especially remarkable.

3. The mineral kingdom; stones, earths, metals, salt, and water of particular kinds, often affording indications of approaching changes.

4. Appearances of the atmosphere, the moon, the general character of seasons, &c. The characters of clouds, the prevalence of particular winds, and other signs, are very commonly attended to.

The *artificial data* are the various meteorological instruments, as the barometer, hygrometer, pluviometer, and thermometer, &c., which are all extremely useful aids to the farmer.

It is a very common error to predict the future state of the season from some *single* appearance in the commencement of it, as an early bee, an early bud or blossom, the premature appearance of a swallow; but this is both unphilosophical and fallacious.

In England a moist autumn, succeeded by a mild winter, is generally followed by a dry and cold spring, in consequence of which vegetation is greatly retarded. Should the summer be uncommonly wet, the succeeding winter will be severe; because the heat or warmth of the earth will be carried off by such unusual evaporation. Farther, wet summers are mostly attended with an increased quantity of fruit on the white-thorn (*Mespilus oxycantha*) and dog-

rose (*Rosa canina*); nay, the uncommon fruitfulness of these shrubs is considered as the presage of an intensely cold winter.

A severe winter is supposed to be indicated by the appearance of birds of passage at an early period in autumn; because they never migrate southward till the cold season has commenced in northern regions. Great storms, rains, or other violent commotions of the clouds, produce a kind of crisis in the atmosphere; so that they are attended with a regular succession either of fine or of bad weather for some months. An unproductive year mostly succeeds a rainy winter, as a rough and cold autumn prognosticates a severe winter. Very cold months or seasons are commonly followed immediately by very rainy ones, and cold summers are always wet ones.

Plants.—The sensitive indications afforded us by many plants first claim attention, and will be found amply to repay the time that may be bestowed upon the singular properties inherent to them.

Very many of our most common plants are unerring guides for the foretelling rain and other atmospheric changes. The opening and shutting of some flowers depends not so much on the action of the stimulus of light as on the existing state of the atmosphere, and hence their expansion or contraction betokens change.

The common chickweed or stitchwort (*Stellaria media*) may be considered a natural barometer; for if the small, white, upright flowers are closed, it is a certain sign of rain; while during dry weather they expand freely, and are regularly open from nine in the morning till noon. After rain they become pendent, but in the course of a few days they again rise.

The purple sandwort (*Arenaria rubra*) is another example of a true prophet prior to a coming shower. The beautiful pink flowers expand only during sunshine, and close at the approach of evening or before rain.

The pimpernel (*Anagallis arvensis*) has been very justly named “the poor man’s weather-glass.” This little plant blooms in June in our stubble-fields and gardens, and continues in flower all the summer. When its tiny brilliant red flowers are widely expanded in the morning, we may generally expect a fine day; on the contrary, it is a certain sign of rain when its delicate petals are closed.

The goat’s-beard (*Tragopogon pratensis*) will not uncloset its flowers in cloudy weather. From its habit of closing its flowers at noon, this plant has received the common name of “Go-to-bed-at-noon,” and in many districts the farmers’ boys regulate their dinner-hour by the closing of the goat’s-beard.

It is stated in *Keith’s Botany*, that if the Siberian sow-thistle shuts at night, the ensuing day will be fine; and if it opens, it will be cloudy and rainy.

When the African marigold remains closed after 7 o’clock in the morning or evening, rain may be expected. If the trefoil and the convolvulus contract their leaves, thunder and heavy rain may be expected. Lord Bacon tells us that the stalks of the trefoil swell and grow more upright previous to rain.

The dark and lovely gentianella opens its blue eyes to greet the midday sun, but closes its petals against the shower.

The germander speedwell (*Veronica chamaedrys*), so universal a favourite in every hedge-row, closes its blue corolla before rain comes on, opening again when it ceases. The red campion (*Lychnis diurna*) uncloses its flowers in the morning. The flowers of the white campion (*Lychnis vespertina*) open and expand themselves towards the approach of night. The wood sorrel (*Oxalis acetosella*, "la Petite Oseille," or *Suselle*, of the French), an unobtrusive, elegant little inhabitant of the moist, shaded bank, as soon as night approaches, as it is of too delicate a structure to bear the storm, closes up its curious triple leaves, hanging its flowers towards the earth, thus preserving the more tender parts from injury; but as soon as the morning sun arises, these expand and regain their beauty. Most of the Hieraciaceae, or hawkweed tribe, also open their flowers with the morning light, going to sleep again in the afternoon. The clear, bright, and gay flowers of the succory (*Cychorium intybus*) foretell the commencement of the daylight. Another of the components of Flora's clock which deserves a passing word, is the common daisy (*Bellis perennis*), opening at sunrise, and closing its flowers at sunset: hence by Chaucer called the "Eie of Day." The great white ox-eye (*Chrysanthemum leucanthemum*), foretelling the coming storm, closes its flowers. The flowers of the alpine whitlow grass (*Draba alpina*), the bastard feverfew, the winter green (*Trientalis Europaea*), all hang down in the night as if the plants were asleep, lest rain or the moist air should injure the fertilizing pollen. The common nipplewort (*Lapsana communis*), that lovely gem, the white water-lily (*Nymphaea alba*, "the naiad of the river;") and several of the diadelphous tribe of plants, in serene, calm weather expand their leaves in the day-time, and contract them during night.

Animals.—Among quadrupeds the following are believed to indicate, by their restlessness and peculiar actions, a foreknowledge of approaching changes of weather. When horses stretch forth their necks, neigh much, snuff the air with distended nostrils, and assemble in the corner of a field with their heads to leeward, rain may be expected.

Sheep are seen running to and fro, jumping from the ground, and in their gambols apparently fighting, previously to a change of weather. Fine weather may be expected to continue when cattle lie in the open field or in the courts instead of the sheds; when sheep take up their lair for the night on the brow of a knoll; when pigs lie down for the night without covering themselves up in litter. Bad weather is said to be prognosticated when asses hang their ears forward, or rub themselves against walls or trees. Swine also become uneasy, restless, grunting and squealing loudly, and return to their sties. Before rain dogs are apt to grow very sleepy and dull, and to lie all day before the fire, showing a reluctance to food, except grass. When cats lose their vivacity, remaining within doors, wet or windy weather may be expected. Finally, when rats

and mice are more than usually restless, forsaking the fields and ditches, approaching rain may be anticipated.

Fallow deer, and many other animals, becoming restless from the uneasiness they feel owing to the altered condition of the atmosphere, prognosticate the approach of rain. If frogs croak more than usual—if toads issue from their retreats in great numbers—if earthworms come forth from their holes—if moles throw up the soil more than usual—if pigs shake and spoil the stalks of the corn—if oxen lick their forefeet—all these signs are said to indicate rain.

It may be remarked that, in summer, when sheep rise early in the morning, it is a sure sign of either rain or a very hot day; and that in all seasons when they jump and play about it is a sign of rain or wind (but generally both) in the summer, and very stormy weather in the winter.

In winter, when the sheep lie under a hedge, and seem loth to go off to pasture, and bleat, it is considered a sign of a storm.

When rabbits come out to feed early in the evening, it is a sign of rain in the night in summer, and of either rain or snow in winter; and when it is likely to be a bad night, they will be apt to return to their burrows before it is dark.

Next, with respect to *birds*: there is an old saying that "when swans fly it is a sign of rough weather," and the correctness of this saying would appear to be proved. A late writer states that he had invariably found that when the swan flies any distance against the wind, however fine the weather may be at the time, so sure will a wind, almost amounting to a hurricane, arise within 24 and generally 12 hours after the bird has taken flight. The early appearance of woodcocks, snipes, fieldfares, and other birds of passage, &c., are prognostics of severe winters. When owls hoot and screech during bad weather, it is a sign of coming fine weather. The missletoe thrush (*Turdus viscivorus*) frequently sings particularly long and loud before rain, and sometimes even during severe storms: hence it is termed the "storm-cock." The blue macaw is said to be a true indicator of the changes of the weather. Dr. Thornton is stated to have had one some years ago whose blue feathers assumed a greenish hue in rainy weather, or gray in clear weather, if likely to change for wet.

When cranes fly exceedingly high, in silence, and ranged in order, it is said to indicate fine weather; but if their flight is in disorder, and they speedily return with cries, it foretells wind. If fowls roll themselves in the sand more than usual, it denotes rain; also when the cocks crow in the evening, or at unusual hours. When peacocks cry at night, rain may shortly be expected. When peacocks roost on the tops of houses, when the raven sails round and round high up in the air, and when the song-birds carol late in the evening, the weather will continue fair.

The croaking of crows is said to indicate fine weather. When ducks and geese fly backwards and forwards, and frequently plunge into the water, or send forth cries; or when pigeons return slowly to their houses, the probability

is that the succeeding day will be rainy. It is a sign of rain or wind when sparrows chirp a great deal; if the redbreast be seen near houses; or swallows fly near the ground, or brush the surface of the water. When sea-fowl and other aquatic birds retire to the sea-shore, or more inland, it generally indicates a change of weather. If larks or kites soar high, and continue so for some time, it is generally a sign of fine weather. If the kingfisher disappear, expect fine weather. If swallows and martins fly lower than usual, foul weather may be expected.

Mr. Yarrell, in his *History of British Birds*, vol. iii. p. 117, records an instance of instinct, showing how useful an attention to the movements of animals, &c., might occasionally prove:—"I am indebted to the kindness of Lord Braybrooke for the following account of a female swan, on the small stream at Bishop's Stortford. This swan was 18 or 19 years old, had brought up many broods, and was highly valued by the neighbours. She exhibited, some 8 or 9 years past, one of the most remarkable instances of the power of instinct that was ever recorded. She was sitting on four or five eggs, and was observed to be very busy in collecting grass, weeds, &c., to raise her nest; a farming man was ordered to take down half a load of haulm straw, with which she most industriously raised her nest and the eggs $2\frac{1}{2}$ feet; that very night there came down a tremendous fall of rain, which flooded all the malt-shops, and did great damage. Man made no preparation; the bird did. Instinct prevailed over reason; her eggs were above, and only just above, the water."

The same author, in his account of the green woodpecker (*Picus viridis*), known in some localities as the "rain-bird," from being very vociferous when rain is impending, alludes to the probable means by which birds and some other animals become cognisant of approaching changes in the weather. The following is the rationale referred to:—

"It is highly probable that no change takes place in the weather without some previous alteration in the electrical condition of the atmosphere, and we can easily understand that birds, entirely covered as they are with feathers, which are known to be readily affected with electricity, should be susceptible of certain impressions, which are indicated by peculiar actions; thus, birds and other animals, covered only with the production of their highly sensible skin, become living barometers to good observers." (*Yarrell's British Birds*, vol. ii. p. 136.)

Insects, being very sensible of every change in the atmosphere, are good weather guides.

When gnats collect themselves before the setting sun, and form a sort of vortex in the shape of a column, it announces fine weather. If they play up and down in the open air near sunset, they presage heat; if in the shade, mild and warm showers; but if they sting those passing them, cold weather and much rain may be expected.

If garden spiders break off and destroy their webs, and creep away, expect continued rain and showery weather.

If spider webs (*gossamer*) fly in the autumn, expect fine weather.

The following curious observations on the singular foreknowledge possessed by the spider are extracted from a little work entitled *The Pocket Barometer*. This despised insect oftentimes indicates a coming change in the weather 10, 12, or 14 days previous to its taking place. The following directions will be a guide to the curious in their observations of this insect:—If the weather is likely to become rainy, or windy, spiders fix the terminating filaments on which the whole web is suspended unusually short. If the terminating filaments, on the contrary, are very long, the weather will be serene, and continue so for 14 days. If spiders be totally indolent, rain generally ensues; though their activity during rain is a certain proof of its short duration, and that it will be followed by fine and settled weather. Spiders usually make some alteration in their webs every 24 hours. If this take place between the hours of 6 and 7 P. M., it foretells a clear and serene night.

The weather is about to become cloudy and change for wet, when flies sting and are more troublesome than usual. Most insects become torpid when their temperature is much reduced. When it approaches the freezing point, they fall into a lethargic state, and require no food. Ants present a remarkable exception to this rule; for they are not benumbed till the thermometer is 27° of Fahr., or 5° below freezing point. When bees do not range abroad as usual, but keep in or about their hives, it is a sign of rain.

In the summer season much information relative to the change of the weather may be gained from watching the movements of ants. The finer the day, the more busily are they employed, as they never bring out their corn to dry but when the weather is clear and the sun very hot. A celebrated naturalist relates the following curious anecdote:—He one day observed these little creatures, after having brought out their corn at eleven in the forenoon, removing the same, contrary to their usual custom, before one in the afternoon. The sun being very hot, and the sky remarkably clear, he could perceive no reason for it; but half an hour after, his surprise ceased—the sky began to be overcast, and there fell a shower of rain, which caused all this bustle, no doubt, among these active little creatures: they evidently foresaw rain, and provided accordingly; and were we minutely to examine into the economy and management of these wonderful artificers, many other similar and equally curious facts might be gleaned relative to the weather.

The leech also possesses the peculiar property of indicating approaching changes of the weather in a most eminent degree. In fair and frosty weather it remains motionless and rolled up in a spiral form at the bottom of the vessel; previous, however, to rain or snow, it will creep to the top, where, should the rain be heavy, or of long continuance, it will remain for a considerable time,—if transient, it will descend. Should the rain or snow be accompanied with wind, it will dart about with great velocity, and seldom cease its evolutions until it blows hard. If a storm of thunder or lightning be approaching, it will be exceedingly

agitated, and express its feelings in violent convulsive starts at the top of the glass. It is remarkable, that however fine and serene the weather may be, and to our senses no indication of a coming change, either from the sky, the barometer, or any other cause, yet, if the leech shifts its position, or moves about sluggishly, the coincident results will undoubtedly occur within 26 hours.

Signs of Rain.—Although we have incidentally glanced already at some of these indications, it may be well to sum them up in a body, as being more easy of reference.

A white mist in the evening over a meadow or a river dispersed by the sun next morning, indicates that the day will be bright. Five or six fogs, successively, portend rain. Where there are high hills, and the mist which hangs over the lower land draws toward the hills in the morning, and rolls up to the top, it will be fair; but if the mist hangs upon the hills, and drags along the woods, there will be rain soon. A general mist before the sun rises is a sign of fair weather.

Against much rain, the clouds grow bigger and increase very fast, especially before thunder. When the clouds are formed like fleeces, but dense in the middle, bright towards the edge, with the sky bright, they are signs of a frost, with hail, snow, or rain. If clouds breed high in the air, in the white train like locks of wool, they portend wind, and probably rain. When a general cloudiness covers the sky, and small black fragments of clouds fly underneath, they are sure signs of rain, and probably it will be lasting. Two currents of clouds generally portend rain, and in summer thunder.

If the dew lies plentifully on the grass after a fair day, it is a sign of another fine day. If not, and there is no wind, rain will follow. A red evening portends fair weather; but if spread too far upward from the horizon in the evening, and especially morning, it foretells wind or rain, or both. When the sky in rainy weather is tinged with sea-green, the rain will increase; if deep blue, it will be showery.

If there be a haziness in the air, which fades the sun's light, and makes the orb appear whitish or ill-defined; or at night, if the moon and stars grow dim, and a ring encircles the former, rain must follow. If the sun appears white at setting, or goes down into a bank of clouds in the horizon, bad weather is expected. If the moon looks pale and dim, we expect rain; if red, wind; and if the natural colour, with a clear sky, fair weather. If the setting sun appears yellow or gold colour, and particularly if accompanied with purple streaks, the following day will be fine.

If the wind veers about much, rain is pretty sure. If, in changing, it follows the course of the sun, it brings fair weather; the contrary, foul. Whistling or howling of the wind is a sure sign of rain.

The aurora borealis, after warm days, is generally succeeded by cooler air. Shooting stars are supposed to indicate wind.

Before rain, swallows fly low; dogs grow sleepy and eat grass; waterfowls dive much; h will not bite; flies are more troublesome;

toads crawl about; moles, ants, bees, and many insects, are very busy; birds fly low for insects; swine, sheep, and cattle are uneasy, and even the human body.

"The air, when dry, I believe, refracts more red or heat-making rays; and as dry air is not perfectly transparent, they are again reflected in the horizon. I have generally observed a coppery or yellow sunset to foretell rain; but, as an indication of wet weather approaching, nothing is more certain than a halo round the moon, which is produced by the precipitated water; and the larger the circle, the nearer the clouds, and consequently the more ready to fall." (*Sir H. Davy.*)

To turn now to the atmosphere: the bulk of our most valuable meteorological observations are, of course, deducible from its electrical condition, and the precise kind of electricity present; from the power of evaporation exercised, from the state and direction of the wind, from a careful examination of the clouds; in fact, the phenomena of the atmosphere are wellnigh endless. But, though endless in the variety of their forms and consequences, and for the most part uncertain in the time of their occurrence, yet they are successively the same in their nature to parts and properties, and are all the production of simple causes. The principal agents in producing these phenomena have already been noticed under the head METEOROLOGY. I need not enlarge further upon the advantages to science in general derivable from the accurate and careful investigation of meteorological researches, aided by the excellent instruments that are now attainable, and at a moderate expense. From the accumulation of a multitude of such facts can we alone hope at some future time to derive that accurate knowledge and insight into the secret springs that would appear to be the movers of these phenomena. This may not be too much to effect from the analogies of the seasons and the results of experience; and this, we may venture to predict, will be the crowning reward of meteorological research. (*Trans. of Met. Soc. vol. i. 1839.*) See MOON, *Influence of.*

Clouds.—The following definition of the descriptive terms now employed by meteorologists to define various clouds, may prove useful to those in the habit of consulting meteorological registers, which are occasionally published in newspapers and scientific journals. It is taken from *Ure's Chemical and Miner. Dict.*, article "Cloud," p. 338.

A cloud is a mass of vapour, more or less opaque, formed and sustained at considerable heights in the atmosphere, probably by the joint agencies of heat and electricity. The first successful attempt to arrange the diversified forms of clouds, under a few general modifications, was made by Luke Howard, Esq. We shall here give a brief account of his ingenious classification.

The simple modifications are thus named and defined—1. *Cirrus*; parallel, flexuous, or diverging fibres, extensible in any or in all directions. 2. *Cumulus*; convex or conical heaps, increasing upwards from a horizontal base. 3. *Stratus*; a widely extended, continuous horizontal sheet, increasing from below.

The *intermediate* modifications which require to be noticed are—4. *Cirro-cumulus*; small, well-defined, roundish masses, in close horizontal arrangement. 5. *Cirro-stratus*; horizontal or slightly inclined masses, attenuated towards a part or the whole of their circumference, bent downward, or undulated, separate or in groups, consisting of small clouds having these characters.

The *compound* modifications are—6. *Cumulo-stratus*; the cirro-stratus blended with the cumulus, and either appearing intermixed with the heaps of the latter, or superadding a widespread structure to its base.

7. *Cumulo-cirro-stratus*, vel *Nimbus*; the rain cloud, a cloud or system of clouds from which rain is falling; it is a horizontal sheet, above which the cirrus spreads, while the cumulus enters it laterally and from beneath.

The *cirrus* appears to have the least density, the greater variety of extent and direction, and to appear earliest, in serene weather, being indicated by a few threads pencilled in the sky. Before storms they appear lower and denser, and usually in the quarter opposite to that from which the storm arises. Steady high winds are also preceded and attended by *cirrus* streaks running quite across the sky in the direction they blow in.

The *cumulus* has the densest structure, is formed in the lowest atmosphere, and moves along with the current next the earth; a small irregular spot first appears, and is as it were the nucleus on which they increase. The lower surface continues irregularly plain, while the upper rises into conical or hemispherical heaps, which may afterwards continue long nearly of the same bulk, or rapidly rise into mountains: they will begin in fair weather to form some hours after sunrise, arrive at their maximum in the hottest part of the afternoon; then go on diminishing, and totally disperse about sunset. Previous to rain the cumulus increases rapidly, appears lower in the atmosphere, and with its surface full of loose fleeces or protuberances. The formation of large cumuli to leeward in a strong wind indicates the approach of a calm with rain; when they do not disappear or subside about sunset, but continue to rise, thunder is to be expected in the night. The stratus has a mean degree of tensity, and is the lowest of clouds, its inferior surface commonly resting on the earth or water. This is properly the cloud of night, appearing about sunset. It comprehends all those creeping mists which in calm weather ascend in spreading sheets (like an inundation of water) from the bottom of valleys and the surfaces of lakes and rivers. On the return of the sun the level surface of this cloud begins to put on the appearance of *cumulus*, the whole at the same time separating from the ground. The continuity is next destroyed, and the cloud ascends and evaporates, or passes off with the appearance of nascent cumulus. This has long been experienced as a prognostic of fair weather.

The *cirrus* having continued for some time increasing or stationary, usually passes either to the *cirro-cumulus* or the *cirro-stratus*, at the same time descending to a lower station in the atmosphere. This modification forms a very

beautiful sky, and is frequent in summer, as an attendant on warm and dry weather. The *cirro-stratus*, when seen in the distance, frequently gives the idea of shoals of fish (a mackerel sky). It precedes wind and rain; is seen in the intervals of storms, and sometimes alternately with the *cirro-cumulus* in the same cloud, when the different evolutions form a curious spectacle. A judgment may be formed of the weather likely to ensue, by observing which modification prevails at last. The solar and lunar *halos*, as well as the *parhelion* and *paraseline* (mock sun and mock moon), prognostics of foul weather, are occasioned by this cloud. The *cumulo-stratus* precedes, and the *nimbus* accompanies rain.

When there are small round clouds, of a dapple-gray colour, with a north wind, it may be concluded that there will be fair weather for 2 or 3 days, but that large clouds like rocks are a sign of great showers. And when small clouds increase, it is a sign that there will be much rain, but if the large clouds are seen to lessen, there will be fair weather.

In summer or harvest, when the wind has been south 2 or 3 days, and it grows very hot, and clouds are seen to rise with great white tops like towers, as if one were on the top of another, and joined together with black on the lower side, it may be considered a sign that there will be thunder and rain suddenly. When two such clouds rise, one on each hand, it is time to make haste to shelter.

When a cloud is seen to rise against the wind or side wind, it is a sure sign that when the cloud comes up near you, the wind will blow the way that the cloud came. It is the same with the motion of a clear place, when all the sky is thick except one edge.

At all times, when the clouds look black in the west, it is sure to rain, or if raining, it is sure to continue, whatever quarter the wind may be in; and, on the contrary, if it breaks in the west, it is sure to be fair.

It is often observed, on those clear sunny mornings which occur in summer and autumn, that it is very likely, if not certain, to rain before evening; and there is frequently much truth in the remark. The reason is, that when moisture accumulates in the air, before it begins to be precipitated, it imparts to it a higher refractive power; and it becomes, in consequence, more bright and transparent. (*British Almanac*, 1830.)

The gradual diminution of clouds, till they are no longer observable, is a sign also of fine weather. So, likewise, is the continuance or abundance of dew upon the grass, after a serene day.

During winter, fleecy clouds being thick and close in the middle, and very white at the edges, the surrounding sky being remarkably blue, indicate hail or snow, or cold, chilling, showers of rain.

Where the clouds appear moving in two opposite currents, and the lowest is wafted rapidly before the wind, it is a certain sign of rain; and if this occurs during summer, or generally in hot weather, it announces a thunder-storm.

It may be a useful piece of information for agriculturists, or those concerned in getting in

their crops, to describe the appearance of a small cloud, which, from its rapid formation and disappearance, is likely to escape the observation of most persons, but which, from my own experience, I have found a very faithful forewarner of foul weather. It appears mostly in the mild weather of spring, summer, and autumn, when its warning token becomes most acceptable. It is a small, delicately soft, thin, white, curved cloud, formed suddenly upon the summit of those fine heaped clouds (termed cumuli) which often prevail in warm weather, and appear to tower up to a prodigious height. It is necessary to keep a watchful eye upon the summit of the cumulus. When this little film, which I term "the storm cap," appears, it lies closely over the rounded summit, like a white silken web; in a very few seconds it will disappear, sinking, I suppose, into the cumulus; but in a little time, and when heavy foul weather threatens, the film again appears, disappearing as shortly as before. (*Mag. Nat. Hist.* vol. iv. p. 444.)

The following indications have been recorded, as shown by the predominance of certain of the prismatic colours of the rainbow, but they are perhaps too fanciful to be deserving of much credence.—1. Red; if this colour be very predominant, wind, or wind and rain, may be expected. 2. Orange; when the orange colour appears strong and very full, it generally indicates approaching rain. 3. Yellow; when yellow is more conspicuous than the other colours, it foretells dry weather. 4. Green; approaching rain may be expected when the green is very predominant. 5. Blue; fine weather may be expected when the blue is particularly full. 6. Purple; if the purple be a very full colour, wind and rain may be expected. 7. Violet; the violet, when very clear, generally indicates approaching fine weather. See RAINBOW.

The Wind.—The earth is surrounded to the extent of 60 miles with an atmosphere, on which all nature mutually depends for life. This aerial ocean revolves with our earth round the sun, is very susceptible of motion, and some parts of it is constantly in restless commotion. These commotions are called winds, and are principally caused by heat from the rays of the sun, which, rarefying the air, causes it to ascend; and the vacuum thus formed is filled with a colder air from the north and south.

Wind has been explained in the following manner:—Heated air has a tendency to rise, and cold air rushes in to supply its place. Thus the heated air of the equatorial regions rises and gives place to a current sent from the polar regions, which is a process that serves to equalize the temperature of the world. But the polar countries lying near to the axis of the sphere, the air from those regions has not received so much motion as that about the equator, or greatest distance from the axis; wherefore it arrives at the equator, where the motion of the earth is greater. If it had no motion before, an east wind would be the consequence, and the force of that wind would be as the difference between the motion of the earth where the air came from, and that where

it arrived: but then, in the northern hemisphere, it has a motion to the south; for it is rushing into a vacuum left by the air which rises; so that the wind will not be from the east, but northeast; and the number of degrees north of the east from which it will blow will depend upon the comparative force of the current of air from the north to the difference between the earth's motion at the equator and at the polar region, whence the air comes. As there must be a corresponding efflux from the equator higher up, according to this theory the wind should everywhere be northeast or southwest, but it blows in very different directions at different times and places, owing chiefly to circumstances connected with the distribution of land and water, and the variations in temperature at different times and places.

From observing the wind a fair idea of the coming weather may oftentimes be drawn; and yet, as Solomon observes, "he that considers the wind shall never sow;" that is, he that busies himself too much about the wind will become superstitious. The indications to be drawn from observing the direction and changes of the wind must vary in different countries, according to the relative positions of these in regard to the sea, lakes, plains, or mountains covered with snow. For an explanation of some of the phenomena of climate and weather, the reader is referred to preceding articles, under the heads of BAROMETER, CLIMATE OF THE UNITED STATES, &c.

In all countries, therefore, particular winds are noted for being accompanied with either wet or dry weather. Thus the south and southwest winds bring much moisture into Britain, while those from the north and northeast are cold, dry, and penetrating. Hence the old English proverb—

"When the wind's in the south,
It's in the rain's mouth."

Not only does this arise from the immense surface of ocean over which these winds sweep south of the equator, the evaporation from which must be prodigious; but from these southerly winds being of a higher temperature, whereby they hold a greater quantity of vapour in suspension or solution, the condensation of which must be proportionally greater on arriving in this colder climate. Accordingly, it has been observed that the wind will turn from the north to the south quietly and without rain; but on returning from the south to the north, will blow hard and bring much rain. Again, if it begin to rain from the south, with a high wind for 2 or 3 hours, the wind falls; but if the rain continues, it is likely to rain for 12 hours or more, and does usually rain until a strong north wind clears the air. For the same reason, winds from the west and southwest are in England considered to bring with them wet weather. (*Chambers' Information for the People*, No. 58, New Series.)

A change in the warmth of the weather is often followed by a change in the wind. Thus, the northerly and southerly winds, though commonly accounted the causes of cold and warm weather, are really the effects of the cold or warmth of the atmosphere.

Mr. Towers (*Quart. Jour. of Agr.* vol. ix. p. 39) relates the case of a person in Somersetshire who had been haymaking nearly 40 years, and had hardly in one instance failed to carry in good condition. He had observed that in the month of June, earlier or later, there are three or more days wherein the wind blows from the northeast, and that period is invariably dry. When that wind first occurred, he seized the opportunity of cutting his grass and carrying the crop before the wind veered to the south. This theory holds good as respects the south-western counties, where the wind from any quarter between north and east is the sure concomitant of dry weather.

The following predictions of the weather are met with in the Holy Scriptures; and, applying with equal correctness in the present day as at the time they were written, I subjoin them:— A south wind, or great heat in summer, portends a whirlwind. (*Job xxxvi. 9.*) Cold or fair weather is indicated by the north wind, which drives away rain. (*Ibid. xxxvii. 9, 22.*) A red sky in the evening foretells fair weather; in the morning, foul. “When it is evening ye say, It will be fair weather, for the sky is red. And in the morning, It will be foul weather to-day, for the sky is red and lowering.” (*Matt. xvi. 2, 3.*) “When ye see a cloud rise out of the west, straightway ye say, There cometh a shower; and so it is. And when ye see the south wind blow, ye say, There will be heat; and it cometh to pass.” (*Luke, xii. 54, 55.*)

It results from observations made by M. Schow, that in the north of Europe the western winds are more frequent than the eastern. This rule is without exception; but the western winds diminish more and more as we approach the centre of the Continent, being more frequent in England, Holland, and France than in Denmark and the greater part of Germany; and more frequent in these latter countries than in Russia and Sweden. At London, the east wind is to the west as 1 to 1.7; at Amsterdam, as 1 to 1.6; at Copenhagen, as 1 to 1.5; at Stockholm, as 1 to 1.4; at Petersburg, as 1 to 1.3. The west winds seem to incline the more to the south according to the propinquity of the Atlantic sea; towards the interior of the Continent they incline more to the northwest. The north winds appear to increase towards the east. Amongst the winds which come from the west, that of the southwest predominates in England, Holland, and France; that of direct west in Denmark and the greater part of Germany; at Moscow the northwest predominates; at Petersburg and Stockholm the north wind is much more frequent than in the western parts of Europe. In the western and middle districts of northern Europe, such as England, France, Denmark, Germany, and Norway, the west winds are much more frequent during the summer than during the winter or spring. This does not appear to be the case in Sweden and Russia. During the winter the west winds are more southerly; during the summer more direct and more northerly; (*Jahrb. der Phys. und Chemie*, 1828.)

With regard to the supposed influence of the moon upon the conditions of the weather, and

the strong evidences to prove that this satellite exerts *no influence* in controlling the atmosphere, so far as wet and dry weather are concerned, see MOON, INFLUENCE OF.

Under the head of BAROMETER it has been observed that changes of weather are indicated, not by the actual height of the mercury, but by its change of height. One of the most general, though not absolutely invariable, rules, is, that where the mercury is very low, and, therefore, the atmosphere very light, high winds and storms may be expected.

In winter the rising of the barometer pre- sages frost; and in frosty weather, if it falls three or four divisions, there will follow a thaw; but if it rises in a continued frost, snow may be expected.

The mercury generally rises very fast after great storms of wind, when before it was very low. In England it has been observed to rise an inch and a half in six hours, after a long-continued storm of southwest wind.

The words on the plate of a barometer are not strictly to be adhered to, though they will in general agree; for a fluctuating and unsettled state of the mercurial column indicates uncertain or changeable weather. The height of the mercury does not so much indicate the weather as its motion up and down: to know, therefore, whether the mercury is actually rising or falling, observe—

1st. If the surface of the mercury is convex (or stands high in the middle), it is then rising.
2d. If the surface is concave (standing low in the middle), it is then falling.

3d. If the surface is plain, or a little convex, it may be considered as stationary.

4th. A small tap on the barometer case, by shaking the tube will sometimes bring the mercury to its approaching height.

The greatest heights of the mercury are on easterly and northeasterly winds; and its lowest station on southerly winds.

If the weather is about to be cold, frosty, or foggy, it rises pretty high; but if going to be windy or tempestuous, it will then sink very low, and, as soon as the first storm is over, it will rise again apace.

The domestic barometer would become a much more useful instrument if, instead of the words usually engraved on the plate, a short list of the best established rules, adapted to the particular locality in which it was situated, accompanied it, which might be either engraved on the plate, or printed on a card. It would be right, however, to express the rules only with that degree of probability which observation of past phenomena has justified. There is no rule respecting these effects which will invariably hold good.

In the following table the mean temperature, mean highest, and mean lowest, have been calculated from observations made on registering thermometers, hung on a post 2 feet 8 inches from the grass, facing the north, and in no way sheltered. The barometer is in a vestibule. No corrections of any kind have been made in registering the barometer. (*Johnson's and Shaw's Farmer's Almanac*, vol. i p. 157.)

Tables showing the mean temperature in most sections of the United States, and also at many noted places in Europe and Asia, will be found under the heads of ATMOSPHERE and CLIMATE.

WEEDS. A weed has been aptly defined "a plant out of place." The clearing of all kinds of crops, and keeping them free from weeds, is an essential part of cultivation: if this be omitted, neglected, or but partially performed, a portion of the crop will be lost, in proportion to the prevalence of such weeds, from defective preparation or partial extirpation. The nourishment drawn from the ground by the roots of all vegetables being somewhat similar, where that nourishment is suffered to be drawn by weeds, it is lost to the intended crop, which will therefore be reduced in produce in proportion as it has been deprived of nutriment from the soil, and prevented from occupying its whole extent of ground. The same observation will apply to pastures, to hedges, and plantations, and to all parts of the earth's surface reclaimed, occupied, and cultivated for the use of man; for therein the growth of noxious or useless plants will be injurious to the success of the useful ones, and in proportion as the former abound, the latter must prove defective.

The clearing of crops from weeds must be effected in two ways: 1. In the preparation; and, 2. During the growth of the crop. In the preparation, attention must be given to distinguish root weeds from seedlings, as their destruction must be effected upon different principles. In the spring of the year particularly, attention should be paid to hoeing and weeding.

And old Tusser's advice may be followed with advantage:—

"In May get a weed-hook, a crotch, and a glove,
And weed out such weeds as the corn doth not love;
For weeding of winter corn, now it is best,
But June is the better for weeding the rest.

The May-weed doth burn, and the thistle doth fret,
The fitches pull downward both rye and the wheat,
The brake and the cockle be noisome too much,
Yet like unto boodle no weed there is such.

Slack never thy weeding, for dearth nor for cheap,
The corn shall reward it, ere ever ye reap;
And 'specially where ye do trust for to seed,
Let that be well used, the better to speed."

The plants we term weeds, considered as respecting mankind, are not totally useless; many of them have valuable medical qualities, and some of them may be applied to useful purposes, so as to pay something towards the expense of clearing them from the ground. Thus, sow-thistles (*Sonchus*) afford food for rabbits or hogs; the hog-weed, or cow-parsnip (*Heracleum sphondylium*), is good for either swine or cattle; horses and asses are fond of young thistles when partially dried, and the seed may be prevented from spreading by gathering the down, which makes good pillows; however, there is some danger of trusting them to this stage of growth, as a high wind would, and frequently does, disperse them over a whole country. Charlock, or wild radish, when drawn, may be given to cows, which are very fond of it, particularly of the smooth kind; and, in the *Oxford Report*, it is stated that it can be converted into good hay. Nettles, fern, and the more bulky hedge-weeds, are, in Staffordshire, collected annually about midsummer and burned; their ashes being afterwards formed into balls, which are of considerable value, being used in composing a ley for scouring and cleaning linen and other clothes.

It is said that pigeons are of use in picking up the seeds of many weeds that would otherwise vegetate; and I have no doubt but that a prodigious quantity of the seeds of weeds are eaten by small birds, particularly of most of the snake-weeds (*Polygonums*), of the spurry (*Spergula*), and, in severe weather, of the different sorts of charlock (*Sinapis*, *Brassica*, and *Raphanus*), and of many other kinds. It has been observed that bees have not thriven so well in England since the extirpation of weeds has been more attended to. In China and Japan, it is said, not a weed is to be seen, and that they only make use of night-soil as a manure, partly with a view of preventing any rise of weeds.

Weeds, like all other vegetables, may be distinguished into annuals, biennials, and perennials, according to their term of duration.

Annuals are those which continue only one year, the plants dying after perfecting their seeds: these are generally very prolific in seed. Biennials are those which continue two years, and die after perfecting their seed: these also produce an abundance of seed. Perennials are those which continue many years: some of these perfect their seeds every year, and others, being very tenacious of growth by their roots, and having the faculty of reproducing themselves in this way, are less prolific in seeds; but many of them increase both by seeds and roots.

The weeds of agriculture are very numerous but by far the greater part are underlings, and

are little noticed; these are comparatively innocent, and a very great portion of them have no local or common names. Mr. William Pitt, in his essay *On the Extirpation of Weeds* (Com. to Board of Agr. vol. v. p. 233), enumerates 55 weeds, and the list might have been greatly extended; but few farmers, whose knowledge is bounded by the soils they respectively cultivate, would think themselves troubled with more than a dozen to twenty; that is, four or five which trouble them in their fallows; four or five, the seeds of which infest their samples of corn; and a few besides, which are locally prevailing and obtrusive, but (as seems to have been too generally considered) *not very hurtful*.

The fact was, that, before the improved agriculture became so generally known, those weeds which did not hurt the samples the farmers cared little about; not considering how much they hurt the crops: and hence it has been, that on the different soils corn poppy, charlock, blue-bottles, corn marygold, May-weed, &c., have been suffered to abound.

The weeds of agriculture may be divided into, 1. Those which infest samples of corn; 2. Rooted or fallow weeds, and such others as are hard to destroy; 3. Those which are principally objectionable as they encumber the soil; 4. Underling weeds, such as never rise with the crop or come into the sickle. Under their respective heads, in alphabetical order, we have already treated of the deteriorating qualities and mode of destruction of each weed; but, following the above arrangement, we shall classify them, and add such further remarks as may be required.

1. *Weeds which infest Samples of Corn.*—In England the weeds of this description do not exceed ten in number, and it very rarely happens that more than two sorts are found associated in one sample of wheat. They vary as to soil so much, that some of the worst weeds in fens and marshes are not known at all on clay, cold soils, and are but very little seen on any sort of dry turnip land. Light loams and deep, loose soils generally have most weeds by nature. The weeds which infest the sample are, darnel, cheat, or chess (*Bromus secalinus* and *mollis*), cockle (*Agrostemma Githago*), tares (*Ervum tetraspernum* and *hirsutum*), melilot (*Melilotus officinalis*), wild oats (*Avena fatua*), hariff (*Galium Aparine*), crow-needles, or shepherd's needle (*Scandix pecten Veneris*), black bindweed (*Polygonum Convolvulus*), annual snake-weed (*Polygonum lapathifolium*), and charlock seeds in barley sometimes.

Of these ten weeds, whose seeds infest samples of corn, five are principally injurious to wheat; the others are partial, and more common in barley and oats.

2. *On Fallow Weeds.*—The objects of a fallow are, and always were, first, to eradicate root weeds, and cleanse and open the soil to the fibres of future crops; second, to pulverize and break down the texture of clay soils, and mix them with manure, in order to bring the land periodically into a mild and fertile condition. Seedling weeds are destroyed incidentally; and good fallows, with good seasons, kill a great many, though it be not the object of fallowing

The English fallow weeds are principally the following: couch, including *Triticum repens*, *Agrostis repens*, *Holcus mollis*, and *Poa pratensis*, rest-harrow (*Ononis arvensis*), saw-wort, the common way-thistle, or pasture-thistle (*Carduus arvensis*), curled dock (*Rumex crispus*), tall oat-like soft-grass (*Holcus avenaceus*), colt's-foot (*Tussilago Farfara*), corn bindweed (*Convolvulus arvensis*), corn mint (*Mentha arvensis*), surface-twitch (*Agrostis stolonifera angustifolia*), black foxtail-grass (*Alopecurus agrestis*), common knot-grass (*Polygonum aviculare*), wild carrot (*Daucus Carota*), hedge parsley, or dill (*Torilis infesta*), common fool's parsley (*Æthusa Cynapium*), spingel or fennel (*Meum Fœniculum*).

3. *Weeds which are principally objectionable as they encumber the Soil, or whose Roots are annual, and whose Seeds pass the Corn-sieve.*—Of this class of weeds, the following deserve particular notice: charlock (several species), corn poppy (*Papaver Rhæas*), blue-bottle (*Centaurea Cyanas*), stinking May-weed (*Anthemis cotula*), corn marigold (*Chrysanthemum segetum*).

To extirpate these weeds, clean corn-seed must be used, not a single plant of these weeds must be suffered to perfect seed in the hedges, and a judicious rotation of crops adopted, so as to admit of the unsparing use of the horse-hoe, as well as of the hand, in weeding; by which means these noxious and disgraceful pests of corn-fields will be overcome and banished from the soil.

The corn-poppy particularly accumulates upon gravelly soils of low quality, also on dry sandy soils, and generally on all dry and shallow lands which are overcropped and neglected. But much better soils, as loamy gravel, &c., are infested with it; only here the crops are generally good enough to keep it under, and being less abundant, it is much easier subdued by weeding. But the corn poppy is never so triumphant as in a hot and dry season, in which case many fields, which should have been corn, are wholly covered with it. One of three things must be done by way of remedy: 1st, the soil must be clayed or marled; 2d, or it must be fed with much larger quantities of farm-yard dung or compost; 3d, if neither of these be easily practicable, the rotation must be changed.

4. *Of the Weeds called Underlings, or such as never rise in the Crop, nor come into the Sickle.*—These are groundsel or Simson (*Senecio vulgaris*), annual meadow-grass (*Poa annua*), chickweed (*Stellaria media*), shepherd's purse (*Thlapsi bursa pastoris*), spurry (*Spergula arvensis*), camomile feverfew (*Matricaria Chamomilla*), fat hen or wild spinach (*Chenopodium album*), corn salad, or lamb's lettuce (*Fedia olitoria*), flixweed (*Sisymbrium Sophia*), common fumitory (*Fumaria officinalis*), and sand mustard (*Sinapis muralis*).

Land may be rendered inert or unfertile from an excess of manure, as well as from the want of it; severe and avaricious cropping, long persevered in, being understood in both cases. Over-stimulus, as in the first instance, wears out, or renders inert, the principle of fertility in the land; and, in the latter instance, the want of stimulus produces the same effect.

Plate 2.

Varieties of Wheat with the most destructive *P. stramineus*.

The underling weeds, above mentioned, flourish and prosper under this state of the land, brought on by either cause. The remedy is therefore obvious, viz., rest, or a clear-out summer fallow; and if in the first mentioned case (which is to be met with in deep fen land and in old garden mould), apply a dressing of lime, and sow down with the superior pasture-grasses and clovers, to remain for not less than five years. In the latter case, or when the fertility of the soil is worn out by injudicious cropping, and a niggardly supply of manure, joined to the naturally thin and poor staple of the soil, then a full application of manure, or marl and manure, the latter consisting as much as possible of cow-dung, should be given, and the land sown down with the superior permanent pasture-grasses suited to the soil, with a due admixture of clover.

5. *Pasture Weeds.*—Some farmers seem to suppose that if they keep the weeds subdued in the growing crops, they have performed wonders (and too many have reason to congratulate themselves if they do this), while all kinds of nuisances in the shape of weeds disfigure and overrun their pastures. But thistles, milkweed, everlasting, John's-wort, sweet elder, &c., flourish undisturbed, and fill the earth with seeds or roots in readiness to spread and grow whenever the earth is moved for their reception. Any plant not wanted on a farm, or not required in course of cultivation, should never be allowed to perfect its seeds on any part of it; if they are, the farmer will find, to his sorrow, that he has suffered an enemy to steal a march upon him, one which it may require much time and labour to subdue. Allow, then, nothing to go to seed on your farm you do not mean to cultivate; dig them up root and branch, or, if this is not practicable, take your scythe and cut them at once.

The following weeds are more frequently found to infest dry, sandy pastures, and calcareous soils, than loamy or damp grass lands. Dwarf-thistle (*Carduus acaulis*), common camomile (*Anthemis nobilis*), ox-eye daisy (*Chrysanthemum leucanthemum*), great fleabane, or ploughman's spikenard (*Conyza squarrosa*), cheese refining, or yellow ladies' bedstraw (*Galium verum*), longrooted hawk-weed, wild thyme (*Thymus serpyllum*), sheep's sorrel (*Rumex acetosella*), knot-grass, or snake-weed (*Polygonum aviculare*), yellow rattle (*Rhinanthus cristagalli*), common Carline thistle (*Carlina vulgaris*).

Where these are found to prevail to a great extent, there is no remedy like breaking up the land and taking a course of crops, for palliative remedies are of little avail. The thistles, sheep's sorrel, and knot-grass, are the most formidable. Hand-weeding, when the weeds are confined to local spots, and are only just beginning to spread generally over the soil, will be found effectual; but when once the pasture becomes generally infected with the seeds and roots of these plants, no time should be lost in using the plough, harrow, and horse-hoe, and a judicious course of cleansing crops, before returning the land again to permanent pasture.

The pasture weeds which generally prevail on loamy soils, and such as are prevalent in

clayey and damp soils, are principally as follows:—yellow goat's beard (*Tragopogon pratensis*), marsh, or red thistle (*Carduus palustris*), melancholy plume-thistle (*Cnicus heterophyllus*), meadow plume-thistle (*Carduus pratensis*), common butter-bur (*Tussilago Petasites*), ragwort (*Senecio Jacobææ*), common daisy (*Bellis perennis*), black knap-weed, or matfellow (*Centaurea nigra*), broadleaved dock (*Rumex obtusifolius*); several species of orchis, common cow parsnip, or hog-weed (*Heracleum Sphondylium*), and sedge (*Carex*).

The means to be adopted for the extirpation of these noxious weeds in pastures must be regulated by the nature of the soil and the comparative prevalence of the weeds. In good pasture land, where, from accident or neglect, these weeds, in part or wholly, have insinuated themselves, hand-weeding may most advantageously be had recourse to; and particularly for the larger weeds, such as thistles, rag-weed, docks, and knapweed, it will be found the best temporary remedy. Should the coarseness of the pasture have been occasioned by too frequent haying, then depasturing closely for two or three years, with a good top-dressing of dung compost applied in the early part of the spring or late in the autumn, with strict attention to hand-weeding, will be found effectual to recover the pasture and extirpate the weeds. Frequent top-dressings are of the greatest use in effecting the above improvements on deteriorated thin pasture lands, as regards the destruction of weeds, as well as of improving the quality of the pasture. When the sedges, marsh-thistle, pestilent wort, &c., prevail in meadows, then recourse must be had to other means than that of hand-weeding, viz., draining, paring and burning, liming, and a judicious rotation of crops under the horse-hoe husbandry, until every vestige of the seeds and roots of these noxious weeds disappear. The ground may then be laid down to permanent pasture, with the seeds of the most valuable species adapted to the soil, and, where water can be commanded, converted to water meadow, by which the value of the land will be considerably increased. (*Holdich's Weeds; Pitt's Essays on Weeds.*) See CANADA THISTLE, CHARLOCK, COUCH, &c., &c.

WEEVILS. In the winged state, the insects thus called are hard-shelled beetles, which, says Dr. Harris, are distinguished from other insects by having the forepart of the head prolonged into a broad muzzle or a longer and more slender snout, in the end of which the opening of the mouth and the small horny jaws are placed. The flies and moths produced from certain young insects, called weevils by mistake, do not possess these characters, and their larvæ or young differ essentially from those of the true weevils. The latter belong to a group called *Rhynchophorida*, literally, snout-bearers.

Among insects of this class is the Pales weevil, *Curculio (Hylobius) Pales*. See Pl. 16, 6. This is a beetle of a deep chestnut-brown colour, having a line and a few dots of a yellowish-white colour on the thorax, and many small yellowish white spots sprinkled over the wing-covers. All the thighs are toothed beneath

and the snout is slender, cylindrical, inclined, and nearly as long as the thorax. On account of the length of the snout this insect has been placed in the genus *Rhynchænus* by some naturalists; but the antennæ are implanted before the middle of the snout, and not far from the sides of the mouth. This beetle measures from two to three-eighths of an inch in length, exclusive of the snout. It may be found in great abundance, in May and June, on board-fences, the sides of new wooden buildings, and on the trunks of pine trees. I have discovered them, in considerable numbers, under the bark of the pitch pine. The larvæ, which do not materially differ from those of other weevils, inhabit these and probably other kinds of pines, doing sometimes immense injury to them. Wilson, the ornithologist, describes the depredations of these insects, in his account of the ivory-billed woodpecker, in the following words. "Would it be believed that the larvæ of an insect, or fly, no larger than a grain of rice, should silently, and in one season, destroy some thousand acres of pine trees, many of them from 2 to 3 feet in diameter, and 150 feet high? Yet whoever passes along the high-road from Georgetown to Charleston, in South Carolina, about 20 miles from the former place, can have striking and melancholy proofs of the fact. In some places the whole woods, as far as you can see around you, are dead, stripped of the bark, their wintry-looking arms and bare trunks bleaching in the sun, and tumbling in ruins before every blast, presenting a frightful picture of desolation. Until some effectual preventive or more complete remedy can be devised against these insects and their larvæ, I would humbly suggest the propriety of protecting, and receiving with proper feelings of gratitude, the services of this and the whole tribe of woodpeckers, letting the odium of guilt fall to its proper owners." (*American Ornithology*, vol. iv. p. 21.) Some years ago Mr. Nuttall procured, near the place above mentioned, specimens of the destructive insects referred to by Wilson. They were of three kinds. Those in greatest abundance were the pales weevil. One of the others was a larger, darker-coloured weevil, without white spots on it, and named *Hylobius picivorus*, by Germar and Schönherr, or the pitch-eating weevil; it is seldom found in Massachusetts. The third was the white pine weevil. It is said that these beetles puncture the buds and the tender bark of the small branches, and feed upon the juice, and that the young shoots are often so much injured by them as to die and break off at the wounded part. But it is in the larva state that they are found to be most hurtful to the pines. The larvæ live under the bark, devouring its soft inner surface, and the tender newly formed wood. When they abound, as they do in some of the pine forests of the United States, they separate large pieces of bark from the wood beneath, in consequence of which the part perishes, and the tree itself soon languishes and dies.

The white pine weevil, *Rhynchænus (Pissodes) Strobi*, of Professor Peck, unites with the two preceding insects in destroying the American pines, as above describe^d. But it em-

ploy also another mode of attack on the white pine, of which an interesting account is given by the late Professor Peck, the first describer of the insect, in the 4th volume of the *Massachusetts Agricultural Repository and Journal*, accompanied by figures of the insect. The lofty stature of the white pine, and the straightness of its trunk depend, as Professor Peck has remarked, upon the constant health of its leading shoot, for a long succession of years; and if this shoot be destroyed, the tree becomes stunted and deformed in its subsequent growth. This accident is not uncommon, and is caused by the ravages of the white pine weevil. This beetle is oblong-oval, rather slender, of a brownish colour, thickly punctured, and variegated with small brown, rust-coloured, and whitish scales. There are two white dots on the thorax; the scutel is white; and on the wing-covers, which are punctured in rows, there is a whitish transverse band behind the middle. The snout is longer than the thorax, slender, and a very little inclined. The length of this insect, exclusive of its snout, varies from one-fifth to three-tenths of an inch. Its eggs are deposited on the leading shoot of the pine, probably immediately under the outer bark. The larvæ, hatched therefrom, bore into the shoot in various directions, and probably remain in the wood more than one year. When the feeding state is passed, but before the insect is changed to a pupa, it gnaws a passage from the inside quite to the bark, which, however, remaining untouched, serves to shelter the little borers from the weather. After they have changed to beetles, they have only to cut away the outer bark to make their escape. They begin to come out early in September, and continue to leave the wood through that month and a part of October. The shoot at this time will be found pierced with small round holes on all sides; sometimes 30 or 40 may be counted on one shoot. (*Harris.*) See CORN WEEVIL, CURCULIO, GRAIN WEEVIL, PEA WEEVIL, PLUM TREE WEEVIL, &c.

WEIGH. In England, a weight of cheese, wool, &c., containing 256 lbs. avoirdupois. Of corn, the weigh contains 40 bushels; of barley or malt, 6 quarters. A weigh of cheese or butter in Suffolk is 256 lbs., and in Essex 336 lbs.

WEIGHTS AND MEASURES. The proportions or quantities by which various sorts of agricultural or other produce are disposed of. In Britain they vary greatly in different districts, and even in different places of the same district or county.

In a general sense the term measure is applied to that by which any thing is compared in respect of quantity. Thus we have measures of extension, of weight, time, force, resistance, temperature, &c.; in short, of every thing of which greater or less can be predicated; and it frequently happens that the unit or measure is not taken in the thing or property which is the immediate subject of consideration, but in something else which depends on it, or is proportional to it. Angular space, for example, is measured by an arc of a circle; time, by the rotation of the earth upon its axis, or its revolution around the sun; force,

WEIGHTS AND MEASURES.

WEIGHTS AND MEASURES.

by the quantity of motion it impresses on a body; degrees of heat, by the expansion of metals or other substances; muscular strength, by the resistance of a spring. See **DYNAMOMETER, STRENGTH, THERMOMETER, &c.**

By measure, in an absolute sense, is understood the unit, or standard, by which we measure extension. We have, therefore, measures of length, of superficies, and of volume or capacity; but, as the two latter may be deduced in all cases from the former, it is only necessary to establish a unit, or standard of length. The choice of such a standard, and the different multiples and parts of it taken for the uses of society, form a metrical system, or system of metrology.

As no precise notion can be formed of the magnitude of a line in any other way than by comparing it with another line of a known length, the necessity of having recourse, for the interchange of ideas, to measures not entirely arbitrary, but fixed by nature and intelligible alike to all mankind, seem to have been perceived in the earliest ages. Hence originated the foot, the cubit, or length of the arm from the elbow to the tip of the middle finger; the *ulna*, arm, or yard; the span; the digit, or finger; the palm; the fathom, or space from the extremity of one hand to that of the other,

when they are both extended in opposite directions; the pace, the barley-corn, the hair's breadth, and other denominations of measure taken from parts of the human body, or from natural objects, which, though not of an absolute and invariable length, have a certain mean value sufficiently definite to answer all the purposes required in a rude state of society. But as civilization advanced, the necessity of adopting more precise standards would be felt, and the inadequacy of such measure as the foot, the cubit, &c. (referred only to the human body), to convey accurate notions, would be rendered most apparent in their application to itinerary measures, or the estimation of great distances.

English System of Lineal Measures.—The unit of lineal measure in England is the yard, all other denominations being either multiples, or aliquot parts of the yard. The yard is divided into 3 feet, and the foot subdivided into 12 inches. The multiples of the yard are the pole or perch, the furlong, and the mile; 5½ yards being a pole, 40 poles a furlong, and 8 furlongs a mile. But the pole and furlong are now scarcely ever used, itinerary distances being reckoned in miles and yards.

The relations of these different denominations are exhibited in the following table:—

Inches.	Feet.	Yards.	Pols.	Furlongs.	M les.
1	0.083	0.028	0.00505	0.00012626	0.0000157828
12	1	0.333	0.06060	0.00151515	0.00018939
36	3	1	0.1818	0.004545	0.00056518
198	16.5	5.5	1	0.025	0.003125
7920	660	220	40	1	0.125
63360	5280	1760	320	8	1

Of the different measures of length used in European countries, the foot is the most universally prevalent. We subjoin the relation between the foot of different countries and the English foot.

	English foot.
Russian foot - - - -	1
Paris foot - - - -	1.065765
Prussian and Danish foot - - - -	1.029722
Bavarian foot - - - -	0.957561
Hanoverian foot - - - -	0.958333
Saxon foot - - - -	0.929118
Austrian foot - - - -	1.037128

See **FOOT, LEAGUE, MILE, &c.**

Measures of Superficies.—In square measure the yard is subdivided, as in general measure, into feet and inches; 144 square inches being equal to a square foot, and 9 square feet to a square yard. For land measure the multiples of the yard are the pole, the rood, and the acre; 30½ (the square of 5½) square yards being a pole, 40 poles a rood, and 4 roods an acre. (See **ACRE.**) Very large surfaces, as of whole countries, are expressed in square miles.

The following are the relations of square measure:—

Square Feet.	Square Yards.	Poles.	Roods.	Acres.
1	0.1111	0.00367309	0.000091827	0.000022957
9	1	0.03305798	0.000526448	0.000206612
272.25	30.25	1	0.025	0.00625
10890	1210	40	1	0.25
43.60	4840	160	4	1

Land is usually measured by a chain of 4 poles or 22 yards, which is divided into 100 links. Three chains in length and one in breadth make an acre, which equals 169 square perches, or 4840 square yards.

Land Measure.

Countries.	Land Measure.	English Square Yard.	No. equal to 10 English Acres.
England -	Acre -	4840	10000
Scotland -	— -	6150	7860
Ireland -	— -	7840	6173
France -	Hectare -	11960	4046
Prussia -	Morgen -	3053	15853
Hamburg -	— -	11545	4192
Amsterdam -	— -	9723	4978
Dantzic -	— -	6650	7278

Square, or Superficial Measure.

144 square inches	=	1 square foot.
9 — feet	=	1 — yard.
30½ — yards	=	1 — rod.
40 — rods	=	1 — acre.
640 — acres	=	1 — mile.

Measures of Volume.—Solids are measured by cubic yards, feet, and inches; 1728 cubic inches making a cubic foot, and 27 cubic feet a cubic yard. For all sorts of liquids, corn, and other dry goods, the standard measure is declared by the act of 1824 to be the imperial gallon, the capacity of which is determined immediately by weight, and remotely by the standard of length. See **GALLON.**

The parts of the gallon are quarts and pints, 2 pints being a quart, and 4 quarts a gallon.

WEIGHTS AND MEASURES.

Its multiples are the peck, the bushel, and the quarter; the peck being 2 gallons, the bushel 4 pecks, and the quarter 8 bushels. The following are the rotations:—

Pints.	Quarts.	Gallons.	Pecks.	Bushels.	Quarters.
1	0·5	0·125	0·0621	0·015625	0·001953125
2	1	0·25	0·125	0·03125	0·00390625
8	5	1	0·5	0·125	0·015625
16	8	2	1	0·25	0·03125
64	32	8	4	1	0·125
1512	256	46	32	8	1

Cubic or Solid Measure.

1728 cubic inches make - - 1 cubic foot.
 27 cubic feet - - - 1 cubic yard.
 40 feet of rough timber }
 50 feet of hewn timber } - 1 load.

This comprehends length, breadth, and thickness.

And 108 solid feet, that is, 12 feet in length, 3 feet in breadth, and 3 feet deep, or commonly 14 feet long, 3 feet 1 inch broad, and 3 feet 1 inch deep, are a stack of wood.

And 128 solid feet, that is, 8 feet long, 4 feet broad, and 4 feet deep, are a cord of wood.

(Loudon's Encyc. of Agr. p. 20.)

English Corn Measures.

4 gills = 1 pint = 34½ cubic in.
 2 pints = 1 quart = 69½
 4 quarts = 1 gallon = 277½
 2 gallons = 1 peck = 544½
 8 gallons = 1 bushel = 2218½
 8 bushels = 1 quarter = 10½ cubic ft.
 5 quarters = 1 load = 51½

See BUSHEL, PECK, QUARTER.

The Winchester quarter is more than the Imperial quarter, being in the proportion of 1 to 0·96945. The English Imperial quarter, in estimating weight, means the ¼ of a ton of 2240 lbs. = 560 lbs. or 1 quarter.

English Measures of Wood and other Fuel.—Cord-wood, being the bigger sort of fire-wood, is measured by a cord or line, whereof there are two measures; that of 14 feet in length, 3 feet in breadth, and 3 feet in height. The other is 8 feet in length, 4 feet in height, and 4 feet in breadth. This last is generally adopted in the United States.

Weights.—Weights are used to ascertain the gravity of bodies, a quality depending partly on their magnitude and partly on their density. The determination of the gravity or weight of different bodies supposes the invention of the balance. Nothing is known of the steps which led to its introduction; but it was used in the remotest antiquity. Weights have frequently been derived from grains of corn. Hence in England, and in some other European countries, the lowest denomination of weight is a grain; and 32 of these grains are directed, by the ancient statute, called *Compositio Mensurarum*, to compose a pennyweight,

WEIGHTS AND MEASURES.

whereof 20 make an ounce, 12 ounces a pound and so upwards.

Tables of Weights and Measures according to the Imperial Standard.

Avoirdupois Weight.	French grammes.
1 drachm =	1·771
16 drachms =	28·346
16 ounces =	453·544
28 pounds =	12 699 kilogram.
4 quarters =	50·796
20 cwt. =	1015 920

In England the stone is generally 14 lbs avoirdupois weight, but for butchers' meat or fish it is 8 lbs. Hence the cwt. equals 8 stone of 14 lbs., or 14 stone of 8 lbs.

Hay and straw are sold by the load of 30 trusses. See HAY and TRUSS.

The custom of allowing more than 16 ounces to the pound of butter used to be very general in several parts of England.

Wool Weight.—Like all other bulky articles wool is weighed by avoirdupois weight, but the divisions differ thus,

7 pounds = 1 clove.
 2 cloves = 1 stone.
 2 stone = 1 tod.
 6½ tods = 1 wey.
 2 weys = 1 sack.
 12 sacks = 1 last.

Cheese and butter.

8 pounds = 1 clove.
 32 cloves = 1 wey in Essex.
 42 cloves = 1 wey in Suffolk.
 56 pounds = 1 firkin of butter.

Miscellaneous Information relative to Weight and Measures.—Specific gravity is determined by weighing the substance first in air, and then in water at the temperature of 60° Fahrenheit. In the latter case the substance loses of its weight a quantity precisely equal to the weight of its own bulk of water. The total weight in air is then divided by the loss of weight in water and the quotient is the specific gravity. This is either over or under that of pure water which is the standard of comparison. The standard of weights is, the cubic inch of distilled water, weighing 253·458 Troy grains the Troy pound, 5760 grains, or 22·8157 inches. The same standard of 7000 Troy grains makes the pound avoirdupois, 27·7274 cubic inches 10 of which, or 277·274, being the imperial gallon, or a quart 69·32; and a gill of 5 ounce of water, equal to 8·664.

The specific gravity of water being 1·000 that of alcohol, pure, is 0·829; beer, 1·034; cider, 1·018; milk, 1·032; linseed oil, 0·94; vinegar, 1·025; sea-water, 1·026; ox bone 1·666; brass, 7·824; brick, 2·; cork, 0·24; gold 19·2587; granite, 2·728; bar-iron, 7·68; lead 11·352; lignum vitæ, 1·33; mahogany, 1·06; marble, 2·716; mercury, 13·58; oak, 1·17; platina, 20·722; silver, 10·474; clay-slate, 2·67; tin, 10·717; limestone, 1·386; elm, 0·671; honey, 1·45. (*Treasury of Knowledge.*)

A cubic foot of loose earth or sand weighs 95 lbs.

A cubic ft. of common soil weighs 124 lbs.
 " " strong soil, " 127 "
 " " clay, " 135 "
 " " mason's work " 205 "
 " " distilled water, 62·5 "
 " " cast-iron, " 450·45 "
 " " steel, " 489·8 "

A cubic ft. of lead,	weighs	709·5 lbs.
“ “ platina,	“	1,218·75 “
“ “ copper,	“	486·75 “
“ “ cork,	“	15 “
“ “ tallow,	“	59 “
“ “ oak,	“	73·15 “
“ “ brick,	“	125 “
“ “ air,	“	·0753 “

The American quintal is 100 lbs. The ton 2240 lbs.

The weight of a cubic inch of distilled water, in a vacuum, is 252·722 grains, and in air, is 252·458 grains.

The Turkish pound is 7578 grains; the Danish, 6941; the Irish, 7774; the Neapolitan, 4952; the Scotch pound Troy, 7620·8.

The imperial gallon contains 10 lbs. avoirdupois of distilled water, weighed in air at 62°, with the barometer at 30 inches. Two gallons are equal to a peck, 8 gallons to a bushel, and 8 bushels to a quarter.

Heaped measure, per bushel, is 2815¼ cubic inches clear.

The Winchester bushel is 18½ inches in diameter, and 8 inches deep, containing 2154·42 cubic inches.

1000 ounces of rain-water are equal to about 7½ gallons wine measure, or to a cubic foot.

Seven lbs. avoirdupois is a gallon of flour.

A chaldron of coals is 58¾ cubic feet.

Twelve wine gallons of distilled water weigh 100 lbs. avoirdupois.

The imperial dry bushel, when not heaped, is 2218·192 cubic inches; the peck, 554·548; gallon, 277·274, and quart, 69·3185. The bushel is 8 inches deep, and 18·8 wide, with a neat 6 inches high.

A bushel of wheat is 60 lbs.; rye, 53 lbs.; barley, 47 lbs.; oats, 38; peas, 64; beans, 63; clover-seed, 68; rape, 48 lbs.

A Scotch pint is equal to 4 English pints.

A Scotch quart is 208·6 cubic inches.

There are 545,267,000 cubic yards in a cubic mile.

According to usage in Philadelphia and other parts of the United States, building-stone, when piled, or “perched,” as it is usually termed, is measured by allowing 25 cubic feet to the perch. But when placed in the wall, only 22 feet are allowed to the perch. In measuring stone wall, 14 inches of thickness is usually allowed. When the thickness of the wall exceeds 14 inches, the extra thickness is estimated and made an additional charge. This is the common rule when the walls have only one face. In double-faced walls, there is commonly an allowance of about one-third more. Three pecks of good lime will generally suffice to lay one perch of stone wall. About 2 one-horse loads of sand are allowed to make mortar for 3 perches of stone wall.

To convert cubic feet into perches, divide by 25; or, what is still more easy, multiply by ·04.

In brick-work, 14 bricks are usually allowed to the cubic foot: sometimes only 13 are allowed. To convert cubic feet into cubic yards, divide by 3, and the product by 9.

Lumber Measure.—In estimating the number of feet in a board, the length in feet is to be multiplied by the width in inches, and the re-

sult, divided by 12, shows the contents in feet. When boards are more than 1 inch thick, all over is added. A board 12 feet long and 1¼ inch thick, would of course be estimated to contain one-fourth more than a board only 1 inch thick.

A bill passed by the legislature of Pennsylvania, in 1833, for the regulation of weights and measures in the state, provides for procuring and preserving standards, which are to conform to those of the United States, when established; the linear standard to be the yard, with the customary multiples allowed.

Superficial Measure.—Acre defined to be 4840 sq. yards.

Capacity Measures.—Wine gallon 231 cubic inches. Beer gallon 282 cubic inches. Bushel 2150·42 cubic inches. Lime bushel 13½ inches diameter at bottom, 15 inches at top, and 13·47 inches deep. A cord of wood to contain 128 cubic feet. A hogshead of cider 110 wine gallons.

Weights.—Troy pound to be equal to that of the United States mint, and the avoirdupois pound to bear to it the ratio of 7000 to 576

60 lbs. of wheat to pass for a bushel.

58 — rye.

58 — corn.

48 — buckwheat.

47 — barley.

32 — oats.

85 — coarse salt (foreign).

70 — ground salt.

62 — fine.

80 — anthracite coal, 112 lbs. to make 1 cwt., and 2240 lbs. = 1 ton.

If the square of the diameter of a circle be multiplied by ·7854, the product is the area. If the diameter of a sphere be cubed and multiplied by ·6236, the product is the solidity; and the square of the diameter, multiplied by 3·14159, is the surface of the sphere.

To find the contents of a cask, add double the square of the bung diameter to the square of the head diameter, and multiply this sum by the head of the cask; then divide the product by 1077 for ale gallons of 280 cubic inches each, or by 882 for wine gallons of 231 cubic inches each.

Method of ascertaining the Weight of Cattle while living.—This is of the utmost utility for all those who are not experienced judges by the eye, and, by the following directions, the weight can be ascertained within a mere trifle. Under the head CATTLE we have already given a useful table on this subject; but the annexed rules will be found of service. Take a string, put it round the beast, standing square, just behind the shoulder-blade; measure on a foot-rule the feet and inches the animal is in circumference, this is called the girth; then with the string measure from the bone of the tail, which plumbs the line with the hinder part of the buttock; direct the line along the back to the fore-part of the shoulder-blade; take the dimensions of the foot-rule, as before, which is the length, and work the figures in the following manner; —Girth of the bullock, 6 feet 4 inches; length, 5 feet 3 inches; which, multiplied together, make 31 square superficial feet; that again, multiplied by 23 (the number of

pounds allowed to each superficial foot of all cattle measuring less than 7 and more than 5 feet in girth), makes 713 lbs.; and allowing 14 lbs. to the stone, is 50 stone 13 lbs.; and where the animal measures less than 9 and more than 7 feet in girth, 31 is the number of pounds to each foot. Again, supposing a pig or any small beast should measure 2 feet in girth, and 2 feet along the back, which, multiplied together, make 4 square feet, that multiplied by 11, the number of pounds allowed for each square foot of cattle measuring less than 3 in girth, makes 44 lbs.; which, divided by 14, to bring it to stones, is 3 stones 2 lbs. Again, suppose a calf, sheep, &c., should measure 4 feet 6 inches in girth, and 3 feet 9 inches in length, which, multiplied together, makes $16\frac{1}{2}$ square feet; that multiplied by 16, the number of pounds allowed to all cattle measuring less than 5 feet and more than 3 in girth, makes 264 lbs.; which, divided by 14, to bring it to stones, is 18 stones 12 lbs. The dimensions of the girth and length of black cattle, sheep, calves, or hogs, may be as exactly taken this way as it is at all necessary for any computation or valuation of stock, and will answer exactly to the four quarters, sinking the offal, and which every man who can get even a bit of chalk may easily perform. A deduction must be made for a half-fatted beast of 1 stone in 20 from that of a fat one, and for a cow that has had calves, 1 stone must be allowed, and another for not being properly fat.

The last act of Parliament on the subject of weights and measures, is the 5 & 6 W. 4, c. 63, which contains some important provisions. It abolishes all local or customary measures under a penalty of 40s. for every sale made by them; it prohibits the mischievous practice of selling by heaped measure; it enacts that coals shall in all cases be sold by weight; that with the exception of the precious metals, jewels, and drugs, all other articles sold by weight shall be sold by avoirdupois weight only; and that a stone shall in all cases consist of 14 lbs. avoirdupois; a hundred weight of eight such stones, &c. Lead and pewter weights are not to be stamped. It enacts that the Winchester bushel, the Scotch ell, and all *local or customary* measures shall be abolished; and every person who shall sell by any measure other than one of the imperial measures, or some multiple or aliquot part thereof, shall be liable to a penalty not exceeding 40s. for every such sale. That the use of heaped measure shall be abolished, and all bargains, sales, and contracts made after the passing of this act, by heaped measure, shall be null and void.

Articles sold by heaped Measure, how to be sold.
—Whereas some articles heretofore sold by heaped measure are incapable of being stricken, and may not be conveniently sold by weight; it is enacted, that all such articles may henceforth be sold by a bushel measure, corresponding in shape with the bushel prescribed by the 5 G. 4, c. 74, for the sale of heaped measure or by any multiple or aliquot part thereof, filled in all parts as nearly to the level of the brim as the size and shape of the articles will admit; but nothing herein shall prevent the sale

by weight of any article heretofore sold by heaped measure.

All coals, slack, culm, and cannel of every description shall be sold by weight and not by measure.

All articles sold by weight shall be sold by avoirdupois weight, except gold, silver, platina diamonds, or other precious stones, which may be sold by Troy weight, and drugs, which, *when sold by retail*, may be sold by apothecaries weight.

The stone, hundred weight, &c.—From and after the passing of this act, the weight denominated a stone shall, in all cases, consist of 14 standard pounds avoirdupois, the hundred weight of 8 such stones, and the ton of 20 such hundred weights; but nothing herein shall prevent any bargain, sale, or contract being made by any multiple or aliquot part of the pound weight.

Fiar prices.—In Scotland, from and after the passing of this act, the *fiar* prices of all grain in every county shall be struck by the imperial quarter, and all other returns of the prices of grain shall be set forth by the same, without any reference to any other measure whatsoever; and any sheriff-clerk, clerk of a market, or other person offending against this provision shall forfeit not exceeding 5*l.* See *FIAR*.

Penalty on price lists, &c.—From and after the 1st of January, 1836, any person printing, or clerk of any market or other person making any return, price list, price current, or any journal or other paper containing price list or price current, in which the weights and measures quoted or referred to denote or imply a greater or less weight or measure than is denoted or implied by the same denomination of imperial weights and measures under the provisions of this act, shall forfeit and pay not exceeding 10*s.* for every copy of every such return, price list, price current, journal, or other paper which they publish. (*Brand's Dict. of Science; McCulloch's Com. Dict.*)

The following observations relative to the weights and measures of the United States are derived from a correspondent of the *Farmer's Cabinet*.

The subject of establishing by the Congress of the United States a uniform standard of weights and measures for the whole confederacy, is a matter of great importance to the agricultural and commercial interests. Most of the states, perhaps all, have legislated on this very interesting, important, and difficult subject, and it is obvious, from the results of their disjointed labours, that there is still room for the exercise of the skill, judgment, and science of the most learned men in the nation, to reduce the chaos to order, and to prepare a uniform system, founded on scientific principles, for the use of the whole nation. Much confusion and loss must be sustained by the great discrepancies which exist in the weights and measures in use in the different states which are in habits of constant commercial intercourse.

On an examination of the learned and able report made by John Quincy Adams to the Senate of the United States in 1821, and that made by F. R. Hassler to the same body in

1832, on this subject, it does not appear that the bushel in any two states contains the same number of cubic inches, and some of them differ materially from each other; the weights also are variant, and the measures do not always correspond with each other. In Pennsylvania the Winchester bushel, 18.5 inches in diameter and 8 inches deep, and containing 2150.42 cubic inches, is understood to be the standard dry measure; one-eighth of this, or 268.8 inches, is a gallon, and 67.2 cubic inches the quart, dry measure. The ale gallon is 282 cubic inches, and the quart 70.5 inches; and this is understood to be the quart by which dry articles are measured. The wine gallon, which is also the measure of all spirituous liquors, contains 231 cubic inches, and the quart 57.75 inches. The reason for these differences is not sufficiently apparent to be recognised by any person of ordinary understanding, but they are calculated to produce much embarrassment, and not a little fraud, for there are always persons who are disposed to sell by the smaller rather than the larger measure. In England, whence we obtained all our standards of weights and measures, a better system has of late years been adopted, by which the pint, quart, and gallon, for wine, ale, beer, and grain or corn, measure the same with regard to magnitude; 8 of these gallons make one bushel; and one gallon contains 277.274 cubical inches, or 10 pounds of distilled water at a temperature of 62 degrees; and the imperial bushel 2218.192 cubic inches, or 80 pounds of water at 62 degrees.

From the above it appears that the English bushel at present in use contains 67.772 cubic inches more than the standard bushel of Pennsylvania.

WELD (*Reseda luteola*). The dyer's weed, yellow rocket, or yellow weed, is in England an indigenous annual plant, growing in waste ground, especially on a chalky soil, as well as in fallow fields, and on walls. The root is tapering. The stem wand-like, striated, leafy, somewhat branched, smooth, like the rest of the herb; 2 or 3 feet high. The leaves are sessile, of a darkish green, linear-lanceolate, obtuse, entire, single-ribbed. The flowers are in terminal clusters, erect, many-flowered, dense, pointed. The flowers themselves, which blow in July, are small, greenish-white, without much scent. Weld is cultivated for the sake of its stalks, flowers, and leaves, which are employed for dyeing wool and other substances yellow, or, mixed with indigo, green. The whole plant is fetid when bruised. When it has attained maturity, which is about the time of flowering, it is pulled, and made into bundles and dried, in which state it is used as a dye-stuff. Weld is preferred to all other substances for giving the lively green lemon-yellow: but, to render the yellow permanent, the wool must be previously prepared with a mordant of alum and tartar. Being an exhausting crop, and liable to failure from many causes, the cultivation of the dyer's rocket is only partially carried on in Essex and a few other places in England.

Weld will grow on any soil, but fertile loams produce the best crops. Loudon gives the fol-

lowing directions for sowing and managing weld.

The soil being brought to a fine tilth, the seed is sown in April or the beginning of May, generally broadcast. The quantity of seed is from two quarts to a gallon per acre, and it should either be fresh, or, if two or three years old, steeped a few days in water previously to being sown. Being a biennial, and no advantage obtained from it the first year, it is sometimes sown with corn crops in the manner of clover, which, when the soil is in a very rich state, may answer, provided also, that hoeing, weeding, and stirring take place as soon as the corn crop is cut. The best crops, however, will obviously be the result of drilling and cultivating the crop alone. The drills may be a foot asunder, and the plants thinned to 6 inches in the row. In the broadcast mode it is usual to thin them to 6 or 8 inches distance every way; often, when weld succeeds corn crops, it is never either thinned, weeded, or hoed, but left to itself till the plants are in full blossom.

The crop is taken by pulling up the entire plant, and the proper period for this purpose is when the bloom has been produced the whole length of the stems, and the plants are just beginning to turn of a light or yellowish colour; as in the beginning or middle of July in the second year. The plants are usually from 1 to 2½ feet in height. It is thought by some advantageous to pull it rather early, without waiting for the ripening of the seeds, as by this means there will not only be the greatest proportion of dye, but the land will be left at liberty for the reception of a crop of wheat or turnips; but in this case a small part must be left solely for the purpose of seed. In the execution of the work, the plants are drawn up by the roots in small handfuls, and set up to dry after each handful has been tied up by one of the stalks, in the number of 4 together in an erect position against each other. Sometimes they, however, become sufficiently dry by turning without being set up. After they have remained till fully dry, which is mostly effected in the course of a week or two, they are bound up into larger bundles, that contain each 60 handfuls, and which are of the weight of 56 lbs. each: 60 of these bundles constituting a load. These last, in places where this kind of crop is much grown, are tied up by a string made for the purpose, and sold under the title of weld cord.

The produce of weld depends much on the nature of the season; but from half a load to a load and a half is the quantity most commonly afforded, which is usually sold to the dyers at from 5*l.* or 6*l.* to 10*l.* or 12*l.* the load, and sometimes considerably more. It is mostly bought by persons who afterwards dispose of it to the dyers occasionally as they find it convenient. The demand for it is sometimes very little, while at others it is so great as to raise the price to a high degree. It is sometimes gathered green, and treated like woad or indigo; but in general the dried herb is used by the dyers in a state of decoction.

The use of weld in dyeing is for giving a yellow colour to cotton, woollen, mohair, silk, and linen. Blue cloths are dipped in a decoction of it, which renders them green; and the yel

low colour of the paint called Dutch pink is obtained from weld.

To save seed, select a few of the largest and healthiest plants, and leave them to ripen. The seed is easily separated.

The chief disease of weld is the mildew, to which it is very liable when young, and this is one reason that it is often sown with other crops.

WELL (Sax.). A term sometimes applied to a chimney or vent-hole left in a rick or mow of hay, or other similar materials, to prevent its overheating.

WHEAT (*Triticum*). This is undoubtedly the most important genus of the order *Gramineæ*; for wheat is that species of grain which is more generally cultivated than any other, and, from the universal demand and high price it obtains, best repays the European farmer's toil and outlay.

The flour of wheat is the most nutritious and palatable of all the cereal grasses used as the food of man. Linnæus comprehended all the different varieties of wheat known in his day under six species; but modern botanists enumerate about 30 species, and some hundreds of sub-varieties brought into existence by continued cultivation. It has been well observed that for mere practical purposes it is sufficient to have two general classes, namely, white and red, and the varieties distinguished by their spikelets, as the smooth or bearded, the woody-chaffed or the hairy-chaffed. There are some varieties characterized, also, as spring or winter (Lammas) wheats, though these are frequently apt to lose their distinguishing characters, and to accommodate their habits to the season in which they are sown.

"It is to be presumed," says Colonel le Couteur, "from the passage 'In the sweat of thy face shalt thou eat bread,' (*Gen.* iii. 19), that wheat was coeval with the creation; and that upwards of a thousand years before the Christian era, some improvement in its culture and some knowledge of a superior variety had been attained, by the circumstance of its being stated that 'Judah traded in wheat of Minnith.'" (*Ezek.* xxvii. 7.)

Columella, who wrote about the time of our Lord, makes some interesting remarks on wheat:—

"The chief and the most profitable corns for men," he observes, "are common wheat and bearded wheat. We have known several kinds of wheat; but of these we must chiefly sow what is called the red wheat, because it excels both in weight and brightness.

"The white wheat must be placed in the second rank, of which the best sort in bread is deficient in weight.

"The trimestrian shall be the third, which husbandmen are mighty glad to make use of; for when, by reason of great rains or any other cause, the early sowing has been omitted, they have recourse to this for relief; it is a kind of white wheat." Pliny says that "this is the most delicious and the daintiest of any sort of wheat, exceeding white, but without much substance or strength, only proper for moist tracts of land, such as those of Italy, and some parts of Gaul; that it ripens equally, and that there

is no sort of corn that suffers delay less, because it is so tender that such ears of it that are ripe presently shed their grains; but in the stalk it is less in danger than any other corn, for it holds its ear always upright, and does not contain the dews which occasion blasting and mildew." (This description of Pliny's seems to accord with the spring wheat of the present day, which, be it remembered, came to us from Spain.)

"The other sorts of wheat are altogether superfluous," continues Pliny, "unless any man has a mind to indulge a manifold variety, and a vainglorious fancy. But, of bearded wheat, we have commonly seen four sorts in use; namely, that which is called clusinian, of a shining bright white colour; a bearded wheat, which is called veniculum; one sort of it is of a fiery red colour, and another sort of it is white, but they are both heavier than the clusinian. The trimestrian, or that of 3 months' growth, which is called halicastrum; and this is the chief, both for its weight and goodness. But these sorts, both of ordinary common wheat and of bearded wheat, must, for these reasons, be kept by husbandmen; because it rarely happens that any land is so situated that we can content ourselves with one sort of seed, some part of it happening, contrary to our expectation, to be wet or dry. But common wheat thrives best in a dry place, and bearded wheat is less affected by moisture."

Hence it appears that Romans were aware of the propriety of selecting their wheat, and that it was then believed that winter or beardless wheat was best suited to dry uplands, and bearded wheat to low or moist lands. In addition to the winter wheats, some of which he states to be bearded, he distinctly alludes to the trimestrian or spring wheat, of which I shall speak hereafter. In the edition of *Gerard's Herbal*, printed in London in 1660, only 5 kinds of wheat are enumerated; and, although this was the leading botanical work of the day, these are most indistinctly described.

Modern writers generally are equally vague; they merely designate a number of varieties; but no attempt appears to have been made to class them correctly, or to ascertain their relative values by comparison.

In *Sinclair's Hortus Gramineus Woburnensis*, 42 of the cultivated varieties are enumerated as winter or spring wheats, according to the arrangement of Linnæus, which this illustrious writer has merely given as a sort of botanical classification.

The *Maison Rustique* for 1835, enumerates 39 varieties; and, although a short notice is given of them, it is by no means sufficient, as their farinaceous qualities are not explained. Mr. Paxton, in his *Botanical Dictionary*, enumerates 25 distinct species, besides several varieties.

A classification of wheat is much required, pointing out the relative value of varieties, in their quantity of meal, the weight of bran and pollards, with the weight of straw of each, and their adaptation to soils. That this is a desideratum no one, I imagine, will deny; but that it requires time, attention, and perseverance, to make such discoveries, will also be conceded, when it is stated that I already possess up-

wards of 150 varieties or sub-varieties. (*Le Couleur on Wheat.*)

The most popular description of the different species of wheat which admit of cultivation for their seed is that given by Professor Low, in his work on the *Elements of Agriculture*, and I shall therefore avail myself of his scientific description.

Specific character.—The calyx of wheat consists of 2 valves or glumes, enclosing several florets. In each of these florets there are 2 valves, forming the corolla, and enclosing the seed. Sometimes the corolla encloses a perfect seed, and sometimes the seed is not perfected. Each calyx, with the florets which it encloses, is termed a spikelet. The part to which the spikelets are attached is termed the rachis or shaft, and the spikelets placed one above the other, on each side of the rachis, form the ear or head. The rachis is jointed, and the spaces between the joints are termed the internodii.

Species.—1. Spring or summer wheat (*T. aestivum*) Pl. 2, a, has awns both on the calyx and corolla. Each spikelet has usually 5 florets, of which 2 are barren. The grain is too tender to bear the frosts of the winter, but as quick in progress from its first shoot to ripeness as barley, oats, or any other spring corn. It requires a shorter period to complete its vegetation than any of the other kinds. Summer wheat is the prevailing species of warmer countries, and is cultivated in many parts of Europe. It is much used in France, where it is called *blé de Mars*, from the season in which it is usually sown, and in some provinces *bleds tremois*, from the time it takes between seed-time and harvest. In Spanish it is called *trigo de margo*; in Portuguese *trigo tremes*; and in German *sommer waitzen*, all which names mark distinctly the difference between this and winter corn. It does not appear from the older books on husbandry, that it was at any period much cultivated in England; the more modern ones are, in general, silent on the subject of it; they mention, indeed, under the name of spring wheat, every kind of winter wheat which will ripen when sown after turnips in February. This is probably the reason why the real spring wheat has been so little known; agriculturists in general conceiving themselves to be actually in the habit of sowing spring wheat, when, in reality, they were substituting winter wheat in its place, have been little inclined to inquire into the properties of the true spring wheat when they had an opportunity of so doing.

Its grains are, for the most part, small, and the produce of the straw is less than that of some other species, when cultivated under the same circumstances. Professor Low says, that “the trials which have been made with it in this country have shown it to be inferior in productiveness and quality to the better kinds of winter wheat. The advantage which it possesses is the earlier period of its ripening, on which account it may be sown so late, even in this climate, as the beginning of May.” The Board of Agriculture being desirous of bringing spring wheat into general cultivation, in 1805 offered large premiums to those who should, in the spring of that year, sow the

greatest quantity of land with spring wheat. In one of the communications made to the Board, Sir Joseph Banks states that “in the countries best acquainted with its culture, spring wheat is preferred to all other corn for raising a crop of seeds. This is owing to the small quantity of leaf it bears, less, perhaps, than any other corn, and to the short duration of the leaf, which fades and falls down almost as soon as it has attained its full size.

“In cases where red wheat has been damaged by the wire-worm, a mischief which seems of late years to have increased in Great Britain, spring wheat appears to hold out an easy and simple remedy. In the first week of May the ravages of the worm have somewhat abated; if then the seed of spring wheat is at that time dibbled, or only raked with a garden rake, into the naked spots left by the worm, though it will not attain the growth at which the worm begins to prey upon it till he has changed his state for that of a winged beetle, it will certainly be ripe as soon as the winter wheat, and may be thrashed out and sold with it; or, if it is preferred, may be reaped separately, as the appearance of the ears, which, in the Lincolnshire sort, have longer beards or awns than the rivet or cone wheat, will point it out to the reapers in such a manner that no great error can happen in separating it from the Lammas.” (*Com. to Board of Agr.* vol. v p. 181.) To the miller this mixture of grain can be of no consequence; but it would be scarcely safe to employ the produce as seed.

From the analysis of Sir H. Davy it may be inferred that bread made of the flour of spring wheat is more nutritious than that made of winter wheat, because the former contains a larger proportion of gluten or half-animalized matter. He found that

	Gluten.	Starch.	Insoluble Matter.
100 parts of the best Sicilian wheat contained - -	21	75	5

100 parts of blighted wheat of 1804 - - - -	13	52	44

2. Winter, or lammas wheat (*T. Lyburnum*), Pl. 2, b, is distinguished from the last by its appearance, being much more vigorous in the stem, more erect and thick in the ear, by having no awns upon the calyx, and only short awns upon the corolla, near the summit of the spike. But the awns not being a good botanical character, many botanists have conceived the species to be the same. The characters, however, of either kind being permanent and remaining under given circumstances unchanged for an unknown period, they may be regarded as species. The winter wheat has usually 5 or 6 florets, of which 2 are barren.

Winter wheat is that which is the most important with relation to its cultivation in Northern Europe. It is, in England, generally sown in autumn, or previously to the winter months, and ripens its seed in the following summer; but it is an annual plant, and may be sown in spring.

"Slight varieties of this species are exceedingly common in different localities, and are probably attributable to some peculiarities in the mode of culture. The common varieties of winter wheat are distinguished from each other according to the colour of the tunic enveloping the grain, and the difference observable in their chaff. The colours are usually divided into white and red, the latter of these including many different shades of brown. Red wheat is commonly said to be more hardy than white; it is therefore thought better suited for cultivation in bleak and upland districts. The plant is, however, not so productive as the white, and the flour which it yields is seldom of so desirable a quality." (*Baxter's Lib. of Agr.* p. 640.)

3. Compact wheat (*T. compactum*) is allied to the two last-named species, and may be merely a variety of them. In it the internodii of the rachis are very short. It is partially produced in different parts of Europe. "I have received specimens of it," says Professor Low, "from France and Sweden, and have cultivated them without observing any change of characters. Whether, however, the characters which distinguish it are sufficiently permanent to entitle it to be regarded as a species, has not been determined. In the mean time, following the authority of Host (*Icones et Des. Gram. Aust.*), I have placed it amongst the species."

4. Egyptian, or many-spiked wheat (*T. compositum*), Pl. 2, c, is distinguished from the others by its branched or compound spike, which no other species tends, under any circumstance, to produce. Its seeds are numerous, and the produce abundant. It requires a good climate and a fertile soil, for in unfavourable situations the branches of the spike are not evolved, and then it assumes the appearance of ordinary wheat. It is cultivated in Egypt and the east, as it is in the south of Europe and different parts of Italy. It was known in Germany about 240 years ago, and in France it is said to have been cultivated for about 80 years, having been brought from the east under the name of wheat of Smyrna. In England it has been partially cultivated as the subject of experiment. It is uncommonly fruitful, and the straw is very strong and tough, whence it has received the name of reed wheat.

The grains, however, do not yield so large a proportion of flour or meal as any of the other species and their varieties, and the flour is scarcely superior to that obtained from the finest barley. Egyptian wheat will bear great degrees of heat and drought without harm, so that it is found to yield abundantly in situations where other kinds would be greatly injured, if not destroyed; a circumstance which points it out as admirably adapted to the arid lands whereon it is chiefly cultivated. It would be more cultivated in England, if its form did not cause it to hold the wet at harvest-time, and hence it is very liable to be laid.

5. Turgid wheat (*T. turgidum*), Pl. 2, d. In this species the corolla is awned, but not the calyx; the spikes are covered with soft hairs, and in some varieties change to a dark colour, and the awns drop off as the seeds become

ripe, in which respect it differs from summer wheat. It is known in different localities under the several names of gray wheat, duck's bill wheat, gray pollard, rivet, pole rivet, cone, pendulum, &c. This species grows very tall, with a thick and rigid stem. The spikes are large and heavy, and nod to one side as the grain increases in weight. The kinds or minor varieties are distinguished by the farmer from their qualities of earlier or later ripening, and greater or less productiveness. One of the most esteemed of these is cone wheat, so named from the conical form of its spike. The turgid wheats are productive in corn and straw, but the grain is coarse and hard, and the flour much browner and of an inferior quality. They are chiefly suited to the inferior clays, upon which in England they are extensively cultivated. They are valued under such circumstances for their productiveness in grain and their large growth of straw; but being inferior to the winter wheats in the quality of their produce, the cultivation of them is not likely to be extended in that country.

6. Dark-spiked wheat (*T. atratum*) is allied to the last species, if it is not rather to be regarded as a variety of it. It has merely been made the subject of experiment, but not of extended cultivation. It is not superior in productiveness to the turgid wheats in common use.

7. Barley-like wheat (*T. hordieiforme*), so named from its peculiar form, resembling that of barley, seems, like that last described, to be derived from Africa. The florets are awned, and the calyx and corolla become dark as the seeds ripen. But it resembles the class to be next referred to, termed spelt-wheat.

8. Far (*T. zea*) is one of the class of spelt-wheats. It is distinguished by the distance of its spikelets from one another. The straw is rigid; the calyx and corolla adhere closely to the seed, and the spikelets again so closely to the rachis, that they cannot be separated from the rachis without breaking it. This wheat is cultivated in some parts of Europe on inferior soils.

9. Spelt-wheat (*T. spelta*), Pl. 2, f, is distinguished like the last by its spikelets being firmly attached to the rachis, and by its rigid calyx and corolla closely enveloping the seed. Spelt is much cultivated in the south of Europe. It is grown extensively in the southern provinces of France, in Switzerland, Italy, in several parts of Germany, and in Arragon, Catalonia, and other parts of Spain, as well as in the north of Africa, and at the Cape of Good Hope. Spelt could be raised in England with facility, and it is probable on soils low in the scale of fertility. It has been cultivated in Scotland, 600 feet above the level of the sea. It is said that spelt-wheat is better adapted than any of the more delicate kinds for culture in Australia, and probably it will be found the more preferable sort in all the more southern wheat-growing countries.

There are two distinct varieties of spelt, distinguished as the awned and the awnless; the latter is perhaps the most naked of all the cerealia. The grains of this are large, but the ear contains only a small number of them. as

a portion of the flowers prove barren. It is generally, if not always, a spring-sown crop; grows strongly, and its stalks are nearly solid. Bread made of its flour is said to be of a dry quality. It is well known in commerce that the incomparable Nuremberg and Frankfort starch and flour are solely obtained from spelt-wheat. The grain cannot be divested of its husks by thrashing, and therefore requires to be passed through a mill. It should however be sown or drilled with the husks on.

10. One-grained wheat, or St. Peter's corn (*T. monoccocum*), Pl. 2, g, is readily distinguished from all the other wheats by its general appearance, in which it resembles barley. Its spikelet consists of three or four florets, one of which only is for the most part fertile, and hence its name of one-grained wheat. The fertile floret has a long awn. The stem of this species of wheat is slender and rigid; and, from being both hard and fine, the straw is excellent for thatching. It is allied to the spelts, with which it was classed by some of the older botanical writers. This species is principally cultivated in the mountains of Switzerland and other elevated regions of Europe, and in barren soils. In consequence of its containing less gluten than common sorts, it answers better for being boiled into gruel and for being baked into bread. The four-sided form of the ripe ear is so regular, that it has the appearance of being carved in ivory. It has never formed an object of cultivation in this country, and does not appear to possess properties to entitle it to be introduced.

11. Polish wheat (*T. polonicum*), Pl. 2, e. This species has long awns, and is distinguished from all the others by its long and leafy calyx and corolla. It is cultivated in Germany, in Poland, and in Spain. It was brought into notice, and partially cultivated, in some of the counties of England, in the latter part of the seventeenth century; and it is said to have been valued on account of its productiveness of flour. But, although it may be possessed of this quality, its florets are often infertile, and it does not merit a more extended culture in this country. Unless sown sparingly, it is apt to lodge, in consequence of which the quality of the corn is impaired.

Varieties.—The minor varieties of any species of wheat are not permanent in their character, though, under given conditions, they will remain unchanged for an indefinite period. Under other circumstances, however, they degenerate; and hence particular kinds that were once valued have now ceased to be so. The best advice that can be given, therefore, in the choice of varieties and sub-varieties, is to select those which the practice and experience of the principal farmers of the neighbourhood have stamped as the best. Colonel Le Couteur, one of the best authorities on the culture of wheat, has given us the result of his experiments and great experience, upon four of the best pure and improved varieties of wheat lately introduced into England. (*Journ. Roy. Eng. Agr. Soc.* vol. i. p. 113.)

1. *White downy.*—This excellent variety is believed to be the same that is so well described by Boys in his *General View of the Agri-*

culture of Kent, as the "Hoary White," or "Velvet-eared," said by him to have been much prized by the millers, but then entirely lost. The seed after being washed and steeped was sown in drills 7 inches apart, at the rate of two bushels or a little more to the acre. The wheat was carefully hand-hoed in the month of May, which caused it to tiller freely. The preceding crop was potatoes. This wheat will withstand the most severe weather. The season 1837 to 1838 was a very trying one, both as to wetness and severity of cold, the thermometer having fallen to 18° below freezing; but the crops of this wheat raised by my neighbours were perfectly insensible to it, and of great produce. This wheat is not remarkable for its early maturity, though it cannot be called a tardy variety. It is not subject to degenerate, and if attention is paid to sowing the seed pure, and annually, or even occasionally, varying the manure intended for it, it is possible that it may never degenerate. The only objection to it is the huskiness or velvety ear, which in damp weather is retentive of moisture; and in snatchy seasons the grain is more apt to sprout than the smooth-chaffed varieties. It is not much affected with dust-brand; and when pickled and limed, has never been found with smut-balls. It is little liable to shed, even when over-ripe, and will resist very heavy gales without being laid or broken.

2. *Jersey Dantzic.*—The seed is described as having been raised from a single ear, originating from seed procured from Dantzic, selected from the finest "high mixed." It is, however, suspected to be identical with some excellent sorts, called in Sussex, Kent, and some parts of Surrey, the "Chittums;" in other parts "Pegglesham;" in Berkshire, "Trump;" in Essex, "Hardecastle;" in some counties, "Old Suffolk;" in Scotland, "Hunter's White;" and assuming several other names. This wheat is not quite so hardy as the "hoary;" it is, nevertheless, considered sufficiently so to succeed throughout the kingdom, excepting the northern parts of Scotland. In rich soils it tillers amazingly, and produces a longer straw than the hoary, nor is it so liable to sprout in a moist climate from being smooth-chaffed: in very severe, moist, and stormy weather, it will be laid sooner than the hoary.

It ripens a week earlier at least than the variety last described, and should be reaped while the grain can be marked by pressure from the thumb-nail, as it is rather liable to shed if over-ripe, a disadvantage which the hoary is peculiarly free from, as it is tenacious to the ear. In the dry season this wheat will afford a beautiful, clean, white straw, fit for bonnet-making, or any purpose of thatching: it is firm and tenacious. In wet seasons it is rather subject to rust, which, under such circumstances, almost all wheat suffers from.

3. *Whittington Wheat.*—The seed was obtained from Mr. Whittington himself, and was a very fine, pure sample. The grain is large, full, and plump, rather of a whitish-red cast, and a little thick-skinned. The seed was washed, pickled, drained, and limed, then sown in drills seven inches apart, about three bushels to the acre. When the seed is large, it is con-

sidered prudent to add half a bushel or more to the acre. I consider this to be a very hardy wheat, affording much herbage and straw, very fit for being eaten down by sheep in the spring when sown early in the fall. The Whittington is rather a late wheat, ripening a week or ten days later than the Jersey Dantzic before described, though it was in bloom on the same day. From the purity of the seed, and the uniform appearance of the crop, it does not appear likely to degenerate, nor does it seem more liable to disease than other wheats. The straw is brittle, and many ears break off. I am of opinion, from what I have witnessed, that the value of this description of wheat is much overrated: the millers dislike it, and in certain situations it is apt to blight.

4. *Bellevue Talavera*.—This admirable variety is invaluable where it is adapted to the soil and climate. The seed being large, a greater quantity of it should be allowed than usual. This wheat has succeeded in the north of Scotland, and is sufficiently hardy to withstand the winter in its grassy state, but it is otherwise more valuable as a spring crop: without doubt it may be sown as late as the first week in February in all the milder parts of England, with a prospect of reaping quite as good an average crop from it as from any other wheat, but with a certainty of obtaining more flour than from most. There is no tendency to degenerate observable in this wheat, as far as the experience of five or six years goes; nor, from its early habits, is it at all likely to become intermixed by fecundation from other varieties, though sown about the same period, as it will, in such cases, flower a fortnight or three weeks before them. It is not more liable to disease than ordinary white wheats, and affords a very fine, clear, white straw: it is, indeed, one of the Italian bonnet-making varieties. There is, however, one disadvantage in it, which is, that

the ear is so heavy that it is apt to break down, though not break off, when swept by a gale about the period of ripening; but it has a countervailing good quality, of ripening the grain equally well though bent down; as is the case with spring wheats, which ripen their seed well though quite laid, which with winter wheats is doubtful. Another peculiarity is the tenacity of the chaff to the ear, more remaining on it after passing through the thrashing-machine than any other variety I am acquainted with.

The following sorts I have also grown experimentally, but, not having raised them in quantities sufficient to warrant a positive opinion, which probably might only tend to mislead, they are merely named.

The "golden drop" is one of the best red wheats, affording great produce in corn and straw, and a larger quantity of flour than some white wheats.

"Hickling's prolific red" is a productive variety, but rather coarse. The properties of this wheat are, straw long, stout at the bottom, and tapering at the head; head short, thick, close, and heavy; kernels four in the row across the ear, and red in colour, with the chaff white; in sample the wheat is short, plump, thin-skinned, and looks as if it would flour well: colour dark orange-red.

Brown's "ten-rowed chevalier," or prolific, is well named, where it suits the soil and climate: it is, when pure, a very fine variety.

"Gale's Hampshire" is a very enormously productive sort of bearded wheat. "Essex red," a very good variety. "The duck's-bill" wheat is very productive, but shedding greatly, and not very farinaceous.

In order to present the particular points of comparison between the four principal varieties above-described, the results are appended in a tabular form:—

Varieties.	Soil.	Manure.	Quantity of Seed per Acre.	Time of Sowing	Harvested.	Produce per Acre.				Produce per Acre in			Net Profit.
						Grain.	Straw.	Chaff.	Weight of Bushel.	Finest Flour.	Flour &c. (Pound and Bran).	Produce of Bread from 18 lbs. of Flour.	
White Downy	Argillaceous schist, light and rich.	Kelp ashes, 9 qrs.	2 bushels.	Jan. 29.	Aug. 16.	bush	lbs.	lbs.	lbs.	lbs.	lbs.	lbs.	L. s. d.
Jersey Dantzic						Ditto.	Ditto.	Aug. 12.	43½	4681	430	63	2161
Whittington	Do. on a red clay bottom.	2 hhds. of lime. 6 qrs. lime ashes. 5 qrs. kelp ashes.	3 bush.	Jan. 8.	Aug. 24.	33	7786	483	61.	1454	524	23½	2 7 6
Bellevue Talavera						Ditto.	Ditto.	Ditto.	Feb. 3.	Aug. 17.	52	5480	282

N. B.—In the estimate of profit, in the last column, the calculation is not made with relation to the respective values of the wheats as to their productiveness in flour, which it might be, but according to the ordinary market-value of good wheat; the straw is valued as intended for manure.

The following is an excellent account of an experiment on the relative values of several varieties of wheat by Mr. John Morton, which I have extracted from the first volume of the *Journ. of the Eng. Agr. Soc.*, p. 39. It is from practical and carefully carried out experiments, such as these, that we shall be able to arrive at the proportionate value of different species and new varieties of wheat, and from which we may be enabled to select the good and reject the bad kinds.

The profits of farming, whether the land be pasture or arable, and the tenant be a feeder of stock or a tiller of the ground, may be increased in two ways. The stock-farmer knows very well that the return he obtains from his cattle depends, not only on the kind of food given to them, and the manner in which it is supplied, but also on the feeding qualities of the breed to which they belong; and he increases his chance of profit as much when, on purchasing from the breeder, he selects with

judgment, as when he adopts an improved mode of feeding. The intelligent farmer of arable land, again, expects a greater crop, the more he has been able to improve the texture of the soil, and the better the nature and state of the manure which it contains. He expects it, because he knows that it depends on the nature of the food given to the plants, and the manner in which they are provided with a constant supply of it. The crop does not, however, depend only on this: for as two beasts, fed in exactly the same manner, may not be equally profitable, owing to a difference between them regarding the quantity and quality of the meat they afford, so two different kinds of wheat, though sown on land precisely similar, and in equally good condition, may give unequal returns, owing to a difference between them regarding the quantity and quality of the flour they afford. Hence the importance, too often overlooked by farmers, not only of preparing the land for the crop in a good and sufficient manner, but also of selecting that kind of seed which experience has pointed out as being most valuable and productive. It was with a view, not only of ascertaining the relative value, hardiness, and other properties of several of the most commonly planted wheats, but also of effecting an improvement in the best of them, that the following experiment was commenced on the 1st of November, 1837. To insure accuracy in the results, it was necessary that the seeds of each variety should be planted so as to have them all at equal distances. To effect this, two boards were used, each 6 inches wide, 9 feet long, and $\frac{1}{2}$ inch thick. Along the centre of each board was a row of holes, 3 inches apart and 1 inch in diameter. A dibble was made to fit into the holes, having

a shoulder at the distance of $2\frac{1}{2}$ inches from the point.

When the board was placed on the ground, and the dibble put through each hole in succession, a series of holes was thus made, 2 inches deep, and 3 inches apart from centre to centre.

After this had been done through the first board, the second, which was touching it, and parallel to it, was served in the same way; and then the first was taken up, and placed on the other side of the second. By proceeding thus, the whole ground was finished, and then one grain of wheat was dropped into each hole. The rows were thus exactly 6 inches apart, and the grains in the rows were 3 inches from one another. The regularity with which the planting was performed was thus mathematically accurate. The ground planted lies on the lower edge of the great oolite formation, and the soil is a stone brash, about 10 inches in thickness. Crops of potatoes had been taken off it for a succession of eight years; and it had been manured every alternate year with a compost of equal bulks of stable-dung and earth, at the rate of about 20 cubic yards per acre. It was 67 feet in length; and 3 rows of each variety of wheat were planted, except the first and last numbers, of which there were 4 rows. The outer row of each of these, however, was not taken into account, because their roots had a much greater extent of ground for their growth than the others, whose roots touched one another all round. The end plants of each row were also rejected for the same reason. Sixty-six feet in length of ground were thus taken up, and three rows of each variety occupied in width $1\frac{1}{2}$ foot: the ground occupied by each variety was thus 99 square feet, the 440th part of an acre:

When planted.	No.	Name of Wheat.	Whence obtained.	No. of Seeds planted.		Produce of 99 sq. Feet.		No. of Ears in one square Foot.	Average No. of Heads per Root. Note.—Specimens, in the straw, of each of the varieties mentioned in the Table, were laid before the Society.

Although the tabular form in which this experiment is detailed explains itself by the headings of each column, yet it is considered necessary to give a somewhat fuller account of it. The seed from which the first ten varieties were raised was carefully selected from specimens of each obtained in the ear. The others were from samples, and here, also, the greatest

care was taken that the seed from which each was raised should be the best and plumpest that could be obtained.

The first five columns need no explanation beyond what is given at the head of each; the sixth shows the number of grains lost from casualties. If the frost had been the only agent in the destruction of so many of the seeds, this column might have been considered as a very accurate index of the relative hardiness of each variety. This, however, is not the case; for the havoc which the birds made must also be taken into account. It was thought at the time that more injury was sustained from the latter cause by those varieties planted on the 21st than by any of the others; but this does not appear to have been the case, for, if the great loss sustained by these had been wholly owing to the havoc committed by the birds, it is evident that the varieties marked Nos. 12 and 15 would not have been so slightly injured, while Nos. 11, 13, 14, and 16 suffered so severely. The figures in this column may, therefore, be said to indicate with tolerable accuracy the relative ability of each variety to withstand the effects of a severe and changeable winter, such as that during which the experiment was made.

The number of plants of each variety which came to perfection is placed opposite the name of each in the seventh column. This was ascertained by pulling each as they respectively ripened, and counting the plants of each before proceeding to the others. In this way, by a simple subtraction, the numbers contained in the sixth column also were ascertained.

When all the plants of any variety had been pulled, the number of ears also belonging to them was counted, and the results are placed in the eighth column.

By dividing these by 99, the number of square feet which each variety occupied, we obtain the number of ears in each square foot; and this is placed opposite the name of each wheat, in the ninth column.

The average number of ears to each root, ascertained by dividing the number of ears by that of the roots, is placed in the tenth column. This column shows the degree in which each species possesses the important property of spreading and shooting out stems, or, as it is technically termed, of *tillering*; and it will be seen that they vary in this respect greatly.

After having been pulled and dried, the wheat was carefully rubbed out; and, after the light and imperfect grains had been separated, the weight of the remainder was taken, and placed opposite each sort, in the eleventh column.

The thirteenth column contains the number of bushels per acre raised from each variety. As the quantity produced was so small, there was some difficulty in obtaining the particulars which this column contains.

The mode adopted was this: The average weight of several of the varieties was ascertained, by weighing 8 pints of each, to be at the rate of 64 lbs. per bushel, some being rather more and others less. The number of bushels were then obtained from the weight of wheat per acre, by dividing it by 64.

The weight of straw, which is placed in the fifteenth and sixteenth columns, was ascertain-

ed after the roots had been cut off, and after it had remained out sufficiently long to dry it perfectly.

After the earth had been removed from the roots, which had been cut off with about two inches of the stem, they were weighed, and the result placed in the seventeenth and eighteenth columns. The object of this was to ascertain the amount of vegetable matter left in the soil after the wheat crop has been removed, and the result greatly exceeds any conception of it that had been previously entertained.

The inferences which, it is presumed, may be drawn from the above details, are the following:—

1st. With regard to the hardiness of the varieties, which, as we have already said, may, to a certain extent, be deduced from the particulars contained in the sixth column, that they may be placed in three classes. Nos. 5, 6, 8, 12, 15, 4, and 2 being the hardiest; Nos. 13, 14, 16, and 10 being the most delicate; and Nos. 1, 3, 7, 9, and 11 occupying an average station.

2d. With regard to the property of *tillering*, of which we have already spoken, that Nos. 12, 14, 16, and 1 possess it in the greatest degree; that Nos. 3, 13, 4, 5, 6, 15, 8, and 2 possess it in the least; and that Nos. 7, 9, 10, and 11 hold a medium rank.

3d. That with respect to the relative value of each variety mentioned in the table, No. 12 is undoubtedly the best of any, in productiveness, and in being sufficiently hardy; that No. 13 is as undoubtedly the worst of any, as will be seen by a reference to any of the columns; and that the others vary greatly, some possessing nearly three times the productiveness of others.

These 16 different sorts of wheat, with the exception of Nos. 13, 15, 16, which are bearded, are merely varieties of one species of the genus *Triticum*; and the circumstance of differences existing among them, some possessing three times the value of others, shows that any variety is capable of improvement. This, indeed, is shown by many other plants besides the wheat. The originals of the potato, the carrot, and the turnip, were comparatively insignificant and useless in their application as food, and it was only by careful and repeated cultivation that they were at length brought to their present condition, and made to hold such an important rank among the many nutritive plants cultivated for the food of man and beast. It is supposed, then, and where it has been tried experience shows it to be a fact, that, by first ascertaining the best of many varieties of wheat, and planting the finest and plumpest seeds selected from the best sample that could be obtained of it, the last of a succession of crops, the first of which was raised in this manner, and all the others from seeds selected out of the produce of the preceding harvests, would, at length, afford a wheat of a more productive and valuable kind than has hitherto been used by the farmer. The experiment here detailed is, then, merely the *first step* in the process; it merely points out the best of the varieties which were tried. The improvement of these by repeated cultivation still remains to be effected.

During the growth of the wheat, a journal

was kept, an extract from which is given here, as it refers to an insect which was observed after the blossoming of the plants, and to which the destruction of many of the seeds was owing.

Observations of this kind might be easily and generally made, and they would be useful as information regarding the nature and habits of the insects which attack wheat; and answers to the how, when, and where, on the subject, which would thus be obtained, afford the only guide to the invention of means for their destruction.

1838. *Extract from Journal.*

July 5th.—All the wheat is in blossom, except Nos. 13 and 15.

14th.—Very rainy and windy weather. Whether will this be found to injure or improve the quality of the grain?

16th.—Since the rain of the 14th, an orange-coloured substance, like rust, has been observed in the seed-vessels of some of the ears, as if the rain had got in and rotted the pollen. A very small fly has been observed about the ears in the evening. Many of the ears are filling rapidly; some are already full, and others are only in blossom.

19th.—In the ears of wheat, which were before-mentioned as having abortive grains, owing, as was thought, to the pollen having been rotted by the rain, I now find small orange-coloured grubs, about the tenth of an inch long, doubtless the offspring of the small fly observed about a week ago.

Aug. 4th.—All these grubs have disappeared.

27th.—Nos. 4, 10, and 11, are ripe and pulled.

28th.—Nos. 3, 5, and 6, are ripe and pulled.

29th.—Nos. 7, 8, and 9, are ripe and pulled.

30th.—Nos. 2, 12, and 16, are ripe and pulled.

Sept. 1st.—Nos. 1 and 14 are ripe and pulled.

2d.—Nos. 13 and 15 are ripe and pulled.

The account of this experiment is thus finished, and there now remains but to state what will have already occurred to the reader, especially if he be a practical man, that it is not one nor many experiments, if conducted on a small scale, which will accurately determine the point this tends to ascertain.

Soil.—Although wheat can be cultivated on any soil, yet heavy loams, strong clays, and marls are considered to be the best wheat soils, and the larger the proportion of alumin in the soil, the heavier will be the grain, and the more productive the crop.

Sandy soils (says a modern writer) are unfavourable to the growth of wheat, for they are deficient in that degree of firmness which is necessary to support the roots of the plants. It is therefore a crop which should never be sown on such land; or if grown, it should only be upon one ploughing of a clover ley, and then afterwards folded by a flock of sheep. (*Brit. Husb.* vol. ii. p. 140.)

Very fine descriptions of wheat are grown

on gravelly, chalky, and flinty soils, which have a dry subsoil.

In England the cultivation of wheat varies in different districts, and according to the nature of the soil. Upon heavy clays, the course of cropping is commonly a twelvemonth's fallow, with from four to six ploughings, &c., and a dressing of manure or lime, or both. On this description of land, wheat also very commonly follows beans, which have been carefully cleaned; and, thirdly, is sown extensively upon clover-leys. On lighter soils, a crop of turnips or rape sown in May, and fed off by sheep early in the autumn, is frequently substituted with advantage instead of a year's naked fallow. And, again, a practice, but which I strongly condemn, is still followed in several parts of England, of sowing dressed or folded rye-grass leys with wheat. (See *ROTATION OF CROPS.*) On soils adapted for turnips, and where the drill and horse-hoe are employed, a course I much approve from the ley's return, from a small expenditure, consists of: 1st, turnips; 2d, oats or barley; 3d, clover; 4th, beans or peas; and then, 5th, wheat.

The quantity of seed varies considerably; and, although I have witnessed large crops grown from one bushel of seed drilled per acre, the rows at foot intervals, yet the general practice may be taken at from two to three bushels per acre. The time of sowing is from September to March; the winter varieties should be in the ground by the end of November, and the spring varieties as early as the season will admit. For the diseases of wheat, see *FLY IN WHEAT, MILDEW, and RUST.* And I may observe that, although subject to several diseases, yet upon the whole it is the hardiest of the cereal grasses, and flourishes under a greater variety of seasons and climate.

Sowing.—Wheat is either sown broadcast, or by the drill or dibble. Drilling is the most preferable mode. When it is sown in drills, the usual distance between the rows is from 9 to 12 inches; but it is conceived that the larger intervals are the better, and that they may in most cases be even more than 12 inches. The best period of sowing, it has been said, is from about the middle to the end of September. The early part of October, however, is well suited to the sowing of wheat, and it may be continued till the middle of November.

The proportion of seed that is necessary must depend upon and be regulated by a variety of different circumstances, but in general from two to three bushels, according to the state of the soil, the nature of the climate, and the period in which it is put into the ground, may be the most suitable proportion for soils of a medium state of fertility, under the broadcast method of husbandry; but where the drill or dibble system of culture is practised, a considerably less quantity may be sufficient for the purpose. See *SEED.*

In the case of summer-fallow the quantity of seed need not exceed two bushels to the acre. When the sowing takes place in spring, the quantity may be extended to three bushels, rather less than more.

The cultivation of wheat is very rapid by

either of the following methods: 1. By selecting the grains of superior ears and dibbling them in a seedling bed, 4 inches apart every way. 2. By dividing and transplanting the roots.

The same weight of Rostock and Dantzic flour from wheat grown in the Baltic, made only 23 pounds of bread, very light and good, but not so white by many shades or well-flavoured as that made from the two first varieties of home growth.

These experiments having been made in my own presence, may be relied on. The dough was worked in the French mode, not pushed down, turned and worked with closed hands, but drawn up into long strings, and repeatedly lifted, in order to expose it to the action of the air as much as possible, which tends greatly to improve the bread, by rendering it more light and easy of digestion. See BREAD.

The superiority of the hoary variety of wheat, which furnished three pounds more bread on a baking of 18 pounds of flour, or an increase of one-sixth over the Dantzic and Rostock, which was also a very fine sample of flour, is thus clearly established. (*Le Couteur on Wheat*, p. 44.)

Securing the crop.—I have already briefly adverted under the head REAPING to the advantages to be derived from harvesting the grain before it is fully ripe, but have reserved to this place some further experiments and details corroborative of the benefit and profit resulting therefrom, by Mr. John Hannam of North Deighton, near Wetherby. This gentleman remarks,—

“Having selected a field of ‘old square-headed red wheat’ for the experiments, on August 4, 1840, I cut a sheaf. At this time it was quite green, *i. e.* both straw and ears were in full vigour, and full of sap. Though the grain appeared perfectly formed, the chaff still adhered so firmly to it that it was scarcely possible to separate them by friction in the hands. When separated it was large and plump, but so full of milk, that the slightest pressure reduced the whole to a juicy consistency or pulp.

“This sheaf stood in the field for a fortnight, when it was housed. On the same day, August 18, I cut another. The wheat was, of course, yet ‘green,’ speaking positively, or ‘not ripe,’ if we speak negatively,—being what farmers commonly term ‘raw.’ This is, the straw, though appearing at a distance green, when examined closely, was of a hue fast approximating to yellow; while, for about a foot upwards from the ground, it was quite yellow. The ears, too, were more open, the chaff tinged with various shades of yellow and green, and the grain itself, when separated, soft and pulpy, but not near so full of fluid as before. The judgment of the farmer will, however, best tell him the conditions of the wheat, both at this and at the preceding cutting, when I say, that in another fortnight the whole field was ripe. At the end of this fortnight, (September 1,) I housed the sheaf cut on August 18, and which had remained exposed to the weather in the interval, and cut a third. This I have said was ‘ripe,’ but by the term I don’t mean that degree of ripeness when the straw breaks, the

ears curl, and the grain shakes out; but that condition in which it is customary to commence reaping it—when the straw, from the roots to the ear, is uniformly yellow, and has lost all symptoms of vivid health.

“On the 14th of September the third sheaf was taken from the field and carefully preserved, along with the other two, till the 1st of November, when, out of each sheaf, I selected 100 ears, and put each parcel into a separate bag. The straw from each of these parcels of ears was preserved carefully.

“The ears in one bag (No. 1, or that cut very green) were now thrashed, the chaff carefully separated, and the gross weight of the corn yielded ascertained by an extremely accurate balance. The weights of a fixed measure of a certain number of grains were next found. *To avoid error, this was repeated several times.*

“No. 2 (cut raw) and No. 3 (ripe) underwent the same process: for the results of which see the following table:—

Comparative Weights of Wheat reaped at different periods.

Time of reaping, and Condition.	Gross Produce.	Equal Measure.	Equal Number of Grains.
No. 1. August 4 (very green)	576	568	19½
No. 2. August 18 (raw)	736	580	23½
No. 3. Sept. 1 (ripe)	650	570	22½

“As this table is merely comparative (the weights used being in parts, and decimal parts of the same, for the convenience of minute experiments), it may not be unnecessary to give the following table of the absolute weights of each sample in ounces, drachms, scruples, and grains Troy:—

	Gross Produce.	Equal Measures.	Equal Number of Grains.
	℥ 3 0 gr.	℥ 3 0 gr.	℥ 3 0 gr.
No. 1.	4 0 0 0	3 7 1 13	0 1 0 5½
No. 2.	5 0 2 13	4 0 0 13	0 1 0 17½
No. 3.	4 4 0 6	3 7 2 0	0 1 0 15½

“The straw belonging to each sample was now weighed (all the parcels having previously been made of the same length, commencing from the bottom of the ear), when the following was the result:—

Comparative Weights of 100 Straws of an equal length, belonging to the samples Nos. 1, 2, 3.

No. 1. (green)	=	550.
No. 2. (raw)	=	475.
No. 3. (ripe)	=	450.

“The next thing to be ascertained was the quality of the produce, or the comparative worth of each description. Believing in the old saying, that,

‘The proper value of a thing
Is just as much as it will bring,’

on the 5th of November I attended market, and asked the opinion of an extensive corn-grower as to the values of the respective samples, according to the prices of the day. His opinion was,

No. 1.	-	-	-	61s. per quarter.
No. 2.	-	-	-	64s. do.
No. 3.	-	-	-	62s. do.

Putting the same samples into the hands of an extensive corn-factor and miller, his opinion of its value, and what he would give to buy, was for

No. 1.	-	-	-	61s. per quarter.
No. 2.	-	-	-	63s. do.
No. 3.	-	-	-	61s. do.

Adding these values respectively together, and taking the mean price of each (by which we shall obtain as near an approximation to the truth as possible), we have

No. 1.	=	61s. 0d. per quarter.
No. 2.	=	63s. 6d. do.
No. 3.	=	61s. 6d. do.

"The loss or gain on these samples, by reaping at different periods, will be best seen from the following

Table of the relative Weights and Value of Wheat cut August 4, August 18, and September 1; that cut last (or ripe) being taken as the standard, and unity assumed as its value in each column.

	Weight of Gross Produce.	Weight of equal Measures.	Weight of an equal No. of Grains.	Value.	Weight of the Straw.
No. 3. Sept. 1. (ripe) -	1	1	1	1	1
No. 2. August. (raw) -	$1\frac{43}{325}$	$1\frac{1}{57}$	$1\frac{2}{91}$	$1\frac{4}{123}$	$1\frac{1}{8}$
No. 1. August. (green) -	$\frac{234}{325}$	$\frac{234}{285}$	$\frac{79}{91}$	$\frac{127}{123}$	$1\frac{2}{5}$

"According to this table, it is evident that the wheat reaped a fortnight before it was ripe has the advantage of the ripe in every point:

- 1st. In weight of gross produce $\frac{43}{325}$, or 13 $\frac{1}{5}$ per cent.
- 2d. In weight of equal measures $\frac{1}{57}$, or nearly $\frac{1}{2}$ per cent.
- 3d. In weight of equal number of grains $\frac{2}{91}$, or nearly 2 $\frac{1}{5}$ per cent.
- 4th. In quality and value $\frac{4}{123}$, or above 3 $\frac{1}{4}$ per cent.
- 5th. In weight of straw $\frac{1}{8}$, or above 5 per cent.

On the other hand, that reaped a month before it was ripe, has an advantage of 22 per cent. in weight of straw, compared with the ripe, but in every other point has the disadvantage: thus,

- 1st. In weight of gross produce $\frac{37}{325}$, or 11 $\frac{5}{13}$ per cent.
- 2d. In weight of equal measures $\frac{1}{285}$, or rather more than $\frac{1}{3}$ per cent.
- 3d. In weight of equal number of grains $\frac{1}{91}$, or better than 13 $\frac{1}{5}$ per cent.
- 4th. In quality and value $\frac{1}{123}$, rather more than $\frac{4}{5}$ per cent.

"It may be here necessary to mention that the sample No. 3 (ripe) was very bold, but rather coarse, feeling rough in the hand; while No. 2 (raw) was quite as bold, but very fine and thin in the skin. No. 3 (green) was also a good and clear sample, but much smaller than either of the others. This will account for the apparently anomalous fact of there being scarcely any difference in the marketable value of the green compared with the ripe, while there is a difference of 13 per cent. in favour of the ripe in weight of equal numbers of grains; for the sample being dry and good, the buyer lost little by this inferiority in the size of grain, as the weights of equal measures were the same,

—the difference of $\frac{1}{285}$ scarcely making $\frac{1}{3}$ lb in the sack.

"Before venturing to draw any deductions from these experiments, let us put their results in a still more practical point of view.

"Suppose we have 3 acres of wheat, 1 of which, reaped when ripe, yields us 30 bushels of corn and 1 ton of straw; what will be the gross value of the same? And what the value of the other 2 acres, according to the data furnished by the foregoing experiments, supposing each acre to be exactly equal in crop, and the one reaped a fortnight and the other a month before the ripe.

"Before answering this, we must fix a value for the straw—say 2d. per stone, which, taking into account that used by the farmer himself—and many cannot sell any—is as much as it is actually worth. Whence we have, for the acre of ripe,

30 bushels of wheat, at 61s. 6d. per quarter	L.	s.	d.
(The price of sample No. 3.)	-	-	- 11 10 7 $\frac{1}{2}$
1 ton of straw, at 2d. per stone	-	-	- 1 6 8
Gross produce	-	-	- £12 17 3 $\frac{1}{2}$

"Let us next take the acre cut 'raw.' Before we can come to its value, we must first resolve the question, How much, in measure, will the acre produce us, supposing it to produce 30 bushels, if cut when ripe?

"In solving this, as we must assume each crop to be exactly equal if cut at the same time, it is obvious that, if we would determine the difference caused by reaping at an earlier period, we cannot found our calculations upon the gross weight of the two samples (Nos. 2 and 3); for, although there is no doubt but that this weight was materially affected by the condition of the wheat at the time of reaping (indeed, the difference in the weight of equal numbers of grains proves the fact), it is possible that, in selecting the 100 ears from the sheaf, I might take out of one sheaf ears with a greater number of grains in them than those taken out of the other. This, then, would affect the total or gross weight; and, therefore, it cannot be taken into account in the present case, where both acres are supposed to have an equal number of grains.

"To the weights of equal measures, and of equal numbers of grains, both the result of many careful trials, this objection cannot be urged; and they are amply sufficient to enable us to tell the produce of an acre of 'raw,' when that of the 'ripe' is 30 bushels. Thus, in the first table, we have,

	Weight of equal Measures.	Weight of equal Numbers of Grains.
No. 2. (raw)	580	23.25
No. 3. (ripe)	570	22.75

Now put m = this measure, and n = the number of grains weighed of each sort; then

$$n : 22.75 :: 1 : \frac{22.75}{n} = \text{the weight of one grain of No. 3., whence}$$

$$\frac{22.75}{n} : 1 :: 570 : \frac{570n}{22.75} = \text{the number of grains of No. 3 in the measure } m.$$

Again, similarly, $n : 23.25 :: 1 : \frac{23.25}{n}$, weight of one grain of No. 2, and

$\frac{23 \cdot 25}{n} : 1 :: 580 : \frac{580n}{23 \cdot 25}$ = the number of grains of No. 2 in the measure *m*.

And $m \div \frac{570n}{22 \cdot 75} = \frac{22 \cdot 75m}{570n}$ = the space occupied by one grain of No. 3 (ripe); and

$m \div \frac{580n}{23 \cdot 25} = \frac{23 \cdot 25m}{580n}$ = the space occupied by one grain of No. 2 (raw).

Now, as there are the same number of grains upon each acre, and as the acre of ripe yields 30 bushels, we have

$\frac{23 \cdot 75m}{570n} : \frac{23 \cdot 25m}{580n} :: 30 \text{ bushels} : 30 \cdot 1307313 \text{ bushels}$, the produce of one acre cut a fortnight before the ripe.

Again, by reference to the second table, we have 1 and $1\frac{1}{8}$ as the relative weights of the straw No. 3 and No. 2; whence, as No. 3 is supposed to produce one ton,

$1 : 1\frac{1}{8} :: 160 \text{ stones} : 168\frac{3}{8} \text{ stones}$, the weight upon the acre reaped when raw. And for the whole produce of the acre, we have

	L.	s.	d.
30·1307 bushels of wheat, at 6s. 6d. per quarter	-	11	19 14
168 stones of straw, at 2d. per stone	-	1	8 14
	£13	7	3 1/2

Adopting the same course for the produce of the acre cut first, *i. e.* a month before the ripe, and which corresponds with sample No. 1, we get

$\frac{568n}{19 \cdot 75}$ = the number of grains of the green in the measure *m*; whence $\frac{19 \cdot 75m}{568n}$ = the space occupied by one grain of green.

But (*vide* above), $\frac{22 \cdot 75m}{570m}$ = space by one grain of the ripe; whence $\frac{22 \cdot 75m}{570n} : \frac{19 \cdot 75m}{568n} :: 30 \text{ bushels} :$

26·1356 bushels, the produce of the acre cut a month before the ripe. And (*vide* "Table of relative weights," &c.

$1 : 1\frac{2}{3} :: 160 \text{ stones} : 195\frac{5}{3} \text{ stones}$ of straw, the produce of the same; whence we have

	L.	s.	d.
26·1356 bushels of wheat, at 6s. per quarter	9	19	3 1/2
195 5-9 stones of straw, at 3d. per stone	-	1	12 7
	£11	11	10 1/2

The total products of the three acres stand thus:—

	L.	s.	d.
No. 3. Reaped when ripe	-	12	17 3 1/2
No. 2. Reaped a fortnight earlier	-	13	7 3 1/2
No. 1. Reaped a month before the ripe	11	11	10 1/2

Showing a *loss* of 1l. 5s. 5d., or about 10 per cent., by cutting very green; and a *gain* of 10s. *per acre*, or nearly 4 per cent., by reaping in a raw state, or a fortnight before it was ripe.

"From the above details, it would appear that it is the farmer's interest to cut his wheat before it becomes thoroughly ripe. Many, no doubt, will be disposed to doubt deductions of such importance, drawn from such limited experiments. This objection the writer anticipates, because it is a natural one, which he felt himself, when he considered the most important conclusions which resulted; when, however, he retraced, *step by step, his investigations, without any variation in that result, he could*

no longer refuse to believe it true till he proved it untrue. He is aware that there are other points of consideration in this subject—that there are peculiarities in the nature of land, of seed, or of season, and that there is, as in all man's investigations, a *possibility* of error; any of which circumstances might materially affect the result of experiments upon so limited a scale as the present one; and for this reason he will, if all be well, give the subject a trial in the ensuing harvest, on a much more comprehensive scale. That the results of *these* experiments will be corroborative in the main points, he has no doubt, and for this cause he feels no hesitation in laying the preceding 'details' before the agricultural world; moreover, as he has in no case given a deduction without the grounds upon which it rested, the degree of 'acceptation' which the reader may give it rests with himself. The most skeptical, he, however, flatters himself, will think it 'worthy of *being tested*, if of nothing more.

"In testing, however, the conclusion which the foregoing experiments warrant, there are some other advantages which strengthen that conclusion, which must not be forgotten. That they have not been considered in the preceding pages, is not because they are of no import, but, on the contrary, because they are of such consequence, that the writer could not assign them an *adequate momentary value*. And had he attempted to do so, he would have at once made the details of his experiments valueless by mixing the real results of *practice* with the imaginary ones of opinion. Before the subject, however, can be thoroughly sifted, they must be considered. The circumstances are these:—independently of the 4 per cent. gain (according to the foregoing experiments) by reaping our wheat a fortnight before it is ripe, we have,

- "1st, Straw of a better quality.
- "2d, A better chance of securing the crop; and,
- "3d, A saving in securing it.

"1st, 'Straw of a better quality.' This is easily demonstrated, both for the purpose of food and manure.

"As an article of food, the value of any vegetable depends upon the gross quantity, or upon the combination of certain substances termed soluble, from their entering into union with water. This rule applies particularly to the grasses which are used for the purpose of feeding stock. The substances generally found in these grasses are saccharine matter or sugar, mucilage or starch, and gluten or albumen, and bitter extract and saline matters. Of these the sugar is, no doubt, the most, and the extractive matter the least, nutritive; the latter having been found, by experiment, to come away in the dung of the animal consuming it, while the other matters were absorbed by the body.

"Now, wheat is a species of grass, and the value of the straw, as an article of food, depends upon the quantity of nutritive matter contained in it. 'This nutritive matter must be very small in straw, as now generally used,' the practical farmer will say, 'for straw *per se* is but poor food, and scarcely able to sustain life.'

This is true; 'from 400 grains of dry barley-straw,' says Sir H. Davy, 'I obtained 8 grains of matter soluble in water, which had a brown colour, and tasted like mucilage. From 400 grains of wheaten straw I obtained 5 grains of a similar substance.' With this paucity of nutritive matter in the straw before us, how can we account for the fact that, in the sap of wheat, the straw, and in all succulent plants, there is *naturally a great proportion of mucilaginous and saccharine matter?* The answer is this: in all grasses and succulent plants, the greatest proportion of this is present before the flower is dead ripe. So in wheat, when we allow the straw to remain till thoroughly ripe, a portion of the sugar is converted, by the action of light, heat, &c., into mucilage, and a great proportion of the nutritive powers of the grass absorbed by the atmosphere, or lost in some manner; for, as Mr. Sinclair observes in his *Report of Experiments of Grasses*, 'there is a great difference between straws or leaves that have been dried after they were cut in a succulent state, and those which are dried (if I may so express it) by Nature while growing. The former retain all their nutritive powers, but the latter, if completely dry, very little, if any.'

"As a manure, too, the straw cut 'raw' is equally superior to the ripe; for, as it is an agricultural axiom, that the better the food of an animal is, the better the manure from it; the manure from a stock consuming this straw, containing a fair proportion of nutritive matter, must be more valuable than that from stock consuming the ripe with *scarcely any in it.*

"But a great proportion of the farmer's straw is converted into manure without undergoing the process of mastication and digestion. For this purpose the unripe straw is equally preferable, as all *unripe vegetables are manures without preparation*; the soluble and nutritive extracts which they contain, being the principal agents in forming vegetable manure; as they not only combine to render the process of decomposition the more rapid, by breaking down the woody fibres, &c., in the manure heap, but are also, in their pure and separate states, stimulants to vegetation.

"It may be urged, that the increased value of the straw is more in favour of that cut very green (No. 1) than that cut a fortnight later (No. 2). This is true; but to produce this increase of value, if we cut our wheat so early as No. 1, we have a *desiccation of the grain to such an extent as to diminish the measured produce above 12 per cent.*; while, by reaping with No. 2, we are, so far from injuring either sample or measure, actually improving both, and at the same time *gaining above 5 per cent. in the weight, and at least as much in the quality of the straw.* For the increase of weight in the latter is not produced by a greater produce, but by the presence of a greater portion of those soluble substances which are alike necessary to animal and vegetable life—are alike the nutritive part of food and the quickening principle of manure.

"2d, We come now to the second advantage, the *'better chance of securing the crop.'*

"This is self-evident. We gain a fortnight

at the commencement of harvest. If the weather be good, we can secure a great portion of our wheat before we should scarcely have begun upon the old system. If not, we can wait; so, under any circumstances, our chances of securing the grain must be greater. Moreover, if we take a retrospect of the harvests for a number of years, we shall find that nearly all the early harvests have been what we term 'good' ones, *i. e.* good as regards weather and the condition in which the grain was secured. When the peculiarities of our climate, its general fickleness, and its still greater liability to change as the autumn advances, are considered, this will require no explanation.

"If we look, too, at the later harvests, we shall, I venture to say, find, that in nine cases out of ten, the grain which was first cut was secured in the best condition. As an example of this, the crop of 1839 will suffice. The crops were late, the beginning of reaping the same, and the result was, that in the North of England *full 75 per cent. of the whole wheat crop was damaged.* And full 75 per cent. of that which was *uninjured*, I will also venture to say, was that which was cut the first. In Yorkshire this was especially seen; for the *earliest wheat* was, with the greatest difficulty, secured. In this village (North Deighton) not a sheaf was in stack till the day before, and on some farms, the *very day* on which the rainy weather set in.

"The frequent recurrence of such years as this, will teach the value of even a fortnight, better than any thing that can be said here. And that they will recur is beyond a doubt. What has happened *once* may happen again, but what has frequently happened (as this sort of harvest has), with the same causes in operation, we are warranted in saying *will* happen again, and *often.*

"3d, The *saving in securing* the crop is a double one. In the first place, there is less waste in moving or reaping, and no danger of 'shaking' or 'necking' in strong winds. In the second place, there is an absolute economy in the expense of reaping the crop, which may be thus illustrated.

"The busy period of harvest with the farmer generally extends over four or five weeks. In this month a certain portion of his work is done by his own hands, *i. e.* by the regular labourers and servants of the farm; therefore, by beginning a fortnight sooner, and extending the season of harvest over six weeks instead of four, it is evident that these regular servants would cut a much greater proportion of his crop—in fact, *one-half more.* By this he is rendered less dependent on those extraneous 'helps' or 'takers' who, in the seasons of hurry and anxiety, fix their own terms.

"To assign a value for these advantages is, as has been said before, for *the farmer himself*; and it will not be an insignificant one. For if beginning harvest a fortnight earlier enables him to save a crop from spoiling once in a lifetime,—if the improved quality of his straw as food for his stock allows him to plough out an acre more, or to pasture another acre of clover with feeding-stock, instead of mowing it for his lean stock, *every grain saved, every extra bushel*

of corn produced, and every extra head of stock fed, is a benefit to the whole community as well as to himself,—is so much added to the gross produce and wealth of the country: there being, in fact, an *increased return without an increased outlay.*" (*Quart. Journ. of Agr.* vol. xii. p. 24.)

In a recent obliging communication, with reference to this important subject, made to me (March 1842), by Mr. John Hannam, he observes in reference to the experiments above detailed, "At the time I wrote you last I stated that the bulk of the wheat reaped by me during the present harvest was unthrashed. I could therefore only give you an idea of the quality of the *raw* and the *ripe* by public opinion from a sample sheaf. Since then the various cuttings (for I made several) have been thrashed and ground. The result of which was, 3½ bushels of the ripe gave 10 st. 11 lbs. of good flour, 1 st. 9 lbs. of seconds (technically termed 'sharps'), and 2 st. 5 lbs. of bran: 3½ bushels of *raw* gave 12 st. 6 lbs. of flour, 12 lbs. of sharps, and 2 st. 1 lb. of bran. From which it appears that the *raw cut* wheat gave 6¼ lbs. of flour to the bushel more than the ripe gave, while the latter gave 3¼ lbs. more sharps and 1½ lb. more bran than the former per bushel.

"Your question as to the effect of early reaping upon the vegetative powers of the seed I have not answered, because I can give no answer but what depends more upon opinion than fact. I have never seen a practical trial made of wheat, as seed, in the various conditions necessary to warrant a final and definite conclusion. An American writer, commenting upon my experiments, while he coincides with my conclusions as incontrovertible, says that it is '*equally indisputable*' that the ripe wheat is preferable for seed. For all this, I am not disposed to assent blindly to any such doctrine, because I have seen early cut wheat used with *perfect success* as seed many times."

The editor of the *Cultivator*, in noticing these facts, remarks:—"A farmer friend of ours, growing wheat extensively, found last season that one of his fields of wheat, then in a very raw or green state, was badly struck with rust. He determined to cut it at once, and did so, amid the laugh or pity of his neighbours, who thought him little better than crazy. The adjoining fields suffered little from rust, and stood till fully ripe; yet, at thrashing, the wheat first cut gave the finest wheat and the best yield." Mr. Hannam mentions a similar instance, in which it was remarked of a farmer who was cutting his wheat earnestly, that he "had cut grass, and stacked muck;" when thrashed it yielded four bushels per acre more than it had been estimated at, and was sold for the highest price in the market. In this country, the same reason, arising from bad weather or a late harvest, does not exist for early cutting, as in England; but there are others which render the subject of little less interest here than there; and the agricultural public of both countries are certainly much indebted to Mr. Hannam for the skill and perseverance with which he has pursued these investigations in all their parts.

The editor of the *Cultivator* proceeds to no-

tice the experiments reported by Mr. Hannam, and in so doing exhibits the results in a manner calculated to be more striking than the statements recently presented in detail. It appears, says the editor, that J. Hannam, Esq., a farmer of Yorkshire, England, made an experiment in cutting wheat by reaping at five different times from the same crop, with the following results as to the time of cutting and value of the produce of an acre, which he sets down at 28 bushels:

- No. 1 was cut a month before fully ripe.
- No. 2 was cut 3 weeks before fully ripe.
- No. 3 was cut 2 weeks before fully ripe.
- No. 4 was cut 2 days before fully ripe.
- No. 5 was cut when ripe.

Taking 100 lbs. of grain, he found it to yield flour as follows:—

No.	Flour.	Seconds.	Bran.
1	75 lbs.	7 lbs.	17 lbs.
2	76	7	16
3	80	5	13
4	77	7	14
5	72	11	15

"It thus appears," says Mr. Hannam, "that No. 3 (cut two weeks before it was fully ripe) is superior to all other varieties; giving more per bushel than No. 5 (cut when fully ripe) by 6½ lbs. of flour, and again of about 15 per cent. on the flour of equal measure of grain. 100 lbs. of wheat of No. 3 makes 80 lbs. of flour; while 100 lbs. of No. 5 yields 72 lbs.; showing an average of 8 per cent. in favour of grain cut raw. In grinding, it was found that No. 5 ground the worst—worse than No. 1. In No. 5 were a greater quantity of flinty particles, which would not pass the bolt, than in any of the others. The bran from No. 5 was coarse and heavy; while that from No. 3 was 'thin as a bee's wing.'"

Mr. Hannam extended his experiments to some length, and sums up the advantages of cutting wheat two weeks before it is fully ripe, as follows: first, there is a gain of 15 per cent. of flour upon equal measures; second, a gain in the weight of straw of 14 per cent.; third, a gain of about 163 in the value of every quarter of wheat; and, fourth, a gain of about 583 upon every acre producing 28 bushels. These calculations are founded upon the price of wheat in England, at the time the experiments were made. The flour produced from No. 3 was of a far better quality than that produced from the grain cut at any other times.

Produce.—The fair produce of wheat (as is well observed by the author of *British Husbandry*) varies so much upon different kinds of land, and is so much governed by climate and mode of cultivation, that it is difficult to form any acreable estimate of the amount or average quality in ordinary seasons and under the common course of management; it may, however, be fairly calculated at 3 quarters, or, perhaps, 28 bushels per imperial acre. To produce the latter quantity, circumstances must, however, be favourable, and any thing beyond that may be considered large, though on some land 4 to 5 quarters are not unusual. The weight may average 60 lbs. per bushel. The straw is generally reckoned to be about double the weight of the grain; an acre producing three quarters of wheat of the

ordinary quality may therefore be presumed to yield about 26 cwt.

The use to which the grain is applied is almost exclusively that of food in its various preparations, and chiefly in that of bread, though a considerable quantity—but generally of an inferior or damaged kind—is employed in the manufacture of starch. This preference is due, not only to the superiority of its nutritive properties, but also to their peculiar nature; for “more water is consolidated in bread made from barley, and still more in that from oats; but the gluten in wheat being in a much larger quantity than in any other grain, seems to form a combination with the starch and water which renders it more digestible than any other.” (*Lectures on Agr. Chem.* p. 121.)

Since the Western States have become thickly settled, and so much of their rich lands been brought under tillage, especially since the completion of numerous canals and rail-roads have opened ready markets in the commercial cities, they have poured into these such vast quantities of wheat as have reduced the price and tended greatly to lessen the profits of husbandry in the old Atlantic States. At present, more than a third of the whole wheat crop in the Union is produced west of the mountains, and the proportion is every year rapidly increasing. By reference to the tabular statements of crops (art. AGRICULTURE) it appears that Ohio stands at the head of the wheat-growing states; her product in 1839 having been estimated at over 16,500,000 bushels. Pennsylvania stands next, having furnished that year upwards of 13,000,000. The produce of New York is estimated at over 12,000,000; and of Virginia, 10,000,000 for the same time. These four large states raised upwards of 52,000,000 of the total amount of 84,823,272 bushels produced that year in the whole United States. The aggregate of the wheat crop of the United States for 1842, has been estimated at 102,317,540 bushels. (*Ellsworth's Report to Congress.*) The

Governor of Ohio, in his message, computes the wheat crop of that state in 1842, at no less than 24,000,000 bushels, of which, he thinks, 14,000,000 may be allowed for exportation, after deducting 10,000,000 for domestic consumption. Some idea of the rapidity with which the wheat crop increases in the Western States, may be formed from the fact, that, in 1840, the amount of wheat shipped from Chicago to Buffalo amounted to only 20,000 bushels, whilst, in the following year, 1841, it amounted in the same period to no less than 200,000 bushels.

The United States present almost boundless facilities over an immense extent of fertile territory for raising wheat. But, great as the aggregate crop at present appears from the preceding statements, it scarcely exceeds that of the comparatively insignificant limits comprehended by the United Kingdom of Great Britain. Notwithstanding her immense domestic product of wheat, England is compelled to import annually many millions of bushels from other countries, for only a small portion of which is she indebted to the American farmers, who have for so long a period worn her cloths and tilled their ground with implements of British manufacture. In 1841, when the imports of foreign wheat into the kingdom amounted to 21,604,840 bushels, the proportion received from her great customer the United States, only amounted to 2,528,600 bushels.

In June, 1840, Lord Palmerston, the British prime minister, caused letters to be addressed to the British consuls in various parts of Northern and Southern Europe, from which wheat is extensively exported. These letters contained certain queries relating to points connected with the grain-growing countries and their markets. A great many highly interesting facts were elicited in the answers to these circulars, many of which have been condensed in the following tabular form.

Answers from	What quantity of Wheat might be expected in England.	Average price of Wheat.		Whether the quantity produced would be materially increased.	Freight per Quarter.		Cost per bush. on board of vessel at Liverpool.

Other facts elicited by these inquiries with respect to other countries competing with the agricultural interests of the United States, may be interesting. Among these are the following:

It appears that in the grain-growing districts in Europe, the soil contiguous to seaports has

already been extensively tilled, and cannot be pushed further without the aid of artificial manures, while the bad roads from the interior shut them out from a competition with this and other countries more favourably situated.

Thus in Russia: The corn districts are too

WHEAT.

remote from the seaports for the grain to be ready, in season, for exportation; the rapid increase of manufactures has withdrawn from tillage, &c.

In Poland, there is a deficiency of manure, and scarcity of hands, and want of skill in cultivation.

From Odessa, the report is that the crops are precarious, on account of drought; tillage is defective, and improvement difficult; distances great; no roads; the rivers unnavigable; the landholders impoverished, and no improvements to be expected.

It may also be gratifying to some to compare the transportation of flour, &c., from Poland (one of the greatest grain-growing districts) and the United States to England.

From Poland to Dantzic, the grain is chiefly brought from the interior in flatboats of the rudest construction, similar to those in use on the western waters of the United States, at an expense of 25 cents per bushel, open to the weather, &c. During the voyage the wheat sprouts, and forms a thick mat or covering for the bulk. On reaching Dantzic, the boat is broken up and sold, the wheat taken out and dried in the fields, then stored in the warehouses at an expense of 6 cents per bushel. From Dantzic to England the freight, &c., not including the duty, is nearly 8*d.*—equal to about 15 cents per bushel; making in all about 46 cents per bushel. From Illinois to Liverpool the whole freight would be 14*s.* per quarter, or 1*s.* 9*d.*—equal to 38 cents per bushel; being about 8 cents in favour of Illinois. There are costs and charges also, in both cases, which would probably be in favour of our export.

In this connection, it may be interesting to compare a detailed estimate of the exports of wheat from Illinois to England, both by New Orleans and Canada.

Illinois wheat, via New Orleans to Liverpool.

Wheat, 4½ bushels, at 50 cents, is	-	-	\$2 37
Grinding and barreling (with offal)	-	-	50
Freight to New Orleans	-	-	62
Freight to Liverpool	-	-	66

4 15

which is a little less than 90 cents per bushel. Charges would be alike in both cases.

View the matter in another point of light. Suppose the wheat or flour of the Western States carried through Canada, and, after the 5th July, to pay 3*s.* on an imperial quarter, viz., (8 bushels), which is about 8½ cents per bushel: Foreign wheat would have to pay, at the present sliding rule, about 60 cents per bushel.

The United States, therefore, could succeed with the greatest competitor; but that competitor cannot supply 1,500,000 bushels—less than the surplus of some of the smaller states of this Union produce; and, indeed, all Europe could not supply England with more than 18,000,000 bushels, under the most favourable circumstances—about three-fourths as much as the state of Ohio now furnishes.

It may be remarked, too, that the crops on the continent are far more precarious than those of the United States; and hence the continental governments find it necessary, and are careful to reserve large granaries, to guard

WHEAT.

against such a misfortune as a failure of the usual harvest. Exportation thence is also forbidden in certain cases, but in the United States no such prohibition exists.

While, therefore, we may look with confidence to advantages in our favour in the British market, we must remember that we have to compete against almost unpaid labour, and cannot expect a great profit on our culture, unless the very cheapest mode of production is studied. Labour (as we have before remarked) must doubtless fall very considerably in agricultural districts, or else farmers and planters cannot hire. (*Ellsworth's Report.*)

With regard to the different kinds of wheat cultivated in the United States, some are best adapted to one latitude and soil, some to another. The fine varieties which succeed so well in England and other parts of Northern Europe, very often fail in the United States, and the most common difficulty with them arises from the circumstance of their tardy habit of maturing, which exposes them to rust and mildew. Seeds from the southern parts of Europe and shores of the Mediterranean, are those which seem best adapted to the climate of the United States, since these mature very early. A fine red variety, now commonly known as the *Mediterranean wheat*, is being very extensively cultivated. It seems to have improved under culture in the United States in the essential qualities for making flour, since the millers, who at first objected to it and would only purchase at a reduced price, now pay the same as for other red wheat. This wheat has been already mentioned as resisting the attacks of that great American scourge of wheat crops, the Hessian fly.

For the following valuable table, showing the exports of flour from the United States, during a long series of years, with the prices per barrel, we are indebted to *Hunt's Merchant's Magazine*.

Exports of Flour from the United States, and Price, from 1795 to 1843.

Year	Flour. Barrels.	Price per Barrel.	Year.	Flour. Barrels.	Price per Barrel.
1795	687,369	\$12 00	1819	750,660	\$8 00
1796	725,194	16 00	1820	1,177,036	5 37
1797	515,633	10 00	1821	1,056,119	4 25
1798	567,558	7 00	1822	877,867	7 00
1799	519,265	10 00	1823	756,702	7 75
1800	653,052	10 00	1824	996,792	6 62
1801	1,102,444	13 00	1825	857,820	5 37
1802	1,156,248	9 00	1826	868,696	5 25
1803	1,311,853	7 00	1827	837,385	8 00
1804	810,808	7 75	1828	860,509	5 50
1805	777,513	13 00	1829	1,227,434	5 50
1806	782,724	7 50	1830	1,806,529	7 25
1807	1,249,819	8 25	1831	864,919	5 62
1808	262,813	6 00	1832	955,768	5 67
1809	846,247	7 50	1833	835,352	5 50
1810	789,436	8 25	1834	955,768	5 00
1811	1,445,012	10 50	1835	779,396	9 06
1812	1,443,492	10 75	1836	505,400	7 50
1813	1,260,942	13 00	1837	318,719	10 25
1814	393,274	14 50	1838	448,161	9 50
1815	862,739	9 25	1839	923,121	6 75
1816	729,053	7 37	1840	1,897,501	5 00
1817	1,479,198	14 75	1841	1,032,011	6 50
1818	1,157,697	10 25	1842	-	4 50

From these tables it appears that, during the period 1795 to 1810, which embraced the European wars, and when the population of the United States averaged 5,000,000, the exports

WHEAT.

of flour averaged nearly 1,000,000 barrels per annum, at near \$10 per barrel, or an export of 1 barrel to every 5 inhabitants. During the non-intercourse, from 1807 to 1811, the price fell very low; and in 1812 the export was resumed, and was so large that the rates again rose very high, so high as to check the export. Under the high successive tariffs of 1824-28-33, the export of flour declined, and with that decline prices fell; until after 1834, when debt and state stocks were exported in return for foreign goods, instead of the legitimate export of produce, and the rage of speculation, by checking agriculture, produced actual scarcity, which again brought up prices. The revulsion drove people to work, and the large crops of 1839, assisted by a scarcity in England, caused a great export, which, with the 1,000,000 barrels sent forward in 1841, raised the value of

WHEAT.

the whole crop \$1 50 per barrel, or 25 per cent. in that year. The surplus of those two years may be estimated at 2,500,000 barrels. According to the census, there were produced in 1839, in round numbers, 8,000,000 barrels of flour, and the product of 1840 was estimated at 12,000,000 barrels, worth \$60,000,000. The export of one-sixth part, or 2,000,000 barrels, raised the price to \$6 50 in 1841, or the value of the crop to \$78,000,000; making a difference, in favour of the farmer, equal to \$18,000,000 or 30 per cent. (*Hunt's Mag.*)

The average price of wheat may be estimated pretty correctly from that of flour, by adopting the miller's rule of computing the price of a bushel of wheat weighing 60 lbs. at one-fifth the price of a barrel of flour. See BREAD, FLOUR, FLY IN WHEAT, GRAIN, GRAIN FLY, &c.

Previously to 1833, the monthly returns of the importation and consumption of foreign and colonial corn were collected together, in annual periods, commencing on 1st January, and terminating on 31st December. From 1833, downwards, they have been made up, like the other accounts of this department, in periods, commencing on 6th January in each year, and terminating on 5th January, in the year succeeding. This circumstance is necessary to be noted, inasmuch as it explains why the aggregate imports and consumption of the several years, from 1825 to 1832 inclusive, as exhibited in the present statement, will be found to differ, to a small extent, from the quantities shown in other accounts, which have been compiled, not, as in this case, from special monthly returns of the corn trade, but from the ordinary records of the general commerce of the country.

* Note.—The returns for 1841 will be liable to alteration (although not to any considerable extent) when the accounts of that year shall have been finally adjusted.

WHEAT, COW (*Melampyrum*, from *melas*, black; and *pyros*, wheat). A genus of branched, spreading, annual, nearly smooth herbs, growing to the height of twelve or eighteen inches. The seeds, which resemble grains of wheat in shape and colour, turn black in drying. There are, in England, four indigenous species of cow-wheat, namely:—

1. Crested cow-wheat (*M. cristatum*), which grows in woods and thickets, and sometimes in corn-fields, flowering in July. Flower rather small, not quite closed, variegated with cream colour and light purple; the palate yellow. The seed-vessel is a crescent-shaped capsule, containing two large seeds in each cell.

2. Purple cow-wheat (*M. arvense*). This species grows in corn-fields on a light soil, and flowers in July. Stem 1½ foot high, purplish, acutely quadrangular; the branches more upright than in the foregoing. Leaves lanceolate,

rough-edged. Spikes long, many-flowered. Bractes loosely spreading, deeply pectinated or pinnatifid, the upper ones entirely, and the lower ones partially, coloured of a delicate purplish rose colour. The flowers are large and scentless. The seeds are two or three in each capsule, but one is often abortive. This is one of the most beautiful of English wild plants. It will grow from fresh seeds in a dry garden, and is well worthy of cultivation.

3. Common yellow cow-wheat (*M. pratense*). Pl. 7, q. This is a very common species in woods and bushy places, especially on clay or loamy soil. It flowers in July and August. Stem smooth, with several wide-spreading branches. Leaves bright green, lanceolate. Flowers axillary, solitary, opposite, turned in pairs to one side. The capsules have a curved point. Cows are reported to be fond of this plant; and Linnæus says the best and yellowest butter is made where it abounds.

4. Wood cow-wheat (*M. sylvaticum*). This species grows in alpine woods, especially in forests of fir. It agrees with the last in general habit, but is rather smaller, especially the flowers, and the capsule is less pointed.

Two or three species of cow-wheat are found in the United States.

WHEAT-GRASS (*Triticum*). Of this genus, to which belongs our cultivated wheat, there are five species indigenous to England.

1. Sea rushy wheat-grass (*T. junceum*), which is frequent on the sandy sea-coast, is a perennial, and flowers in July. The root, with its widely creeping, numerous woolly fibres, is well calculated for binding the loose sand, which purpose it serves in common with *Elymus arenarius*, *Arundo arenaria*, &c. The whole plant is glaucous and rigid, like those grasses. Stem 12 or 18 inches high, simple, inclining, smooth, even and polished, tinged with a bright violet hue below, striated above. Leaves involute, sharp-pointed.

2. Creeping wheat-grass, or couch-grass (*T. repens*). Pl. 10, i. This is a common pest everywhere, in waste as well as cultivated land. The long-jointed, creeping root-stock, or

rhizome, strikes so deeply and widely as to be very difficult of extirpation. It is, in fact, an underground stem, vivacious, and consequently shooting up stems and leaves at every joint. The stem above ground is slender, 2 feet high, and leafy. Leaves linear, flat, of a dull, somewhat glaucous green, most numerous on the lower part of the stems. But the plant is so well known that it requires no description. Forking out the roots after the plough is doubtless the best mode of extirpating this noxious weed; but the process must not be discontinued while a particle of the root-stock is suspected to remain in the soil, as the least portion will grow, and the land being so much broken and loosened by the operation, gives double encouragement for the rapid growth of the plant. It does not thrive well when combined with other grasses, but is naturally more common in hedges. The root-stock contains a large proportion of nutritive matter; it is esteemed abroad for feeding horses. At Naples the root-stocks are collected in large quantities for this purpose, and brought to market. The nutritive matter from the leaves contains an excess of bitter extractive and saline matters. Dogs eat the leaves, and also those of the *Holcus avenaceus*, to excite vomiting; hence it is sometimes called dog's grass, and in other places bears the name of quitch or quicks. See Couch.

3. Fibrous-rooted, or bearded wheat-grass (*T. caninum*). This differs essentially from the common couch-grass last described, in having the root fibrous, without a rhizome. It grows in woods and shady hedges on a chalky or limestone soil. The stems are 2 feet high, very smooth. Leaves nearly upright, lanceolate, taper-pointed, thin, flat, bright green, rough on both sides. As this grass yields a large supply of early spring herbage, and produces a sufficiency of seeds, which vegetate quickly on all soils except such as are tenacious or retentive of moisture, it might be cultivated to advantage on soils of an inferior quality instead of rye-grass. But for soils of the best quality it does not, as yet, uphold a sufficient claim, the awns of the spike being objectionable, and the produce of the latter-math very inconsiderable.

4. Crested wheat-grass (*T. cristatum*), a native of Scotland. The roots of this species consist of several long, strong woolly fibres, suited to a sandy soil. The culms are ascending, 12 or 18 inches high, simple, rigid, slender, leafy; hairy at the top. This grass seems well adapted, from its comparative merits, for culture on light heath soils; the produce of early herbage in the spring being superior to most of the alpine grasses, or those which affect sandy dry soils. The latter-math is productive, and very nutritious. It flowers about the second week of July, and the seed is ripe about the end of August.

5. Dwarf sea wheat-grass (*T. loliaceum*). This is an annual species, growing on the sandy sea-coast, flowering in June and July. The root is formed of many long downy fibres. Stem rigid and wiry, branched from the bottom, generally 2 or 3 inches high, but various in luxuriance, leafy, very smooth, and polished,

erect or decumbent. Leaves linear, acute, nearly smooth, involute when dry.

WHEEL. A circular piece of wood, metal, or other substance, that revolves on an axis. It consists of three principal parts, the nave, heel, or the centre; the spokes or radii, and the periphery or ring. The strength of the wheel depends much on the framing and the arrangement of the spokes, every one of which should stand perpendicularly to the nave. In England and other parts of Europe, the elm is considered the best wood for making naves, as it bears the cutting of the mortices truer than any other. See *ELM*. In making wheels, after they are loosely put together, they are either left to season in a current of air for some weeks, or they are exposed to a heat of 140° Fah. in a kiln. After this they are examined, and if every thing is correct, the tire or iron hoop is put on, whether made of one hoop or separate pieces. Some years since a patent was taken out in England by Mr. T. Jones for making iron wheels, many of which are now in use. These wheels are not conical, nor what is termed *dished*, but cylindrical, which enables them to run lighter and also prove less destructive to roads. They are not heavier than wooden wheels, they require less draught, and are more durable. Some improvements have been made on Mr. Jones's wheel by Mr. William Howard, but the merits of this have not yet been fully proved.

The utility of wheels to carriages may be said to be twofold; namely, by diminishing or more easily overcoming the resistance or friction from the carriage, and more easily overcoming obstacles in the road. In the first the friction on the ground is transferred, in some degree, from the outer surface of the wheel to its nave and axle, and in the latter they serve easily to raise the carriage over obstacles and asperities met with on the roads. In both these cases the height of the wheel is of material consideration; as the spokes act as levers, the top of an obstacle being the fulcrum, their length enables the carriage more easily to surmount them, and the greater proportion of the wheel to the axle serves more easily to diminish or to overcome the friction of an axle, as has been shown by Jacob in his work on *Wheel Carriages*.

Carriages with four wheels are much more advantageous than carriages with two wheels, as carts; for with two wheels, it is plain, the tiller horse carries part of the weight in one way or other; in going down hill the weight bears upon the horse, and in going up hill the weight falls the other way and lifts the horse, which is still worse. Besides, as the wheels sink into the holes in the roads, sometimes on one side, sometimes on the other, the shafts strike against the tiller's sides, which destroys many horses; moreover, when one of the wheels sinks into a hole or rut, half the weight falls that way, which endangers the overturning of the carriage.

With respect to the utility of broad wheels, in amending and preserving the roads, it has been so long and generally acknowledged as to have occasioned the legislature to enforce their

use. At the same time the proprietors and drivers of carriages seem to be convinced, by experience, that a narrow-wheeled cart is more easily and speedily drawn by the same number of horses than a broad-wheeled one of the same burden: probably because they are much lighter, and have less friction on the axle.

WHEEL-PLOUGH. See **Plough**.

WHEY. A provincial term applied to the serous part of the milk, from which the curd has been separated.

Whey, when new and of a pale green colour, forms an agreeable beverage, and with oatmeal makes an excellent gruel or porridge. Left till it gets sour, it undergoes the vinous fermentation as readily as buttermilk. Among the Tartars and Scythians a spirituous liquor is prepared from milk which has undergone fermentation.

Whey is divided into two sorts, green and white; the former escaping readily from the curd, while the latter is freed from it by means of pressure. There are different methods of extracting the whey. In some dairies the whole whey, when taken from the cheese-tub, is put into pails or other vessels, where it remains for about 24 hours; when it is creamed, and the whey is applied to the use of calves and pigs, which are said to thrive as well on it after the cream has been taken from it as before. The cream, when skimmed off the whey, is put into a brass pan and boiled, and afterwards set in pans or jars, where it remains till a sufficient quantity for churning is procured, which in large dairies happens generally once, but sometimes twice, in the week. In Ayrshire whey is given to horses. See **DAIRY** and **MILK**.

WHEY BUTTER, as its name implies, is butter made from the whey which is taken from the curd, after the milk is coagulated for the manufacture of cheese. It is chiefly made in those counties where cheese is manufactured, and where it forms no inconsiderable part of the profits of the dairy. In the county of Derby, more butter is said to be made from whey than from the cream of milk, or from milk churned altogether. A similar preparation in the United States goes under the names of cottage cheese, schmeer case, &c.

WHIN, or GORSE. See **FURZE**.

WHISKY. A spirit obtained by distillation from corn, sugar, or molasses, though generally from the former. Whisky is the "national spirit," if we may so term it, of Scotland and Ireland; but that distilled in the former is generally reckoned superior to that of the latter.

WHITE CROPS. A term used in England to designate crops of grain, such as wheat, barley, oats, &c.

WHITE-ROT (*Hydrocotyle*; from *hydor*, water, and *cotyle*, a cavity; in reference to the plants growing in moist situations, and the leaves being hollowed like cups). One species only is indigenous, the common white-rot or marsh penny-wort (*H. vulgaris*), which grows very frequent on moist heaths, boggy commons, and the margins of little clear rivulets. It is perennial in habit, flowering in May or June. The roots are fibrous; stems creeping

to the extent of 2 or 3 feet, slender, smooth, often subdivided, quite prostrate. Leaves solitary or aggregate, on upright, simple foot-stalks, 2 or 3 inches high; orbicular, peltate, smooth, cloven at the base. Umbels very small, of diminutive white or reddish, nearly sessile flowers. Fruit somewhat wrinkled, compressed. This herb is acrid, and, probably, like others of the umbelliferous tribe growing in wet places, poisonous. But whether it causes the rot in sheep, and, indeed, whether these animals ever touch it, is doubtful. Too moist a pasture is known to produce that disease, and there the *Hydrocotyle* is generally to be found. See **Ror**.

WHITE-THORN. See **HAWTHORN**.

WHITE-TOP (*Agrostis alba*). See **HERD'S** and **YELLOW-TOP**.

WHITLOW-GRASS (*Draba*, from *drabe*, acrid, biting; alluding to the taste of the leaves). Some of the species of this genus are very pretty, being well adapted for ornamenting rock-work or growing in pots among other alpine plants. A mixture of loam and peat suits them best; and they increase with facility, either by dividing at the root or by seeds. There are in England five native species: the common whitlow-grass (*D. verna*); the yellow alpine whitlow-grass (*D. aizoides*); the simple-haired whitlow-grass (*D. hirta*); the twisted-podded whitlow-grass (*D. incana*); and the speedwell-leaved whitlow-grass (*D. muralis*). The leaves are undivided; the flowers either white or yellow.

WHORTLEBERRY (*Vaccinium*). A genus of shrubs mostly of very humble growth, with simple, alternate, evergreen, or deciduous leaves. Flowers stalked, solitary or aggregate, reddish or white, very elegant. Berries blue, black, or red, acid and eatable. The genus is chiefly American, and the foliage turns red in decay. All the species are well worth cultivating, some of them for the sake of their fruit, some for curiosity, and others for ornament. The different kinds of whortleberry and bilberry succeed well in peat soil or very sandy loam. Some of them grow best in moist situations, and others in dry. They may be raised from root suckers, creeping roots, trailing rooting stems, or from seeds. There are four indigenous species, namely:—

1. In England the black whortleberry or bilberry (*V. myrtillus*), is a shrub growing on stony heaths, and in woods where the soil is turfy, chiefly in mountainous countries, abundantly flowering in May. The stem is bushy, from 1 to 2 feet high, with irregular, smooth, green, leafy, angular branches. Leaves stalked, ovate, serrated, about an inch long, bright green, smooth, thin, delicate, and veiny; deciduous. Flowers on simple, axillary, solitary, drooping stalks. Corolla ovate, bright red, with a waxy transparency. Berries bluish-black, of 5 cells, acid, but not agreeable nor wholesome except when dressed. They are, nevertheless, eaten raw in some countries with boiled cream and sugar. The leaves contain a good deal of tannic acid, and have been substituted for those of *Uva ursi*, as an astringent medicine, but are very inferior to them.

1. Bog whortleberry or great bilberry (*V*

uliginosum), grows on boggy, mountainous heaths, and is common in the Highlands of Scotland. It flowers in May. Taller than the preceding, with round branches. Leaves obovate, entire, smooth, deciduous. Flowers several together, flesh-coloured. Berries large, bluish-black, less acid, and less wholesome than the former.

3. Red whortleberry, or cowberry (*V. vitis idæa*.) This species grows on dry, stony, turfey heaths, or in mountainous woods, in many parts of Scotland, Wales, and the north of England. It is plentiful in Derbyshire. It is an evergreen, flowering in June. The roots are creeping; stems erect, 3 or 4 inches high, with a few irregular, wavy, leafy, downy branches at the summit. Berries globose, deep red, astringent, and acid, with much bitterness, which they lose by immersion for some hours in water before they are made into pies, rob, or jelly. In the latter state this fruit is excellent for sore throats, as well as for eating with venison or other roast meat, as is practised generally in Sweden. The leaves of this species are often mistaken for those of *Uva ursi*. They contain much astringent matter, and are little inferior to *Uva ursi* as a medicine.

4. Marsh whortleberry, or cranberry (*V. oxycoccus*). This species grows in clear, watery, turfey bogs, among mosses. The roots are creeping, with many long fibres. Stems slender, wiry, trailing, and creeping, with numerous leafy branches. Leaves ovate, entire, smooth, revolute, acute, perennial. Flowers very elegant, drooping, on simple red stalks, several together at the end of each branch. Berries spotted in an early state, finally deep red, very acid, highly grateful to most people in tarts or other preparations with sugar; though in Sweden they serve only for the acid liquor to boil silver plate in, to eat away the minute external particles of the copper alloy.

Mr. Nuttall enumerates twenty-five species of whortleberry, or huckleberry, natives of the United States, 17 of which are deciduous, and 8 evergreens. The following is his enumeration:

1. Leaves deciduous.

1. *Vaccinium stamineum*. Berries large, partly pyriform, and green when ripe; bitter and scarcely edible. 2. *album*. 3. *arboreum*. The largest species of the genus in North America; branches divaricated; flowers partly as in *V. stamineum*; berries rather dry but sweet, with a granular pulp. 4. *dumosum*. Very low, and running profusely; berries perfectly black to appearance, conspicuously crowned by the persistent calyx. 5. *frondosum*. Berries and under side of the leaves glaucous; fruit large and rarely copious; agreeable, but quickly deliquescent, and subject to be infested by the larva of insects. 6. *pallidum*. 7. *resinosum*. Flowers reddish, angular. Fruit not much esteemed. 8. *corymbosum*. Fruit subacid, and agreeable, as well as that of the following. 9. *amoenum*. 10. *virgatum*. 11. *fuscatum*. 12. *galezans*. 13. *ligustrinum*. 14. *tenellum*, sometimes called sugar-huckleberries, small and rather too saccharine, but a very agreeable fruit, brought in great quantities to the Phila-

delphia market. 15. *uliginosum*. The European whortleberry. 16. *myrtilloides*. 17. *caespitosum*.

2. Leaves sempervirent.

18. *Vitis idæa*. Berries scarlet, farinaceous, and insipid. A small subalpine species, indigenous also to the north of Europe. 19. *myrtifolium*. 20. *crassifolium*. A variety probably of the following. 21. *nitidum*. Branches procumbent and repent. From Virginia to Georgia. 22. *myrsinites*. 23. *burifolium*. 24. *ovatum*. 25. *obtusum*. These two last are indigenous to the northwest coast.

Vaccinium is a North American genus, with the exception of 3 species in Europe, 1 in Jamaica, 1 in the island of Tahiti, in the Pacific, 1 indigenous to Madeira and Cappadocia, and 3 in Japan.

The species first named by Mr. Nuttall, is what is commonly called in the Middle States squaw huckleberry and deerberry, the stems of which are low. The 5th species, or leafy vaccinium, is commonly called blue huckleberry, and blue-tangles. The stems grow from 2 to 5 feet high. The large and dark blue berries of this species are a very agreeable fruit. The 7th species, or resinous vaccinium, is commonly known in the Middle States by the appellation of black huckleberry; the fruit of this has larger seeds than the species last described, and, though pleasant, is not so much esteemed. The 8th species, or corymbose vaccinium, is what is known in the Middle States as the swamp, or tall huckleberry, a stout shrub, growing from 5 to 10 feet high, yielding abundantly large berries, one-third of an inch in diameter, purplish-black when ripe. Some other species, especially the *V. fuscatum*, and *V. amoenum*, are confounded with this by some naturalists. The 14th species is also called the Pennsylvania vaccinium, and commonly the sugar-huckleberry. The stem of this is from 1 to 2 feet high, and much branched. The berries are middle-sized and covered with a little silvery powder or bloom when mature. The product is very abundant and the fruit sweet and pleasant.

In Kent county, Delaware, a new species or variety of whortleberry has been recently discovered, the fruit of which is of a beautiful rich white colour with a yellowish tinge. The flavour is extremely pleasant, and free from the least harshness or acerbity. They are of course exempt from the objection to the common kinds, that of staining the teeth and lips.

In the valley of the Columbia river a new species of bushberry has been discovered, called Pambina.

WIKES. A provincial term in England, signifying temporary boundaries or marks, set up to divide swath, to be mown, such as boughs in the common fields, or meadows. Also boughs set upon haycocks for tithes, &c.

WILD OATS. A name given to the tall oat-like soft grass (*Holcus avenaceus*). A noxious weed in arable lands. See HOLCUS.

WILD PEAR TREE. See JUNE BERRY.

WILLOW (*Salix*: from *sal*, near, and *lis*, water (Celtic); in allusion to the place of its growth: or from *salire*, to leap, because of the rapidity of its growth). An extensive genus of well-known useful and ornamental trees

and shrubs. They all delight to grow in swampy places, and are increased by cuttings, though some of the more rare alpine kinds root with difficulty. There is no tribe of trees of such various magnitude as the willows, from the large white willow to the minute *Salix herbacea*, six of which may be placed between two leaves of a duodecima, roots, stems, leaves, and flowers. Many of the species of willow, under the names of osier and sallow, are extensively grown for the manufacture of basket-ropes; the best sorts for which are the great round-leaved sallow (*S. caprea*) and the common osier (*S. viminalis*). The branches of some of the species are used as stakes, poles, handles to rakes, hoes, and a great variety of economical purposes. Loudon (*Arb. Brit.*) says, "In the north of Europe the bark of *S. alba* is used for tanning leather, and for dyeing yarn of a common cinnamon colour; and the leaves and young shoots are given to cattle in a green state, or dried like the twigs of the birch, and laid up for winter fodder." The bark, however, is less valuable than that of some of the other species. The leaves of the least willow (*S. herbacea*), soaked in water, are employed in Iceland for tanning leather. (*Paxton's Bot. Dict.*) The arrangement of the species of willows is a matter of considerable difficulty, as well as their technical discrimination. Among the numerous species of willows there are only a few which are cultivated for farm purposes: of these we shall enumerate and describe the following:—

1. The long-leaved triandrous willow (*S. triandra*). This tree is very common in wet woods, hedges, and osier grounds. It is of an upright form, rising naturally, when not injured, to the height of 30 feet; towards autumn casting the bark of its trunk and larger branches in broad, solid portions, cracking angularly asunder, like the plane tree. The young branches are erect, long, tough, and pliant, smooth, leafy, brownish, somewhat brittle at their joint or insertion. Leaves linear-oblong, serrated, smooth, rather unequally sloping at the base. The narrower-leaved willows generally come under the denomination of osiers, of which this is one of the most valuable. It is cultivated for white basket-work, producing rods 8 or 9 feet long, tough and pliant, even when stripped of their bark, and very durable. They are cut down every year. There are several varieties of this species; one, called the French willow, is cultivated in Sussex and in the eastern parts of England; it is more slender in form, and only about 12 or 15 feet high.

2. Bedford willow (*S. Russelliana*). When this tree was first recommended for cultivation, by the name of the Leicestershire, or Dishley willow, it was regarded with scorn as "only the crack willow" (*S. fragilis*), a sort notoriously useless. This ignorance and prejudice are now removed, and this willow is found the most profitable for cultivation of any species of the genus, for the value of its timber as well as bark, the rapidity of its growth, and the handsome aspect of the tree. This species of willow was first brought into notice by the late Duke of Bedford, who engaged an

able chemist, Mr. Biggin, to make experiments upon it. It was found to contain in its bark more of the tanning principle than any other tree of England, except the oak. The bark also contains the largest quantity of *salicina*, a salt which has been found useful as a substitute for the quinia and cinchona in agues, and which is much less liable to excite irritation in the stomach than the salts of the cinchona. It is of great importance that the distinctions between this willow and the crack willow (*S. fragilis*) should be clearly pointed out, on account of the wide difference in their qualities and value. This tree is more handsome than the crack willow in its mode of growth, as well as altogether of a lighter or brighter hue. The branches are long, straight, and slender, not angular in their insertion, like *S. fragilis*; and the trees, when stripped of their leaves, may always be distinguished by these marks. They are polished, very tough, flexible, round, and smooth. Leaves lanceolate, tapering at each end, serrated throughout, and very smooth. Those of *S. fragilis* are ovate-lanceolate; the foot-stalk, also, is longer than the scale, whilst in *S. fragilis* it is so short that the leaf is nearly sessile. In both it is glandular or leafy.

3. Bitter purple willow (*S. purpurea*). This is a shrub growing in low meadows, about the banks of rivers and ditches, but not common. The trunk is 3 or 4 feet high, with long, slender, very smooth branches, spreading widely, and, if not supported, trailing on the ground, of a rich and shining purple, with a somewhat glaucous hue. Leaves partly opposite, obovate-lanceolate, serrated, very smooth, narrow at the base. This is a very valuable osier for fine basket-work, but more especially for plating into low, close fences, to keep out hares and rabbits; the leaves and bark being intensely bitter, those animals will not touch either. The twigs, moreover, are so long, tough, and flexible, that they may be interwoven into any shape, and kept very close to the ground, as they always retain their horizontal mode of growth. Such a fence is scarcely inferior to one made of wire, and is, perhaps, more durable, as continually producing young shoots, to supply the place of those that decay. It is important to distinguish this useful and elegant willow from that to be next described. The bark contains much *salicina*.

4. The rose willow (*S. helix*) grows in marshes, osier holts, and about the banks of rivulets. It is a tree of humble growth, erect, about 10 feet high, smooth in every part, altogether of a lighter hue than the last. The branches not trailing, but upright, smooth, and polished, of a pale yellowish or purplish ash colour, tough, and pliable, less slender and elongated than the foregoing species, though useful for the coarser sorts of basket-work. Leaves partly opposite, oblong-lanceolate, pointed, slightly serrated, very smooth, linear towards the base. Their colour a light, rather glaucous green, turning blackish in drying. The leaves and twigs are less bitter than the former, and the greater size of the trunk, as well as branches, renders this species fit for several purposes which that is not. It also

makes a better figure in plantations, and the roots give more solidity to the banks of rivers or ditches.

5. Common white willow (*S. alba*). This is a tall tree, whose bark is thick, full of cracks, useful for tanning; and, as yielding much salicina, good also for the cure of agues, though inferior in quality to that of the true Bedford, or Huntingdon willow. The bark is called *cortex salignum*, and *anglicanum* by some writers. The branches are numerous, spreading widely, silky when young. Leaves all alternate, elliptic-lanceolate, pointed, serrated, silky on both sides; the lowest serratures glandular. There is a variety which is very superior in the value of the wood and bark, and the rapid growth as well as handsome aspect of the tree, to the original species. See OSIRIN and SALLOW.

The willow genus contains more than 130 species, chiefly distributed over the northern parts of Europe and America. Many of the species are alpine. Only 4 have as yet been found indigenous to South America, whilst in North America botanists enumerate upwards of 25 indigenous kinds. Some of these are mere shrubs.

The black willow (*S. nigra*) is the most common of the American willows, and the most analogous to that of Europe. It is less multiplied in the Northern and Southern than in the Middle and especially in the Western States. It is found on the banks of the great rivers, such as the Susquehanna and the Ohio, and is called black willow, or simply willow.

The black willow is rarely more than 30 or 35 feet high and 12 or 15 inches in diameter. It divides at a small height into several divergent but not pendent limbs, and forms a spacious summit. The leaves are long, narrow, finely denticulated, of a light green, and destitute of stipulæ. In the uniformity of its colouring the foliage of this species differs from that of the European willow, the lower surface of which is glaucous.

Upon the trunk the bark is grayish and finely chapt; upon the roots it is of a dark brown, whence may have been derived the specific name of the tree. The roots afford an intensely bitter decoction, which is considered in the country as a purifier of the blood, and as a preventive and a remedy for intermittent fevers.

The wood is white and soft, and the branches are easily broken from the tree. Neither the wood nor the twigs are applied to any useful purpose. (*Michaux*.)

Michaux describes two other species of American willow. One, from being found on the shores of Lake Champlain, he calls Champlain willow (*S. ligustrina*). It grows 20 to 25 feet high, with 7 or 8 inches diameter, and very much resembles the black willow, except that the leaves are longer and narrower. The other is the shining willow (*S. lucida*), so called on account of the brilliancy of its foliage. This *Michaux* found only in the Middle and Northern States. It is found in moist but open grounds, and is more common on the edges of the salt meadows than in the interior of the forests; it is also seen on the islands, not co-

vered with woods, in the rivers, and near the shores of the lakes.

This species is easily distinguished by the superior size of its leaves, which are oval-acuminate, denticulated, and sometimes 4 inches in length.

The shining willow attains the height of 18 or 20 feet; but its ordinary elevation is 9 or 10 feet. Baskets are made of its branches, when those of the European willow, which are preferable, cannot be obtained; but it possesses no property that recommends it to attention.

Many species of willow are found in the United States and in Canada, the greater part of which are susceptible of no useful employment. The three species described are distinguished only by their superior height; but even these are greatly inferior to the European willow in size and in the properties of their wood. In the Northern and Middle States, particularly in Pennsylvania and in some townships in the lower part of New Jersey, great numbers of the European willow have been planted, of which light baskets are fabricated for the market of Philadelphia. This tree furnishes the charcoal for the manufacture of gunpowder. (*Michaux*.)

The common yellow willow is the *S. vitellina* of botanists. It is also frequently called golden willow, and by some egg-yolk willow. The French call it *Le Saule*. This, says *Dr. Darlington*, was early introduced here as a shade tree, and has become partially naturalized in many places. I think I have never seen any but the pistillate plant. A variety with paler bark (perhaps the *S. alba* of authors) is also occasionally to be met with. The handsome *S. babylonica*, or weeping willow, is more generally preferred as an ornamental shade tree, and the pistillate plant of that species is extensively propagated about houses, but it can hardly be said to be naturalized.

WILLOW-HERB (*Epilobium*, from *epi*, upon, and *lobos*, a lobe; the flowers have the appearance of being seated on the top of the pod). Many of the species of this genus are very ornamental, as *E. angustifolium*; while a few others, such as *E. montanum*, are mere weeds. They all grow well in any common soil, and are either increased by seeds or by dividing the roots. The indigenous species are nine, namely, the rosebay willow-herb (*E. angustifolium*), the great hairy willow-herb (*E. hirsutum*), the small-flowered hoary willow-herb (*E. parviflorum*), the broad smooth-leaved willow-herb (*E. montanum*), pale smooth-leaved willow-herb (*E. roseum*), square-stalked willow-herb (*E. tetragonum*), round-stalked marsh willow-herb (*E. palustre*), chickweed-leaved willow-herb (*E. alsinifolium*), and the alpine willow-herb (*E. alpinum*).

These are all perennial herbs, with simple, generally toothed, leaves; flowers mostly purple, in terminal leafy clusters or spikes, without scent. The most common of these are—

1. The rose-bay willow-herb (*E. angustifolium*), which grows wild in meadows and moist, shady places, chiefly in the north of England. The root is creeping, fleshy, with numerous buds, stems from three to six feet high, erect, roundish, leafy, smooth, reddish, seldom branch-

ed. Leaves scattered, numerous, nearly sessile, linear-lanceolate, acute, various in breadth, veiny, smooth. Flowers crimson, inodorous, very handsome, numerous, in long terminal upright clusters. This is a very ornamental flower, common in gardens, where it increases but too rapidly; thriving, like many mountain plants, even in the smoky air of London. There is a white variety. 2. The great hairy willow-herb (*E. hirsutum*). This species is very common in England in all watery places, ditches, and the margins of rivers; among reeds, coarse grasses, and willows. It has an extensively creeping root. The whole herbage is downy, soft, and clammy, exhaling a peculiar but transitory acidulous scent, justly compared to the flavour of boiled codlings and cream. Stems four feet or more in height, round, leafy, copiously branched, and bushy. Leaves half, clasping the stem, ovate-lanceolate, hairy. Flowers in leafy corymbose clusters, large, of a delicate pink. Of this genus, which is most multiplied in the North of Europe, there are 8 species enumerated in *Nuttall's Genera* as indigenous to North America.

WILLOW-LICE. See APHIDIANS.

WILLOW-WEED. In England, a name applied in the fens to the snake-weed, or pale-flowered persicaria (*Polygonum lapathifolium*), an annual plant, which grows very freely on all loose and deep soils, and on marshy lands, though it be scarcely known to any of the cultivators of clay, and it is as rarely to be seen on any sort of turnip land. This plant grows commonly from 18 inches to 2 feet; its stalks are tender and succulent, pale, spotted, or reddish; the joints much swollen. The plant branches most when it has free growth, and produces a great number of crowded spikes of seeds. The leaves resemble those of the willow, but are charged with dark spots in the middle. The seeds are very bright and heavy, highly nutritious, and therefore very grateful to birds, especially partridges. Those who keep decoys for catching wild ducks will buy the seeds to feed and entice the fowl. Pigs will do well on them, if boiled. These seeds very much infest samples of fen corn, whether wheat, oats, or barley. As a weed in fen soils, this plant is the most ramping and cumbersome of any weed that grows.

WIND. See WEATHER.

WIND-FLOWER. One of the names of the marsh gentian. See GENTIAN.

WIND, in HORSES. See BROKEN WIND and ROARING.

WINDMILL. A well-known contrivance for grinding corn or raising water, which is put in motion by the action of the wind upon its sails or vanes. They are of two kinds, *vertical* and *horizontal*, but the former is generally preferred. Since the extensive introduction of improved horse power, hand, and steam machinery, windmills are becoming much less common throughout the country; and from depending entirely upon the caprice of the weather, they are only suited to elevated or exposed situations, where they will catch every passing breeze; and are much less useful than water-mills, which can generally be kept at work continuously, or for a much longer

period. A set of arms and sails might be advantageously used in some situations for pumping up water from a well into a trough or cistern for cattle, or for the purposes of irrigation. In the West Indies, a simple apparatus of this kind is usually attached to the pump or well in the farm-yard. The velocity of the sails of a windmill, in a moderate wind, was calculated by Mr. Ferguson to be thirty miles an hour.

WIND-PLANT. Wood or Grove Anemone (*A. nemorosa*). An American plant, with a perennial root, found in the moist woodlands and thickets of the Middle States, flowering in April and May. Flowers white, often tinged with purple.

WINDROW. A term signifying in England the green parts, or borders of a field, dug up, in order to carry the earth on other land to mend it; so called because it is laid in rows, and exposed to the wind. It is also applied to a row of peats or a line of hay exposed to dry, and also to turfs cut up in paring and burning.

WINE (*Vinum*, Lat.; *vin*, Fr.; *vino*, Ital. and Span.; *vinho*, Portu.; *wein*, Germ.; *wijn*, Dutch; *win*, Swed.; *vün*, Dan.; *vino*, Russ.) A well-known agreeable, and, when moderately used, wholesome liquor, prepared from the juice of the grape, and that of some other fruits. The invention of wine is involved in the obscurity of the earliest ages. The sacred writings, however, lead us to believe that it must have been known before the deluge; for we are informed that the patriarch Noah, immediately after that overwhelming event, "began to be a husbandman; and he planted a vineyard; and he drank of the wine, and was drunken" (*Genesis*, ch. ix. v. 20, 21), a sufficient reason for supposing that it was a fermented liquor, and not merely the simple juice of the grape. It is, indeed, natural to imagine, that in those countries where the vine is a native, the spontaneous fermentation of the juice of the fruit, when it was expressed, either purposely or accidentally, and not immediately used as a beverage, would have naturally led to the invention of making wine at a very early period. It is, nevertheless, certain, that until modern times the preparation of wine was purely empirical.

The history of wine is of great interest, but it would be impossible to attempt even a very brief sketch of it in an article of this description, and therefore we shall confine our remarks upon that part of the subject to some account of the wines used in England, our object being rather to treat of the general rules to be followed in making and preserving wine, and to explain its dietetic qualities, than to trace its history.

Wine, at a former period, was made in England for sale, and most of the large abbeys were supplied with it from grapes raised in their own vineyards; but at no time was it considered equal in quality to foreign wine; and certainly no stronger reason for the neglect into which wine-making in England fell need be stated. Soon after the Norman conquest, much encouragement was given to the importation of the wines of Anjou and of Poitou; and in the time of Henry III. we find those of the

Moselle and St. John, probably an Italian sweet wine, were added to the imports. But for a considerable period the foreign wines were not drunk in their genuine form, but were mixed with honey, sugar, orange juice, and even opium. Chaucer, in the *Knights Tale*, speaks of

“A clarrie (claret) made of certain wine,
With narcotise and opie of Thebes fine.”

These mixed wines received different names, according to the nature of the wine employed. When made with Burgundy or Bordeaux, the mixture was called *Bishop*; when with old Rhenish, its name was *Cardinal*; and when with Tokay, it was dignified with the title of *Pope*. In the reign of Edward II. the taste for sweet wines prevailed; and consequently we find the wines which Alsace then furnished, which were chiefly sweet, were much used. In the time of Elizabeth, the profusion and diversity of wines displayed on the tables even of the citizens of the metropolis, and the inhabitants of the southern provinces, almost exceed belief. Harrison, in his account of the mode of living in England in that reign, states, that there were upwards of eighty-six different wines in use; “whereof,” he adds, “Vernage, Cate-piment, Raspis, Muscadell, Romnie, Bastard, Tire, Oseie, Caprike, Clareie, and Malmeseie are not least of all accounted of, because of their strength and valure.” (*Hollinshead's Chron.* p. 167.) Sack, with which all are familiar who have read the works of our immortal dramatist, was a dry Spanish wine; but sugar was often added to it, with the view, as Venner informs us, to lessen the hot and penetrative quality of the wine. In truth, the best sack (for there were several kinds in use) was of the growth of Xerez, or in other words sherry. In *Pasquil's Palinodia*, published in 1619, this is stated in the following lines:—

“— give me sacke, old sacke, boys,
To make the muses merry;
The life of mirth, and the joy of earth,
Is a cup of good old sherry.”

The Spanish wines still retained the first place on English tables, at the commencement of the seventeenth century. After this time, the preference was given to the Canary wines, more of which, Howell (*Familiar Letters*, part ii. 60) informs us, “was brought into England than to all the world besides.” Champagne appears to have been unknown in Britain until a present from Louis XIV. of two hundred hogsheads of wine, consisting of Champagne, Burgundy, and Hermitage, was sent to the king of England; but it was long after this time unknown to those not connected with the court, and, therefore, it was regarded, as Venner terms it, “a regal wine.” Even at this period, however, although much wine was drunk, yet few persons kept a stock of it in private cellars; the chief consumption was in taverns.

The war with France in 1689 introduced the use of the wines of Portugal, particularly the red wine, or port, as a substitute for the growths of Bordeaux; and the celebrated Methuen treaty, which obliged us to receive the wines of Portugal in exchange for our woollen manufactures, and at one-third less rate of the duty

levied on French wines, confirmed the taste of Englishmen for this strong and intoxicating beverage, a taste which is again happily, as respects health and longevity, on the decline.

From the foregoing sketch it is evident that the English taste in wine has varied considerably at different periods. For five or six centuries, the light wines of France and the banks of the Rhine, and the rich sweet wines of the Mediterranean and the Archipelago, were in high estimation. Then came the dry Spanish wines; and at the close of the seventeenth century the red growths of the Bordelais were in most frequent demand; which, however, owing to the wars with France, were given up, and the rough wines of Portugal substituted for them. But, as we have already said, the use of these is now on the decline, and our growing intercourse with the continent has revived the taste for light wines. (*Henderson's History of Wine.*)

As far as concerns what is denominated home-made wines, there is in England scarcely any, if we except the gooseberry (intended to imitate Champagne) and raisin wine, that merit any notice. Indeed, it is an incontrovertible fact, that grapes ripened on walls and trellises are in general unfit for the manufacture of wine; and, in England, those cultivated under glass are too valuable for the dessert and other purposes, in their recent state, to be employed for making wine. Still, however, to make home-made wine forms one of the occupations of the wife of a farmer, and tolerable wine may be made with a mixture of raisins and grapes cultivated in the open air, in favourable seasons. The principles of wine-making are the same, whatever kind of fruit is employed: in knowing, therefore, the manufacture of grape-wine, it is easy to modify the process, so as to render it applicable to every other description of wine.

The juice of the grape, when chemically analyzed, is found to consist of a considerable portion of sugar and water, mucilage, tannic acid, bitartrate of potassa, tartrate of lime, phosphate of magnesia, chloride of sodium, sulphate of potassa, and a *mucososaccharine* principle, on which the fermentative process productive of the wine depends. Thénard, a distinguished French chemist, assures us that this substance excites the vinous fermentation by abstracting a portion of oxygen from the sugar, by means of its carbon, forming carbonic acid gas, whilst its hydrogen and the remaining oxygen and carbon of the sugar are converted into alcohol, the basis and exciting principle of all wines. When the *must*, or expressed juice of the grape, is exposed to a temperature of 65° Fahr., this chemical change or fermentation commences; an intestine motion takes place in the liquor; bubbles are evolved, which buoy up the grosser matter, increasing the bulk of the mass, and forming a scum upon the surface. An augmentation of temperature now takes place; the *must* loses its saccharine taste; it acquires a deeper colour than before, and a vinous flavour, which increases with the advancement of the process. After a few days: the fermentation gradually subsides, the mass returns to its original bulk, the scum sinks to

the bottom of the vessel, the liquor becomes transparent, and it is now *wine*. The constitution of the must is liable to be greatly influenced by the quality, the variety, the climate, and the culture of the grapes, as well as the nature of the seasons. In a cold year, owing to the deficiency of the saccharine matter, the wine is weak, harsh, and acescent; in wet seasons it is devoid of a competent quantity of spirit: high winds and fogs are also injurious.

In England, the mode of training the vine high upon walls is a disadvantage for making the fruit into wine. In the best wine countries, it is never allowed to grow more than 3 or 4 feet high; and it is found that the bunches nearest to the soil, if they do not touch it, are always the richest. It is a mistake to suppose that sweet wines are the most susceptible of decomposition; on the contrary, they can be kept for almost an indefinite length of time without undergoing any deleterious change. All wines continue to suffer a certain degree of fermentation after they are racked off and put into casks; and as long as the saccharine matter is supplied to maintain this slow fermentation, the wine remains good; but, when that is exhausted, the acetous fermentation begins, and the wine is converted into vinegar.

Admitting, however, the goodness of the fruit, and the wine to be made consequently expected to be excellent, many circumstances may destroy that hope, for the process does not proceed in the regular manner above described, unless certain rules be strictly observed: these are the following:—1. The grapes should be well and equally bruised or trodden; for the juice that first flows contains little *mucosaccharine* matter, and consequently does not ferment freely. That substance is contained chiefly in the insoluble organized parts and the skin, which also contains the greatest part of the acid, the resinous extractive, and the colouring principle. 2. The fermentation should be conducted at a temperature of 60° to 65° Fahr., below which it languishes, and above which it proceeds too violently. When it progresses too slowly, that evil may be remedied by the addition of a little boiling *must*. 3. The contact of air is essential in the commencement; and this affords another reason for the good bruising of the fruit, as much air is absorbed in that stage of the process. But after the fermentation is established, the air should be excluded, for the sake of preserving the aroma; and to secure this, the French chemist, Chaptal, who paid much attention to the manufacture of wines, recommends the vats to be covered with boards and linen cloths. 4. The greater the bulk of material, the more perfect the wine. 5. When the wine is perfected and racked off, it should be sulphured by burning sulphur-matches within the casks intended to contain it, in order to restrain, within a certain degree, the further fermentation.

When good wine is actually produced, much of the advantage expected from the possession of it depends on the future management and preservation of it; for every wine contains within itself the sources of both improvement and decline. The chief points to be attended to are guarding against vicissitudes of tempera-

ture and the contact of air. Wines in the cask or wood, as the term is, are liable to become sour, either by a sudden transition from cold to heat, or the reverse; and the same susceptibility to acescency is favoured by defect of proper fining; but this process should not be frequently repeated, as it impairs the flavour and the body of the liquor. Wines are mel- lowed by the slow precipitation of the tartar, which carries down with it the colouring matter and the salts of lime; and this occurs in the ratio of the evolution of the alcohol, during the continued gradual fermentation which goes on even after the wine is bottled. This would strengthen wine in the cask, were it not balanced by the evaporation of the alcohol through the sides of the cask. Old Rhenish wines kept in the barrel lose nearly one-half of their original alcohol; yet it is an undoubted fact, that wine in bottles, not corked, but tied over with a bladder, becomes stronger:—that membrane permitting water to pass through it, but not spirit. Another curious fact, however, must not be forgotten, namely, that whilst the wine becomes weaker when kept in cask, it becomes much improved in its other qualities; a fact which is illustrated by the transportation of Madeira to India, or keeping it in a warm place.

The adulteration of wine is too comprehensive a subject to be here fully treated of; but, independent of this evil, every foreign wine sent to Great Britain, except the best of the Rhenish wines, contains much uncombined brandy, which tends not only to render them unwholesome, but impairs their original flavour, and risks their partial decomposition. Were home-made wines free from this evil, it would tend greatly to encourage a new branch of trade which has lately sprung up in Scotland, chiefly at Edinburgh, Leith, and Glasgow. From a parliamentary return, we find that 24,848 gallons, equal to nearly 150,000 bottles, were sent to England in 1839, and 23,089 gallons in 1840. Of the 24,848 in 1839, about 13,000 gallons were shipped from Leith, and 11,000 from Glasgow; and of the quantity in 1840, about 14,700 gallons went from Leith, and 7,000 from Glasgow.

In the present day, when temperance has made so favourable an impression on the habits of all classes of society, some remarks on the dietetic properties of wine become essential in an article devoted to its other qualities. Were technical phraseology allowable, we should say that wine is stimulant and salutary in small, narcotic and poisonous in large quantities. This opinion, however, neither implies that it is necessary as an ordinary article of diet, nor that it is deleterious even in the largest doses, as a medicinal agent. Wine, moderately used, in the artificial state of modern civilized society, is not at all essential for the healthy, however occupied, except under exposure to unusual fatigue. But were this principle of necessity to guide the regulation of diet and beverage, the art of cookery would be annihilated; and the growth of wine, as well as the manufacture of every spirituous liquor, under whatever name it is known, ardent spirits, cider, or malt liquor, would cease to exist

In noticing, therefore, the dietetic properties of wine, we must take society as we find it, not as it ought to be constituted. The stimulant operation of wine is exerted on the nerves of the stomach, and the secreting powers of that organ are influenced by these; and thus a beneficial effect results when the digestive powers are depressed. This, in a great degree, depends on the alcohol contained in the wine; yet it is a fact, that the same quantity of brandy diluted with water, to the strength of wine, will cause intoxication more speedily than when it is taken in the form of wine, especially if the wine contains no uncombined alcohol. The stimulant power of wine, however, depends on the quantity of alcohol in its composition; but this power is much greater in those wines that contain adventitious and imperfectly combined spirit. On this account, Port-wine is more apt to derange the stomach, and to cause intoxication, than Sherry of the same strength; and Claret or Rhenish less than either. But besides the evils arising from wines containing uncombined brandy, those wines that contain much acid are usually deleterious to persons of sedentary habits, or who have weak stomachs. Indeed, the daily use of the best wine can only be supported with impunity by those who take much exercise in the open air. But, if we admit that wine is a necessary article of life for the healthy, there can be only one opinion respecting the superiority of the better kinds of Bordeaux. Whatever wine is taken, it should not be conjoined with other sorts, as nothing impairs digestion more than mingling several sorts of wine at one meal.

Such are the general effects of the moderate use of wine; its abuse is so well known, both in reference to mind and body, that it is unnecessary to make a single remark, in this place, upon the subject, except to caution those who feel no immediate injurious effects from a pint of Port, or indeed of any wine, daily, not to rely too confidently upon their apparent powers of resisting its evil influence; for a foundation may be slowly formed for maladies, that, when they appear, are always difficult of cure, and often altogether irremediable.

With respect to the comparative value in reference to the wholesomeness of different wines, a few remarks may be necessary, before concluding this article. Among the brisk wines, Champagne is the least noxious, even when it is drunk to excess, the excitement is of shorter duration, and the subsequent exhaustion is less. It is said to be hurtful to the gouty; but gout is almost unknown in the province where it is made; and more of the evil said to be caused by Champagne is due to the variety and the nature of the dishes, and the period of the day at which they are eaten, than to the wine itself. The red wines of Burgundy are strong, heating, and consequently intoxicating, and they should only be taken in very small quantity. The Bordeaux wines, as we have already stated, are the safest for daily use. They certainly do not excite inebriety so rapidly as most other wines. The wines of Oporto abound in astringent matter, and in uncombined brandy. They are unfit for weak stomachs; they tend to cause sleep rather than

to elevate the spirits, and they are the most pernicious as daily beverage. The Spanish wines, especially Sherries, are less objectionable, but they should never be drunk without dilution with water, unless for medicinal purposes. The same opinion may be hazarded with respect to Madeira; and perhaps no wine is more suited for the dyspeptic, if hypochondriasis be absent. The best light wines of the Rhine and the Moselle are, of all others, the most wholesome. They contain little alcohol, and that little is wholly combined. They prove, in many instances, refrigerant, and have a tendency, from the nature of the acid which they contain, the tartaric, to diminish obesity. Lastly, all sweet wines are apt to disorder the stomach; and when used freely they intoxicate as readily, and cause as deleterious subsequent effects as the stronger wines. But, after all, we must revert to the opinion, that wine is an unnecessary article of diet for all who are healthy and robust; and must truly be regarded, beyond certain limits, either as a medicine or a poison. (*Henderson's History of Ancient and Modern Wines; Maculloch on Wine-making.*) See ALCOHOL and VINE.

Account of the Quantity of Foreign Wine retained in England for Home Consumption, in Wine Gallons, from 1789 to 1836.

American Wine Making.—For their efforts to introduce the grape culture into the United States, great credit is due to the German vine dressers. But for the first demonstration that good wines resembling those of the Rhine and Moselle can be made on this side of the Atlantic, we are indebted to Mr. Longworth, of Cincinnati, whose zeal, intelligence, liberal expenditures, and final triumphant success, entitle him

to the lasting gratitude of his countrymen. This gentleman, who now owns in the vicinity of Cincinnati 122½ acres in vineyards, cultivated by 27 tenants—says, “I have for 30 years experimented on the foreign grape, both for the table and for wine. In the acclimation of plants, I do not believe; for the White Sweet Water does not succeed as well with me, as it did 30 years since. I obtained a large variety of French grapes, from Mr. Loubat, many years since. They were from the vicinities of Paris and Bordeaux. From Madeira I obtained 6000 vines of their best wine grapes. Not one was found worthy of cultivation in this latitude, and were rooted from the vineyards. As a last experiment, I imported 7000 vines from the mountains of Jura, in the vicinity of Salins, in France. At that point the vine region suddenly ends, and many vines are there cultivated on the north side of the mountain, where the ground is covered with snow the whole winter, from 3 to 4 feet deep. Nearly all lived, and embraced about twenty varieties of the most celebrated wine-grapes of France. But after a trial of five years, all have been thrown away. I also imported samples of wine made from all the grapes. One variety alone, the celebrated Arbois wine, which partakes slightly of the Champagne character, would compete with our Catawba. If we intend cultivating the grape for wine, we must rely on our native grapes, and new varieties raised from their seed. If I could get my lease of life renewed for twenty or thirty years, I would devote my attention to the subject, and I would cross our best native varieties with the best table and wine grapes of Europe. I have heretofore wanted faith in the doctrine of French horticulturists, that to improve your stock of pears, you must not select the seed of the finest fruit, but of the natural choke-pear. I am half converted to their views. The Catawba is clearly derived from the common Fox grape. In raising from its seed, even white ones are produced, but I have not seen one equal to the parent plant; and in all, the white down on the under side of the leaf, and the hairs on the stalk, common to the wild Fox grape, are abundant.”

The Catawba, which has led the way in America to the production of wines calculated to compete with the finer vintages of Europe, at present stands without a rival as a wine grape. It makes an excellent sparkling wine, resembling sparkling Moselle, and also a good, dry Hock. Its colour varies from almost clear water to straw colour and pink, and it possesses a fine fruity flavour, and most grateful aroma. It requires no sugar in fermentation when the grapes are well ripened. It is but justice to one of the most persevering pioneers in the grape culture and wine making in the United States, Major Adlum, of the District of Columbia, to say that he had long since entertained the most exalted views in regard to the valuable qualities presented by the Catawba grape. In a letter to Mr. Longworth he says—“In bringing this grape into public notice, I have rendered my country a greater service than I would have done, had I paid off the National Debt;” and Mr. Longworth expresses his concurrence in this enthusiastic estimate.

In regard to the present cost of making wine in the valley of the Ohio, Mr. Buchanan states, from his own experience, that when done by hired labour, the gathering, pressing, and filling

the juice into casks, comes to an average of \$25 to \$30 per acre. It is the German emigrants who make wine to greatest profit, as the most of the work is done by their wives and daughters. The largest profits will accrue to those who bring into requisition the most intelligence and skill, who take care to have the fruit gathered when fully ripe, the green and decayed berries picked out, (from which by the addition of 8 or 10 ounces of sugar to the gallon, wine of an inferior quality may be made,) who use a clean press, clean casks, a cool cellar from which the external air can be excluded, who, during the period of fermentation, which continues from two to four weeks, attend to keeping the casks filled to within four or five inches of the bung, (which last must be put on loosely,) and racking off at the proper time in spring, always keeping the casks after fermentation, full and air-tight, never bottling till 4 or 5 years old, and finally selling without their names in seasons when wine is not of the best quality.

The great secret, for such it has been generally kept among wine-makers—of producing an effervescing wine, consists simply in mixing the wine of the new vintage with wine of the previous vintages, half and half.

Although 400 and even over 600 gallons of wine per acre have been occasionally obtained from Ohio vineyards in some very favourable seasons and situations, Mr. Buchanan sets down the average produce of an acre (containing 2420 vines, planted 3 by 6 feet apart), in fair seasons at 300 to 400 gallons. A probable average for 8 or 10 years, with but little rot, would be 250 gallons. And with a reasonable allowance for loss by rot, frosts, &c., 200 gallons might be set down as a fair average.

A bushel of grapes on the stem will yield from 3 to 3½ gallons of juice. Some have yielded 4 gallons, but this is rare. In measuring, the bushel is “heaped,” or liberally rounded on the top. A recapitulation of Mr. Buchanan’s statements would give the costs and profits of an Ohio vineyard as follows:

Cost of the vineyard per acre, say \$250,	
interest per annum	15 00
Cost of attendance per acre	60 00
Cost of making the wine	25 00
	\$100 00

Probable average annual product:
200 gals. of wine, at, say \$1.00 . . . \$200.00

Supposed profit per annum \$100.00

A press capable of expressing from 160 to 300 gallons per day, will cost \$60 to \$150—the vessels \$10 to \$15, and the casks from 4 to 8 cts. per gallon, according to size and quality. The loss in quantity in making the wine, by fermentation, lees in racking, and by evaporation, is about 10 per cent. See VINE.

The experiment of letting the grapes, after being mashed, ferment in the skins *slightly* before pressing, has been found to afford some advantages. The mashed grapes are allowed to stand in large open hogsheads, for 24 to 30 hours, or until they begin to ferment, and the grapes rise to the surface. They are then pressed. *Too much* fermentation in this state would be injurious, and give a bitter, astringent taste to the wine; but a *slight* fermentation adds to the colour and aroma.

Mr Longworth states that it is a very great error in wine making, to have the grapes gathered too soon, and before the saccharine principle is fully developed. The richness of the wine is estimated by the weight of the *must* or fresh juice, the average of the least being 95 deg. on the scale of the Hydrometer. He states that in the neighbourhood of Cincinnati he found some from well matured fruit which weighed 101, whilst that of other vineyards weighed only from 65 to 80. He says that he would rather pay 75 cts. per gallon for *must* weighing 95, than 5 cts. for that which weighs only 75.

Fermentation.—The casks are to be filled up till within 3 or 4 inches of the bung, and this is to be put in loosely. The gas escapes without the wine running over. Usually in 2 to 4 weeks the fermentation ceases, and the wine becomes clear; then *fill up* the casks and *tighten* the bungs.

In February or March, rack off the wine into clean casks. A second but moderate fermentation will take place late in the spring, after which the wine becomes clear and is ready for sale. If the casks are kept well filled, and the bungs tight, it will improve for many years. Use no brandy or sugar if the grapes are sound and well ripened.

It was a long time disputed whether alcohol existed already formed in the wine, or whether it was developed through the application of heat in distillation. Gay-Lussac succeeded in extracting alcohol from wine in a vacuum at the temperature of 59 deg. Fahrenheit, thus demonstrating that it was not developed by the heat used in distillation.

When it is necessary to add sugar to grape juice, experience has proved in France that *glucose*, or the sugar made from starch, is to be preferred, since it more resembles that of the grape than the sugar made from the cane or the beet. Sugar ought, however, never to be added except with the greatest caution and judgment, being apt to make the wine thick, flat, and acid. Although it may increase the proportion of alcohol, the quality of the wine will never equal that of good seasons, when sugar can be dispensed with. Some add alcohol instead of sugar to the fermenting *must*. But although this may furnish the wine with strength, it will never be equal to that in which sugar has been used.

The safest way of keeping the wine is in bottles well corked and sealed, and placed on their sides. The fewer rackings it receives, and the less exposure to the air, the sweeter and better it will keep. The bottling may take place one year after racking, although better deferred till the lapse of 2 years. Never bottle *before* the *second* fermentation, which takes place in the spring succeeding the vintage, unless it is where the sparkling quality is desired, which, as has been already stated, is imparted by mixing the wine of the new with that of an old vintage. The fining of wine can be done to the greatest perfection by bottling or racking off during the *very coldest weather in winter*, at which time it will of course deposit most of its soluble materials. This was an important secret, kept and practised upon with great success by a celebrated Philadelphia wine merchant.

Consumption of Wines in Great Britain and the United States.—The importations of wine into the United Kingdom of Great Britain in

1849, amounted to 7,970,067 galls., and the increase in the home consumption, compared with the previous year, was 115,315 galls. The proportions in which the various wines were consumed in England in the year 1849, are stated as follows: Of the total amount drunk, Cape constituted 3.87 per cent.; French, 5.30; Portugal, 42.36; Spanish, 39.16; Madeira, 1.14; Rhenish, 0.74; Canary, 0.32; Sicilian and other sorts from the Mediterranean, 7.11; total, 100.00.

As nearly all the wine imported in the United States is consumed at home, the following statement will show the proportions of various wines consumed, and consequently exhibit the American taste.

The values of the different wines imported into the United States in one year, namely, from July 1st, 1847, to July 1st, 1848, were as follows:

Wines.	In Casks.	In Bottles.
Burgundy	\$1,716	\$2,181
Madeira	21,630	1,916
Sherry and San Lucar	109,983	1,379
Port	170,134	4,141
Claret	221,416	109,638
Teneriffe and Canary	14,087	—
Fayal and other Azores	5,816	—
Sicily and other Mediterranean	67,364	—
Austria and other German	1,998	—
Red Wines not enumerated	180,928	—
White Wines	193,358	—
Champagne	—	288,256
All other kinds	—	38,068

Thus it appears that the English taste runs mainly upon Port and Sherry, which constitute 81½ per cent. of all the wines they drink. Their consumption of French wines, or Claret and Champagne, amounts to only 5.30 per cent., and of Madeira to only 1.14 per cent. In the United States, on the contrary, the French wines, including Champagne and Claret, constitute over 56 per cent. of the value of all the wines consumed, Port and Sherry 19, Madeira about 1.64, and Claret and other red wines alone, 36.

WINE-PRESS. The one most commonly used near Cincinnati is made somewhat like a "Screw Cider Press." The screw, which is of iron, and about 3 or 4 inches in diameter, is placed either in a strong upright frame, or coming up through the centre of the platform, the last plan being the cheapest and most simple. A strong, tight, box platform, 6 or 7 feet square, made of 2 or 3 inch plank 6 or 8 inches high at the sides, is wedged into heavy timbers, and, in this, a box of 1½ inch boards, 5 or 6 feet square, perforated with holes near the lower edge, 8 or 10 inches high at the sides (made so as readily to be taken apart), is placed to contain the grapes. Boards to fit loosely inside of this box, and lie on top of the pile of mashed grapes (or the "cheese"), and pieces of scantling, to lay across to receive the pressure, complete the press. The pressing power is applied by a strong lever attached to the nut or female screw, and the juice runs out through a hole.

WINNOWER-MACHINE. A contrivance employed for separating, by an artificial current of air, the chaff from the grain, after it has been thrashed out of the straw. Various are the accounts (remarks Mr. J. A. Ransome in his *Treatise on the Implements of Agriculture*) given of the introduction of this machine, and many of the claimants for the credit of having been the first maker of this piece of mechan-

ism in England or Scotland. All, however, agree that the idea, design, or model was originally furnished from Holland, earlier, however, than the date of any of these by at least a period of twenty years. We learn from the papers of Robert Somerville of Haddington, that in 1710, pursuant to articles of agreement between himself and Fletcher, laird of Saltoun, James Meikle (father to Meikle of thrashing-machine memory) visited Holland for the purpose of learning "the perfect art of sheeling barley," in order to the introduction of the barley-mill. The same authority, 1805, states, "that on Meikle's return he made the first fan-ners which were seen in Britain;" and that these were in use only a few years before that date at the Saltoun barley-mills. That the machine was not made public till many years afterwards may be attributed to a clause in the above-mentioned agreement, by which Meikle was bound, on leaving Saltoun's service, "not to profit any more by this mill, nor communicate the arts he had learned to any other." In 1737, through the medium of Rogers of Cavers and others, it was brought into more general use; and in 1768, A. and R. Meikle obtained a patent for a machine of this kind. Although a very considerable advantage over the plan of dressing by hand, these still appear to have been but very imperfect, the corn having to be passed through them twice or thrice, in order to be perfectly separated. And in 1798, R. Douglas, in his *Agricultural Survey of Roxburghshire*, remarking upon these defects, mentions an improvement invented by one Moodie of Lilliesleaf, "in which he had happily combined some properties of other fans, so that the grain at one operation could be both separated from the chaff and lighter seeds, and completely riddled of all sorts of refuse."

Other patents had been taken out which do not appear to have involved much real improvement, till, in 1800, I. Cooch of Northampton patented the machine which has since been known by his name, and has obtained deserved commendation, being in use and approved beyond most at the present day. This machine dresses all kinds of seeds, and its work is performed in a perfect manner: its principle involved more mechanical combinations than were at that time generally understood by the class for whose use it was intended; and this, together with its then cost, retarded its more general adoption.

In 1812, John Elmy obtained a patent for improvements in winnowing-machines, and produced a very efficient implement; the arrangement of its various parts were simple, and greater effect was obtained from the blast. Comparing this with the drawings and description of one we find in the *Edinburgh Journal of Agriculture*, and with that described by Professor Low, we have little doubt of their general identity with this, the model upon which the machines in general use are now made.

In 1839, T. F. Salter obtained a patent for a machine for winnowing and dressing corn and seeds, which at the R. A. S. E. meeting at Cambridge was exhibited, and obtained the silver medal.

In this invention are combined the princi-

ples of Grant's hummelling machine, described in *British Husbandry*, vol. xi. p. 204, and of Hall's smut machine (*Loudon's Ency. of Agr.* p. 439, fig. 403), with the operations of the common winnower.

The undressed grain from the hopper passes through a cylindrical sieve, having within it a rotary spindle, upon which short blunt arms are arranged in a spiral direction; these agitate the grain as it passes along, and thus separate the small dirt and dust as well as the awns of barley, which fall through in a closed box or cupboard. The cylinder is placed in a slanting direction, and is provided at each end with slides, which regulate the quantity and speed with which the grain shall pass. Through the slide aperture at the lower end the grain is introduced upon other sieves, which, having a backward and forward motion, distribute it equally over their surface, when it is subjected to the blast of the fan, driving obliquely through the sieves; this carries the chaff out of the machine; the grain falls on a screen, which, having a similar motion to the sieves, separates from it all small seeds, and the dross corn is carried away in a division formed for the purpose. The grain, dross, corn and chaff are thus all thoroughly separated from each other, and the dust, dirt, and small seeds, having fallen in an enclosed box from the cylinder, may be entirely removed.

We have heard this machine highly approved by many, and when pains are taken to separate the corn from the short straw, &c., previously to submitting it to the machine, we believe it to be very effective; but as there is some degree of complication in its details, it is chiefly suited to those to whom a high degree of excellence in the manner of "making up their corn" is a matter of more importance than the time or labour it may require.

We now come to the description of the winnower used in combination with the thrashing apparatus at Whitfield, in which the principal feature is the improvement of the fan or blower. Having noticed that the ordinary form and position of the fans, which are flat boards, radiating from the centre, tended to keep the air constantly whirling within the casing, rather than to force it forwards; and that if, instead of being flat, they were curved forward in the direction of their motion, they would draw the air in from the tube and force it out at the sides, J. Clyburn of Uley, the engineer by whom the machinery at Whitfield was executed, constructed a blower, in which, by a certain curvature of the fans, and a different arrangement of the chamber in which they revolve, the tendency to form a vacuum is considerably increased, and greater force is consequently obtained from the blast.

We are not disposed to leave this part of our subject without some allusion to an invention for still further carrying out the process of cleaning corn, known as Tuxford's reeing-machine. This consists of a series of sieves, to which a rotatory motion is given: the grain is by this means separated from any small dust and dirt, which passes through the wires of the sieve, while all the lighter rubbish is by the motion brought to the top, whence it is re-

moved by hand. This implement is more, perhaps, adapted for millers; and its cost presents, in its present form, a bar to its general introduction. If it could be reduced to the power of being worked by hand, it would be a very valuable assistant to the proper preparation of the grain for market.

The American machines for cleaning grain are commonly designated *Fans*, *Grain Fans*, and in the Eastern States, *Winning Mills*. Their construction differs materially from such as are used for similar purposes in Europe, being much more simple, and not having more than half the machinery. The old "Dutch Fan," formerly used, and which had no *shaking screen*, is now superseded by highly improved fans. The principal modern improvement in these consists in the application of a screen attached to the shaker, which more effectually rids the grain from cockle and dirt that cannot be blown out. The ordinary size of an American fan is about 5 feet in the frame or boarding, 3½ feet in height, and about 2 feet 4 or 6 inches in width. The blower or fan is about 2½ feet in diameter. Screens and riddles from 18 to 20 inches square, from 3 to 6 riddles accompanying each fan. The most simple arrangement for working a shaker is a small crank attached to a rod leading from the side of the fan to the riddle-frame or shaker.

A fan of the dimensions described will clean from 40 to 60 bushels of wheat per hour. English farmers who have come to the United States, say that these simple winnowing-machines do far more work than the English, which last are complicated with much machinery, for cleaning smut, &c. (See SMUT-MILL.) The English winnowing-machines cost from \$40 to \$60, whilst the American are made for \$16 to \$24, according to the size and number of screens; at which prices they are furnished, among other places, at No. 196 Market street, Philadelphia, by Mr. Chandler, agricultural implement maker.

WINTER CHICKWEED. See CHICKWEED, EUROPEAN.

WINTER-CRESS (*Barbarea*, on account of its being formerly called the herb of St. Barbara). There are, in England, two indigenous species; 1. The bitter winter-cress, or yellow rocket (*B. vulgaris*), a perennial, which is common in rather moist waste ground, about hedges, or in marshy meadows. The root is tapering, somewhat woody; stem about 2 feet high, simple or branched, leafy, stout, angular, and furrowed. Lower leaves lyrate, the terminal lobe roundish; upper obovate, toothed, strongly ribbed, of a fine texture, quite smooth. Flowers bright yellow, in round-headed corymbose clusters. Pod quadrangular, about an inch long. The whole herb is nauseously bitter, and in some degree mucilaginous. A double-flowered variety, with innumerable petals produced in long succession, and turning white as they fade, is frequent in gardens. 2. Early winter-cress (*B. præcox*). This biennial species is found in watery, grassy places, or on the banks of ditches. Stems, one or more, erect, 1½ or 2 feet high, smooth, a little branched, tinged at the bottom with a violet hue. Lower leaves lyrate: upper deeply pinnatifid, with linear, oblong, entire segments; flowers fewer,

smaller, and paler than those of *B. vulgaris*. Pods thrice as long as in that species, exactly square, smooth. This species propagates itself abundantly by seed, but the root is not perennial. It may be eaten like water-cresses, with which it agrees in flavour, except being rather more pungent.

WINTER-GREEN (*Pyrola*, from the leaves being similar to those of the pear tree). A genus of very pretty plants, rather difficult to cultivate. A shaded peat border appears to suit them best, and they are readily increased by divisions or seeds. The whole genus is astringent and tonic. There are, in England, five native species, all perennials, as follows:— 1. Round-leaved winter-green (*Pyrola rotundifolia*). 2. Intermediate winter-green (*P. media*). 3. Lesser winter-green (*P. minor*). 4. Serrated winter-green (*P. secunda*); and, 5. Single-flowered winter-green (*P. uniflora*). They all inhabit alpine wooded localities; the flowers are white or reddish, often highly fragrant. *P. uniflora* is one of the most curious and elegant of British flowers.

WINTER-GREEN, AMERICAN (*Pyrola umbellata*), Pipsissiwa. The *Chimaphila umbellata* of Nuttall. This plant is very abundant in cool situations in the United States. It has a long creeping root, and ascending stem 3 to 6 inches long, leafy at the top. The leaves are of a deep green and very glossy, possessing a peculiar flavour, some bitterness, and a moderate degree of astringency. Under the Indian name of *Pipsissiwa*, this plant has been long noted as a popular medicine. It has doubtless some virtues, but its properties are very often misapplied in its empirical use.

The *Spotted Winter-Green* (*Pyrola maculata*) is also a common plant in the United States erroneously called Pipsissiwa by Pursh. Its properties are similar to those of the first-named species, though weaker. Five or six additional species of the *Pyrola* genus are found in the United States.

WINTER-PROUD. A term provincially applied to wheat which in winter puts on a more green and luxuriant appearance than it is able to support in the following summer; or in which the ramifications become too numerous to be kept up, or brought to maturity, from the previous over-exertion of the soil. In these cases the crops decline during the spring and summer, and at harvest yield imperfectly, falling much below other crops which had a more backward appearance in the winter.

WINTER-WEED. A name given, in Norfolk and other parts, to the ivy-leaved speedwell (*Veronica hederifolia*). See SPEEDWELL.

WIRE-WORM (*Elater segetis*). These are larvæ of that tribe of insects named *Elaterideæ*, or click-beetles, which are readily known by having the sternum produced behind into a strong spine fitted to enter a groove in the abdomen situated between the intermediate pair of legs. By bringing these parts suddenly into contact, the insects are enabled to spring to some height into the air, and thus recover their natural position, when they happen to fall on their backs, which they frequently do, when dropping from plants to the ground. A special provision of this kind is rendered

necessary, in consequence of the shortness and weakness of their legs. The wire-worms have a long, slender, and cylindrical body, covered by a hard crust, which has obtained for them the above name. They are composed of twelve segments fitting closely to each other, and are provided with six conical scaly feet, placed in pairs on the three segments next the head. The latter is furnished with short antennæ, palpi, and two strong mandibles or jaws.

Upwards of sixty different species of these insects occur in Britain, and it is probable that a considerable proportion of them feed upon the most valuable cultivated plants. The same species of larva does not appear to confine itself to one kind of food, but attacks indiscriminately the roots of grain and other grasses, as well as esculent roots, such as turnips, carrots, radishes, &c. But it is at the same time deserving of notice, that as a strong similarity prevails among larvæ specifically distinct, it is probable that different kinds may often have been confounded, and a more correct knowledge may prove them to be more restricted in their choice of food than is at present supposed: this, at least, is rendered not unlikely by what is observed in analogous cases. We are as yet acquainted with the metamorphoses and habits of a very small number of these insects; and it is, therefore, highly desirable that whenever a destructive species of wire-worm prevails, it should be traced to the perfect condition. This, however, is attended with considerable difficulty, owing to the length of time they continue in the larva state, extending, in many instances, to several years.

This insect occurs in considerable plenty throughout the country in grass fields and pasture lands, and is usually found creeping among the herbage, or lying at the sides of stones; it is scarcely ever observed on the wing. The extent of the injury they sometimes occasion may be estimated from the fact, that a single worm has been observed to bite from 8 to 20 plants in a very short time; and they are occasionally so abundant, that from 4 to 8 have been turned up by the spade in a space of 4 square feet. The depredations of the wire-worm in England being principally confined to wheat sown upon clover leys, old pastures recently broken up, pea and bean stubbles, &c., we may suppose the general average of the injury to amount to about a twentieth part of what is sown upon this description of lands. This may be deemed a very fair and moderate calculation.

When the fields lie fallow, these insects continue to feed on the grass and other weeds, which are frequently allowed to overrun the surface; whereas, if the soil were kept clean, they would either die for want of food, or be compelled to remove to some other place. As these larvæ invariably live beneath the surface of the soil, every plan suggested for their destruction must be founded on this consideration.

Without adverting to this fact, many superficial applications, such as strewing the surface with quicklime, soot, &c., have been tried without effect. The most obvious remedy is to saturate the soil with some fluid which has been previously ascertained to destroy the in-

sects without injuring the plants; that is, if the latter be of a kind which it is necessary to preserve, as will usually be the case. In a fallow field, this precaution need not be observed, as a double benefit would ensue from the destruction of both insects and weeds. More carefully conducted experiments, and on a more extensive scale than any that have yet been undertaken, will be necessary to show what kind of liquid is best adapted for this purpose. Probably, different substances will be found most useful in different situations, according to the nature of the soil and the chemical ingredients which enter into its composition. The latter consideration should be particularly attended to in all experiments on the subject, as most likely to suggest the most appropriate remedy; and it might even happen that the fluid employed to destroy the insects might be so managed as to produce a most beneficial change in the chemical qualities of the soil. If a strong saline solution, for example, should be found to kill the insects, as it is very likely to do, there are few soils which would not derive benefit from such an application. Of course, many substances prove speedily fatal to these insects, and among these the choice would have to be determined by cheapness and ease of application. Beirlander, a Swedish observer, who has investigated their habits, found that they lived among—

	Days.	Hours.
Garlic - - - -	9	0
Spruce leaves - - - -	0	14
Fir leaves - - - -	0	12
Ledum palustre - - - -	0	9
Myrica gale - - - -	0	2
In water - - - -	4	0

He suggests that such of these plants as proved most speedily fatal should be mixed with the manure. He also considers it of great advantage to cause children to follow the plough, and pick up all that happen to be turned up. He states that in this way he has seen 351 wire-worms collected in a field not exceeding 600 feet by 56.

Sir Joseph Banks suggested a very simple plan for alluring the wire-worms from the plants, and collecting them that they might be destroyed. This consisted merely in burying slices of potato, stuck upon skewers, near the seeds sown. As the larvæ are very fond of this root, they leave the young plants and fix upon it. These slices require to be examined every day, and the wire-worms collected upon them destroyed. Mr. Tallant affirms that he has frequently freed fields entirely from wire-worms by sowing a crop of white mustard-seed. The experiment he has tried so frequently, and in circumstances so well calculated to demonstrate its effects, that he is perfectly satisfied that the remedy is efficient. "Encouraged," he observes, "by the results of my former trials, I sowed a whole field of 42 acres, which had never repaid me for 19 years, in consequence of nearly every crop being destroyed by the wire-worm; and I am warranted in stating that not a single wire-worm could be found the following year; and the crop of wheat throughout, which was reaped last harvest, was superior to any I had grown for 21 years. I am, therefore, under a strong persua-

sion that the wire-worm may be successfully repelled and eradicated by carefully destroying all weeds and roots, drilling white mustard-seed, and keeping the ground clear by hoeing." (*Brit. Farm. Mag.* 1831.)

Nature herself has taken means to check their superabundant increase by making them the prey of a small ichneumon, which searches out their retreats, and deposits its eggs in their bodies, which are consumed by the parasitical larvæ as soon as hatched." (Mr. Duncan, *Quart. Journ. of Agr.* vol. viii. pp. 96, 348.) (See INSECTS.) Under the head BEETLE, at page 174, the American wire-worms have been described as materially differing in structure and habits from those of Europe.

WISP. A term applied to a small bunch of hay or straw, when used in rubbing down horses or cattle.

WITHY. A name sometimes given to the flexible boughs of willows and osiers.

WOAD, DYER'S (*Isatis tinctoria*). This is a biennial plant, growing wild in cultivated fields and about borders in England, but rare. As the ancient Britons are reported to have painted their bodies with the blue colour obtained from this plant, which is still used in dyeing, the woad is most probably an original production of England; though what occurs now and then about cultivated fields is supposed to have escaped from the crops occasionally raised, chiefly in the middle part of the island. The naturalized plants are less perfectly smooth, and far less luxuriant than the cultivated ones. This plant has a tapering and fibrous root. The stem rises 2 or 5 feet high, wand-like, slightly glaucous, leafy, paniced at the top. Panicle of many compound racemose branches, beset with diminished lanceolate leaves, all of a yellow hue as well as the stalks. Flowers numerous, small, bright yellow.

Woad has been cultivated in France from time immemorial. In England its culture is mostly confined to Lincolnshire, where it is a common practice to take rich flat tracts near rivers, at a high price, for the purpose of growing it for 2 or 4 years. Those who engage in this sort of culture form a sort of colony, and move from place to place as they complete their engagements. It is sometimes, however, grown by stationary farmers. The leaves are the parts of the plant used, and it is considered as a severe crop.

There is a *variety* of woad, called the Dalmatian, described by Miller, and also a wild sort, but only the common is cultivated in England.

The soil for woad should be deep and perfectly fresh, such as those of the rich, mellow, loamy, and deep vegetable kind. Where this culture is carried to a considerable degree of perfection, as in Lincolnshire, the deep, rich, putrid, alluvial soils on the flat tracts extending upon the borders of the large rivers, are chiefly employed for the growth of this sort of crop; and it has been shown by repeated trials that it answers most perfectly when they are broken up for it immediately from a state of sward.

The preparation of the soil, when woad is to be grown on grass land, may either be effected by deep ploughings, with the aid of the winter's

frost; cross-ploughing and harrowing in spring; by deep ploughing and harrowing in spring; by paring and burning; or by trench-ploughing or spade-trenching. The first mode appears the worst, as it is next to impossible to reduce old turf in one year, and even if this is done, the danger from the grub and wire-worm is a sufficient argument against it. By ploughing deep in February, and soon afterwards sowing, the plants may germinate before the grub is able to rise to the surface; by trench-ploughing the same purpose will be more effectually obtained; and, best of all, by spade-trenching. But a method which is equally effectual with the first, more expeditious, and which has a superiority over it in more completely destroying grubs, insects, and other vermin, which are apt to feed on the plants in their early growth, is that of paring and burning. This is, however, chiefly practised where the sward is rough and abounds with rushes, sedge, and other plants of the coarse kind, but might be had recourse to on others with benefit.

The time of sowing may be extended from February to July. Early sowing, however, is to be preferred, as in that case the plants come up stronger, and afford more produce the first season.

The mode of sowing is generally broadcast, but the plant might be most advantageously grown in rows and cultivated with the horse-hoe. The rows may be 9 inches or a foot apart, and the seed deposited 2 inches in depth. The quantity of seed for the broadcast method is 5 or 6 lbs. to the acre; for the drill mode, 2 lbs. are more than sufficient, the seed being smaller than that of the turnip. New seed, where it can be procured, should always be sown in preference to such as has been kept for some time; but when of the latter kind, it should be steeped for some time before it is put into the ground.

The after-culture of the woad consists in hoeing, thinning, prong-stirring, and weeding, which operations may be practised by hand or horse-tools, as in the culture of teazle.

In respect to the business of gathering the crops, with the spring-sown ones, the leaves will generally be ready to be gathered towards the latter end of June or beginning of July, according to the nature of the soil, season, and climate; but for those put in at a later period in the summer, they are often fit to be gathered earlier. This business should, however, constantly be executed as soon as the leaves are fully grown, while they retain their perfect green colour and are highly succulent, as, when they are let remain till they begin to turn pale, much of their goodness is said to be expended, and they become less in quantity, and of an inferior quality for the purposes of the dyer. In the execution of this sort of business, a number of baskets are usually provided in proportion to the extent of the crop, into which the leaves are thrown as they are taken from the plants, which is effected by the hand, by grasping them firmly and giving them a sort of a sudden twist. In favourable seasons, where the soils are rich, the plants will often rise to the height of 8 or 10 inches; but in other circumstances they seldom attain more than 4 or 5; and where the lands are well ma-

naged in the culture of the plants, they will often afford two or three gatherings, but the best cultivators seldom take more than two, which are sometimes mixed together in the manufacturing of them. It is necessary that the after croppings, when they are taken, are constantly kept separate from the others, as they would injure the whole if blended together, and considerably diminish the value of the produce. It is said that the best method, where a third cropping is either wholly or partially made, is to keep it separate, forming it into an inferior kind of woad.

The produce is mostly from about a ton to a ton and a half of green leaves. The price varies considerably; but for woad of the prime quality it is often from 25*l.* to 30*l.* the ton, and for that of an inferior quality 6*l.* or 7*l.*, and sometimes much more.

To prepare it for the dyer, it is bruised by machinery to press out the watery part; it is afterwards formed into balls and fermented, re-ground, and fermented in vats, where it is evaporated into cakes in the manner of indigo. The haulm is burned for manure or spread over the straw-yard, to be fermented along with straw-dung.

The use of woad in dyeing is as a basis for the black and other colours.

To save seed, leave some of the plants undened of their leaves the second year, and when it is ripe in July or August, treat it like turnip-seed.

The only diseases to which the woad is liable are the mildew and rust; when young it is often attacked by the fly, and obliged to be re-sown, and this even on winter-ploughed grass lands more than once. (*Loudon.*)

WOLF'S-BANE (*Aconitum*). A genus of ornamental, tall, free-flowering, very hardy plants, succeeding well under the shade of trees; increased by division or by seeds. All the species are to be dreaded, being of a poisonous quality, highly narcotic, and acid. The aconite has, however, become of great service as a narcotic in many very troublesome disorders. One species, the common wolf's-bane or monk's-hood (*A. napellus*), is a native of Greece, but now grows wild in this country in watery places. It is perennial in habit. Root fleshy, tapering; stem erect, simple, leafy, clothed with minute, close hairs, and terminating in a solitary, simple, upright, spike-like panicle of large, dark-blue, helmeted flowers, without scent. The nectaries are full of honey, and form the spur of the flower. Leaves deeply five-cleft, cut, with linear segments, furrowed above, and of a deep green, but pale beneath. See **ACONITE**.

WOOD. The fibrous or ligneous substance of which the branches, trunks, and roots of trees are principally composed. In vascular trunks, the hardest wood is always in the centre. See **BARK**, **LIBER**, **LIGNIN**, **TIMBER**, **TREES**, &c.

WOODBINE. See **HONEYSUCKLE**.

WOOD-RUSH (*Luciola*, from the *Gramen Luzula*, or glow-worm grass of Bauhin). These plants are nearly related to *Juncus*, from which they are at once distinguished by their flat leaves. They possess little beauty, and are of

the easiest culture. There are seven indigenous species, all of which are described in *Smith's Eng. Flor.* vol. ii. p. 177.

WOODSIA (named in honour of Joseph Woods, F. L. S., an excellent practical British botanist, who first illustrated our native species of *Rosa*). A genus of small ferns, of which two species only have hitherto been discovered:—the oblong *Woodsia* (*W. ilvensis*), and the rounded-leaved *Woodsia* (*W. hyperborea*). These ferns grow best in peat and loam mixed, and are increased by division, or by seed. Their roots are fibrous; fronds tufted, erect, stalked, pinnate, pinnatifid, clothed with simple hairs, or narrow-pointed scales. (*Smith's Eng. Flor.* vol. iv. p. 322.)

WOOD-SORREL (*Oxalis*, from *oxys*, acid; the leaves have an acid taste). Most of the plants of this genus deserve cultivating on account of their very pretty blossoms, which are produced in great abundance. The hardy species should be planted in a shady border, where they will grow and flower very freely. The seeds of the hardy annual species may be sown in the open border in spring. There are in England two wild native species,—1. The common wood-sorrel (*O. acetosella*), which grows abundantly in groves and shady places. Stalks radical, single-flowered. Leaves ternate, inversely heart-shaped, hairy; root of many scaly joints. Leaflets of a delicate bright green, often purplish at the back, drooping at night, on long, hairy, radical, purplish foot-stalks. Flowers solitary, drooping, bell-shaped, either white or purplish, always streaked with fine branching purple veins. When ripe, the blackish shining seeds are projected to a distance on the slightest touch or motion, by their elastic tunics, which remain contracted and wrinkled in the capsule. This herb is powerfully and most agreeably acid, making a refreshing and wholesome conserve with fine sugar; its flavour resembling green tea. Few of our wild flowers are more elegant.

2. Yellow procumbent wood-sorrel (*O. corniculata*). This species is annual, growing in shady, rather moist waste ground. The root is fibrous, and it has become almost a weed in gardens. Stems branched, procumbent. Flower stalks in small umbels of yellow flowers.

Several species of *oxalis* have been found in the United States, among which are the following, enumerated by Nuttall. 1. *O. acetosella*. 2. *violacea*. This species appears often to flower again late in the autumn, and is then destitute of leaves. 3. *Lyoni*. 4. *Corniculata*. 5. *Stricta*. 6. *Dillenii*. These two last are scarcely distinct species.

This genus of more than 100 species is, with a few exceptions in Europe and America, peculiarly indigenous to the Cape of Good Hope. The leaves of all the species are more or less sensitive and nictitant. (*Paxton's Bot. Dict.*; *Smith's Eng. Flor.* vol. ii. p. 323.) See **SORREL**.

WOOD-WASP. See **SAW-FLY**.

WOOD-WAXEN. See **GREENWEED**.

WOOL (Germ. *wolle*; Dutch, *wool*; Rus. *wolna*). The soft, hairy, or downy substance which forms the covering of sheep, and is found in smaller proportion on many other animals. It is an article which has continued

from the earliest period down to the present day to be of primary importance, having always formed the principal part of the clothing of mankind in most temperate regions. Authors have seemed to imagine that the production of wool was confined to the sheep; practical men, however, know that there is a numerous list of animals, on whom, at some season of the year at least, wool is found.

M. Chevreul, who has long devoted himself to the examination of wool, has proved that wool contains three or four different substances. The following is the result of an examination of 100 parts of a merino fleece:—

Earthy substances	-	-	-	Parts
Fat matters dissolved by washing	-	-	-	26·06
Fat matters	-	-	-	32·74
Clean wool	-	-	-	9·97
				31·23
				<hr/>
				100 00

A consideration of the most important properties of wool cannot be better introduced than in the words of one to whom the agriculturist, whatever department of husbandry may chiefly occupy his attention, is much indebted.—“Fine and coarse,” says Arthur Young, “are but vague and general descriptions of wool; all fine fleeces have some coarse wool, and all coarse fleeces some fine. I shall endeavour, for the information of my readers, to distinguish the various qualities of wool in the order in which they are esteemed and preferred by the manufacturer. First, fineness with close ground, that is, thick-matted ground. Second, fineness. Third, straight-haired, when broken by drawing. Fourth, elasticity, rising after compression in the hand. Fifth, staple not too long. Sixth, colour. Seventh, what coarse is in it to be very coarse. Eighth, tenacity. Ninth, not much pitch-mark; but this is no other disadvantage than the loss of weight in scouring. The bad or disagreeable properties are,—thin, grounded, toppy, curly-haired, and, if in a sorted state, little that is very fine, a tender staple, no elasticity, many dead white hairs, very yolky. Those who buy wool for combing and other light goods that do not want milling, wish to find length of staple, fineness of hair, whiteness, tenacity, firmness, elasticity, and not too many pitch-marks.” (*Annals of Agriculture*, vol. xviii. p. 329.) The fineness of the wool differs greatly on the different parts of the sheep. That running down the side of the neck, and covering the shoulders, the ribs, and the back, is the finest; the next covers the superior parts of the legs and the thighs, and extends up to nearly the haunch and the tail, and a still inferior portion runs along the upper part of the neck, the throat, the breast, the belly, and the lower part of the legs. There is considerable variation in this respect in different breeds, and in individuals of the same breed; and although a fleece, taken generally, may be said to be adapted to a particular use, yet a portion of it may be employed in the manufacture of a much more valuable article; and at the same time, a greater quantity will be thrown aside as not sufficiently fine for the originally intended purpose. The influence of temperature on the growth of wool is very considerable. Sheep in a hot climate will yield a

comparatively coarse wool, and those in a cold climate will carry a finer, but, at the same time, a closer and a warmer fleece. The natural instinct of the sheep would seem to teach the wool-grower the advantage of attending to the influence of temperature on him. He is evidently impatient of heat. In the open district, and where no shelter is near, he climbs to the highest parts of his walk, that if the rays of the sun must still fall on him, he may nevertheless be cooled by the breeze; but if shelter is near, of whatever kind, every shaded spot is crowded with sheep. Pasture has a very great influence on the fineness of the fleece. The staple of the wool, like every other part of the sheep, must increase in length or in bulk when the animal has a superabundance of nutriment; and, on the other hand, the secretion which forms the wool must decrease, like every other, when sufficient nourishment is not afforded. Connected with fineness is true-ness of staple—as equal a growth as possible over the animal—a freedom from the shaggy portions, here and there, which are occasionally observed on poor and neglected sheep. These portions are always coarse and comparatively worthless, and they indicate an irregular and unhealthy action of the secretion of wool, which will probably weaken or render the fibre diseased in other parts. Soundness and elasticity are also very important properties in wool.

If the pile is sound, there are few qualities in wool of so much consequence as softness. Fashion has done much in effecting this. Softness of the pile is evidently connected with the presence and quantity of yolk. There is no doubt that this substance is designed, not only to nourish the hair, but to give it richness and pliability. Bad management, neglect, exposure, starvation, impair the pliability of the woolly fibre, but chiefly so because they arrest the secretion of the yolk, or change its properties. The colour of the fleece is of minor, and yet of no trifling importance. The alteration of the colour was the first recorded improvement of the sheep; and its purity, its perfect whiteness, should never be lost sight of by the sheepmaster of the present day. To a certain extent, the fleece is frequently stained with the colour of the soil on which the animal grows. In some parts of Gloucestershire the wool acquires an orange colour; in Hertfordshire and Warwickshire it is of a brownish red; and in the fens of Lincoln and Cambridge it has a dark blue tint.

In some districts, and particularly in the west of England, the farmer needlessly uses a considerable quantity of ochre or ruddle, either in the composition of his salving mixture, or to gratify a foolish fancy. The tar gives consistence to the oil or butter, and although it is often with considerable difficulty washed away, yet while it remains on the fleece, it gives a permanency to the smearing process; not one plea, however, can be offered in favour of the ruddle. See SALVING.

It is not necessary (nor, indeed, would our space permit it) to go into the construction of wool, as seen through the microscope. We shall pass on, therefore, to point out the differ-

ence between hair and wool. The fibre of wool is crisped or curled, the curls increasing according to the fineness and felting property of the wool: hair is often disposed to curl, but in an inferior degree. The distinction, therefore, between these substances is more in degree than intent. Wool is decidedly crisped and serrated; hair is sometimes curled, but to an inferior degree, and the irregularities of its edge, in some few cases, assume the form of slight serrations. Wool will felt; hair will only entangle and harle to a limited extent. See FELT and HAIR.

The old and apparently simple division of wool was into *long* and *short*, or, according to the purposes to which it was devoted, "combing" and "clothing wool;" but there was considerable difficulty in arranging some fleeces which were of intermediate lengths, and convertible to either purpose. A third subdivision, that of "middle wool," has recently been added. These are again divided into subordinate classes, according to the fineness of the fibre. "In sorting wools," says Mr. McCulloch, "there are frequently eight or ten different species in

a single fleece; and if the best wool of one fleece be not equal to the finest sort, it is thrown to a 2d, 3d, or 4th, or to a still lower sort, of an equal degree of fineness with it. The best English short native fleeces, such as the fine Norfolk and Southdown, are generally divided by the wool-sorter into the following sorts, all varying in fineness from each other:—viz. 1. Prime; 2. Choice; 3. Super; 4. Head; 5. Downrights; 6. Seconds; 7. Fine Abb; 8. Coarse Abb; 9. Livery; 10. Short coarse, or breech wool. The relative value of each varies, according to the greater demand for coarse, fine, or middle cloths." (*Youatt on Sheep; Bakewell's Observations on Wool; Luccock on Wool; Anderson on Wool.*) See ALPACA, FLEECE, LAMB-SKINS, and SHEEP.

Price of Southdown Wool in England, in different Years.

1826	- 25 - 65	1838	- 45 - 47
1827	- 25 - 50	1839	- 45 - 60
1828	- 30 - 50	1840	- 43 - 44
1829	- 25 - 45	1843	- 25 - 30
1830	- 33 - 68		

An interesting view of the foreign wool trade and the check upon this effected through the protection received from Congress, is exhibited in the following account derived from the columns of the *New York Journal of Commerce*, (for Sept. 1843.)

In a communication to the *Middlebury People's Press*, dated 10th July last, and signed by the Hon. William Slade, late a member of Congress from Vermont, some interesting facts are stated as to the operation of the new Tariff upon the importation of wool from foreign countries. By information received from the Register of the Treasury, it appears that during the 1st half of the present fiscal year, which commenced on the 1st of October last, about a month after the new Tariff went into operation, there was imported into the United States, of wool costing 7 cts. a lb. or under, only 881,568 lbs. and of wool costing over 7 cts. a lb., only 175,962 lbs. Making a total of only 1,037,530 lbs. of all descriptions of wool in 6 months! This is a most extraordinary falling off, compared with the importations of previous years, as will be seen from the following schedule:

Year.	Under 8 cts.	Over 8 cts.
1835	5,543,626	388,830 lbs.
1836	11,033,010	806,370
1837	9,480,195	703,276
1838	6,551,126	445,478
1839	7,398,519	527,620
1840	9,303,992	675,009
1841	11,409,764	981,281
1842	10,558,998 lbs.	351,384

Making, on an average of 7 years, something over 9,000,000 lbs. per annum, $\frac{1}{13}$ ths of which, at the place whence imported, cost less than 8

cts. a lb. The new Tariff makes the minimum 7 cts. per lb. instead of 8 cents, and levies a duty of 5 per cent. on wool not above that minimum, whereas under the old Tariff such wool was duty free. But these changes are so slight, that they are not at all sufficient to account for the immense decrease in the amount imported. Lest such should be the inference of the wool-growers, Mr. Slade tells them that through the efforts of the Vermont delegation in Congress, the word "coarse" was inserted in connection with cheap wool, so that now, in order to be admitted at the low duty of 5 per cent. (which cannot exceed $3\frac{1}{2}$ mills per lb.), wool must not only have been bought at 7 cts. a lb. or under, but must also be *coarse*: and he adds, "I have no doubt that with a careful and thorough execution of the coarse wool provision, according to its true intent and meaning, the reduction [in the quantity of wool imported] would have been still greater." To illustrate this point, he states the following particulars:

"It appears from the Custom House returns that 1101 sheep, of the aggregate value of \$10,565—averaging \$9 60 each, and therefore presumed to have been merino bucks—were exported from the United States to Buenos Ayres in the years 1837 and 1838. The quantity of wool, the product of the crossings of these merino with the native South American sheep, imported into the United States at and below the value of 8 cts., cannot, of course, be ascertained. The importations from that country of wool costing 8 cts. and under, were greatly increased in the succeeding years; embracing, as is well known, much fine wool, and therefore presumed to have been the product of the crossings referred to. That increase will appear by the following statement of the importations of wool costing 8 cts. and under, from Buenos Ayres, during the years 1839, 1840, and 1841, compared with the previous 3 years.

In 1836	- - - -	2,256,887 pounds.
1837	- - - -	2,108,582
1838	- - - -	2,515,833
1839	- - - -	683,535
1840	- - - -	566,468
1841	- - - -	8,870,799

"The French blockade of Buenos Ayres in 1839 and 1840 diminished the exports of those years, and consequently swelled those of 1841 when the blockade was raised. The annual average of the 3 years was 3,373,600 lbs. That of the preceding 3 years was 2,293,784 lbs.; making an excess of the average of the last 3, over that of the first 3 years, of 1,079,816 lbs.—an increase of about 47 per cent.

"It was the extraordinary quantity of fine wool thus cheapened in the market of Buenos Ayres, and thrown, in large quantities, upon our own, that suggested the necessity of the introduction of the word 'coarse' into the clause in question. Its intended effect was, to subject to the higher duty all wool *not* coarse, though costing less than 7 cts."

This higher duty, which applies to all wool costing over 7 cts. a lb., and, according to Mr. Slade's construction, to all wool not coarse, whatever may be its cost, is 3 cts. a lb. and 30 per cent. ad valorem. Hence the duty on wool costing 10 cts. at the place whence imported, is 6 cts. a lb.; and on wool costing 20 cts., 9

cts. a lb. This is a large per centage, we admit; but not so large as that established by the Tariff of 1832, which on all wool over 8 cts. a lb. levied a duty of 4 cts. a pound and 32 per cent. ad valorem. On wool costing over 8 cts., the duties during all the years embraced in the second of the above tables, except a part of 1842, were, on an average, as high as they are now. We wish this fact to be particularly noted; for it affords conclusive evidence that the smallness of the importations of wool since the new Tariff went into operation, is not occasioned by that Tariff. It is occasioned, in part, by the market having been over-stocked with coarse wool during 1841 and 1842 (nearly 17,000,000 lbs. having been imported during those 2 years from Buenos Ayres alone),—partly by the prostration of carpet manufacturing in this country for the last year or two, on account of low prices and the scarcity of money,—and partly by the cheapness of wool grown in the United States. This last is what is going, very soon, to nullify the Tariff, and importations too, so far as wool is concerned. We have no doubt that in 10 years—perhaps less—we shall become a wool-exporting country to such an extent that protection against imported wool will be as effective as it now is against imported cotton;—and no more so. [We still lay a duty of 3 cts. a pound on cotton, which does neither hurt nor good.] The great west is coming, with her immense prairies, admirably adapted to sheep,—and she will soon deluge the country with wool and sheep-skins, as she now does with hogs, bacon, pork, lard, lard-oil, soap, &c.

WOOLLEN RAGS. See RAG.

WORK. See LABOUR.

WORLIDGE, or WOOLRIDGE, JOHN. An early English agricultural writer. But little more is known of his history, than that he was a gentleman who was a great lover of rural affairs and gardening. Of his works I am only acquainted with the following:—1. *Systema Agriculturæ; The Mystery of Husbandry discovered and laid open*, 1669—77—81, 1687, folio, 1716, 8vo. 2. *Treatise on Husbandry*, 1675, folio. 3. *Systema Horticulturæ*; or, *The Art of Gardening*, 1677. 4. *Vineta Britannicæ*, 1678—91, 8vo. 5. *The most easy way of making Cyder*, 1678. 6. *Apiarium*, 1691, 12mo.

The *Systema Agriculturæ* was the most bulky folio volume on agriculture that had yet appeared, and its comprehensive themes are all set forth in its first page. The authors of those days seemed to consider it essential that their readers should have, in the title-page of a book, a complete summary of its inviting contents. Woolridge was evidently of this opinion, for his title-page announces that this was the "*Systema Agriculturæ, or the Mystery of Husbandry discovered*;" treating of the several new and most advantageous ways of tilling, planting, sowing, manureing, ordering, improveing, of all sorts of gardens, orchards, meadows, pastures, corn-lands, woods, and coppices; as also of fruits, corn-grain, pulse, new hays, cattle, fowl, beasts, bees, silk-worms, and fish, with an account of the several instruments and engines used in the profession; to which is added, *Kalendarium Rusticum, or the husbandman's*

monthly directions; also the prognosticks of dearth, scarcity, plenty, sickness, heat, cold, frost, snow, winds, rain, hail, thunder, &c.; and *Dictionarium Rusticum, or the interpretation of rustick terms*; the whole work being of great use and advantage to all that delight in that most noble practice." It is dedicated to the gentry and yeomanry of England, and opens with a preface laudatory of agriculture.

Notwithstanding, however, the ill aspect of this heavy title-page, the book contains more useful and more enlightened observations on many points of husbandry than any which had preceded it. He was a warm friend to the enclosure of commons and other waste land, and he suggested, what in fact he appears (p. 21) to have carried into effect in 1665, at Wilton, the erection of water-works for the purpose of *flooding* meadows, an improvement of which I think not nearly so much has been made as is possible in this land of steam and steam-engines. He was evidently well acquainted with the management of water-meads, and his directions with relation to them are practical and sensible. He advises that sandy meadows should be chalked, and ashes applied to sour rushy grasses. When speaking "of several new species of hay or grass," he enumerates clover-grass, trefoyle, St. Foyn, La Lucern, ray-grass, &c. He also recommends the deep ploughing or digging of land, and on all occasions seemed alive to any improvement in the implements of agriculture. After giving an account, at some length, of the rude and clumsy contrivance of Gabriel Platte, for a dibbling-machine, he elaborately and earnestly advocates the use of a drill, an engraving of one of which, primitive enough, it is true, in its appearance, he gives in his work. "To remove," he says, "all manner of errors or inconveniences that can be found in setting or hoeing of corn, I shall here give you a plain and perfect description of an easy and feasible instrument that shall disperse your corn, grain, or pulse, of what kind soever, at what distance, and in what proportion you please." The farmer may be curious to know the construction of this drill of a century and a half since. It had a coulter, a pipe, a hopper, wheels, and axletrees. He was the first English author, I believe, who suggested the use of the manure-drill, for, when speaking of the drill, he says (p. 52), "By the use of this instrument also, you may cover your grain or pulse with any rich compost you shall prepare for that purpose, either with pigeon's dung, dry or granulated, or any other saline or lixivial substance made disperseable, which may drop after the corn, and prove an excellent improvement; for we find experimentally, that pigeon's dung, sown by the hand on wheat or barley, mightly advantageth it by the common way of husbandry; much more might we, therefore, expect this way, where the dung, or such like substance, is all in the same furrow with the corn, where, in the other vulgar way, a great part thereof comes not near it. It may either be done by having another hopper, on the same *frame*, behind that for the corn, wherein the compost may be put, and made to drop successively after the corn, or it may be sown

with another instrument to follow the former, which is the better way, and may both disperse the soil, and cover both soil and seed."

Woolridge was evidently an observer who was able and willing to think for himself. He advocated change of seed "from dry, hungry, barren land, to rich and fat land; also from land inclining to the south, to land inclining towards the north, and the contrary;" all of which, he well adds (and the reader must remember that Woolridge was writing when chemistry existed only in name), "are manifest signs that there is some particular thing wherein each seed delights, which if we did but understand we might properly apply it, and gain riches and honours to ourselves; but because we are ignorant thereof, and are content so to remain, we must make use of such soils, dungs, composts, and other preparations and ways of advancement of the growth of vegetables as are already discovered and made use of." (p. 57.)

He extols the use of steepes for seed-corn, mentions with approbation for this purpose nitre, common salt, as well as urine, and gives a recipe for making a kind of liquid manure with sheep-dung ($\frac{1}{2}$ bushel), saltpetre ($\frac{1}{2}$ lb.), and common salt (1 lb.), boiled together for ten minutes in water (20 quarts), and this he commends very highly as a steep; and I am inclined to believe that something of this kind of rich liquor, more especially if the seed was afterwards dried by being sprinkled with some of the very fine manure powders at present proposed, such as the urate of the London Manure Company, the composition of M. Poittevin, the guano, gypsum powder, &c., might be used more profitably by the cultivator than at first sight he may be inclined to believe. He was in favour of paring and burning on some soils, and had the good sense to discern the advantages capable of being derived from the permanent improvement of the soil by the use of earthy manures. He devotes, therefore, a chapter to the soils and manures taken from the earth (p. 65); notices the uses, for this purpose, of chalk, lime, marl, clay, fuller's earth.

The value of sand as a fertilizer did not escape our author's attention. He notices the value to some soils of that of the calcareous shores of Cornwall, and of the Suffolk craig formation, and of that which he advises the farmer to lay under his farm-yards and sheep-pens.

The excrements of fowls were strongly recommended by Woolridge as a fertilizer. He describes those of pigeons and hens as "incomparable,—one load is worth ten loads of other dung;" commends the use of "all marrow-bones, fish-bones, horn, or horn-shavings;" but he fell into the error with regard to those which it required a century and a quarter to remove, viz., he fancied that all the enriching qualities of the bones were to be attributed to the grease they contained, instead of to their phosphate of lime. He advocated the mixture of peat, saw-dust, and tanners' refuse bark with dung-heaps,—a plan which is even now not nearly so extensively adopted as its merits deserve. Indeed, as honest John Woolridge concludes his section (p. 85), "The well-pre-

paring of *dung-mixt* is a piece of husbandry not to be slighted, on which point of good or ill husbandry depends the rise and fall of the rents or values of many farms in this kingdom."

Every account of live-stock given by the earlier agricultural writers betrays the total want of attention then paid by the farmers to the breeding of stock, or if they do mention the points to be commended in an ox or a sheep, they are precisely those which a modern breeder endeavours to avoid. For instance, the chronicler Hollingshed commends the English cows for their largeness of bone, and even Woolridge, writing centuries after him, although very elaborate on most points of husbandry, treats of the farmer's live-stock in a manner that clearly indicates that in those days, to use a Norfolk phrase, "a cow was a cow, and a sheep a sheep." Thus *all* the instruction he gives the breeder with regard to the selection of a cow is, that "the best sort is the large Dutch cow, that brings two calves at one birth, and gives ordinarily two gallons of milk at one meal." His account of sheep I will also give, without abridgment, for its facts will sound still more novel to a modern farmer:—"There are divers sorts, some bearing much finer wool than others: as the *Herefordshire* sheep about Lemster bear the fairest fleeces of any in England. Also they are of several kinds as to their proportion: some are very small, others larger. But the Dutch sheep are the largest of all, being much bigger than any I have seen in England, and yearly bear two or three lambs at a time. It is also reported that they sometimes bear lambs twice in the year." This seemed to convince Woolridge, and very naturally, too, of their value, for he adds, "It may doubtless be of very good advantage to obtain of those kinds and also of Spanish sheep that bear such fine fleeces."

The scientific modern breeder, when he smiles at this negligence and folly of a by-gone race of farmers, must remember, however, the difficulties under which they laboured, not only from lack of knowledge, but also of the means to improve at a reasonable rate their ill-shaped, large-boned, and slow-feeding race of oxen. He should recollect that they had not had the advantage of a Bakewell, a Culley, or a Collings, to labour during a lengthened period for their improvement,—the days of the Smithfield Club, and of the Highland Society, were yet far distant. They had not even a suspicion of what improved breeding would effect; and if they were ignorant, as they evidently were, that their breeds were inferior, we can hardly wonder that they were content to labour on, since the very first step to improvement, a belief in greater excellence being possible, was wanting.

The opinions, however, of Woolridge with regard to plantations of timber-trees were evidently more enlightened; for although he lived a century before the days of our modern extensive planters—of such men as the Lords Athol, Devonshire, and Fife, and of Sir Henry Steuart—yet he earnestly advised the planting of the poorer soils of our island; he asked the landowners of his time, after describing to

them the profit they might derive from such foresighted enterprise, "What can be more pleasant than to have the bounds and limits of your own property preserved, and continued from age to age by the testimony of such growing and living witnesses, in the spring yielding a reviving cordial to your winter-chilled spirit, giving you an assurance of the approaching summer by their pregnant buds and musical inhabitants? In the summer, what more delectable than the curious prospect of the variety of greenness, dark shades, and retirement from the scorching sunbeams?" He well knew, too, what some of my northern friends are only now proving to be practically the case, that "woods also finely refrigerate the air in the summer's parching heats, and qualify the dry and injurious winds, both in winter, spring, and autumn." He devotes a long chapter to the profits and pleasures of fruit trees, and ridicules very quaintly the objection too commonly made to such plantations, viz., "that their fruit would be stolen." "When," he says, "they become more common, they will be little regarded by these fitchers, or if they do borrow a few sometimes in their pockets, or to make a few apple-pies withal, yet that is a poor discouragement to an ingenious spirit, and much like that rustick humour of one that would not improve a very good piece of ground for that purpose with fruit trees, because the parson would have the decimation of it, and so denied himself the nine parts, because the parson should not have the remainder."

Of the ploughs employed 150 years since, he mentions the double-wheeled or Hertfordshire plough, the turnwrest or Kentish plough, "which surpasseth for weight and clumsiness" the one-wheeled plough, the plain plough, and the trenching plough.

Woolridge gives also sundry directions for angling, fowling, bird-catching, horse-breeding, and sundry other rural affairs, and finally he winds up with a *Kalendarium Rusticum*. In these he gives various monthly directions, of which one specimen will suffice, of the mode of farming then commonly adopted. In May he directs the farmer "to kill ivy, to feed down or mow rank corn; to sow barley, buckwheat, pease, hemp, and flax, clover-grass, St. Foy, and other French grasses; to pare and burn land, and wean lambs." He every month, as if in rivalry of the almanac-makers of former generations, treated the farmer to some poetry, often of a most absurd description; thus, in the month of March, after having told them that "this month ushers in the most welcome season of the year," and that "now gentle Zephyrus fans the sweet buds, and the celestial drops water fair Flora's garden," he could not help adding some of his own poetry, telling them what must have been indeed novel information, that now

"The lofty mountains standing on a row,
Which but of late were perriwig'd with snow,
Doff their old coats, and now are daily seen
To stand on tiptoes all in swaggering green;
Meadows and gardens are prankt up with buds,
And chirping birds now chant it in the woods

Woolridge labored hard, however, in spite

of occasional absurdities of expression, to elevate the science of agriculture; and that it was deemed a science in the 17th century, is evident in this opening address to the farmer, when he says, "Agriculture hath been (not undeservedly) esteemed a science that principally teaches us the nature and divers properties and qualities, as well of the several soils, earths, and places, as of the several productions or creatures, whether vegetable, animal, or mineral, that naturally proceed or are artificially produced from, or maintained by, the earth." This he promises the husbandman he will do "after a plain and familiar method." He soon, however, begins to illustrate his "plain and familiar method," by talking of the "secret, mystical, and mechanick indagations of nature, the universal spirit, or spirit of mercury and of salt;" and gives us but a mean opinion of his natural philosophy, by gravely telling us that "soon will horse-hairs receive life lying in rain-water but a few days in the heat of the sun in spring-time."

But in spite of these occasional mistakes, the book of Woolridge was perhaps the most practical, and therefore the most useful book which had yet appeared treating of agriculture and rural affairs. The very publication of such an expensive folio, of 326 pages, betray the increasing thirst for knowledge of the cultivators of those days, and the same remarks apply generally to those of Platte and of Hartlib; in truth, both agriculture and agricultural writers could hardly fail to keep pace with the rapid increase to the general stock of knowledge which the age in which they flourished received to so remarkable an extent; and this improvement was not, as my brother, Mr. George Johnson remarks (*Hist. of Gard.*), in only one branch of knowledge, but in the whole circle of the arts and sciences. The reformation was not confined to religion. By delivering the human mind from servile thralldom; and teaching man, instead of bowing blindly to custom, merely on account of its antiquity, to have a self-dependence, it gave an impulse to improvement which no tyrant opposition of either bigotry, indolence, or self-sufficiency could check. Such men as Bacon, Peiresc, and Evelyn arose, and whilst the first traced the path which men of science should tread, the two latter lent their talents and their wealth to sustain them in the pursuit. Bacon, it has been truly observed, was the first who taught men that they were but the servants and interpreters of nature, capable of discovering truth in no other way than by observing and imitating her operations; that facts must be collected, instead of speculations formed, and that the materials for the foundations of true systems of knowledge were to be discovered, not in the books of the ancients, not in metaphysical theories, not in the fancies of men, but by careful, and laborious, and patient experiments and observations in the external world. Peiresc was a munificent man of letters; his advice, his purse were open to the votaries of every art and every science; his library was stored with the literature of every age and nation, his garden with the rarest and most useful exotics, and these last he delighted to spread over the

country. When, indeed, we cast our eyes over a list of the men of science and literature of all kinds that adorned this age, especially in chemistry and in botany, the two sciences perhaps of all others the most important to agriculture, we need not be surprised to find how rapidly it was rising from being a mere art of empiricism; and when we note how rapidly the thirst for foreign research was prevalent, we can easily perceive how improved modes of culture and new plants were acquired to agriculture. Cavendish, but especially Raleigh, by their visits for lucre as well as fame to the Spanish settlements of America in 1580-8, led the way in a path which Lancaster and Raymond followed in 1791, and laid the foundation of that anomalous copartnership of commercial monarchs, the East India Company. Annual fleets now returned from the east and west, laden with the curiosities of both the animal and vegetable kingdoms; of these the potato, tobacco, and tea need alone be instanced; and although the views of men were not yet liberal enough to prompt them to voyages of discovery, with an unmixed desire of extending the field of science, or an enlarged wish to benefit mankind, yet new plants, in common with other hitherto strange natural products, attracted their attention, and, though at first imported as novelties, soon became by degrees to be desired and sought for as the luxuries and necessaries of life. (*Quart. Jour. Agr.* vol. xii. p. 460.)

WORM. See CUT-WORM, EARTH-WORM, WIRE-WORM, &c.

WORM-SEED (*Chenopodium*). See GOOSE-FOOT.

WORMS, INTESTINAL. A troublesome sort of vermin found in the intestines of horses and other animals. There is, perhaps, nothing so destructive to the health and appearance of the horse as worms. When they have obtained a settlement in the intestines, neither the labour of the groom nor the liberality of the master will prove of any avail towards improving the animal's condition: for as fast as the chyle is formed from the aliment, which ought to be converted into blood, these numerous guests first satiate their craving appetites, and leave but a scanty supply for the exhausted system of the horse, so that a double allowance of corn would not preserve a healthy state; because the digestive organs cannot exert an extraordinary power for any length of time, without producing such a state of debility as to render them incapable of performing afterwards their proper office.

In these animals, the most common kinds are the following:—1. Bots, which many young horses are subject to in the spring; 2. Those that resemble earth-worms, and which, by physicians, are called *lumbrici*; 3. Those that are about the size of the largest sewing-needles, with flat heads, called *ascarides*; 4. That species of worm called *tania*, or tape-worm. See BOTS, FLUKE-WORM, &c.

WORMWOOD (*Artemisia*, so named in honour of Artemisia, wife of King Mausolus, or of Diana *Αρτεμις*). There are four perennial-rooted bitter aromatic herbs included under this name, and cultivated solely for medicinal

purposes:—Common wormwood (*A. absinthium*) is a native of almost every part of Europe, and in England is found by road-sides on heaps of rubbish, &c. It is an erect under shrub, with hoary tri-pinnatisert leaves. The flowers in small, globose, nodding, racemose panicles. The same remarks apply to the drooping sea-wormwood (*A. maritima*), which is found on salt marshes and the sea-coast. Roman wormwood (*A. pontica*) is a native of Italy; and Santonicum or Tartarian wormwood (*A. Santonica*), which is a mere variety of *A. maritima*, of Persia and Siberia. The soil best suited to the growth of these plants is one that is dry, light, and poor, otherwise they become luxuriant, and are defective in their medicinal qualities, as well as in their power to withstand the rigour of the winter. Any situation will suit the common and the sea-wormwoods that is open and unconfined; but the exotic species require to be sheltered from the severe aspects. In a severe winter, the Tartarian can only be preserved under a frame. The sea-wormwood seldom flourishes from the want of a genial soil; the application of salt would undoubtedly be beneficial.

They are all propagated by seed, as well as slips and cuttings, the first of which may be sown in March or April, and the latter planted during June, July, and beginning of August. The seed is sown thinly broadcast, and when the plants arrive at a height of 2 or 3 inches, are weeded and thinned to 6 inches asunder; and those taken away pricked out at a similar distance, water being given if the weather is at all dry. The slips and cuttings are planted in a shady border, about 8 inches apart, and water given regularly every evening until they have taken root. They are all to be transplanted finally early in the following spring, by whichever mode they are raised, setting the plants at last 18 inches apart. See MUGWORT, and SOUTHERNWOOD.

WOUNDWORT (*Stachys*, from *stachys*, a spike, alluding to the mode of flowering). A genus of rather weedy-looking plants, hardly worth cultivating for ornament. They all succeed in common garden soil. The perennial kinds are easily increased by dividing the roots in spring or autumn. The seeds of the annual kinds should be sown in spring, in the open border. As a vulnerary these plants have no power. There are five indigenous species: the hedge woundwort (*S. sylvatica*); the ambiguous woundwort (*S. ambigua*); the marsh woundwort (*S. palustris*); the downy woundwort (*S. germanica*); and the corn woundwort (*S. arvensis*). The marsh woundwort has a fleshy root, creeping extensively; throwing out in autumn a number of tuberous shoots, which render it, in low, wet ground, very difficult of extirpation. This, therefore, should be attempted in summer before these knobs are produced, when the flowers are appearing.

Several species of woundwort, or hedge-nettle, are found in the United States. One, called *S. sylvatica*, is found on the banks of the Ohio, on the skirts of thickets, giving out the same fetid odour as the European species. The flowers are, however, paler. (*Nuttall*)

Y.

YAM (*Dioscorea sativa*). A climbing plant, cultivated in the East and West Indies. Its roots are very large, flattened, sometimes palmated. It is boiled or roasted like the potato, and is wholesome, palatable, and nutritious. The flour is also used for puddings and bread. The *D. alata* is equally cultivated; its root is 3 feet long, and often weighs 30 lbs. Of both kinds there are numerous varieties.

YARD-DUNG. See FARM-YARD MANURE.

YARD OF LAND. A quantity of land which in some counties in England signifies 15 acres, in some 20, and in others 24, 30, and 34 acres.

YARROW (*Achillea*). A genus of showy, free-flowering plants, succeeding well in any common soil, and readily increased by dividing the roots. The species are possessed of aromatic, bitter, tonic, and stimulating qualities. In England the following are indigenous perennials:—

1. Sneezewort yarrow, or goose-tongue (*A. ptarmica*), which grows in wet hedges, or about the banks of rivers, flowering in July and August. The root creeps widely, and is difficult of extirpation where the soil is moist. Stems upright, about 2 feet high; corymbose at the top. Leaves sessile, linear, pointed, equally and sharply serrated, and of a glaucous green. Flowers numerous, small, milk-white in the disk as well as in the radius, with an irregular number of ligulate florets. The whole plant has a pungent flavour, provoking a flow of saliva, and this flavour renders it acceptable, as Schreber asserts, to sheep, who delight especially in saltish food. The sneezing caused by the dried and powdered leaves is rather owing to their little, sharp, marginal prickles. Its name is derived from this property of causing sneezing.

2. Serrated yarrow (*A. serrata*). This is a much less common species, in which the root is fibrous, leaves linear, lanceolate, downy, deeply serrated. Flowers of a yellowish-white or buff colour, not half the size of the foregoing. The whole herb has a powerful aromatic scent and bitter flavour, somewhat like tansy.

3. Common yarrow or milfoil (*A. millefolium*), Pl. 9, k. This species grows abundantly in English meadows and pastures. The root is creeping, with smooth, reddish, subterraneous shoots, which are warm and agreeably pungent, partaking of the flavour and salivatory quality of the pellitory of Spain (*A. pyrethum*). Stems furrowed, erect, about a foot high. Leaves doubly pinnatifid, hairy; segments linear, toothed, pointed. Flowers numerous, white, occasionally reddish or purple. The whole herb is astringent, and weakly aromatic. Although considered a bad weed in pasture and arable lands, in consequence of its creeping root, Dr. Anderson and others have recommended it for cultivation; but its productive and nutrient properties are very inferior to many other plants equally adapted to light soils; 64 drachms of the leaves and stems, cut when in flower, afforded 98 grains of nutritive matter. Linnæus says that its properties are vulnerary and styptic. An essential oil is ex-

tracted from the flowers; and an ointment made of the leaves is reckoned good against the scab in sheep. *A. moschata*, an exotic species, a native of Italy, is sudorific and acrid, and makes a wholesome food for cattle.

4. Woolly yellow milfoil, or yarrow (*A. tomentosa*). This species grows about dry hilly pastures in Scotland and Ireland. The root is woody, slightly creeping, with many long fibres. Stems scarcely a foot high, curved at the base, then erect. Leaves doubly pinnatifid, woolly, segments linear, crowded, acute. Flowers densely corymbose, on woolly stalks, of a bright golden yellow. The whole herb, as well as the flowers, has an aromatic scent when rubbed. It serves to decorate rock-work in gardens, but will not bear wet or shade.

YEARLINGS. A term applied to calves, colts, and other young stock, when they have completed their first year.

YEAST. The froth or scum which rises on beer during the act of fermentation. (See BREWING and FERMENTATION.) It contains a variety of components; among others, carbon, acetic and malic acids, alcohol, potassa, lime, a saccharine, mucilaginous extract, gluten, and water.

Yeast is an article of the greatest importance in domestic economy, forming a necessary ingredient in the manufacture of bread, which would otherwise become heavy and unwholesome. When put in contact with saccharine matters, at a temperature of between 50° and 60°, it causes fermentation, and changes the sugar into alcohol and carbonic acid. Yeast may be dried and yet retain its properties, but a temperature of 212° destroys it.

The yeast prepared by the Hungarians will keep for a whole twelvemonth. During the summer season they boil a quantity of wheaten bran and hops in water; the decoction is not long in fermenting, and when this has taken place they throw in a sufficient portion of bran to form the whole into a thick paste, which they work into balls, that are afterwards dried by a slow heat. When wanted for use they are broken, and boiling water is poured upon them; having stood a proper time, the fluid is decanted, and in a fit state for leavening bread. See BREAD.

"The substance called yeast or ferment, derives its name from the power it possesses of causing fermentation in sugar, or saccharine vegetable juices. It possesses," says Liebig, "all the characters of a compound of nitrogen in the state of putrefaction and eremacausis.

"Like wood in the state of eremacausis, yeast converts the oxygen of the surrounding air into carbonic acid, but it also evolves this gas from its own mass, like bodies in the state of putrefaction. (Colin.) When kept under water, it emits carbonic acid, accompanied by gases of an offensive smell (Thénard), and is at last converted into a substance resembling old cheese. (Proust.) But when its own putrefaction is completed, it has no longer the power of inducing fermentation in other bodies. The presence of water is quite necessary for sustaining the properties of ferment, for by simple pressure its power to excite fermentation is much diminished, and is completely destroyed by dry

ing. Its action is arrested also by the temperature of boiling water, by alcohol, common salt, an excess of sugar, oxide of mercury, corrosive sublimate, pyroligneous acid, sulphurous acid, nitrate of silver, volatile oils, and, in short, by all antiseptic substances.

"The insoluble part of the substance called ferment does not cause fermentation. For when the yeast from wine or beer is carefully washed with water, care being taken that it is always covered with this fluid, the residue does not produce fermentation.

"The soluble part of ferment likewise does not excite fermentation. An aqueous infusion of yeast may be mixed with a solution of sugar, and preserved in vessels from which the air is excluded, without either experiencing the slightest change. What then, we may ask, is the matter in ferment which excites fermentation, if neither the soluble nor insoluble parts possess the power? This question has been answered by Colin in the most satisfactory manner. He has shown that in reality it is the soluble part. Before it obtains this power, the decanted infusion must be allowed to cool in contact with the air, and to remain some time exposed to its action. When introduced into a solution of sugar in this state, it produces a brisk fermentation; but without a previous exposure to the air it manifests no such property.

"During the fermentation of sugar by yeast, both of these substances suffer decomposition at the same time, and disappear in consequence. But if yeast be a body which excites fermentation by being itself in a state of decomposition, all other matters in the same condition should have a similar action upon sugar; and this is in reality the case. Muscle, urine, isinglass, osmazome,* albumen, cheese, gliadine, gluten, legumin, and blood, when in a state of putrefaction, have all the power of producing the putrefaction or fermentation of a solution of sugar. Yeast, which by continued washing has entirely lost the property of inducing fermentation, regains it when its putrefaction has recommenced, in consequence of its being kept in a warm situation for some time.

"If we consider the process of the fermentation of pure sugar, in a practical point of view, we meet with two facts of constant occurrence. When the quantity of ferment is too small in proportion to that of the sugar, its putrefaction will be completed before the transformation of all the sugar is effected. Some sugar here remains undecomposed, because the cause of its transformation is absent, viz., contact with a body in a state of decomposition.

"But when the quantity of ferment predominates, a certain quantity of it remains after all the sugar has fermented, its decomposition proceeding very slowly, on account of its insolubility in water. This residue of ferment is still able to induce fermentation, when introduced into a fresh solution of sugar, and retains the same power until it has passed through all the stages of its own transformation.

"Hence a certain quantity of yeast is neces-

sary in order to effect the transformation of a certain portion of sugar, not because it acts by its quantity increasing any affinity, but because its influence depends solely on its presence, and its presence is necessary, until the last atom of sugar is decomposed.

"We have seen that ferment or yeast is a body in the state of decomposition, the atoms of which, consequently, are in a state of motion or transposition. Yeast, placed in contact with sugar, communicates to the elements of that compound the same state, in consequence of which, the constituents of the sugar arrange themselves into new and simpler forms, namely, into alcohol and carbonic acid. In these new compounds, the elements are united together by stronger affinities than they were in the sugar, and therefore under the conditions in which they were produced further decomposition is arrested.

"We know, also, that the elements of sugar assume totally different arrangements, when the substances which excite their transposition are in a different state of decomposition from the yeast just mentioned. Thus, when sugar is acted on by rennet or putrefying vegetable juices, it is not converted into alcohol and carbonic acid, but into lactic acid, mannite, and gum.

"Again, it has been shown, that yeast added to a solution of pure sugar gradually disappears, but that when added to vegetable juices which contain gluten as well as sugar, it is reproduced by the decomposition of the former substance.

"The yeast with which these liquids are made to ferment, has itself been originally produced from gluten.

"The conversion of gluten into yeast in these vegetable juices is dependent on the decomposition (fermentation) of sugar; for, when the sugar has completely disappeared, any gluten which may still remain in the liquid does not suffer change from contact with the newly deposited yeast, but retains all the characters of gluten.

"Yeast is a product of the decomposition of gluten; but it passes into a second stage of decomposition when in contact with water. On account of its being in this state of further change, yeast excites fermentation in a fresh solution of sugar, and if this second saccharine fluid should contain gluten, (should it be wort, for example,) yeast is again generated in consequence of the transposition of the elements of the sugar exciting a similar change in this gluten.

"After this explanation, the idea that yeast reproduces itself as seeds reproduce seeds, cannot for a moment be entertained." (*Liebig.*)

YELLOW-BEAR. See CATERPILLAR.

YELLOW-TOP (*Agrostis alba*). A variety of Herds. Called also, in the New England states, White-top.

YELLOW-WEED. See WELD.

YELLOW-WOOD (*Virgilia lutea*). This tree, says Michaux, is confined to that part of West Tennessee which lies between the 35th and 37th-degrees of latitude, where it is commonly designated by the name which is here adopted.

* An extractive animal matter on which the peculiar flavour of broth is supposed to depend; hence its name, from the Greek for odour and broth.

This tree grows of preference on gentle declivities, in a loose, deep, and fertile soil, and is usually accompanied by the red mulberry, coffee tree, sweet locust, black walnut, and other species whose presence evinces the richness of the land. It rarely exceeds 40 feet in height and 1 foot in diameter, and in general it does not attain even these dimensions. Its trunk is covered with a greenish bark, which is smooth instead of being furrowed like that of most other trees.

The leaves of the yellow-wood are 6 or 8 inches long on old trees, and of twice this size on young and thriving stocks. They are composed of two rows of leaflets, smooth, entire, nearly round, and about an inch and a half in diameter. The leaflets are 3, 4 or 5 on each side, borne by short petioles, and surmounted by an odd one, which is supported by the common footstalk. As in the buttonwood, the lower part of the footstalk contains the bud, which becomes visible in plucking the leaf.

The flowers form elegant, white, pendulous bunches, a little larger than those of the locust, but less odoriferous.

The seeds of the yellow-wood also nearly resemble those of the locust, and are contained in pods that differ only in being a little narrower. The seeds are ripe in the vicinity of Nashville about the 15th of August.

YEOMAN. A term applied to the first or highest degree of cultivators in England. The yeomen are properly freeholders, and such as cultivate their own lands. This term has been derived from various words by different authors. Dr. Johnson seems to incline to the word *geman*, Frisick, a villager; Fortescue derives it from *gemen*, or *yemen*, Saxon for a commoner. Sir Thomas Smith's definition of a yeoman is, "a free-born Englishman who may lay out of his own free lands in yearly revenue to the sum of 40s."

YEW TREE (*Taxus*). A genus of ornamental evergreen trees, well adapted for under-wood, as they thrive under the shade and drip of other trees; they are also very ornamental when planted to form hedges. They will grow in any moist soil, but succeed best in loams and clays. They are chiefly propagated from seeds, which should be sown as soon as ripe; but can also be increased by cuttings formed of either one or two years' wood, and planted in a shady border in the beginning of April or end of August. In England the common yew tree (*T. baccata*) is the only indigenous species. The trunk is straight, with a smooth deciduous bark. Leaves two-ranked, crowded, linear, flat, about an inch long, dark green. Fruit drooping, consisting of a sweet, internally glutinous, scarlet berry. The leaves are fetid and very poisonous, and prove speedily fatal to cattle accidentally tasting them when young and tender. The berries have a sweet mawkish taste, and may be eaten without danger. The wood of the yew tree, being of extremely slow growth, is hard and tough, formerly highly valuable for making bows, but now chiefly used for fine cabinet-work or inlaying. It makes handsomer chairs than many exotic woods.

YOKF. A frame of wood fixed with bows

over the necks of oxen, whereby they are coupled together, and harnessed to the plough, &c. It is sometimes written "yoak," and is composed—1. of a thick piece of wood that passes over the neck, and is strictly called the "yoke;" 2. of a bow, which encompasses the neck; and 3. of the "wreathings," or "stitchings," that serve to connect the whole. Besides these parts, there are employed a ring, denominated the "yoke-ring," and a chain for securing the traces.

YOKE of land. In England, the quantity of land which a yoke of oxen can plough in a day. Hence, in some parts of Kent, a little farm, from its only requiring a yoke of oxen to till it, is called a "yokelet."

YOLK. See **EGG**, and **WOOL**.

YOUNG, ARTHUR. A celebrated agricultural writer and farmer; perhaps the most popular author on rural affairs that England or any other country has produced. His characteristics were great zeal, enterprise, and energy, with a copious flow of plain and intelligible language, which the meanest capacity could readily comprehend; and although he possessed few claims to be ranked as a scientific farmer, yet he succeeded by his labours in exciting a general love of agriculture in the upper classes of his countrymen, which has, since his day, never materially subsided. And this feeling, although attended, through a want of practical information, with considerable individual loss, has yet produced great public advantages. It has been remarked, indeed, of the writings of Arthur Young, that they produced more private losses and more public benefit than those of any other author. A memoir of this extraordinary man was published soon after his death by Dr. Paris, his friend and medical attendant.

His services to agriculture were important, and they would have been still more valuable if he had confined himself to the improvement of the science of agriculture, and avoided all those many political and party themes of which he was ever too ready to be the champion. This morbid feeling he carried with him to the Board of Agriculture; and, in consequence, both Arthur Young and the board of which he was long the chief spirit, experienced the same fate,—they obtained the support of only a section of the farmers of England, and they much too often laid themselves open to the charge of being more intent upon the advancement of the interests of their party than of those of practical agriculture. Thus the very first sentence of the first volume of the *Annals of Agriculture*, published in 1790, is as follows;—"The parties of one country and the debility of another having at last extinguished the torch of discord;" and the entire essay comprehends hardly any thing else than a political survey of the state of the kingdom, and its possessions, fisheries, &c. It speaks with much zeal of the French Revolution, union with Ireland, customs, exports, tonnage, produce of the taxes, population, national debt, West Indian plantations of Great Britain; indulges in all kinds of visions; gives a statement of what the editor would do if he were made a king, &c., &c.; and hardly a page is reserved for practical

agriculture, of which his work was to be "the annals."

Arthur Young was the descendant of a respectable family, who had resided on their estate at Bradfield Combust, near Bury St. Edmund's, in the county of Suffolk, for more than two centuries; he was born in London, on the 7th of September, 1741. His father, the Reverend Arthur Young, rector of Bradfield, had three children; John, and a daughter Elizabeth; the third was Arthur, the subject of the present memoir, who was educated at Lavenham, a school about six miles from Bradfield Hall.

Arthur Young was brought up for mercantile pursuits, in a merchant's counting-house at Lynn, where, at the age of 17, he commenced his literary career by writing a political pamphlet, entitled *The Theatre of the present War in North America*; and then four novels—*The Fair American*, *Sir Charles Beaufort*, *Lucy Watson*, and *Julia Benson*, or *the Innocent Sufferer*. In 1763 he returned from the residence of his uncle in London to his mother at Bradfield Hall, without any prospect of a pursuit, profession, or employment. His whole income, during the life of his mother, arising from a copyhold farm of 20 acres, and producing only as many pounds, she was anxious that he should reside with her; and, as the lease of her farm of 80 acres would shortly expire, she urged him to undertake its cultivation, a scheme so much in unison with his taste and wishes, that he did not long hesitate in accepting her proposal, and he embarked as a farmer. Young, eager, and totally ignorant, as he then was, of every necessary detail, it is not surprising, as he used to say, that he should have squandered large sums, under golden dreams of improvements, especially as he had a thirst for experiment, without a knowledge of what is demanded for its success. In this year (1765) he married Miss Martha Allen, of Lynn, and in the year 1767 undertook the management of the farm of Samford Hall, in Essex, which consisted of about 300 acres of land. Various unforeseen circumstances, and embarrassments from the want of capital, soon induced him to give 100*l.* to a farmer for taking the estate off his hands; and this farmer, by the advantages of capital, realized a fortune upon it. It was here, uniting the plough with the pen, that he wrote his work entitled, *Political Essays on the Present State of the British Empire*, but which was not published until 1772, in 1 vol. 4to. He now advertised for another farm, and the knowledge which resulted from viewing the different estates that were on this occasion presented to his notice, furnished him with the materials for his tour, which he called *The Six Weeks' Tour through the Southern Counties*. By the advice of his Suffolk bailiff, he hired a farm of 100 acres in Hertfordshire; and, from viewing it in an uncommonly favourable season, they were both deceived in the nature of the soil. "I know not," said Young, "what epithet to give this soil; sterility falls short of the idea; a hungry, vitriolic gravel—I occupied, for 9 years, the jaws of a wolf. A nabob's fortune would sink in the attempt to raise good arable crops, upon any extent, in such a country: my experience and knowledge had increased from travelling and from prac-

tice; but all was lost when exerted upon such a spot. I hardly wonder at a losing account, after fate had fixed me upon land calculated to swallow, without return, all that folly or imprudence could bestow upon it." It will be here naturally asked, why he did not go to land decisively good? He answers the question very satisfactorily. "It was on account of the houses; for, although I saw numerous farms that would have suited well, they had wretched hovels on them."

Finding, about the year 1783, that his income was barely sufficient to meet his expenditure, he engaged to report the parliamentary debates for the *Morning Post*; this he continued to perform for several years; and after the labours of the week, he walked every Saturday evening to his farm, a distance of 17 miles from London, from which he as regularly returned every Monday morning. This was the most anxious and laborious part of his life: "I worked," says he, "more like a coal-heaver, though without his reward, than a man acting only from a predominant impulse." In 1774, he published *Political Arithmetic*, a work which met with high consideration abroad, and was immediately translated into several languages. Mr. Young has left a memorandum which states that he received for his different writings, in the interval between the years 1766 and 1775 the sum of 3000*l.*

In 1784 he commenced the publication of his *Annals of Agriculture*, in which he appeared in the double capacity of editor and author, a work which he continued to the period of his blindness; it extends to 45 vols. 8vo, and presents a vast store of information upon subjects of agriculture and political economy. The plan upon which it was conducted was one which ought to have ensured for it more extensive and profitable patronage, for, instead of recording anonymous correspondence, it refused admittance to any paper that had not the name and address of its author; it can accordingly boast of communications from the most exalted and enlightened characters in Europe, at the head of whom stands our late most gracious sovereign, who transmitted to Mr. Young for publication an account of the farm of Mr. Duckett, the able cultivator of Petersham, which is recorded in the 7th volume of the *Annals*, under the signature of "Ralph Robinson." During the progress of this work he travelled (and he published a popular description of his travels) over most parts of England, into Ireland, and in France.

In 1793, animated as he always was by the spirit of adventure, he could not resist an opportunity that occurred for realizing the favourite speculation he had so long entertained—that of cultivating a large tract of waste land. He accordingly completed the purchase of 4,400 acres of waste in Yorkshire. But his fates had decreed other things for him. The Board of Agriculture was established in the August of 1793, and he was immediately appointed its secretary. An individual is rarely appointed to an official situation on account of his possessing in an eminent degree those qualifications which its duties require; but in the instance of Mr. Young this was undoubtedly the fact;

his general and profound knowledge in agriculture was the only circumstance that marked him as the most proper person to fill a situation in every respect so important and honourable. "The gratification," says he, "of being elected into so respectable a situation, in which opportunities of still giving an humble aid to the good cause of the plough could scarcely fail of offering, would not permit me to decline the appointment; although, to a person established in the country, the salary, with the residence annexed, was not that pecuniary object which has been represented; and I must have improved on bad principles indeed, if it would not, in a few years, have turned out a more profitable speculation. (The salary was 400l. per annum, with a house free from all charge.) What a change in the destination of a man's life! Instead of entering, as I proposed, the solitary lord of 4,000 acres, in the keen atmosphere of lofty rocks and mountain torrents, with a little creation rising gradually around me, making the desert smile with cultivation, and grouse give way to industrious population, active and energetic, though remote and tranquil; and every instant of my existence *making two blades of grass to grow where not one was found before*—behold me at a desk, in the smoke, the fog, the din of Whitehall. 'Society has charms;' true, and so has solitude to a mind employed. The die, however, is cast, and my steps may still be, metaphorically, said to be in the furrow."

At the Board Arthur Young continued, to his death, zealously employed on all occasions as its secretary, in the service of agriculture;—old age at last crept on; he became blind, and afflicted with the complaint which caused his death. He was attended (concludes Dr. Paris) by Mr. Wilson, Mr. Chilver, and myself; and although the incurable nature of his disease defied every hope of permanent relief, yet his sufferings were greatly palliated by the resources of art, and he died without entertaining the least suspicion of the malady under which he suffered. Pious resignation cheered him in his illness, and not a murmur of complaint was heard to escape his lips. On the 12th of April, in the year 1820, at his house in Sackville street, after taking a glass of lemonade, and expressing himself calm and easy, he expired. His remains were conveyed to Bradfield, and deposited in a vault in the church-yard.

I have thus offered a brief sketch of the principal labours of Arthur Young, a man who filled a large space in the public eye for a long series of years, but whose name and talents appear to have commanded still greater notice and respect in foreign countries than in his own. That he reflected lustre on the age and the country in which he lived can be hardly denied. Of what other philosopher can it be said that at one time he entertained, under his humble roof, pupils of seven different nations,

each of whom had been sent to him, for instructions in agriculture, by his respective government? I was lately informed by his daughter, that the late Duke of Bedford breakfasted at Bradfield on one of the mornings of a Newmarket race-meeting, and was met by pupils from Russia, France, America, Naples, Poland, Sicily, and Portugal. His numerous works are distinguished by vivacity of thought, quickness of imagination, bias to calculation, and fondness for political speculation; and had they been less successful, posterity might perhaps have regarded these traits of genius as fatal defects, and as pregnant sources of fallacy and disappointment.

YUCCA (commonly called Adam's needle) An American genus of plants found on the sandy sea-coasts of the Southern States and tropical regions, several of which are made to subserve valuable purposes. Nuttall gives the following description of the characters of the genus and individual species:—

Proper stem none; caudex inconspicuous or assurgent and shrubby; leaves comose (or crowded and terminal), ensiform, spiny at the point, sometimes with a sphacelate filamentiferous margin; flowers in a terminal, irregular panicle, each protected by two spathes; corolla white, roundish campanulate.

Species. 1. *Y. filamentosa*. 2. *Angustifolia* Stemless; leaves glaucous, long, linear, and mucronate, margin filamentose; capsules large and dry, oblong-ovate. Habitat on the banks of the Missouri, from the confluence of the river Platte to the mountains. Flowers large and white; leaves scarcely half an inch wide.

3. *Recurvifolia*. In sandy fields, North Carolina. 4. *Gloriosa*. Capsule internally filled with a sweetish pulp of a purple colour. This plant is called *petre* by the Mexican Spaniards, and used for cordage, ropes, &c., as well as for packing-cloth, and is extremely durable. 5. *Aloifolia*. There is also a 6th species of this genus, discovered by the late Mr. John Lyons, improperly called *Y. angustifolia* by the gardeners around London; it is nearly allied to *Y. filamentosa*, but has much narrower leaves; with its specific characters I am unacquainted.

The soil and climate of East Florida are believed to be well adapted to the culture of these and many other plants, the fibres of which are converted into fabrics and cordage of great value. The general government, a few years since, granted a large tract of land in that territory to the late Dr. Perrine for the purpose of encouraging the introduction of the Sisal hemp, and other filamentous plants and tropical productions. The recent melancholy massacre of this gentleman and his family by the Indians have frustrated these attempts, for a time at least. See HEMP.

ZAPZIEGER, or SAP-SAGO, a kind of cheese made in Switzerland. See CHEESE and SAP-SAGO.

THE END.
