AMERICAN FARMER'S

ENCYCLOPEDIA;

EMBRACING

ALL THE RECENT DISCOVERIES IN AGRICULTURAL CHEMISTRY, AND THE
USE OF MINERAL, VEGETABLE AND ANIMAL MANURES,

WITH

DESCRIPTIONS AND FIGURES OF AMERICAN INSECTS.

INJURIOUS TO VEGETATION.

BEING A COMPLETE GUIDE

FOR THE CULTIVATION OF

EVERY VARIETY OF GARDEN AND FIELD CROPS.

ILLUSTRATED

BY NUMEROUS ENGRAVINGS OF GRASSES, GRAINS, ANIMALS, IMPLEMENTS, INSECTS, ETC.

BY GOUVERNEUR EMERSON, OF PENNSYLVANIA,

UPON THE BASIS OF

JOHNSON'S FARMER'S ENCYCLOPEDIA.

NEW YORK :

AL BOOK PUBLISHER,
STREET.

PREFACE

OF

THE AMERICAN EDITOR.

THE *Farmers' Encyclopædia*, as originally published in England, contained much matter not particularly interesting to those living on the western side of the Atlantic. In the American edition, the localisms and irrelevant portions have been supplanted by the introduction of much information more immediately relating to rural affairs in the United States. In effecting these alterations, the matter introduced by the American editor amounts to about thirty per cent., all of which has been derived from the best sources of intelligence. The main objects which interest the American farmer, such as cattle, and the great crops of maize, cotton, tobacco, hemp, and other staples of the north and south, have received the most particular attention.

In treating of farm-stock, implements, &c., the editor has had no individual interests to serve, and no prejudices to bias him. He has, therefore, doubtless, often failed to say all that partiality or predilection might have dictated in particular cases, and the discussion of the relative merits or demerits of contested agricultural subjects he has left to be carried on in the most appropriate places, namely, the pages of the numerous excellent periodical publications, industriously employed in diffusing the lights of agricultural science through every part of the Union. To many of these the editor is deeply indebted for most valuable information, the particular sources of which he has been careful to acknowledge in the proper places.

EXPLANATION OF PLATES.

PLATE 1.

Short-Horned Cows.

PLATE 2. p. 1117.

Varieties of Wheat, with the most destructive Enemies.

- a*, Summer or Spring Wheat.
- b*, Winter or Lammas Wheat.
- c*, Egyptian Wheat.
- d*, Turgid Wheat.
- e*, Polish Wheat.
- f*, Spelt Wheat.
- g*, One-grained Wheat.
- h*, The Wheat Fly of Scotland, New England, &c., the larva or worm of which destroys the grain in the head or chaff.

i, One of the Worms magnified.

k, The Hessian Fly, which attacks the stem near its root.

l, A portion of Wheat Straw affected with Rust, magnified, to show the parasitic plant or fungus giving rise to the disease called Rust, Blight, and Mildew.

m, Another portion of a Diseased Stem in a green state, and before the fungus is quite ripe.

n, The small portion marked *l* (*l*) is still more strongly magnified.

o, p, q, r, s, t, u, Very highly magnified representations of the Fungus Parasite in different stages of growth and maturity.

o, Showing it in the young state; *p*, full-grown; *q*, two plants bursting and shedding their seeds when under water in the microscope; *r*, two plants bursting in a dry place; *s*, apparently abortive; *t*, seeds in a dry state; *u*, a small part of the bottom of a pore with some of the parasitic fungi growing upon it.

PLATE 3. p. 139.

Barley, Oats, Buckwheat, and Millet.

- a, b, c, d*, Varieties of Barley.
- e*, White, or Common Oat.
- f*, Siberian or Tartarian Oat.
- g*, Common Buckwheat.
- h*, Tartarian Buckwheat.
- i*, Emarginated Buckwheat.
- k*, German Millet.
- l*, Common Millet.
- m*, Italian Millet.
- n*, Polish Millet.
- o*, Indian Millet.

PLATE 4. p. 1044.

Rice, Sugar, Tobacco, &c.

- a*, Canary corn.
- b*, Rice Plant.
- c*, Wild Rice.
- d*, Sugar Cane.
- e*, Indigo Plant.
- f*, Virginian Tobacco Plant.
- g*, Common Green Tobacco.
- h*, Havanna Repanda Tobacco.
- i*, Quadrivalvis Tobacco of the Rocky Mountains.
- k*, Mana Tobacco of the Rocky Mountains.

PLATE 5. p. 575.

Hay-Grasses adapted to particular Soils and Situations.

The first group exhibits the Tall Hay-Grasses of temporary duration; the second group, Tall Hay-Grasses of permanent duration; the third group, Grasses adapted to particular soils and situations.

a, Ray or Rye-Grass (*Lolium perenne*), Perennial Darnel, Perennial Rye-Grass.

b, Orchard Grass, or Cock's-foot (*Dactylis glomerata*).

c, Woolly or Creeping Soft Grass (*Holcus mollis*).

cc, Tall Oat-like Soft Grass, Andes Grass (*Holcus avenaceus*).

d, Meadow Barley-Grass (*Hordeum pratense*).

dd, Meadow, or Fertile Fescue (*Festuca pratensis*).

e, Tall, or Infertile Fescue (*Festuca elatior*).

f, Spiked, or Darnel Fescue Grass (*Festuca loliacea*).

g, Meadow Foxtail (*Alopecurus pratensis*).

h, Great, or Smooth-stalked Meadow Grass, Spear-Grass (*Poa pratensis*).

i, Rough-stalked Meadow Grass (*Poa trivialis*).

k, Timothy, or Meadow Cat's-tail (*Phleum pratense*).

l, Floating Fescue (*Festuca fluitans*).

m, Water Meadow Grass (*Poa aquatica*).

n, Fiorin (*Agrostis stolonifera*).

PLATE 6. p. 576.

Grasses.

The first group exhibits the Early Pasture Grasses; the second and third groups Pasture

Grasses adapted to particular soils and situations.

- a, Sweet-scented Vernal Grass (*Anthoxanthum odoratum*).
- b, Downy Oat-Grass (*Avena pubescens*).
- c, Annual Meadow Grass (*Poa annua*).
- d, Fine Bent (*Agrostis vulgaris mutica*).
- e, Narrow-leaved Meadow Grass (*Poa angustifolia*).
- f, Dog's-tail Grass (*Cynosurus cristatus*).
- g, Hard Fescue (*Festuca duriuscula*).
- h, Smooth Fescue (*Festuca glabra*).
- i, Long-awned Fescue (*Festuca hordeiformis*).
- k, Sheep's Fescue (*Festuca ovina*).
- l, Alpine Meadow Grass (*Poa alpina*).
- m, Turfy Hair Grass (*Aira cæspitosa*).
- n, Common Quaking Grass, or Ladies' Tresses (*Briza media*).

PLATE 7. p. 577.

Grasses, &c., found in Fields and Meadows.

- a, Field Brome Grass (*Bromus arvensis*).
- b, Soft Brome (*Bromus mollis*).
- c, Darnel (*Lolium temulentum*). The Chess or Cheat of Europe.
- a, White Darnel (*Lolium arvense*).
- e, Welsh Fescue (*Festuca Cambrica*).
- f, Crab, or Finger Grass (*Digitaria sanguinalis*).
- g, Red Top (*Tricuspis*).
- h, Blue Grass (*Poa compressa*).
- i, Creeping Soft Grass, or Couch Grass.
- k, Creeping Dog's Tooth (*Cynodon dactylon*).
- l, Upright Sea Lime Grass, Star, or Bent (*Elymus arenarius*).
- m, Matt Grass (*Psamma arenarium*).
- n, Gama Grass.
- o, Scott's Grass (*Panicum hirtellum*).
- p, Guinea Grass (*Panicum polygamum*).
- q, Cow Wheat (*Melampyrum pratense*).
- r, Tare, or Common Vetch (*Vicia sativa*).
- s, The Lentil (*Ervum lens*).
- t, Chick-Pea (*Cicer arietinum*).
- u, Spanish Lentil (*Lathyrus sativus*).
- v, Canadian Lentil (*Vicia pisiformis*).
- w, White Lupine (*Lupinus albus*).

PLATE 8. p. 339.

Plants cultivated for Hay or Herbage.

- a, White, or Creeping Clover (*Trifolium repens*).
- b, Common Red, or Biennial Clover (*Trifolium pratense*).
- c, Meadow, or Cow Clover (*Trifolium medium*).
- d, Yellow, or Shamrock Clover (*Trifolium procumbens*).
- e, Lupuline Clover (*Medicago lupulina*).
- f, Flesh-coloured, or Roussillon Clover (*Trifolium incarnatum*).
- g, Saintfoin (the Bourgogne or Esparcette of the French).
- h, Lucern (*Medicago sativa*).
- i, Yellow Lucern (*Medicago falcata*).
- k, Long-rooted Clover (*Trifolium macrohizum*).

PLATE 9. p. 619.

Inferior Herbage, Plants occasionally cultivated.

- a, Burnet (*Poterium Sanguisorba*).
- b, Spurry (*Spergula arvensis*).

- c, Furze or Whin (*Ulex Europæus*).
- d, Common Broom (*Spartium scoparum*).
- e, Spanish Broom (*Spartium junceum*).
- f, Parsley (*Apium petroselinum*).
- g, Bird's-foot Trefoil (*Lotus corniculatus*).
- h, Lotus Tetragonolobus (*Lotier cultiva*, Fr.).
- i, Ripple Grass, or Ribwort Plantain (*Plantago lanceolata*).
- k, Yarrow (*Millefeuille*, Fr.).

PLATE 10. p. 1108.

Weeds and Plants troublesome to the Farmer.

- a, Cockle, or Corn Champion (*Agrostemma Githago*).
- b, Mellilot Clover (*Trifolium officinalis*).
- c, Tares. Smooth Tare (*Ervum tetraspermum*).
- d, Black Bindweed (*Polygonum Convolvulus*).
- e, Dodder (*Cuscuta Europæa*).
- f, Mellilot trefoil of Switzerland.
- g, Charlock, or Wild Radish (*Raphans Raphanistrum*).
- h, Hariff, Cleavers, &c. (*Galium Aperine*).
- i, Couch Grass (*Triticum repens*).
- k, Rest Harrow (*Ononis spinosa*).
- l, Colt's-foot (*Tussilago Farfara*).
- m, Corn Mint (*Mentha arvensis*).
- n, Black Foxtail (*Alopecurus agrestis*).
- o, Wild Carrot (*Daucus Carota*).
- p, Hedge Parsley, or Dill (*Torilis infesta*).
- q, Fool's Parsley (*Æthusa*).
- r, Bawd-Money. Fennel. (*Meum bunias*).
- s, Corn Poppy (*Papaver Rhæus*).
- t, Buttercup (*Ranunculus bulbosus*).
- u, Blue Bottle. Ragged Robin. (*Centaurea Cyanus*).
- v, Mayweed. Stinking Chamomile. (*Anthemis Cotula*).
- v, v, St. John's Wort (*Hypericum*).
- w, Ox-eye Daisy (*Chrysanthemum Leucanthemum*).
- w w, Chamomile Feverfew (*Matricaria Chamomilla*).
- x, Common Fumitory (*Fumaria officinalis vel vulgaris*).
- x x, Yellow Toad-Flax (*Linaria vulgaris*).
- y, Cinquefoil (*Potentilla Pennsylvanica*).
- y y, Soap Wort. Bouncing Bet. (*Saponaria officinalis*).

PLATE 11. p. 628.

Russian Bee-Hive and *Echium vulgare*, called in Russian Ciniak.

- 1, The Hive with the upper door removed so as to show the interior, and arrangement of the honey frames. a, Movable doors; b, wooden pegs; c, movable pieces on which the doors are supported; d, slats separating the comb from the doors; e, frames in which the honey is deposited; f, entrances with slides.
- 2, One of the Honey Frames drawn out.
- 3, Grating, or Adapter.
- 4, Movable Board for separating.
- 5, A Transverse Section of the Hive, showing, at f, the places of entrance; at a, the depth to which the frames extend; and at c, one of the combs.
- 6, The *Echium vulgare*, or Ciniak, with its Root, Efflorescence, and nut-like Fruit.

Cattle.

- 1, Short-Horned Bull.
- 2, Ayrshire Cow.
- 3, Devon Bull, 2 years old.

Horses.

- a, Arabian.
- b, English Racer.
- c, English Hunter.
- d, English Improved Hackney.
- e, English Black Horse.
- f, English Draught Mare.
- g, Suffolk Punch.
- h, Clydesdale Horse.
- i, Irish Racer.
- k, Shetland Pony.

Grain Drills.

- 1, Cooke's Grain Drill.
- 2, The same arranged as a Horse Hoe, or Cultivator.
- 3, Suffolk Corn and Manure Drill.
- 4, Groundsell's Patent Drop Drill.
- 5, Pennock's Grain Drill.

Harrows, Extirpators, and Scarifiers.

- 1, Gang of Harrows.
- 2, Berwickshire Harrow.
- 3, Biddell's Extirpating Harrow.
- 4, Harrow Tooth.
- 5, Finlayson's Self-cleaning Cultivator, or Scarifier.

Destructive Insects, &c.

- 1, The Oak Pruner (*Elaphidion putator*). See BORERS, page 205.
- 2, Locust Tree Borer (*Clytus flexuosus*). See page 206.
- 3, Potato-vine Bug (*Criociris trilineata*).

4, Cucumber Tree (*Haltica striolata*). Magnified. See pages 172 and 173.

5, May Beetle, or Dor Bug (*Phyllophaga quercina*). See pages 172, 173.

6, Pine Tree Weevil (*Hyllobius pales*). A most destructive insect to the Southern pine forests. See WEEVILS.

7, Moth of the Corn Cut-Worm (*Agrotis clandestina*). See CUT-WORM.

8, Female Fly of the Peach Tree Worm (*Ægeria eritosa*). See PEAR TREE BORER.

9, Bee, or Wax Moth (*Galleria cereana*). See page 168.

The three insects which follow are to be regarded as friendly to the interests of man, as they prey upon those which are destructive.

10, Carabus Gorgi, one of a large family which preys upon caterpillars, &c.

11, Lady Bird, or Lady Bug (*Coccinella borealis*). This insect lives upon plant-lice and other injurious insects.

12, Troglus Fulvis, an insect of the Ichneumon Family, which commit great havoc among caterpillars and grubs. See ICHNEUMON FLIES.

N. B. Most of the subjects of this plate were furnished expressly for this work by Professor Haldeman, of Marietta, Pennsylvania, and drawn under his inspection by Miss Lawson, of Philadelphia.

Ploughs.

- a, The Holland, or Rotterdam Plough.
- b, Small's Chain Plough.
- c, d, East Lothian Plough, two views, with scale of feet, &c.
- e, English Swing Plough.
- f, Skeleton Plough of Kent.
- g, Subsoil Ploughing.
- h, English Plough Head.
- i, Scotch Plough Head.
- k, Ploughshare for Stony Ground.
- l, Ploughshare for Clear Ground.
- m, m, Skin Coulters.
- n, Wheel Coulters.
- o, Smith's Subsoil Plough.

THE AMERICAN EDITOR'S

INTRODUCTION.

“To render Agriculture more productive and beneficial to all, it is necessary that its principles should be better understood, and that we should profit more from the experience of each other, and by the example of other countries which excel us in this great business.”—BUEL.

THE work upon husbandry now ushered before the American public is the production of an English gentleman of great intelligence, assisted by some of the best authorities upon rural subjects in his country. By collecting and condensing the most interesting details relative to farming, chiefly derived from living authors, such as Professors Liebig, Lowe, Sir J. E. Smith, Brande, Youatt, Stephens, Thompson, Lindley, I. F. Johnson, etc., etc., he has been enabled to present the very latest information, and furnish a fund of matter which cannot fail to attract all who take an interest in rural affairs, so long studied and so thoroughly understood as these must needs be in Great Britain.

The absence of speculative views, with the very practical and matter-of-fact character of the information given upon all subjects treated of, will perhaps be found to constitute the highest recommendation of “*C. W. Johnson's Farmers' Encyclopædia, and Dictionary of Rural Affairs.*”

The comparatively limited range of English Agriculture is strongly contrasted with the diversity of culture met with in the United States. A work limited to an account of productions of the soil and climate of England would leave out many of the most important crops which exact the attention of the American farmer and planter. Hence the necessity of adapting a book of the kind to the new localities into which it is introduced. This, as may be well supposed, presents a task of no small labour.

It has been charged upon agriculturists, that improvements in husbandry encounter great opposition, and generally work their way very slowly; whereas inventions and improvements made in the manufacturing and mechanic arts are seized upon and put to profit almost as quickly as promulgated. The late and justly celebrated Mr. Coke, of Holkham, England, the great benefactor of his own country, and, indeed, of every other country where agriculture is cherished, succeeded, by the adoption of an enlightened course of tillage, in converting a sandy and comparatively sterile district into one of very great productiveness. But, though his improvements were on so large a scale, and the results so very striking to observers, such was the general ignorance, apathy, or prejudice prevailing in the neighbouring counties, that he estimated the rate at which his improved process spread around him, at only about three miles a year. A better condition of things would seem to exist at present in the United States, doubtless owing to the extension of education. But a few months have passed since the treatise upon Agricultural Chemistry of the celebrated Dr. Liebig, reached this side of the Atlantic, and though much of it is couched in the abstruse phraseology of science, still has it been eagerly sought after in all directions, and gone through several editions. Can any stronger proof be furnished of the high state of intelligence pervading a large portion of the agricultural population of the United States?

The advances in agricultural improvement have, of late years, been in what mathematicians call a geometrical ratio, the pace increasing with great celerity at every successive step. In proportion as the influences of modern education become diffused, the savage characteristics of man are softened down, and the better feelings of his nature ac-

quire predominance. Bloody and desolating wars are viewed in their true light, and the useful arts of peace appear the only proper sources of individual pleasure and national prosperity. As, among these arts, none possesses the vital importance of agriculture, from its furnishing the means of immediate subsistence, so it may fairly be said, no other excites at the present day a greater and more pervading interest throughout Europe and America, with all who seek independence or the gratification of the most rational of tastes.

The inhabitants of the United States possess advantages for the prosecution of agricultural pursuits, which, for variety and extent, surpass those enjoyed by any other people on the globe. They occupy the greatest portion of the North American continent, embracing all varieties of soil and surface, with a climate which in the southern parts admits the culture of many of the most valuable productions of the tropics, whilst the northern limits verge upon, but do not reach the less favoured regions where too severe and enduring frost entails a scanty vegetation.

Commencing nearest the tropical limits, the chief attention of the planter is directed to the culture of the sugar-cane, rice, tobacco, indigo, and especially cotton, more of which last is raised in the Southern States than in all the rest of the world besides. In the amount of sugar procured from the cane, Louisiana takes the lead, though Florida, Alabama, and others of the extreme southern states produce considerable quantities. South Carolina yields the most rice, which is also raised to a greater or less extent throughout the southern states, and even as high as Tennessee, Kentucky, and southern Virginia. The cotton region is still more extensive, spreading throughout the extreme southern and south-western states, from the Atlantic far west of the Mississippi, and rising into middle Virginia, and even the lowest portion of Delaware. In the quantity of tobacco produced, Virginia stands foremost, being followed successively by Kentucky, Tennessee, Maryland, North Carolina, etc.

The Middle States raise in the greatest abundance, maize or Indian corn, wheat, rye, barley and oats, whilst in a large portion of the Northern States, the wheat, rye, oat, potato, and especially grass crops, are extremely productive and valuable. Although maize is most extensively cultivated in the middle states, it is abundant in almost every section of the country, and from its affording so large an amount of the food of man and animals, is universally regarded as the most valuable cereal crop of the United States. Besides these there are many other rich products of the fields and forests, which enter largely into the aggregate of national wealth.

The first history of American Agriculture differs from that of countries in the old world, where the advances in the arts were slow, and every acquisition marked by rudeness and simplicity. Not so, however, in America, whose intelligent European settlers came with all the appliances of advanced civilization, prepared to chop down the forests and clear away the thickets which had so long encumbered the ground and furnished a scanty subsistence to the savage hunter. For a time the roots obstructed the plough and prevented the deep turning of the soil: but they afforded no impediment to the raising of grain crops, since the light virgin mould, abounding in the alkalis and all other elements of fertility, required but the slightest stirring of the surface to answer the purposes of the plough and harrow. Here then commenced the career of the American planter and farmer, upon a capital accumulated by nature herself through the most gradual accessions. Rich harvests of grain, crops of tobacco and other products sent to Europe and sold at high prices, stimulated to renewed exertions, and the generous soil was subjected to a scourging course of tillage, by which many of the essential elements of its fertility were finally exhausted without any compensating additions. In Virginia, where the primitive settlements were made, large tracts of many hundreds and even thousands of acres, the once profitable culture of which is shown by the extensive ruins of stately mansions, now lie waste and uncultivated, or are covered with a new growth of the oak and pine, renewing forests to which the deer, once driven away, has returned.

The lands bordering on the Atlantic have thus been worn out by successive years of culture without adequate help, the thinnest soils first, and next the deeper moulds. But let not those whose lots are cast in other and more prosperous parts of the Union sympathize over the decayed fortunes of once flourishing districts, and overlook their own gradual decline. It is in vain for the farmers of the western valleys and prairies to boast of the depth and inexhaustible productive powers of their lands. With every

crop, some of the elements of fertility must of necessity be removed, and the greater the crops the speedier the exhaustion, unless some adequate compensation be made. The following fact, stated in the fifth volume of that valuable American periodical, "The Cultivator," shows the progress of deterioration in one of the finest wheat districts in the whole country.

"Thomas Burrall, Esq., has a most excellent wheat farm in the neighbourhood of Geneva, (New York,) which he began to clear and improve twenty-one or twenty-two years ago, and on which he has made and applied much manure. Mr. Burrall informed us, in the summer of 1836, that he had noted down the average product of his wheat crop every year; that dividing the twenty years into three periods, he found that his wheat had averaged twenty-nine bushels per acre during the first of these periods; twenty-five bushels the acre during the second; and but twenty bushels the acre during the third period—thus showing a diminished fertility of nearly one-third, under what may there be denominated a good system of husbandry."

All, then, who are engaged in agricultural pursuits, and even those now luxuriating upon the most fertile soils, must, sooner or later, be reduced to the necessity of adding to their fields some of the agents of fertility, and of adopting new means by which they can obtain crops that may be compensating and profitable.

The late Judge Buel, in referring to a picture drawn by the Hon. James M. Garnett, of the deteriorated condition of Virginia agriculture, says:—"Let not the Northerners take credit to themselves, from this outline of old Virginia husbandry, or from the ingenuous detail of the causes which brought it to so low a condition. Though not exactly the like causes have operated, the same deteriorating system of husbandry has prevailed with us, though perhaps to a more limited extent. Though we have personally attended more to the art—to the practice—yet we have been equally deficient in the science with our brethren in Virginia—equally indifferent to the study and application of the principles upon which good husbandry must ever be based. And although we may have begun earlier in the business of reform, whether from necessity or from choice we will not say, we are still too defective in practice to boast of our trivial acquirements. The truth is, we have regarded the soil as a kind mother, expecting her always to give, without regarding her ability to give. We have expected a continuance of her bounties, though we have abused her kindness, and disregarded her maternal admonitions. We have managed the culture of the soil as a business requiring mere animal power, rather than as one in which the intellect could be brought largely to co-operate."

"But," continues the judge, in the full fervour of his zeal for the promotion of agriculture, "there is a redeeming spirit abroad. The lights of science are beaming upon the agricultural world, and dissipating the clouds of superstitious ignorance which have so long shrouded it in darkness. The causes which have for some time been actively operating to improve the condition of the other arts, and to elevate the character of those who conduct them, are extending their influence to agriculture."

The course of tillage followed in America since its first settlement, and with such exhausting and disastrous effects upon the soil, has been of late aptly styled the *old system*, to distinguish it from the *New Husbandry*, which last consists in the employment of means calculated not only to arrest and prevent the exhaustion of soils, but to increase their productiveness. It is indeed gratifying to know that in many parts of our country which have suffered from the impoverishment of the land; agriculture has for many years shown signs of progressive improvement, reduced farms having been brought into increased value, and the products of many of them being raised even above the amount afforded in the days of their first exuberant culture. This has occurred in New England, in the Valley of the Hudson, in New Jersey, Pennsylvania, the upper portion of the Peninsula including Delaware and Eastern Maryland, in several parts of Western Maryland, Old or Eastern Virginia, etc.

It is the chief object of the numerous and many admirable agricultural publications so extensively circulated at the present day, as well as of the active societies everywhere instituted, to set forth the principles and practical details of the *new system* of husbandry, and to demonstrate the advantages resulting from the judicious application of manures and all sorts of fertilizing agents;—from good tillage;—from proper rotation of crops;—from the assistance to be derived from root-culture;—from the substitution for naked fallows, of clover and other good fallow crops. All these means are to be

adopted in conjunction with ample draining, with or without the additional advantages derived from sub-soil ploughing.

Many of the processes which may be resorted to in carrying out the *new* system are in a great degree mysteries to thousands in the United States, although familiarly known and long employed in other countries, where with not half the natural advantages the labour of the husbandman is far better rewarded. Such has been the agricultural improvement effected in Flanders, that the whole country may almost be styled a garden, each acre being capable of supporting its man. Scotland, in little more than half a century, has changed from comparative unproductiveness, into one of the richest agricultural districts in Europe. In Great Britain, the products of the grain harvests have increased within sixty years, from one hundred and seventy to three hundred and forty millions of bushels. The system inculcated by the new principles, has even in some districts of our own country, where they have been well followed up, increased the value of farms, two, three, and four hundred per cent.—from twenty and thirty dollars to one hundred dollars per acre. “It has,” says Buel, “made every acre of arable land, upon which it has been practised ten years, and lying contiguous to navigable waters, or a good market, worth, at least, one hundred dollars, for agricultural purposes.”

The zeal for the promotion of good husbandry which pervades the country at large, is displayed in the geological surveys which have been finished, or are in progress, in most of the states; in the agricultural surveys in several others, together with the liberal premiums appropriated by legislative authority, and innumerable societies, for the encouragement of every thing tending to improve and advance the agricultural interests. It is also shown by the extensive circulation of the many periodicals devoted in whole or in part to agricultural topics. Every section of our extensive country has more or less of these invaluable aids for the dissemination of useful information. Although wishing to avoid, as far as possible, all invidious distinctions, where there are so many just claims to notice, some of these publications cannot be suffered to remain without a passing notice. Such are, “*The American Farmer*,” recently published in Baltimore by John S. Skinner and successors, the pioneer of American periodicals specially devoted to agriculture: “*The Cultivator*,” published in Albany, N. Y., by the late Judge Buel and successors: “*The New England Farmer*,” by Thomas G. Fessenden and successor, the Rev. H. Coleman: “*The Southern Agriculturist*,” in Charleston, S. C., by B. R. Carroll; and “*The Farmer’s Register*,” by Edmund Ruffin at Petersburg, Virginia. These able works constitute the chief officials on agricultural subjects in the northern, middle, and southern states.

Book-farmers have long suffered under general discredit, and been exposed to abundance of taunt and ridicule, even from their own agricultural brethren. Doubtless the imperfection of much of the scientific data furnished and practised upon has often given occasion to unsatisfactory results. But the rapid progress of science has developed new facts, and furnished much more accurate information. Under the direction of Davy, agricultural chemistry made vigorous advances. His many splendid discoveries, and especially his demonstration that the common alkalis, potash and soda, and the alkaline earths, magnesia, lime, and alumine, were not simple elementary substances, but the oxides of metals, seemed to give a new impulse to those who sought to make chemistry subservient to agriculture. But even with the brilliant achievements of Davy and the subsequent valuable researches of Count Chaptal in France, agricultural chemistry remained very imperfect. Too exclusive attention had been devoted to the mineral constituents of soils. Most gratifying and important results have been since obtained through the able investigations of several eminent French chemists, among whom we may name, Raspail, De Saussure, Braconnot, and Boussingault, all of whom have devoted special attention to ascertaining the nature and properties of organic substances entering into the composition of soils. What England commenced by Davy, and France followed up so ably by her distinguished chemists just named, Germany seems to have the honour of almost perfecting through the brilliant achievements of her chemist, Dr. Liebig, the highly important results obtained by whom have been quite recently placed before the world in a treatise entitled “*Organic Chemistry*.” The interesting developements made in this work of the chemical agencies operating in the various stages and conditions of growth,

maturity, and subsequent decomposition of vegetable and animal substances, and the mutual relations subsisting between these and the earth and atmosphere, have drawn upon Liebig the admiration of all Europe and America.

It must, nevertheless, be owned that though generally adopted, the accuracy of some of Liebig's results has been more than questioned by distinguished chemists in Europe and the United States. The particulars of these and the effects of the several agencies acting upon the life of vegetables and animals, will be found in the *Encyclopædia of Agriculture*, arranged under various heads, such as, Soils, Humus, Carbon, Oxygen, Azote or Nitrogen, Hydrogen, Ammonia, etc.

Whilst agriculture has, within the last few years, been thus receiving such rich tributes from abroad, many scientific investigators of the highest merit have been zealously and successfully engaged in the United States, in experimental researches which have added greatly to the stock of useful knowledge. Among these, it would be signal injustice to pass unnoticed the names of Professors Jackson and Dana of Massachusetts, who have devoted great attention to the analyses of soils, the chemical composition and properties of humus as found in ordinary mould, and in peats and bog-mud, the results of which have been published in the reports of the Agricultural and Geological Surveys of Massachusetts, and in separate essays. Professors Rogers and Booth of Philadelphia, the former in his *Geological Report of New Jersey*, and the latter of Delaware, have furnished numerous and highly accurate analyses of the valuable calcareous marls and green-sand deposits found so abundantly in the states named, as well as in others of the middle and southern regions, together with much information relative to the application of these inexhaustible agents of fertility;—Nor can we omit the name of Dr. Harris of Massachusetts, whose highly interesting and useful *treatise upon destructive insects*, is a most valuable acquisition to the stores of agricultural knowledge.

The success with which science has developed the agencies concerned in the various stages and processes of vegetation, and the certainty with which deficiencies of soil can now be detected and remedied, have suddenly elevated agriculture from the condition of an art under the guidance of common observation and empirical experiment, to a science regulated by recognised principles of induction. We are indeed much mistaken if the day has not arrived when the successes of the book-farmer shall cause his incredulous brother farmer of the old routine system, to cease his taunts and spend some of his leisure hours in searching into books containing modern information in regard to matters of husbandry.

In preparing the work for the American farmer, the editor has had several objects to fulfil. Of these, one of the principal was the reduction of the price, the cost of the imported copy being so great as to prevent any extensive circulation of it in the United States. Much of the irrelevant and less important materials in the original have been omitted, their place being supplied by the addition of information connected with the interests of American husbandry. In the selection of such information, the editor has to acknowledge his great indebtedness to distinguished writers at home and abroad, who have contributed, by elaborate works, separate treatises and communications in periodicals, to promote the cause of agriculture.

The American edition will contain a far greater number of plates and figures illustrating the various subjects; notwithstanding which, its cost will be only about one-fourth that of the imported work.

THE
FARMER'S ENCYCLOPÆDIA,
AND
DICTIONARY OF RURAL AFFAIRS.

A.

ABATE (French, *abbatre*; Spanish, *abatir*; Italian, *abbatere*); to beat down. In commerce, to let down the price in selling.

In law, means the beating down or removal of an obstruction or nuisance, which, according to the common law of England, any person may remove, provided he does it in a peaceable manner, so as not to occasion a breach of the peace, such as the obstruction of an ancient light, which is a private nuisance, or the erection of a gate across a common road, which is a public nuisance, and which any one may beat down and remove.

ABELE TREE (*Populus alba*). European White Poplar, or Dutch Beech, otherwise called the Arbeel. The Abele is a tree of very rapid growth, but seldom exceeds forty or fifty feet in height. The leaves are large, and divided into three, four, or five lobes, which are indented on their edges.

This tree is not to be considered as a native of England. Hartlib, in his "Complete Husbandman," 1659, states that some years ago, there were ten thousand Abeles at once sent over into England from Flanders, and transplanted into many counties; that the timber is incomparable for all sorts of wooden vessels, especially trays; and that butchers' trays cannot be made without it, it being so exceedingly light and tough.

"A specimen of their advance," says Evelyn, "we have had of an Abele tree at Sion, which being lopped in Feb. 1651, did, by the end of October, 1652, produce branches as big as a man's wrist, and seventeen feet in length. As they thus increase in bulk, their value advances likewise, which, after the first seven years, is annually worth one shilling more. The Dutch, therefore," he continues, "look upon a plantation of these trees as an ample portion for a daughter." Besides the uses of the wood before stated, it is considered good for wainscoting, for floors, laths, and packing cases; and, from the boards of it not splitting by nails, but closing over the heads, it is esteemed superior to deal for the latter purpose. It is found to answer for works under

water. Peaty and low damp soils are the most proper for the Abele, and in these it is well worthy the attention of the forest planter. It should never be planted near the margins of, nor in grass fields, for it extends its roots under the grass to a great distance, and sends up numerous shoots. The Abele is propagated by layers, cuttings, and off-shoots or suckers. The month of February is the best season for planting the cuttings. In two years, many, if not all that have rooted, will be fit to plant out for good, on the sites where they are to remain for timber. The size of the plants considered the best for final transplantation, is from one and a half to three feet in length, but much larger plants will succeed very well by paying proper attention to keep the roots as perfect as possible.

The Abele is sometimes made a variety of the Gray Poplar (*Populus canescens*), and several British as well as foreign botanists have confounded the two species, but they are very distinct.

There are many varieties of the Abele, arising from local circumstances. The variety, called on the continent, *Polan de Holland*, is preferable for avenues and for landscape gardening, from its rapid growth, its majestic height and aspect, and from its fine white leaves contrasting well with the green of other leaves. There are some magnificent ones near the Hague, and more particularly extensive avenues of them along most of the high-ways in the lower districts of Belgium, near Bruges and Ghent. It is so common on the romantic banks of the Rhone, that some French authors call it *Arbre du Rhone*.

According to M'Intosh, the best cuttings, are taken from the wood of the preceding year; and when made, each cutting should be nine inches in length, and planted in nursery lines eighteen inches apart, and the cuttings about six inches distant from each other. When inserted in the ground, they should be put in deep enough to resist the drought; and if only two inches of the top appear above ground, it will be found sufficient. In two years, or three at most, these cuttings will be fully grown to fit them for being finally planted out; but if

they are to remain the third year in the nursery, they ought to be taken up and re-planted at a greater distance. The Abele often sends up naturally vast numbers of suckers from its roots, and such are sometimes used for young plants; cuttings are, however, preferable. Langley asserts that he has known great quantities produced by chips only, where the trees have been hewed after felling; and one of our earliest authors has proposed ploughing down these chips, with a view to produce an economical coppice.

Amongst other uses of this tree, it may be mentioned that, on the Continent, the wood of the larger branches is prized, on account of its lightness, for making wooden shoes; while the smaller twigs are used for fire-wood. By splitting the wood into thin shavings, like tape or braid, the stuff called *sputerie* used for hats, is manufactured. These shavings are always made from green wood. One workman can, with the aid of a child to carry off the shavings, keep several plaiters employed. The ancient Greek athlete wore crowns made of the branches of this tree, because it was sacred to their patron deity, Hercules. (*Julius Pollux, de Ludis. Miller's Dict.*)

ABIES. In botany, the Fir or Pine tree genus, well known for the valuable timber obtained from many of the varieties. The origin of the Latin name is unknown, that of the English appellation is the Saxon *Furh-wude*, fir-wood. See **FIR TREE**.

ABLACTATION (Latin, *ablacto*). The weaning of an animal. Also a method of grafting, without cutting the scion from the stock.

ABORTION (Latin, *abortio*). In veterinary surgery, miscarriage, slipping, slinking, casting, or warping, all meaning the expulsion of the fœtus at so early a period of pregnancy as to render it impossible for it to live. The immediate causes appear to be the death of the fœtus, or derangement in the functions of the womb or its dependencies, arising from some external cause or causes operating on the mother. Amongst these operating causes may be reckoned too much, or too little food, producing plethora or emaciation; sudden fright acting on the nerves, or sympathy with certain smells or sights, such as the smell or sight of blood, of bones, of horns, and particularly of the aborted fœtus of another animal;—on a similar principle, perhaps, to that which causes even some strong-nerved men to faint away on witnessing a surgical operation. Accidents, also, such as falls, bruises, over-driving, or fatigue, and the like, may frequently bring on abortion.

The signs of approaching abortion are, great languor, uneasiness, and restlessness: sometimes a discharge of bloody matter, and the sudden filling of the udder, similar to the signs of approaching parturition.

Abortion in the Horse.—Abortions very frequently happen among mares. This often arises in consequence of over-exertion during the latter period of pregnancy. Mares are liable, also, very frequently, to various accidents in their pastures, which may be the cause of their slipping their foal, such as

kicks, tumbling into holes and ditches, over-exerting themselves to get over fences, and the like. On this account, when a mare is near her time, she should be kept by herself, in some convenient place. But there is another, and we suspect a very general, cause of these accidents in mares; we mean a stinting of them in their food, either in quantity or quality. It appears, indeed, that some imagine that the mare, when she is in foal, may be turned out almost any where: but this opinion is ill founded; for although the mare does not require to be kept so high in condition as when she is at hard work, yet she is not to be turned out into a pasture where she may be in a manner starved: but how often do we see the mare-in-foal on the worst piece of ground in the whole farm, exposed, during the rigorous winter season, to endure the cold, as well as to put up with scanty food. Every well-informed farmer knows that the slinking of the foal is often the consequence of such treatment. On the other hand, when the mare is not worked at all, and indulged with too high keep, she is almost equally in danger of abortion, her high condition having a tendency to cause inflammation and other disorders; and these deranging the reproductive organs, frequently produce miscarriage. It would seem, then, that moderate exercise and diet are best suited as means to avoid the misfortune of the premature exclusion of the foal.

Abortion in the Cow.—Abortion occurs oftener in the cow than in all other domestic animals put together. Perhaps it is one of the greatest annoyances the proprietor of cows has to encounter, and unfortunately, for aught we see to the contrary, it is likely so to continue; for in spite of the improved state of veterinary medicine, and the researches of skilful veterinary surgeons, both at home and abroad, abortion still continues as frequent and annoying as ever. The causes are frequently involved in obscurity; but it may be mentioned, that an extremely hot and foul cow-house, a severe blow, violent exertion, starvation, plethora, an overloaded stomach, internal inflammations, constipated bowels, bad food or water, improper exposure, and the like, will now and then produce abortion. Any thing whatever, indeed, that seriously affects the health of the animal in general, or the state of the reproductive organs in particular, may do so. But abortion occurs again and again when no such causes as those enumerated can be traced. The disease, if such it may be called, as we think it may, is even said to be infectious. No sooner does it show itself in one animal than it is seen in another, and another, till it has spread over the most part of the cow-house. Some say this is to be attributed to the odour arising from the things evacuated. Possibly it may be so, there is nothing unreasonable in the supposition; for although we cannot perceive the smell, nor account for its peculiar influence, it is still quite within possibility that such an odour does exist, having the power attributed to it. There can be no great harm, however, in acting as if we were assured that the mischief has its origin in the source so commonly supposed, provided we do

not shut our eyes to any other which accident or investigation may reveal. In the meantime, the number of abortions may be diminished by carefully avoiding all those causes which are known to be capable of producing it. Let the cows be regularly fed; let their food be good, and in proper quantities; let them have water as often as they will take it; avoid sudden exposure to cold or heat; and, above all, let the cow-house be well ventilated. Prohibit all manner of rough usage on the part of those who look after the cows, whether they be pregnant or not. If any of them accumulate flesh too rapidly, gradually reduce their allowance; and, on the other hand, if any become emaciated, discover the cause, and remedy it, always by slow degrees. Sudden changes in the matter or mode of feeding should also be avoided. The same sort of diet does not agree equally well with all the cows; and this, in general, is indicated by undue relaxation, or constipation of the bowels; this should be watched, and removed at once. Attention to these, and many other minor circumstances, will amply repay the proprietor for the little additional trouble.

"That improper or too little food," says Mr. Lindsay, "is a prominent cause of abortion, is strongly indicated by the following facts. A friend of mine, a respectable grazing farmer, kept a dairy of twenty-two cows, ten of which slipped calf at different periods of parturition. The summer had been very unfavourable in every respect, both as regarded the ground where the cows were pastured, and in getting in the hay crop. He had little or no hay of the last year's growth, and the hay of that year when cut into was in a very bad state; but as he had no other, he was obliged to give it to his cattle. The consequence was as mentioned above; and besides, many of his stock died of various disorders; and many of those which recovered remained long weakly."

"The most common cause of abortion in cows," says White, "is improper feeding during winter and spring, before they are turned to pasture. The filthy pond-water they are often compelled to drink, and feeding on the rank fog-grass of October and November, especially when covered with hoar-frost, are likewise frequent causes of miscarriage. I remember a farm near Berkeley, in Gloucestershire, which afforded a striking proof of the injuries of stagnant pond-water, impregnated with dung and urine. This farm had been given up by three farmers successively, in consequence of the losses they sustained through abortion in their cattle, their not being in season (that is, not conceiving), red water, and other diseases. At length a Mr. Dimmery, after suffering considerably in his live stock for the first five years, suspected that the water of his ponds, which was extremely filthy, might be the cause of the mischief. He therefore dug three wells upon his farm, and having fenced round the ponds to prevent his cattle from drinking there, caused them to be supplied with well-water, in stone troughs erected for the purpose; and from this moment his live stock began to thrive, became uncommonly healthy, and the quality of the butter

and cheese made on his farm was greatly improved. It should be observed, that on this farm the cattle were regularly fed with good hay during the winter, and kept in good pasture in summer: so that there cannot exist a doubt that the losses sustained by Mr. Dimmery were entirely attributable to the unwholesome water the animals were compelled to drink."

"In order," adds Mr. White, "to show that the accident of warping may arise from a vitiated state of the digestive organs, I shall here notice a few circumstances tending to corroborate this opinion. In January, 1782, all the cows in the possession of farmer D'Euruse, near Grandvilliers, in Picardy, miscarried. The period at which they warped was about the fourth or fifth month. The accident was attributed to the excessive heat of the preceding summer; but as the water they were in the habit of drinking was extremely bad, and they had been kept upon oat, wheat, and rye straw, it appears to me more probable that the great quantity of straw they were obliged to eat in order to obtain sufficient nourishment, and the injury sustained by the third stomach in expressing the fluid parts of the masticated mass, together with the large quantity of water they probably drank while kept upon this dry food, was the real cause of their miscarrying. A farmer at Charentin, out of a dairy of twenty-eight cows, had sixteen slip calf at different periods of gestation. The summer had been very dry, and during the whole of this season they had been pastured in a muddy place, which was flooded by the Seine. Here the cows were generally up to their knees in mud and water, and feeding on crowfoot, rushes, and the like. Part of the stock had recently been brought from Lower Normandy, where they had all been affected with indigestion by feeding upon lucerne, from the effects of which they had been relieved by the operation of paunching. In one, the opening made was large enough to admit the hand for the purpose of drawing out the food; the rest were operated on with a trocar. In 1789, all the cows in the parish of Beaulieu, near Mantes, miscarried. All the land in this parish was so stiff as to hold water for a considerable time; and as a vast quantity of rain fell that year, the pastures were for a long time, and at several periods, completely inundated, on which the grass became sour and rank. These, and several other circumstances which have fallen under my own observation, plainly show that keeping cows on food that is deficient in nutrition, and difficult of digestion, is one, if not the principal, cause of their miscarrying. It is stated by Mr. Handwin, that feeding in pastures, when covered with white frost, has been observed to occasion abortion in these animals."

If there be any probability of a cow miscarrying from exposure to any of the common causes already enumerated, let her by all means be put apart from the others; and let a skilful person attend to the evil from which she is expected to suffer. If the approach of abortion be evident, bleeding may be had recourse to; for if it do not check abortion, it

will yet do no harm though it take place. When there are any premonitory symptoms of abortion, they are precisely the same as those which present themselves in ordinary labour, with the exception of their being less marked.

Fumigation of the cow-house is resorted to as one of the means of preventing the spread of abortion: tar, sulphur, gunpowder, feathers, and the like, are burned for the purpose of destroying the odour. We have never seen a single instance of the practice being attended with the smallest success; while it is obvious that, if carried beyond a certain point, it may produce the very evil it is intended to remove or mitigate.

It is a remarkable feature in the history of this complaint, that those cows that have once miscarried are particularly liable to do so again at the same period of their succeeding pregnancy. Greater care is therefore requisite to guard against those causes which do, or are supposed to, excite it. The treatment of abortion, when it does take place, differs not from that adopted in cases of parturition, only that the cow which miscarries should be removed with all that belongs to her from among pregnant cows.

If the signs of approaching abortion be discovered early, the accident may sometimes be prevented. If the cow is in good condition, then immediately let it be bled to the extent of five or six quarts, and the bowels opened with half a pound of Epsom salts, three or four drams of aloes in powder, or as many ounces of castor oil, administered in a quart of gruel; but if the cow is in very poor condition, and the miscarriage is anticipated from her having been exposed to cold, it would be more advantageous to avoid bleeding, and give her a warm gruel drink, with an ounce of laudanum in it. If after this abortion does take place, let her be kept in a comfortable place by herself; and if the after-birth has not passed off, let no injudicious and unnecessary administration of violent forcing medicines, such as capsicum or hellebore, be given. Nature, with a little assistance, is generally equal to the perfect restoration of the animal.

Abortion in the Sheep. Ewes are much subject to abortion, in consequence of the numerous accidents they are liable to, such as fright, overdriving, being worried or run with dogs, a remarkable instance of which came under my own observation. A pack of hounds, in pursuit of a hare, got among a flock of sheep belonging to a farmer, and so hurried and alarmed them, that thirty out of a flock of two hundred ewes prematurely dropped their lambs. It is the same in sheep as in the other cases of domestic animals,—scarcity of food, and exposure to severe cold, having a great tendency to make the ewes prematurely drop their lambs, or produce them weakly and crippled at the full time; and although there may be a little danger in giving too much food, such as allowing them to feed all the winter on turnips, the danger is trifling compared with the starving system. (*Miller.*)

ABORTIVE. A term applied by gardeners and farmers to flowers, seeds, and fruits, which

do not come to maturity, in consequence of external injury from the weather, from insects, or other causes affecting their growth. Thus fruit often becomes abortive, in consequence of cold winds or frosts in spring checking the flow of the nutritive juices; and after losing its healthy colour it shrivels, and falls. The same effects arise when the leaves of fruit-branches are devoured by caterpillars, or the fruit-stalks sucked by insects (*Aphides, Cocci, &c.*). The only preventives are sheltering from cold, and destroying the insects.

ABSCESS (Latin, *abscessus*). In veterinary surgery, a circumscribed cavity in an animal, containing matter. [In common language, an imposthume or gathering.] The deposition of matter in a solid part of the body is always preceded, and in some degree accompanied, by inflammation. The local symptoms are, pain on pressure, heat, swelling, hardness, and, where it can be seen, redness. These are easily recognised, in proportion as the inflamed part is near the external surface. If the part in which an abscess is about to form be soft, yielding, and well supplied with blood, it soon softens and points, the pain diminishes, the skin becomes thin, a fluid is felt fluctuating under it, and by and by the skin bursts, or a portion of it drops out, and the matter escapes. What is called the process of granulation succeeds to this; and, provided the matter be completely evacuated, and the outlet be such as not to retain any that may form subsequently, the cavity soon fills up.

Such are the different stages of an ordinary abscess. The general health of the animal is rarely affected; but if an abscess form in a dense unyielding texture, in a part which cannot without much difficulty accommodate itself to an increase of volume, then the swelling may be less, but the animal will endure a great deal more pain, [as is often exemplified under similar circumstances in the disease called felon or whitlow in the finger or human hand.] The irritation, indeed, is sometimes so great, from this cause, as to induce fever, and even death; and hence the formation of an abscess in the foot of an irritable horse is not an unfrequent cause of death. During the deposition of the matter in such cases, we have general symptoms added to those termed local. There is loss of appetite, thirst, a hot skin, quick and hard pulse, constipated bowels; in short, the animal is *fevered*. When an abscess forms in a part remote from the surface, its presence is not easily recognised. The general practitioner has here an advantage over the veterinary surgeon. The expressed feelings of the patient, and the occasional slight shivering fits which accompany the formation of matter, are guides which the veterinary surgeon can rarely or never command. The shivering, if it occurs, passes unobserved, and the animal can give no account of himself; dissection, therefore, sometimes reveals large abscesses, whose existence was not even suspected during life. Fortunately these are not frequent.

It is a curious circumstance, and one that well illustrates the preservative principle of a living being, that, unless there be some me-

chanical obstacle, as in the case of the horse's foot, the matter always seeks its exit by an external opening. If this were not a law in the animal economy, and if the matter were to spread indiscriminately on all sides, it might not only accumulate to an enormous extent, and produce much destruction, but by encroaching upon vital organs, it might be a very frequent cause of death. The instances of such a thing happening are rare; but they are easily accounted for by the presence of some mechanical obstacle which the absorbents could not overcome. Why an abscess should point at one part rather than another, is truly wonderful; but it is not more so than almost every other process of importance in the animal economy. We may attempt to explain it; but, in truth, to perceive that such is the case, and that because it would have been wrong had it been otherwise, is as far as we can proceed. We know that the absorbents remove a portion of that side of the cavity which is next to the external surface; but we do not know what urges them to act on that side in preference to any other; and, perhaps, in a practical point of view, we need not care to know.

The causes of abscess may in general be traced to an injury done to the texture of a part, or to the introduction of some foreign substance by which it is irritated. In the former, the formation of matter is a part of the process by which the injury is repaired; in the latter, it becomes necessary to interpose a bland insensible medium between the surrounding parts and the irritating substance, while the same means serve to expel it. Thus a severe bruise, the insertion of a thorn, a nail, or any similar agent, may be followed by an abscess.

The treatment of an ordinary abscess is very simple; as a general rule, the matter should be evacuated as soon as discovered. Let a broad-shouldered lancet be used, and let the opening be made sufficiently large; and, what is of still more consequence, let it be at the lowest part of the tumour, in order that the cavity may be completely and constantly drained. The general practitioner has some scruple about making an artificial opening, often for good reasons. His patients dread the lancet more than a tedious cure; while the skin is thinner, and consequently the natural outlet is sooner formed. But in the horse, and the dog, and still more in the ox, the skin is thick, its removal proportionally slow, and the natural process is both tedious and painful. It is, therefore, better both for the animal and his owners, to have an artificial outlet made for the matter as soon as the abscess is brought to a head, either naturally, or by the application of a bran poultice. Little more is necessary than to keep the part clean; trim the hair from the edges of the orifice, and by applying hogs'-lard, prevent the acrid discharge from adhering to, and removing the hair from the skin beneath. Let no pretender stuff the cavity with a candle, or tent of tow, or rowels, or any thing else. All these interfere with nature's operations, prevent the escape of the matter, produce fistula, and other evils, often far more serious than the original

abscess. If the cavity do not fill up so readily as might be expected, allow the animal a little more nourishing food than that recommended for invalids; and inject once, or even twice a day, a liniment composed of equal parts of spirits of turpentine and sweet oil; or, if the matter discharged, instead of being thick, pale yellow, and without smell, be dark-coloured, variegated, and smell offensively, a solution of chloride of lime, or one to three drachms of nitre in six ounces of water, may be used.

A hernial tumour [or rupture] has been mistaken for an abscess; and, in consequence, the blacksmith has plunged a lancet into the gut, or inserted a rowel. This is a most unlikely mistake for a veterinary surgeon to make. The heat, the pain, the rigidity, and the situation of an abscess, would be sufficient to distinguish it from a hernial swelling. If there be met with a tumour without heat or pain, very compressible, elastic, and situated on the belly, the veterinary surgeon would pronounce it a rupture, or hernia; and of course would never dream of touching it with the lancet.—*Miller.*

ABSORBENT SOILS. Such soils as imbibed water. See **EARTH**, the use of, to vegetation.

ABSORBENTS. In veterinary medicine, those drugs are termed absorbents that are given internally for the purpose of neutralizing any acid which forms in the stomach and bowels, in consequence of impaired digestion. Prepared chalk is generally used for this purpose. Those medicines are likewise termed absorbents which are applied externally for absorbing moisture. Armenian bole, calamine, flour, and the like, are employed in this way. They are sometimes dusted between folds of the skin when galled, and raw from friction, blisters, or grease. They are likewise useful in canker of the horse's foot, foul in the foot of cattle, foot-rot in sheep, and sores between the toes of dogs; and they are beneficial in some forms of mange, in staying bleeding, and assisting the cure of a penetrated joint.

ABSORBENTS. In veterinary physiology, a class of vessels whose office it is to convey the product of digestion, and the residue of nutrition into the circulation, to be mixed with and repair the waste of the blood. They are divided into lacteals and lymphatics. The former are all situated in the cavity of the belly; and by extremely minute mouths, opening on the inner surface of the stomach and intestines, they receive the nutritious portion of the food, and carry it to a vessel which runs along the left side of the spine, and which, in its turn, empties itself into the left jugular vein.

The lymphatics are distributed over every portion of the frame, at least over every portion that contains blood. Their different branches are so minute and so numerous, that a celebrated anatomist who attempted their dissection, is said to have thrown down his knife in despair, exclaiming, "that the body is entirely composed of absorbents." The uses of the lymphatics are, to remove the residue of nutrition; and when the supply of food is deficient, to remove such portions of the body as can be spared and converted into blood. It

is they that effect the removal of parts which disappear without the action of external agents. The lymphatics ultimately empty their contents into the same vessel as the lacteals; and they follow, in their distribution through the body, the same course as the veins. In the horse they are liable to a disease termed farcy; and in all animals they are frequently inflamed in the neighbourhood of a sore. The absorbents, both lacteals and lymphatics, are very delicate in their sides, nearly transparent, have numerous valves which compel their contents to flow only in one direction; and their larger trunks have numerous glandular bodies on them. The use of these glands is not well known; but, from one or two circumstances, it would appear that they have to produce some change on the fluid which passes through them before it is fit to mingle with the blood.

ABSORPTION. An important process in vegetable physiology. As plants are not furnished with any individual organ similar to the mouth of animals, how, it may be asked, do they effect the introduction of food into their bodies; Is it by the general surface of their stem, leaves, or roots, or by any peculiar part of these? By whatever part it may enter, it must, at any rate, pass through the covering of the outer bark (*epidermis*), which the earlier physiologists thought it could not do, but by means of pores more or less visible. Yet some of them describe the outer bark as being so close and compact a texture, that the eye, aided even by the best microscopes, was unable to discover in it the slightest vestige either of pores or of apertures. But Hedwig and De Candolle detected superficial pores in the leaves, at least, of many plants; and so will any one else, who will be at the trouble of repeating their observations with lenses of similar powers.

The next difficulty was with regard to the outer bark (*epidermis*) of the flower, fruit, and root. No pores had been detected in the flower and fruit, though it was evident that they were refreshed and invigorated by the access of moisture and of atmospheric air; and no pores had been detected in the root, though it was evident that the whole of the nourishment which the plant derives from the soil must of necessity pass through the root. It was also evident that no aliment could be taken up by the plant, except in the state of a liquid, or of a gass—that is, by absorption or by inhalation, as the chyle is taken up into the animal lacteals, or the air into the cells of the lungs. The greediness with which plants absorb water was perceived and acknowledged even in the earliest times, and even by men who were not botanists. Anacreon, in one of his little trifles in honour of drinking, makes the very trees of the forest drink:

Ἡ γῆ μέλαινα πίνει,
Πίνεν δὲ δένδρα' αὐτήν. Ode xix.

“The black earth drinks, and the trees drink it;”

that is the moisture which it contains.

By merely immersing in water a plant of almost any species of moss that has been some time gathered, or long exposed to

drought, so as to have had its leaves shrivelled up, the moisture will immediately begin to penetrate the plant, which will thereby resume its original verdure; an experiment which proves the fact of the entrance of moisture into the plant through the outer bark (*epidermis*).

It might be doubted whether any of the moisture thus imbibed had passed through the root. But if the bulb of a hyacinth is placed on the mouth of a glass bottle filled with water, so as that the smaller roots (*radicles*) only shall be immersed, the water is imperceptibly exhausted, and the plant grows. The moisture must, consequently, have passed through the root. Plants seem, indeed, to be peculiarly well adapted for the absorption of fluids by the roots, from the infinite number of little absorbent fibulous sponges (*spongiolæ*), in which the fine fibres of the root terminate. It is owing to this important property that the scientific gardener, in the transplanting of his young trees, or the scientific and ornamental planter, in the transplanting of his trees of full growth, is so extremely careful to preserve entire even the minutest fibres and extremities of the root. Sir Henry Steuart's *Planter's Guide* has taught him the great importance of these little organs.

Hales instituted a variety of experiments to show the absorbing power of roots, and the force with which it acted; as did also Duhamel and Marriotte, to show the absorbent power of leaves. But the most complete set of experiments upon the absorbent power of leaves is that of M. Bonnet, of Geneva, whose main object was to ascertain whether the absorbing power of both surfaces of a leaf was alike. With this view he placed a number of leaves over water, so as that they only floated on it, but where not immersed; some with the upper surface, and others with the under surface, applied to the water. If the leaf retained its verdure the longer with the upper surface on the water, the absorbing power of the upper surface was to be regarded as the greater; but if it retained its verdure the longer with the under surface on the water, then the absorbing power of the under surface was to be regarded as the greater. Some leaves were found to retain their verdure the longer when moistened by the upper surface, and some when moistened by the under surface; and some were indifferent to the mode in which they were applied to the water. But the inference deducible from the whole, and deduced accordingly by Bonnet, was that the leaves of herbs absorb moisture chiefly by the upper surface, and the leaves of trees chiefly by the under surface. What is the cause of this singular difference between the absorbing surfaces of the leaf of the herb, and of the tree? The physical cause might be the existence of a greater, or of a smaller number of pores, found in the leaves of the herb and tree respectively. The chemical cause would be the peculiar degree of affinity existing between the absorbing organs and the fluid absorbed. Duhamel seems to have been content to look to the physical cause, merely regarding the lower surface of the leaf of the tree as being endowed with the greater

capacity of absorbing moisture chiefly for the purpose of catching the ascending exhalations which must necessarily come in contact with it as they rise, but which might possibly have escaped if absorbable only by the upper surface, owing to the increased rapidity of their ascent at an increased elevation; and regarding the upper surface of the leaf of the herb as being endowed with the greater absorbing power, owing to its low stature and the slow ascent of exhalations near the earth. This did not throw much light upon the subject; and the experiments were still deemed insufficient, as not representing to us the actual phenomenon of vegetation, though the fact of the absorption of moisture by the leaf is fully confirmed.

If, after a long drought, a fog happens to succeed before any rain falls, so as to moisten the surface of the leaves, plants begin to revive, and to resume their verdure long before any moisture can have penetrated to their roots. Hence it follows incontestably, either that moisture has been absorbed by the leaf, or that exhalation has been suddenly stopped by closing the pores of the leaf, or both. The efficacy of rain and of artificial waterings may be accounted for partly on the same principle; for they have not always penetrated to the root when they are found to have given freshness to the plant by either or both of the processes just alluded to. The moisture, then, that enters the plant as an aliment, is taken up by means of the pores; or, in default of visible pores, merely by means of the absorbent power of the outer bark (*epidermis*), not only of the root and leaf, but often, as it is to be believed, of the other parts of the plant also, at least when they are in a soft and succulent state.

It is to the modern improvements in pneumatic chemistry, and to them alone, that we are indebted for our knowledge of the real functions of the leaves of plants, and of their analogical resemblance to the lungs of animals, it being now proved indisputably that the leaves of plants not only contain air, but do both inhale and respire it. It was the opinion of Dr. Priestley that they inhale it chiefly by the upper surface; and it has been shown by Saussure that their inhaling power depends entirely upon the integrity of their organisation. A bough of *Cactus Opuntia*, detached from the plant and placed in an atmosphere of common air, inhaled in the course of a night four cubic inches of oxygen; but when placed in a similar atmosphere, after being cut to pieces and pounded in a mortar, no inhalation took place. The inhalation of air, therefore, is no doubt effected by the pores of the outer bark, (*epidermis*) of the leaf.

It is important to attend particularly to the distinction pointed out above, that it is not the whole of the root which is endowed with the power of absorbing nourishment, but only the points of the root fibres, termed spongelets. The surface of the root whose outer bark has acquired a certain consistence does not absorb the moisture of the soil in contact with it; but the roots, and also the smallest rootlets, constantly lengthen at their extremities; and these extremities are composed of a fine cellular

tissue, compact, spongy, and the whole newly developed, possessing in a high degree the hygroscopical faculty proper to vegetable tissue.

M. Carradori (*Degli Organi Assorbenti*) has remarked that there is a slight absorption, either by the surface of the roots, or by the fugacious hairs with which the roots of young plants are often furnished: but this effect seems owing to general hygroscopicity; and he himself agrees that this absorption is extremely feeble, especially in old and woody roots, comparatively with that which takes place at their extremities. These experiments, however, are not made with such minute accuracy as to enable us to appreciate this comparison.

When we cut a branch of a tree and plunge it into water, its woody tissue thus laid bare quickly absorbs a quantity of water; and in this manner is the life of branches preserved which are kept for ornamental purposes, but this effect has a limit. The extremity which has been cut and plunged in the water is not renewed, as in the case of the root; and is, consequently, more or less quickly altered or deteriorated by being in contact with the water. We renew its action by cutting off the rotting extremity, and thus place a new and healthy surface in contact with the liquid. The water which in this manner penetrates into the woody tissue of vegetables, preserves their existence, at least for a certain time, as if it entered by the spongelets. This is the same thing, we may rest assured, in these phenomena, as is presented in the development of the cuttings of trees, which are also nourished in general only through the water sucked up by the surface of their denuded wood. These means of nutrition are, however, accidental or artificial; and absorption is a natural operation by the spongelets in general, or by the suckers in some vegetable parasites. M. Senneber observed that, if we divide a plant into three parts, the roots as far as the crown, the stem as far as the branches, and the leafy top, then plunge the lower ends of these into water, the whole three will pump up a certain quantity, but the leafy parts more than the others. This absorption particularly takes place at the cut surface, where the woody parts are laid bare.

A branch of raspberry put in water and exposed to the sun has absorbed a hundred and fifty grains, but only imbibed eight grains when the division has been covered over with wax. It sucked up no more when, having the divided part covered, it was plunged in the whole of its length, than when only a short zone at the extremity was immersed. This proves that the outer bark is impenetrable to water.

The woody portion, when laid bare, sucks up moisture in every way; that is to say, when we cut a branch and place it in the water, it sucks it up, either when put into it by the upper or by the lower cut part. The habitual or upright direction, however, appears to offer certain facilities for this more than an inverse one. This, indeed, results, first, from the observation of M. Pollini (*Elem. di Botan.*, i. 281) for the watery juices mount a little less high

in the branches placed in an inverse direction; secondly, from the observation of common gardeners, and of Mr. T. A. Knight, that, in the cuttings made in an inverse manner, it is more frequently only the lower buds which are developed, and not the higher ones, as happens in those made in a direct manner. It is necessary, in order to render these experiments comparative, that the horizontal cuttings be made equal; and, as we were doubtful whether this circumstance had been taken into consideration, we made the following experiment:—We placed two branches of willow in water, the one in a direct manner, the other inverted, and contrived in such a manner that these two absorbing bodies were equal; but the branch which was placed inverted pushed its roots a little slower than the direct one. (*Mém. sur les Lenticelles, Ann. des Sc. Nat.*, 1825, Jan., pp. 18, 19.)

The wood tends not only to absorb the water by its transverse section, but also lengthways. Thus we placed in water (*ibid.*, p. 4) a branch of willow, the section of which was covered with mastic, but which had the part immersed denuded of the bark by taking off a cortical ring of an inch in length. This branch pushed its buds and roots in a manner similar to the branches which are immersed by a transverse section.

The hygrometrical power of wood is such that when we expose it to the air it easily imbibes the surrounding moisture; and, when preserved in shady places, it never dries of itself. Count Rumford (*Mém. sur le Bois et le Charbon*: 8vo, Paris, 1812) dried in an oven a piece of wood taken from the interior of a beam which had been placed for one hundred and fifty years in a battlement, and observed that it lost about ten per cent. of its own weight; and he thinks that this is the greatest degree of natural desiccation which wood can attain in our climate. An oak faggot, exposed eighteen months in the air, and which might be regarded as excellent wood for burning, lost twenty-four per cent. The same experimenter observed that, when chips of wood have been well dried in a stove, on their exposure to the open air they very freely imbibe water. If these chips are placed for twenty-four hours in a room, the extremes of this power of absorption have proved to be, on one side, the Lombardy poplar, whose chips, five inches long by six lines broad, have sucked up 0·87 grains; and, on the other, a billet of oak of the same dimensions, which sucked up 1·40 grains. When the same chips were exposed for eight successive days, it was found that they did not increase in weight if the air had remained at the same temperature, but they lost in weight if the air became more heated. This experiment, then, proves that the absorption is rapid; and that the equilibrium it attains will be determined by the surrounding atmosphere, and certainly also by its own hygrometrical power.

These necessary conditions of existence have been effected by the organization of the spongelets as organs of suction, and by the nature of the water, which is abundantly dif-

fused over nature, and also impregnated with their principal nourishment.

The nature of the action of the spongelets is remarkable in this, that the choice which they seem to make of the matter which they absorb does not appear to be determined by the natural wants of the plant, but the facility is less or more influenced by the nature of the liquids. Thus, M. Théodore de Saussure (*Rech. Chim.*, ch. 8) found, that if we place plants in water, with which is mixed sugar, gum, or the like, the spongelets will absorb a greater proportion of water than of the materials which are dissolved in it; for the water which remained after the experiment was more saturated than before the roots were put into it. Again, if we plunge the roots into different solutions, they will absorb so much the more of these in proportion to their fluidity, although at the same time such solutions may be injurious to the plant, and yet will they absorb a less proportion of viscous matter, although this may contain more nutritive materials. Thus, of blue vitriol (*sulphate of copper*), the most hurtful of the substances employed, they absorbed a large quantity, but a very small quantity of the gum, which is not injurious. When we placed plants in solutions of gum, of different degrees of thickness, we found that the quantity absorbed was smaller in proportion as the solution was more viscous. Sir H. Davy, also, observed that plants perished in those solutions in which there was a large quantity of sugar or gum; and prospered when the solutions had only a small quantity of either. (*Agricultural Chem.*)

The effect of the viscosity is obviated when we put the roots in water which holds organic matters in suspension. Thus, the drainings of dunghills, and impure waters, are taken up by the roots in smaller quantities than pure water. It should seem that these particles have a tendency to obstruct the imperceptible pores, passages, or cells of the spongelets. M. Th. de Saussure remarks that analogous laws may be observed in the case of liquids in which different substances are dissolved, the more fluid being absorbed in a greater quantity than others. It would accordingly appear that the roots exercise a kind of choice in the soil; but that the choice, far from being relative to the wants of the plants, is a circumstance purely mechanical.

On the other hand, M. Pollini, who has repeated these experiments, found that of the solutions of different substances in water, the roots sucked up different quantities, without any apparent regard to their viscosity. Thus he constantly found, he says, that the roots absorbed more of common salt, or of potash, than of the acetate or of the nitrate of lime, and more of sugar than of gum. He found, on the other hand, that if he cut the extremity of a root, the water which entered by the wound contained indifferently all the salts which had been dissolved in the water; and the portion which remained after absorption did not contain more than before. (*Saggio di Osserv. e di Sperienze sulla Veget. degli Alberi*: Verona, 1815.)

Another circumstance remarkable in the

experiments which we have before detailed is, that the disorganized tissue of the spongelets appears to give a much freer passage to the juices than that which had been uninjured. Thus plants can only live for two or three days in a solution of blue vitriol (*sulphate of copper*), of which they absorb a large quantity; while they will live eight or ten days in a solution of gum, of which they absorb only a very little. Branches cut and plunged in the different solutions follow similar laws, and absorb both water and its solutions.

It is very probable that the spongelets of different species of plants are not all organized in a uniform manner, and that there are some which more easily admit of certain substances; but microscopical observations are still far from accounting for these differences, and the facts drawn from culture are equally obscure in directing our judgment upon the point.

The manner in which plants of different kinds exhaust the soil relatively to each other, the general action of manures, the prodigious number of different plants which we can cultivate in the same patch of a garden, tend to prove that the differences of absorption in vegetables are of great importance. Instead of the variety, however, of aliments which sustain the life of animals, we find among vegetables a great uniformity of the substances absorbed. The quantity of liquid absorbed at different epochs of the life of plants, and under the influence of different atmospherical circumstances, appear more intimately connected with the ascent of the sap than with its suction.

Absorption varies according to the state of the plants and the periods of their growth; going on more rapidly in proportion as the leafing is rapid. At the time of flowering and fruiting, also, more nourishment is absorbed from the soil. We likewise know that absorption, as well as the progression of the fluids absorbed, depends greatly on the influence of heat and light; that it is most active in spring, that it diminishes in autumn, and is reduced almost to nothing, if it do not altogether cease, in winter.—*Miller*.

ABSTERGENT REMEDIES, in *furriery*, are those used for the purpose of resolving or discussing tumours and concretions on the joints and other parts of animals. They mostly consist of volatile, stimulant, and saponaceous matters.

ACACIA TREE (*Robinia Pseud-Acacia* Linnaeus). The Acacia tree is well known in America, from which it was introduced by the name of the Locust tree. It grows very rapidly in the early stages of its progress; so that in a few years, from seeds, plants of eight and ten feet high may be obtained. It is by no means uncommon to see shoots of this tree eight or ten feet high in one season. The branches are furnished with very strong, crooked thorns; the leaves are winged with eight or ten pairs of leaflets, egg-oblong, bright green, entire, and without foot-stalks. The flowers come out from the branches in pretty long bunches, hanging down like those of the laburnum, or the still more lovely *Wistaria sinensis*. Each flower grows on a slender foot-stalk, smelling very sweet. It is of a white colour, but there

is a rose-red variety. It blows in June; and when the tree is full of bloom makes a handsome appearance, and perfumes the whole air around. The flowers are followed by seed-pods, oblong, flat, having a longitudinal rib next the seeding suture, on the outside of that being drawn out into a membranous margin; one-celled, and two-valved. The seeds are sometimes as many as sixteen, kidney-shaped, ending in a hooked beak, like a lens, and are of a rusty colour.

In North America, where this tree grows to a very large size indeed, the wood is much valued for its duration. Most of the houses which were built at Boston in New England, on the first settling of the English, were constructed of this wood; and since then it has been much used in America for various purposes.

The seeds of the Acacia tree were first brought to Europe by M. Jean Robin, nurseryman to the King of France, and author of a "History of Plants." M. Robin brought the first seeds from Canada; in consequence of which, succeeding botanists have, in honour to his name, termed the genus *Robinia* to which the Acacia tree belongs. Soon after its introduction into France, the English gardeners received seeds from Virginia, from which many trees were raised.

The wood, when green, is of a soft texture, but becomes very hard when dry. It is as durable as the best white oak of North America, and esteemed preferable for axletrees of carriages, trenails for ships, and many other important purposes. The turner finds the wood of the Acacia hard and well suited to his purpose, and is delighted with its smooth texture and beautifully delicate straw colour.

The tree, when aged, abounds with certain excrescences or knots, which, when polished, are beautifully veined, and much esteemed by the cabinet-maker. It makes excellent fuel, and its shade is said to be less injurious than that of any other tree; while the leaves afford wholesome food for cattle. A gentleman in New England sowed several acres of it for this purpose alone.

It has been employed with signal success in Virginia for ship building, and is found to be very superior to American oak, ash, elm, or any other wood they use for that purpose. In New York it has been found, after repeated trials, that posts for rail-fencing, made of the Acacia tree, stand wet and dry near the ground better than any other in common use, and will last as long as those of swamp cedar.

The Acacia tree seems happily adapted to ornamental planting. Whether as a single tree upon the grass, feathering to the ground line, or as a standard in the shrubbery, towering above a monotonous mass of sombre evergreens, the Acacia has great charms for us, and may justly be called a graceful tree; and although its light, loose, and pleasing foliage admits the light, and seems to harmonize so delightfully with the polished lawn, or the highly cultivated shrubbery (and there is hardly a shrubbery to be found without them), yet we should like much to see the Acacia tree planted in the woods everywhere, where forest timber is an object of attention.

In France the Acacia tree appears to have been more generally diffused throughout the country than [in England]; for it does not only ornament their gardens, and shade their public walks, but the sprightly foliage of this beautiful tree shines through their woods and forests in every direction; so much so that it might be taken for an indigenous inhabitant of the soil.

In one of the Memoirs by the Agricultural Society at Paris, the properties of this tree are very highly extolled. Its shade, it is said, encourages the growth of grass. Its roots are so tenacious of the soil, and shoot up such groves of suckers, that when planted on the banks of rivers it contributes exceedingly to fix them as barriers to check the incursions of the stream. Acacia stakes, too, are more durable than any other known wood.

The choicest pieces only of the best oak timber are applied to the purpose of trenail-making in ship-building; and, as the Sussex oaks are generally reckoned the best, most shipwrights, even in the north, have them from thence, and the demand for them is so great, that trenail-making is there become a very considerable manufacture. If it be proved that the Acacia tree is equal to our best oak for this important purpose in our naval architecture, then do we strongly recommend (and we write practically) to every landed proprietor to plant the Acacia as a forest tree, more especially as it will grow upon almost any description of soil, but more particularly upon sandy or gravelly shallow soils, where the oak does not thrive.

In forty years the Acacia tree will grow sixty feet high, and will girth six feet, three feet from the ground; and, although brittle in a young state, the characteristics of the timber of a grown tree are toughness and elasticity.

As a durable timber, it has been proved that nothing can exceed the Acacia wood, when of proper age. But there is one important use to which these trees may be applied, which has hitherto escaped the notice of the planter, namely, hedges. From its rapidity of growth it forms a fence capable of resistance in one-fourth of the time of any other plant hitherto used for that purpose. Had we to fence in a whole estate, we should, in preference to all others, plant Acacias. They bear clipping, and may be raised to twenty or thirty feet high, if required, and are so strong that no animal can force through them. The only instance of an Acacia hedge we know of, on the continent of Europe, is to be seen round part of the boulevard of the city of Louvain. Plants for this purpose should be taken from the nursery lines four feet high. At every point where the stems cross one another, a natural union or grafting takes place, and, as the stems increase in size, the spaces between will gradually decrease; so that in the course of a few years the fence becomes a complete wooden wall, not occupying a space more than twelve or fifteen inches, forming a barrier that no animal can force. Fences of this description may either be made on the level ground, or concealed from the distant view.

It is difficult to account for the name commonly given to this tree by the Americans, namely, Locust tree; for the Locust tree (*Hymenæa Courbaril*) is a native of South America.

In the arboretum of the gardens of the Horticultural Society of London, there is a proof, perhaps the very best proof that this country affords, of the great rapidity of growth, and also the beauty of this truly interesting and highly valuable tree. About twelve years ago, this arboretum was planted for the express purpose of introducing the trees of all countries—the research of enterprising men. The Acacia was planted with the other individuals of this very splendid collection, and the result has been, that the Acacia has made greater progress than any of the oaks, the ash, the elm, the maple, or, indeed, any of the hardwooded timber trees within the wall of the gardens.

The Acacia trees, in their rapidity of growth, are exceeded only by a few of the poplar and willow tribes.

There is a singular character about the suckers of this tree. They are rarely seen to appear on the lawn, but in the shrubbery frequently. They rise singly, not like the elm, and other trees, in thick masses, choking one another, but they start out of the ground at once, with all the boldness and vigour of a healthy shoot from a powerful stool; and in a sheltered situation will grow, the same year, from twelve to fifteen feet long from the ground; and it is the more remarkable, that these suckers grow in this vigorous way immediately under the shade of the parent, and other large trees. What is also very singular, so strongly are they attached to the root below the ground, at the insertion, that they are very rarely from accident displaced.

Mr. William Lindsey mentions a very striking instance of the astonishing rapidity of the growth of this tree. He observed a strong shoot make its appearance in one of the woods at Chiswick, and he had the curiosity to see what would be the result by applying a stake to this sucker for protection. By the end of the season, it was twenty feet high, and measured three inches in circumference. When the full-grown old Acacia trees are felled, the following year hundreds of suckers will start up from the roots in all directions, and grow as freely as if a fresh plantation had been carefully made. So that, on the score of economy, we know of no tree that can be planted equal to the Acacia. As an underwood, it far exceeds any other tree in produce; and for stakes, arbour-poles, hop-poles, and for pale-fencing, there is no wood equal to the Acacia. In America, the use of the Acacia has been confined to trenails of ships, in consequence of its scarcity. But were it, either in that or this country, as plentiful as oak, it would be applied for more purposes in naval architecture, such as knees, floor-timbers, and foot-hooks, being far superior to oak for its strength and duration; and from the tree arriving much sooner at perfection, and spreading into so many branches, it affords full as

large a proportion of crooks and compass-timber as the oak tree.

A cubic foot of *Acacia*, in a dry state, weighs from forty-eight to fifty-three pounds weight. If we compare its toughness, in an unseasoned state, with that of oak, it will not be more than 8-100 less. Its stiffness is equal to 99-100 of oak; and its strength nearly 96-100; but, if it were properly seasoned, it might, possibly, be found much superior to oak in strength, toughness, and stiffness. A piece of *Acacia*, unseasoned, two feet six inches long, and an inch square in the vertical section, broke when loaded with a weight of two hundred and forty-seven pounds avoirdupois. Its medium cohesive force is about 11-500 pounds. (*Dictionary of Architecture.*)

We are not aware that this tree has added in any shape to the list of medicines. The *Acacia* of the shops was formerly made from the unripe pods of the true *Acacia* tree; but of later years, the *Acacia Germanica* of the shops is made from unripe sloes, and is preferred as an astringent medicine to the true *Acacia*.

The *Acacia* is easily propagated from seeds or suckers. (*Miller.*)

[The following highly interesting account of this tree, and the mode of cultivating it in the United States, is given by Dr. S. Ackerly.

"The cultivation of the locust tree, on Long Island, and in other parts of the state of New York, has been attended to with considerable profit to the agricultural interest, but not with that earnestness which the importance of the subject demands. This may have arisen from the difficulty of propagating it by transplanting, or not understanding how to raise it from the seed.

* * * * *

"The locust is a tree of quick growth, the wood of which is hard, durable, and principally used in ship-building. To a country situated like the United States, with an extensive line of sea-coast, penetrated by numerous bays, and giving rise to many great rivers, whose banks are covered with forests of extraordinary growth, whose soil is fertile, rich, and variegated, and whose climate is agreeably diversified by a gradation of temperature; to such a country, inhabited by an industrious and enterprising people, commerce, both foreign and domestic, must constitute one of the principal employments. As long as the country possesses the necessary timber for ship-building, and the other advantages which our situation affords, the government will continue to be formidable to all other powers. We have within ourselves four materials necessary for the completion of strong and durable naval structures. These are the *live-oak*, *locust*, *cedar*, and *pine*, which can be abundantly supplied. The former is best for the lower timbers of a ship, while the locust and cedar form the upper works of the frame. The pine supplies the timber for decks, masts, and spars. A vessel built of *live-oak*, locust, and cedar, will last longer than if constructed of any other wood. Naval architecture has arrived in this place and other parts of the United States, to as great perfection, perhaps, as in any other country on

the globe. Our 'fir-built frigates' have been compared with the British oak, and stood the test; and in sailing, nothing has equalled the fleetness of some of our sharp vessels. The preservation and cultivation of these necessary articles in ship-building, is a matter of serious consideration. It might not be amiss to suggest to the Congress of the United States to prohibit the exportation of them. The pine forests appear almost inexhaustible, and they will be so in all probability for many generations to come; but the stately cedars of Mobile, and the lofty forests of Georgia, where the *live-oak* is of a sturdy growth, begin to disappear before the axe of the woodsman. The locust, a native of Virginia and Maryland, is in such demand for foreign and domestic consumption, that it is called for before it can attain its full growth. It has been cultivated as far eastward as Rhode Island, but begins to depreciate in quality in that state. Insects attack it there, which are not so plentifully found in this state, or its native situations. These give the timber a worm-eaten appearance, and render it less useful. The locust has been extensively raised in the southern parts of the state of New York, but the call for it has been so great, that few trees have attained any size before they were wanted for use. Hence they are in great demand, and of ready sale, and no ground can be appropriated for any kind of timber with so much advantage as locust. Besides its application to ship-building, it is extensively used for fencing; and for posts, no timber will last longer, in or out of the ground. On Long Island, where wood is scarce and fencing timber in great demand, the locust becomes of much local importance from this circumstance alone, independent of its great consumption in this city among the ship-builders. In naval structures it is not exclusively applied to the interior or frame. In many places where strength is wanting, locust timber will bear a strain which would break oak of the same size. Thus an oak tiller has been known to break near the head of the rudder in a gale of wind, which has never happened with a locust one. Tillers for large sea vessels are now uniformly made of locust in New York. It is the best timber also for pins or trenails (commonly called trunnels), and preferable to the best of oak. The tree generally grows straight with few or no large limbs, and the fibres of the wood are straight and parallel, which makes it split well for making trenails, with little or no loss of substance. These are made in considerable quantities for exportation.

"The locust tree does not bear transplanting well in this part of our country, but this in all probability arises from the custom of cutting off the roots, when taken up for that purpose. Most of the roots of the locust are long, cylindrical, and run horizontally not far under the surface. In transplanting, so few of the roots are left to the body of the tree removed, that little or no support is given to the top, and it consequently dies. If care was taken not to destroy so much of the roots, a much larger proportion of those transplanted would live and thrive. So great has been the difficulty in raising the locust in this way, that another

method of propagating it, has been generally resorted to. Whenever a large tree was cut down for use, the ground for some distance around was ploughed, by which operation the roots near the surface were broken and forced up. From these roots suckers would shoot up, and the ground soon become covered with a grove of young trees. These, if protected from cattle, by being fenced in, would grow most rapidly, and the roots continuing to extend, new shoots would arise, and in the course of a few years, a thrifty young forest of locust trees be produced. The leaves of the locust are so agreeable to horses and cattle, that the young trees must be protected from their approach. When growing in groves they shoot up straight and slender, as if striving to out-top each other, to receive the most benefit from the rays of a genial sun.

"Another difficulty has arisen in propagating the locust, from inability to raise it from the seed. The seed does not always come to perfection in this part of the state of New York, and if it does, it will not sprout, unless prepared before planting. The method best adapted to this purpose was proposed by Dr. Samuel Bard; but it is not generally known, or if known, is not usually attended to. When this shall be well understood and practised, the locust will be easily propagated, and then, instead of raising groves of them, the waste ground along fences, and places where the Lombardy poplar encumbers the earth, will be selected to transplant them, as, by having them separated and single, there will be an economy in using the soil, the trees will grow much better, and the timber be stronger.

"Doctor Bard's method of preparing the seeds was to pour boiling water on them, and let it stand and cool. The hard outer coat would thus be softened, and if the seed swelled by this operation, it might be planted, and would soon come up. This has been followed with success in Long Island; and on a late visit to North Hempsted, I was led to admire Judge Mitchell's nursery of young locust trees, planted in the spring.

"The judge took a quantity of seed collected on this island, and put it in an earthen pitcher, and poured upon it water near to boiling. This he let stand for twenty-four hours, and then decanted it, and selected all the seeds that were any ways swelled by this application of heat and moisture. To the remainder he made a second libation of hot water, and let it remain also twenty-four hours, and then made a second selection of the swelled seeds. This was repeated a third time on the unchanged ones, when nearly all were swelled, and then he prepared the ground and planted them. He planted the seeds in drills about four feet apart, and in eight or ten days they were all above ground, and came up as regular as beans, or any other seeds that are cultivated in gardens. When I saw them, the middle of July, they were about a foot high, all thrifty and of a good colour and condition.

"It is the judge's intention to leave them in their present situation about three years, and then transplant; and provided he does not mutilate the roots in removing them, they will

bear transplanting, live, and thrive, and be the most productive forest tree that a farm can have. This method of preparing the seeds and planting the locust, cannot be too warmly recommended to the farming interest. On Long Island, where fencing timber is growing scarce, the cultivation of the locust tree is of great moment. In the centre of the island, on and about Hempsted plains, where there is no timber at all, it must be a most valuable acquisition; and from the trials made in raising it from the seed, all difficulty must be removed to its extensive cultivation."

After this account was written, Judge Mitchell transplanted the young trees referred to, on a side hill of waste ground which had lain for many years uncultivated, and his farm was soon improved by the addition of a large grove of valuable locust trees, in the most thrifty condition.

When planted out from the nursery, the young trees must be protected from cattle, which are fond of the young buds.

Professor Henshaw lately made some experiments, with the view of determining how far the vitality of the seeds of the locust acacia was impaired by heat. He put some of these seeds into boiling water; others he actually boiled 1½, 3, 6, and even 15 minutes; he planted them afterwards in the earth, and they all sprouted and grew in half the time that seeds did which had not been boiled or soaked.]

ACACIA. The Rose Acacia (Lat. *Robinia hispida*). This graceful shrub is a native of North America. It grows twenty feet high, when the soil and situation agrees with it, and its beautiful rose-coloured drooping flowers bloom in June. It often blows again in July and August. Its branches are covered with prickles till they are two years old, when they fall off. This gives it the appellation of *hispida*, or hairy. It loves a good soil, and is very hardy. The flowers bloom on the wood of the same year; therefore the plants should be shortened every season, unless they are planted in a shrubbery, in which case cut away only the dead wood. The *smooth tree Acacia* (Lat. *Mimosa Julibrissin*) is a green-house shrub, and a native of the Levant, but it succeeds in the open ground if carefully sheltered from frost and cold wind. It loves a fresh, light mould, and blows its beautiful rose-coloured flowers in August. It is multiplied by layers. The *Sponge tree Acacia* (Lat. *Mimosa farnesiana*) is also a green-house shrub; but it will thrive in the open air if very carefully protected. It comes originally from St. Domingo, and in August it throws out a small head of sweet-scented yellow flowers. It loves a good rich soil, with a sheltered south aspect. It is raised by seed, and multiplied by layers. (*L. Johnson.*)

ACANTHA. The prickle of thorny plants.

ACANTHUS. The plant called groundsel.

ACANTHUS (Lat.). The name of the herb bear's breech, remarkable for being the model of the foliage on the Corinthian capital. Milton, in his *Paradise Lost*, iv. 696, speaks of it,

"On either side
Acanthus, and each odorous bushy shrub,
Fenced up the verdant wall."

Todd's Johnson.

In modern botany, *Acanthus* is a genus of herbaceous plants found in the South of Europe, Asia Minor, and India, belonging to the natural order *Acanthaceæ*.

ACCLIMATION OF PLANTS. This term has been applied to the act of accustoming plants to support a temperature or a climate different from that in which they are found originally growing. This differs from *naturalization*, which is the act of transporting or transferring a plant into a country different from its native place of growth. Nobody can deny the possibility of these naturalizations; but there are some doubts upon the acclimations of plants, doubts which have been corroborated by M. Schubler (*Linnaea*, 1829, p. 16); and it renders this important question the more deserving of examination, that the facts which are reported are complex and somewhat contradictory.

On the one hand, we see wild plants appear fixed within the same climate from the epoch of which we have any knowledge, and cultivated trees, such as the olive, that have for many centuries kept within the same limit.

On the other hand, we see certain trees, such as the horse-chestnut, which, although originally from the tropics, have reached as far north as Sweden. We see that in gardening, the *Aucubajaponica* and the *Pæonia Moutan*, after having been cultivated in the hothouse, have passed into the greenhouse, and now flourish in the open air. But before we infer from these facts the possibility of acclimation, it will be necessary to analyze them more fully.

Taking the instance of a plant which may have been placed at the first in the hothouse, and afterwards cultivated in the open ground, what are we to conclude, but that, while ignorant of its nature, and while its rarity rendered it more precious, we were unwilling to run the risk of losing it. There is not a gardener, or one who has had the management of a botanic garden, who has not made such calculation a hundred times, and who, doubtful of success, has been led to follow this prudent course with a multitude of plants. Those plants which are received from tropical countries are usually thus treated, on the supposition that they partake of the general nature of plants brought from those countries; and we afterwards try, by groping in the dark, those which form exceptions to the general law. We thus succeed in naturalizing some of them; but this does not yet prove that they have been acclimated, for they have not been exposed on their arrival in the climate they were afterwards seen to support. Even had this been done, the experiment would have been frequently doubtful; for when plants arrive in Europe they are for the most part weak, and too young to try the experiment with; while every one knows that young plants, such as those of the bead tree and the silk tree, will thrive in a temperate climate in their adult age, if they are very vigorous when planted, but which are easily destroyed by the frost when young.

An exact knowledge of the manner of living of each species tends to explain some of the illusions which we are apt to fall into on this subject. Thus, when a plant newly arrived in

Europe, and consequently little known, is cultivated in the open ground, it often happens that it is placed in a soil or a position contrary to its nature, that it is watered too much or too little, and that it is pruned unseasonably, and the like; it consequently perishes without the temperature of the climate being to blame. Some years afterwards its nature becomes better known, and the management which it requires; it is planted anew in the open ground, is properly cultivated, and it succeeds, and we then say it is acclimated, while it is simply naturalized.

The greater number of cultivators think that plants produced from seeds collected in the same country are much stronger than those produced from foreign seeds, and make this an argument to prove the doctrine of acclimation. Sir Joseph Banks (*Trans. Hort. Soc. i. 21*), in particular, adduces in favour of this opinion the culture of *Zizania aquatica*, established by him at Spring Grove; but he also relates that the first seeds collected in England produced delicate plants, and the second strong plants, so that this example proves as much against as in favour of the theory. Dr. Macculloch, also (*Journ. of Science*, 1825, p. 20; *Feruss. Bull., Sc. Agr.*, ix. p. 262), in his Essay on the Island of Guernsey, strongly doubts this pretended superiority of plants coming from seeds. We will not stop to notice that this opinion is in opposition to the very generally received idea, that the changing of seeds is useful. We do not think it less probable that those seeds taken from trees supposed to be languishing, in consequence of not being yet properly acclimated, produce young plants much stronger than those which are taken from trees more healthy, and growing in their natal soil. We will not discuss that which certain cultivators, such as M. J. Street (*Trans. Hort. Soc.*, viii. 1; *Ferussac, Bull., Agr.*), assert, that the individual plants coming from cuttings are much stronger than those coming from seeds; but we will ask whether this experiment has been made with any degree of certainty, that is to say, in a comparative manner; and when the fact is so, that native seeds have had better success, whether this may not have arisen from the circumstance that certain sorts of seeds do not succeed well when they are not sown immediately after maturity, as in the case of the coffee plant, or perhaps from their being a greater number of seeds to dispose of, and more of them sown? In fine, supposing that experiments are in accordance with the admitted opinion, does this prove any thing more than that a tree which produces good seed is of a nature to accommodate itself to the soil; and is not this rather a proof of naturalization than of acclimation? Let us see if there exist any clearer proofs of the reality of acclimation.

One of the principal results of culture is the formation of varieties which otherwise would have no existence in nature, and which have different degrees of susceptibility according to the temperature. We know that these varieties, in many instances, are much more delicate than the wild species. We may instance varieties of double flowers, which are

hardy than those of single varieties of the same species; varieties of white flowers, which are generally less hardy than red or yellow varieties; and the varieties of the oleander, with double rose-red flowers, and with single white flowers, are often killed by the frost, while the common oleander, with single rose-red flowers, may stand the winter.

It is, however, those species produced by culture, and chiefly by hybridizing, which are of a more hardy nature than the wild species. Now we conceive that the choice of these varieties affords the means of introducing certain sorts into climates where the original species could not have succeeded. This effect is most apparent in such varieties as have undergone some change in the season of vegetation: thus the late variety of the walnut tree, which we call St. John's walnut, will thrive in those localities where the frosts are felt late in the spring, and where the common walnut tree is soon killed by the cold. Thus the very early varieties of the vine will bear fruit in certain climates, where either from there being little heat, or from the rapid approach of autumnal frosts, other varieties would not succeed.

There exists, in many species of plants, the remarkable phenomenon of certain individuals being more early or more late than others, without our being able to attribute the circumstance to the influence of locality; while, at the same time, we cannot perceive any sensible difference in the organization. Now, by carefully collecting the seeds, or the layers, or the tubercles, or grafts, of such early and late varieties, we obtain artificially such agricultural sorts or varieties as present certain useful qualities, and such, in particular, as will thrive in climates where the original species would not succeed. For example, by gathering the tubers of such potatoes as ripen first, and by repeating the same, many times in succession, we may by this means obtain a variety which will ripen in three months. To us, such a variety is of no more advantage than in giving us an early vegetable; but if cultivated in climates farther north, it might introduce the useful culture of the potato in places where this was previously unknown. Attentive observation of such species and varieties may furnish means of advancing the culture of certain vegetables beyond their ordinary limits. For example, if the varieties of the olive brought from the Crimea, which appear less affected with cold than European varieties, should come to be introduced on the shores of the Mediterranean; or if they should propagate extensively the variety called *Caillou* in Provence, we might be led to conclude that the olive is accustomed to a greater degree of cold, although there might only be the substitution of a hardier sort for a more delicate one.

In fine, although we are not authorized to observe that the vegetable tissue cannot, by the effects of habit, accustom itself to a different temperature than that of its native climate; and although we are disposed to recognise, in many cases, this influence of habit, yet the preceding facts seem to lead to the following inferences: 1. That if certain species of vege-

tables are susceptible of being acclimated, this occurs within very narrow limits; and we frequently exaggerate these limits by confounding acclimation with naturalization. 2. That the cases in which acclimation appears to take place in reality, chiefly, if not exclusively, comprise species where there is a formation of new varieties, or where we have managed to change the season of the vegetation of plants, as arising from periodicity. 3. That practical results, almost as important as those of acclimation, more properly so called, are obtained by ably following up certain processes of culture. (*Miller's Dictionary.*)

[A sensible and eloquent writer in the American Journal of Geology, has, in a paper upon the "Acclimating Principle of Plants," treated the subject in a highly interesting manner, and illustrated it by referring to many instances where plants have actually adapted their growth and habits to a great extent of country, and diversity of latitude. His views, it will be seen, are not in exact accordance with those contained in the preceding article upon a similar topic. They are, however, calculated to be particularly interesting in the meridian of the United States.

"Plants," observes the writer referred to, "have *directly* no locomotive powers, but *indirectly*, they have in a great degree the faculty of changing their places, and, consequently, their climate. The embryo germ wrapped in a kernel, or seed, is virtually a plant, ready to germinate when thrown upon its parent earth, and affected with heat and moisture. It is in a most portable shape, and can be transported with ease to an unlimited distance. Nature in many instances superadds to seeds, wings, down, feathers, and chaff, by which they become buoyant, and are carried by the winds of heaven, by the storms that sweep the forest, and by the streams, and currents of rivers, and the ocean, to an immense distance, and through many degrees of latitude! They become finally deposited in some genial soil, and at one remove, or through a succession, they occupy extensive regions. Nature manifests her great care of the embryo, by coating some of her seeds with shells, which protect them from the attacks of insects, and the action of the elements; others have bitter, narcotic, or poisonous qualities, which forbid animals eating them; and many are filled with oily, or resinous matter, which resists, for ages, and even centuries, the action of the elements, unless acted upon by the proper degree of heat and moisture. By such qualities they endure, and await a suitable time and conveyance to their destined place, in order to extend and vary their families.

Birds also convey the seeds of plants in their crops over a wide extent, before they become triturated and digested; and when these winged carriers die, or decay, from accident or age, the seeds are deposited, and take root in some distant land. Animals also convey them in their stomachs to a considerable distance, and pass them uninjured by the powers of digestion.

Man, more provident than all, to whom plants are necessary, whose support, whose

comforts, and whose pleasures connect him with them, carries their choice seeds, slips, and scions, far and wide. His interests foster their growth, his attentions enrich their products, and his skill and science preserve their existence, and adapt them to their new condition. In an improved community, man's wants multiply; he has occasion for the more varied and rich fruits; more abundant and luxurious clothing, and furniture of vegetable growth; odours to regale his senses, vegetable flavours to pamper his appetites, and all the medicinal plants to heal his various diseases, and invigorate his shattered constitution. He attaches himself to agriculture and horticulture: plants become his companions; he carries a creative resource into those departments, and by his attentions, forms new varieties and excellences, unknown to the wild state of vegetable existence. Such are the means nature has provided for the propagation and extension of plants; such are the indirect locomotive powers they possess. We must no longer, therefore, consider vegetables such inert and sluggish beings.

Human care, and the providences of nature, have given to many plants a great extent of climate and latitude, an enlarged growth, and an increased and improved product. Let us bring together such instances as are within the knowledge of all, and which ought to stimulate our cultivators to greater efforts.

The valley of the Euphrates was doubtless the native region of all those fine and delicious fruits which enrich our orchards, and enter so largely into the luxury of living. We thence derived all the succulent and nutritious vegetables that go so far to support life; and even the farinaceous grains appertain to the same region. The cereal productions began in that same valley to be the staff of life.

Our corn, our fruit, our vegetables, our roots, and oil, have all travelled with man from Mesopotamia up to latitude 60°, and even farther, in favourable situations. The cares of man have made up for the want of climate, and his cultivation atoned for this alienation from their native spot. The Scandinavians of Europe, the Canadians of North America, and the Samoides of Asia, are now enjoying plants which care and cultivation have naturalized in their bleak climes. Melons and peaches, with many of the more tender plants and fruits, once almost tropical, have reached the 45th degree of latitude in perfection, and are found even in 50°. Rice has travelled from the tropics to 36°, and that of North Carolina now promises to be better than that of more southern countries. The grape has reached 50°, and produces good wine and fruit in Hungary and Germany. The orange, lemon, and sugar-cane, strictly tropical, grow well in Florida, and up to 31½°, in Louisiana, and the fruit of the former much larger and better than under the equator.

Annual plants grown for roots and vegetables, and grain, go still farther north in proportion, than the trees and shrubs, because their whole growth is matured in one summer; and we know that the developement of vegetation is much quicker when spring does open

in countries far to the north, than in the tropics. In Lapland and on Hudson's Bay, the full leaf is unfolded in one or two weeks, when spring begins, although it requires six or eight weeks in the south. Nature makes up in despatch for the want of length in her seasons, and this enables us to cultivate the annual plants very far to the north, in full perfection. The beans, pumpkins, potatoes, peas, cabbages, lettuce, celery, beets, turnips, and thousands of others, seem to disregard climate, and grow in any region or latitude where man plants and cherishes them. The fig is becoming common in France; the banana, pineapple, and many other plants, have crossed the line of the tropics, and thousands of the plants valuable for food, clothing, and medicine, and such as are cultivated for their beauty, fragrance, or timber, are extending their climates, and promise much comfort and resource to man. Plants lately introduced, whose cultivation has not run through many ages or years, have acquired but little latitude in their growth, and show but little capacity to bear various climates, because time has not yet habituated them to such changes, and human cares have not imparted to them new habits and new powers.

Nothing can be effected by suddenness in *acclimating* plants; too quick a transition would shock them; it must be a very gradual process, embracing many years, and many removals. The complete success that has attended the plants first named, the earliest companions of man, proves this. In the more recent plants, success is exactly in proportion to the length of time that a plant has been in a train of experimental culture.

The most striking method of testing the effect of climate on plants, is to carry suddenly back to the south, such as have been extended far, and become habituated to a northern climate. Such plants have so much vigour, and the habit of a quick and rapid growth so firmly fixed on them, by a long residence in the north, that when suddenly taken to the south, although the season be long and ample, they continue, from habit, to grow and mature quick, and obtain the name of rare-ripe; because they do not take half of the time to mature, that those of the same family require, which have never been so changed. Gardeners give us early corn, peas, fruit, and turnips, by getting seed from places far to the north; and cotton growers renew the vigour of the plant by getting the most northern seed. This practice is common in the case of most plants, and is founded on the supposition that plants do, and can acquire habits.

The fact supported in the first number of the *American Journal of Geology and Natural Science*, "that plants are most productive near the northern limit in which they will grow," that they bear more seed or fruit, and have more vigour of constitution, offers much encouragement to agriculturists. This proves that it is not a meager, stunted existence, devoid of profit or productiveness, that we give to plants, by pushing their culture far north, but a strong and healthful growth, one that repays the labour and attention, by a greater

product than belongs to more southern situations.

Every view that we can take of this interesting subject, every fact within our knowledge, whether drawn from the actual state of cultivation, or from physiological investigations into the habits, nature, and construction of plants, goes to show that plants do become acclimated, both in the natural and artificial way, to a great extent. Enough has been witnessed to prove that plants have a physical conformation, that does accommodate itself to circumstances, and have capacities more extensive than are generally ascribed to them: enough has been realized to encourage farther efforts, and to give us hopes of much future benefit."

As allied to this subject see *Climate, influence of, on the Fruitfulness of Plants.*]

ACCOUNTS, FARM. See FARM ACCOUNTS.

ACER. The Roman name for a genus of trees, comprehending different species of the large deciduous kind, as the sycamore, &c. See MAPLE TREE.

ACETIC ACID, and ACETUM, terms employed to signify *Vinegar*, which see.

ACETOSA. See SORREL.

ACHILLEA. A genus of plants consisting of sixty or seventy species, found exclusively in the colder climates of the northern hemisphere. They are all herbaceous, perennial weeds of little importance, except to botanists, and are only seen in cultivation in the collections of the curious.

ACIDS (Lat. *acetum*; Goth. *acit*; Sax. *æced*). Liquids and other substances are called acids, which commonly, but not always, affect the taste in a sharp, piercing, and peculiar manner. The common way of trying whether any particular liquor hath in it any acid particles is by mixing it with syrup of [blue] violets, when it will turn of a red colour; but if it contains alkaline or lixivial particles, it changes that syrup green. [The blue liquor obtained by steeping purple cabbage leaves in hot water, is also a convenient test liquor for acids as well as alkalies.] They combine with various earths, alkalies, and metallic oxides, and form the peculiar class of bodies called salts. (*Todd's Johnson.*)

[In agricultural chemistry, the acids are divided into the *inorganic* and *organic*. The first kind, or inorganic, are derived from sources wholly mineral. The second kind, or organic, are derived from animal or vegetable organized substances. The *sulphuric acid*, or oil of vitriol, is one example of a mineral or inorganic acid. It exists abundantly in nature, combined with mineral bases, as in plaster of Paris, where it is combined with lime, forming the sulphate of lime, or gypsum. *Muriatic acid* is another very abundant inorganic or mineral acid, and abounds in sea-salt, combined with soda, forming the muriate of soda or common salt. *Nitric acid*, or *aqua fortis*, is another of this class of acids, existing abundantly in the well known substance called saltpetre, or nitrate of potash. These three constitute the principal *inorganic* or mineral acids.

As all vegetables contain acids, these may be regarded as essential to their life. But these

acids do not always exist in a free state, being generally combined with some of the alkalies or alkaline substances, such as potash, soda, lime, and magnesia. "These bases evidently regulate the formation of the acids, for the diminution of the one is followed by a decrease of the other: thus, in the grape, for example, the quantity of potash contained in its juice is less, when it is ripe, than when unripe; and the acids, under the same circumstances, are found to vary in a similar manner. Such constituents exist in small quantity in those parts of a plant in which the process of assimilation is most active, as in the mass of woody fibre; and their quantity is greater in those organs whose office it is to prepare substances conveyed to them for assimilation by other parts. The leaves contain more inorganic matters than the branches, and the branches more than the stem. The potato plant contains more potash before blossoming than after it.

"Now, as we know the capacity of saturation of organic acids to be unchanging, it follows that the quantity of the bases united with them cannot vary, and for this reason the latter substances ought to be considered with the strictest attention both by the agriculturist and physiologist.

"We have no reason to believe that a plant in a condition of free and unimpeded growth produces more of its peculiar acids than it requires for its own existence; hence, a plant, on whatever soil it grows, must contain an invariable quantity of alkaline bases. Culture alone will be able to cause a deviation.

"In order to understand this subject clearly, it will be necessary to bear in mind, that any one of the alkaline bases may be substituted for another, the action of all being the same. Our conclusion is, therefore, by no means endangered by the existence of a particular alkali in one plant, which may be absent in others of the same species. If this inference be correct, the absent alkali or earth must be supplied by one similar in its mode of action, or in other words, by an equivalent of another base.

"Of course, this argument refers only to those alkaline bases, which, in the form of organic salts, form constituents of the plants. Now, those salts are preserved in the ashes of plants, as carbonates, the quantity of which can be easily ascertained.

"From these considerations we must perceive, that exact and trustworthy examination of the ashes of plants of the same kind growing upon different soils would be of the greatest importance to vegetable physiology, and would decide, whether the facts above mentioned are the results of an unchanging law for each family of plants, and whether an invariable number can be found to express the quantity of oxygen which each species of plant contains in the bases united with organic acids. In all probability, such inquiries will lead to most important results; for it is clear, that if the production of a certain unchanging quantity of an organic acid is required by the peculiar nature of the organs of a plant, and is necessary to its existence, then potash or lime must be taken up by it, in order to form salts with this acid

that if these do not exist in sufficient quantity in the soil, other bases must supply their place; and that the progress of a plant must be wholly arrested when none are present.

“Seeds of the *Salsola Kali*, when sown in common garden soil, produce a plant containing both potash and soda; while the plants grown from the seeds of this contain only salts of potash, with mere traces of muriate of soda. (*Cadet*.)

“The existence of vegetable alkalies in combination with organic acids gives great weight to the opinion, that alkaline bases in general are connected with the developement of plants.

“If potatoes are grown where they are not supplied with earth, the magazine of inorganic bases, (in cellars for example,) a true alkali, called Solanin, of very poisonous nature, is formed in the sprouts which extend towards the light, while not the smallest trace of such a substance can be discovered in the roots, herbs, blossoms, or fruits of potatoes grown in fields. (*Otto*.)

“When roots find their more appropriate base in sufficient quantity, they will take up less of another.”—(*Liebig's Organic Chem.*)

Vegetable acids abound in most plants; thus, the *Acetic acid* (*vinegar*) is found in the chick pea (*Cicer arietinum*), in the elderberry (*Sambucus nigra*), in the date palm tree (*Phoenix dactylifera*), and in numerous others.

The *Oxalic acid* is found combined with potash in the *Oxalis Acetosella*, or wood-sorrel (whence its name), and many other plants; united with lime, it is detected in the root of the rhubarb, in parsley, fennel, soapwort, squills, &c.; and in an uncombined state in the liquid which exudes from the *Cicer arietinum*, [*chick pea*, or *Spanish Garbanza*.]

Tartaric Acid [or *Cremor tartar*] is commonly procured from *tartar* or tartrate of potash (whence its name). It has been detected in many plants, such as in grapes, tamarinds, bilberries, white mulberries, the Scotch fir, couch grass, dandelion, &c. &c.

Citric Acid has been found in oranges and lemons, cranberries, red whortleberry, bird-cherry, woody nightshade, the hip, and the onion.

Malic Acid is the only acid existing in the apple, [pear,] barberry, plum, sloe, elder, service, &c. It is found with the citric acid in the gooseberry, currant, bleaberry, cherry, strawberry, raspberry, &c.; combined with lime, it is found in the house-leek, wakerobin, &c.; and with potash and lime, in rue, garden purslane, madder, spinach, lilac, mignonette, &c.

Benzoic Acid.—This acid is found in benzoin, balsam of Tolu, storax, &c.; and in marjoram, clary, chickpea, Tonkin bean, &c.

The *Prussic*, or *Hydrocyanic Acid*, exists in laurel leaves, peach blossoms, bitter almonds, flowers of the sloe, leaves of the bay-leaved willow, &c.; there is little doubt but that all the bitter almond kernels contain this acid.

Gallic Acid abounds in the barks of many plants, such as the elm, oak, chestnut, beech, willow, elder, plum tree, sycamore, birch, cherry tree, sawlow, mountain ash, poplar, hazel common ash, sumach, &c.

These are the chief vegetable acids. There are others which have been detected occasionally; such as the moroxylic, in the *Morus alba*, or white mulberry; the boletic, in the *Boletus pseudo-ignarius*; [a species of mushroom,] the meconic, in opium; the kinic, in the bark of the *Cinchona officinalis*; the camphoric from camphor; the suberic from cork, &c.; but none of these are of that importance to the cultivator to require a particular notice in this place. The composition of the principal vegetable acids is much more similar than the intelligent farmer might be inclined to suspect, as will be readily seen from a comparison of the following table of their composition, chiefly by M. Berzelius:—

	Hydrogen.	Carbon.	Oxygen.
Acetic acid	- - 6.35	46.83	46.82
Oxalic acid	- - 0.244	33.222	66.534
Tartaric acid	- - 3.951	36.167	59.882
Citric acid	- - 3.800	41.369	54.831
Benzoic acid	- - 5.16	74.41	20.43
Gallic acid	- - 5.00	56.64	38.36

(*Thomson's Chem.*)

[The organic acids of *animal* origin are, like those obtained from vegetables, very numerous. As examples, there are, the *formic acids*, first obtained from ants, but now ascertained to exist in sugar and some other vegetable substances: *Lactic acid*, obtained from milk;—*Uric acid*, procured from human urine, and *Hippuric acid*, from the urine of the horse and other animals when stall-fed: *Margaric* and *Stearic acids* from fat, etc. The *Phosphoric acid*, though found combined with minerals, is very abundant in the animal system, being combined with lime to form the bones, and existing in the urine and other fluids and solids, in union with alkaline bases, forming phosphates of soda, potash, lime, and magnesia.

Phosphoric acid has also been found in all plants, the ashes of which have been examined by chemists, always, however, in combination with potash, soda, magnesia, or lime. Most seeds contain certain quantities of the phosphates formed by the union of phosphoric acid with some one or more of the alkalies just named. In the seeds of different kinds of grain, there is abundance of phosphate of magnesia.

Phosphoric acid, in one or other of its combinations, plays indeed an important part in agriculture, and is an indispensable constituent of all good land.

“The soil in which plants grow furnishes them with phosphoric acid, and they in turn yield it to animals, to be used in the formation of their bones, and of those constituents of the brain which contain phosphorus. Much more phosphorus is thus afforded to the body than it requires, when flesh, bread, fruit, and husks of grain are used for food, and this excess in them is eliminated in the urine and the solid excrements. We may form an idea of the quantity of phosphate of magnesia contained in grain, when we consider that the concretions in the ræcum of horses consist of phosphate of magnesia and ammonia, which must have been obtained from the hay and oats consumed as food. Twenty-nine of these stones were taken after death from the rectum of a horse belonging to a miller in Eberstadt, the total weight of which amounted to 3 lbs.

"It is evident that the seeds of wheat could not be formed without phosphate of magnesia, which is one of their invariable constituents; the plant could not, therefore, under such circumstances attain its proper development, so far as its fructification was concerned."]

The *Crenic*, is another organic acid lately discovered by Berzelius. From its containing nitrogen and being a constituent in all fertile soils, it is believed to exercise a beneficial action on vegetation. It is always accompanied by the *Apocrenic* acid, changed from the *crenic* by oxidation.

ACINUS. The stone of any berry.

ACONITE. See WOLFSEBANE.

ACORNS. The seed or fruit of the oak; *акорн*, Saxon, from *ac*, an oak, and *corn*, corn or grain; that is, the grain or fruit of the oak.

The Greeks had a tradition, that the oak was the first created tree; and hence, having a similar idea as to the Arcadians being the first created men, they compared them to the oak. Virgil tells us to

— "Thresh the wood,
For masts of oak, your father's homely food."

And Ovid corroborates their use:—

"Content with food which nature freely bred,
On wildings and on strawberries they fed,
Cornels and bramble berries gave the rest,
And fallen *acorus* furnish'd out a feast."

Turner, who is the earliest English author on this subject, writes, "Oke, whose fruit we call *acorn*, or an *eykorn* (that is, the corn or fruit of an *cyke*), are hard of digestion, and nourish very much, but they make raw humors. Wherefore, we forbid the use of them for meates." They were long the food of the early Greeks, as they are of the lower order of Spaniards, even to this day; but then it must be remembered, that the acorns of Spain are more sweet and nutritious than those of England. And yet the early Britons certainly eat them: their priests, or Druids, taught them, that every thing that was produced on the oak, even to the parasitical mistletoe, was of heavenly origin, a superstition which was common, also, to the Persians and the Massagetæ.

The Saxons valued them chiefly for fattening swine. Their king Ina, in the seventh century, gave them a law, respecting the fattening of their swine in the oak woods, which privilege was called a pawning, or pannage.

The oak is often mentioned in Holy Writ, as the oak of Ophra, *Judges* vi. 11; of Shechem, *Gen.* xxxv. 4; and of Deborah's Grave, *Gen.* xxxv. 8. See OAK.

Although acorns are said to have been the primitive food of mankind, at present they are only used in raising young oaks, or for the purpose of fattening deer and hogs, for which last they are said to be a very proper and useful kind of food.

In Gloucestershire, according to Mr. Marshall, they are in high esteem among the farmers, who seem to be as anxious about them as their apples. They consider them as the best means of fattening hogs, and think they make the bacon firm, and weigh better than bean-fed bacon. The price of acorns there is from 1s. 6d. to 2s. per bushel, according to the season and the price of beans. Few are sold,

however; every farmer collecting his own, or letting his pigs feed upon them.

Some care is necessary to be taken when hogs are fed upon acorns, for otherwise they will be subject to constipation, and the disease called the garget. These may, however, be avoided, by mixing laxative substances with them, and not allowing them to have too many at a time; at first a few, twice a day is often enough; afterwards three times a day. The hogs, while they eat this food, should not be confined to the sty, but be suffered to run at large; for if their liberty be too much abridged, they never thrive well, or grow fat on this sort of food.

In Hertfordshire, and the New Forest in Hampshire, it is no uncommon thing, with the management above directed, and the assistance of a little wash, and a few grains now and then, for a farmer to kill several hogs in a season, which weigh from eight to ten score, and sometimes even more. Hogs fed in this way make very good well-flavoured meat; but it is not thought by some so fine as when they are taken up, and four or five bushel of pease or barley-meal given to each to complete their fattening.

"The pigs are gone *acorning*," is a very common provincialism (see *Mr. Wilbraham's Cheshire Glossary*); and the expression is also confirmed by Shakspeare's "full-*acorn'd* boar."

Acorns are sometimes given to poultry, and would be found an advantageous food for them, when dried and ground into meal.

Tusser, speaking of acorns, says,

"Some left among bushes shall pleasure thy swine,
For fear of a mischief, keep *acorns* from kine"

They are considered injurious to cows, because they swell in their stomachs, and will not come up to the cud again; which causes them to strain as it were, to remit, and to draw their limbs together.

In medicine, a decoction of acorns is reputed good against dysenteries and colics. Pliny states, "that acorns beaten to powder, and mixed with hog's lard and salt, heal all hard swellings and cancerous ulcers; and when reduced into a liniment, and applied, stays hæmorrhage." (*Phillip's Fruits*.)

When employed for raising oak timber from, the method of planting the acorns, which is practised by some, is to make holes to receive them, at the distance of 12 or 15 inches from each other, in an oblique direction, so as to raise up a tongue of turf under which they are to be deposited, and where they require no farther kind of nursing. In the course of from twenty to thirty years, in this mode of planting, the spot, it is said, will be fit to be coppiced, that is, partially cut down as underwood, leaving the most healthy plants. The thinnings may be sold for railing, and generally fetch a good price. A better method is, however, to dibble them on land that has been properly prepared by ploughing or digging, which may be done by women, three or four within a square yard; or they may be sown broad-cast, when the surface is fine and moist, and rolled in with a light roller. The former is probably the better practice. They may likewise be set about the middle of November, by a land chain,

a quarter of a rod asunder, and six inches apart in the rows; dibbling them in, zigzag, alternately on either side a line stretched tightly on the surface, with blunt-pointed dibbles, letting a little mould fall down to the bottoms of the holes, to prevent water lodging round them, and burying them about two inches beneath the surface. Each square rod, when planted in this way, takes 132 acorns, nearly a pint, when they are middle-sized, which is equal to two statute bushels and a half on an acre. The expense, in England, of planting acorns in this manner is about 5s. an acre. See PLANTING.

ACORUS, from the Greek *α*, privative, and *ακρον*, the pupil of the eye. The botanical name of a plant of the thistle kind, that produces the drug called in the shop *Calamus aromaticus*. It is found abundantly in the neighbourhood of freshwater marshes. The ancient practice of srewing the floors with the leaves of these sweet rushes is still kept up in some of our cathedral churches upon certain high festivals. The plant, which belongs to the natural order *Aroidæ*, flourishes luxuriantly in loose, moist soils, and sends forth many deep-green, long sword-shaped leaves from its perennial, creeping, and horizontal stems. It seldom flowers, but the blossoms which it sends forth are of a greenish colour. The root, or more properly the stem, is the part which, when dried, is used medicinally, occasionally as a stimulant. It is slightly acrid and aromatic. (*Thomson's Dispensary*.)

ACRE (*accpe*, Sax. *Acre*, Lye says, is common to all the European languages. *Sax. Dic.*) He might have added further, that it is an Eastern word; and that *agr*, *akora*, and *akkoran*, denote in the Hebrew, Syriac, and Arabic, a field, a husbandman. So the Saxon *accpe*mon, a husbandman. Wachter, in his *Glossary*, gives *akerman*, a day-labourer. (*Todd's Johnson*.) In *Shakspeare's King Lear*, we have—

“ Search every acre in the high grown field,
And bring him to our eye.”

The prevailing and standard measure of land in Britain. An acre in England contains 4 square roods; a rood, 40 perches, rods, or poles, 5½ yards, or 16½ feet each, according to the statute in the act passed in 1824, for the equalization of weights and measures throughout the United Kingdom, which is in this instance confirmatory of the old law of England. But in some parts of England there are other measures under the same designation of *acre*. For example, in Devonshire, and part of Somerset, 5 yards (instead of 5½) have been reckoned to a perch; in Cornwall, 6 yards (anciently called the Woodland perch); in Lancashire, 7 yards; in Cheshire and Staffordshire 8 yards; in the Isle of Purbeck, and some parts of Devonshire, 15 feet and 1 inch. In the common fields of Wiltshire and the neighbouring counties, 120 poles, or 3 roods, were reckoned to an acre.

The Irish acre is 7840 square yards, and is equal to 1 acre, 2 roods, and 19 poles, nearly, of English measure.

The Scotch acre contains 5760 square Scotch

ells, and is equal to 1 acre, 1 rood, 2 poles nearly, of English measure.

The following Table shows the comparative quantity of each of the above measures:—

A. R. P.	Devonshire customary measure,	} Equal to 100 statute acres.
120 3 20	Isle of Purbeck, ditto,	
119 2 26	Cornish or Woodland ditto,	
84 0 4	Lancashire or Irish ditto,	
61 2 37½	Cheshire and Staffordshire ditto,	
47 1 2½	Wiltshire tenantry ditto,	
133 2 0	Scotch measure,	
79 1 6½		

The French acre, or *arpent*, according to Mr. Greave's calculation, consists of 100 perches, of 22 feet each, amounting to 48,400 square French feet, which are equal to 51,691 square English feet, or very near one acre, and three quarters of a rood, English measure. The Strasburg acre is about half an English acre.

Table exhibiting the Number of Plants which may be raised on a Perch of Land, at different distances:—

In a perch are 272½ square feet, or 39,204 square inches. A perch will contain

Trees or Plants.	Inches over.	Number of Inches asunder.	Square Inches to each.

Table of Land Measure.

In an acre are

4 roods, each rood forty perches.

160 perches, sixteen feet and a half each.

4,840 square yards, nine feet each.

43,560 square feet, 144 inches each.

174,240 squares of six inches each, thirty-six inches each.

6,272,640 inches, or squares, of one inch each.

ACRIMONY (*Acrimonia*, Lat.). A sharp property in some plants and vegetables, by which they excoriate and blister the tongue, mouth, or other parts of the body, on being applied to them. The nature of this sort of acrimony has not yet been sufficiently examined by chemical investigation. It seems to differ in some measure according to the nature of the plants; as in the common onion, water-cresses, cabbages, &c., a part of their acrimony is lost, by their being exposed to a boiling heat; while other kinds, as ginger, capsicum, arum, &c., do not become much milder by undergoing that process.

The juice of the fungous excrescences of some trees possess so much acrimony as to be capable of blistering; and some kinds of *fungi* contain a juice or liquor of a very corrosive quality; and it is probably on this account that many of those which are commonly procured disagree so much with the patient, when made use of as articles of diet. By being more perfectly stewed, or otherwise prepared by means of heat, they might most likely be rendered safe and nutritious. Much caution should, however, be used, even when thus prepared, in eating such kinds as are unknown. "There be some plants," says Bacon, in his *Nat. Hist.*, "that have a milk in them when they are cut; as figs, old lettuce, sow-thistles, spurge. The cause may be an inception of putrefaction: for those milks have all an acrimony, though one would think they should be lenitive."

ADAPTER (*Adopto*, Lat.). In the management of bees, is a board used to place the hives or glasses upon.

ADDER (Αεττεν, αεττον, ναδδρε, as it seems, from ειττεν, Sax. poison; Mæs-Goth. *nadr*, viper; Teut. *adder*). A viper, a poisonous reptile, perhaps of any species. In common language, however, adders and snakes are not the same, the term adder being generally understood to imply a viper. See **ANIMAL POISONS**.

ADEPS. In veterinary science, animal oil or fat. The fat differs in different animals; and hence it has received different names. In the horse it is called grease; in the ox and sheep, tallow, fat, suet; and in the hog, hog's lard. At a low temperature all these possess various degrees of consistence; but in the living animal, they all exist in a fluid state, and are distributed over various parts of the body. An immense quantity of fat is often found in the belly, all deposited in extremely small cells, which have no communication with each other. No fat is ever found within the skull.

Fat performs important functions in the animal economy. When the supply of ali-

ment, for example, is greater than the demand, the surplus is stored away in the form of fat; and when the demand, either from deficiency of food, over-exertion, or disease, becomes greater than the supply, then the absorbents carry the fat into the circulation, and thus, for a time, the evils that would very soon arise from a defect in the quantity of blood are prevented. Some animals accumulate fat more readily than others. Health, a round chest, a short back, and tranquil temper are highly favourable to its formation; and when to these qualities are added inaction, clean litter, and a plentiful supply of nourishing food, the animal is soon fit for the butcher. A warm atmosphere, provided it be a pure one, is also favourable to fattening. [See **LARD OIL**, &c.] (*Miller's Dictionary*).

AERATION. The process by which the soil is exposed to the air and imbued therewith, air being indispensable to the healthy growth of plants. When a flower-pot is filled with rather dry earth, if it be plunged under water a profusion of air-bubbles will be seen to rise, owing to the water penetrating between the particles of the dry earth, and forcing out the air previously lodged there. As the more loose and porous a soil is, the greater quantity of air it will contain, it will follow, that the more a soil is ploughed and harrowed, or dug and raked, the better it will be aerated—one of the chief beneficial effects of frequently repeating these operations.

Besides the direct influence of the atmosphere, the agency of water is all-important in the process of aeration. All water openly exposed contains more or less atmospheric air; and, in consequence of this, it acquires an agreeable taste, always destroyed by boiling, which renders it rapid and disagreeable, by expelling the air. The importance of air contained in water to the growth of plants appears from water being found beneficial in proportion as it has had opportunities of becoming mixed with air. But the best water, with respect to the properties of the air it contains, is rain, which, falling in small drops, often tossed about by the wind, has an opportunity of collecting a large proportion of air, and, according to Liebig (*Organic Chem.*), ammonia, during its descent to the earth; and hence the smaller the bore of the holes in a garden watering-pot, the better; and the more minutely the garden-engine scatters the water, the more advantageously, so far as the air is concerned.

There is another point of view in which aeration appears beneficial, arising from the excrementitious matters thrown into the soil by growing plants, as ascertained by M. Macaire; for as these matters become decomposed in the processes of fallowing, irrigation, and draining, the gases there produced would not so readily be carried off from the soil, but for a due circulation of the common air through the earth. See **GASES**, their use to vegetation. (*Miller's Dictionary*).

AEROLITES (From the Greek *αερ*, air, and *λιθος*, a stone). Meteoric stones, bodies that fall from the heavens. The origin of these remarkable bodies is still a mystery.

AFRICAN MARIGOLD (*Tagetes erecta*, Lin.). A favourite hardy annual, which does not come from Africa, as its name would indicate, but from Mexico. See **MARIGOLD**.

AFTER-GRASS, or **AFTERMATH**. The second crop of grass, or that which springs after mowing, or the grass cut after some kinds of corn crops.

The composition of the after-grass generally varies considerably from that of the first or spring crop. The nutriment of the latter, from most of the grasses, is materially less than that of the former. This was clearly ascertained by the elaborate experiments of the late Mr. G. Sinclair, the results of which are dispersed throughout his valuable work on the Grasses. To give a few instances only—

	First Crop. dr. gr.	Second Crop. dr. gr.
64 dr. of round-panicked cock's-foot grass afforded of nutritive matter	2 1	1 2
Meadow fox-tail grass - - -	3 1	2 0
Larger-leaved creeping bent-crested dog's-tail grass - - -	4 1	2 2
Hard fescue grass - - -	3 2	1 1
Welch fescue grass - - -	2 1	1 1
Yellow oat grass - - -	3 3	1 1

And the same remark applies to the rye-grass (*Lolium perenne*), not only of upland pastures but of meadows. Thus, Sinclair found (*Hort. Gram. Wob.* 384) that this grass when flowering, taken from a water meadow that had been fed off with sheep till the end of April, yielded of nutritive matter 72 grs.

But the same grass from the same meadow which had not been fed off, yielded 100 grs.

The same weight of this grass, from a rich old pasture that had been shut up for hay at the same time, yielded of nutritive matter 95 grs. But the grass from the same field, which had not been depastured, yielded 120 grs.

Some of them, however, contain exactly as much nutritive matter in the aftermath as in the first crop: thus, 64 drs. of the

	First Crop. dr. gr.	Latter Crop. dr. gr.
Sweet-scented soft grass yielded	4 1	4 1
Smooth-stalked meadow grass	1 3	1 3
Short blue meadow grass - - -	2 0	2 0
Cow grass - - -	2 1	2 1
Creeping fescue - - -	1 2	1 2

and one or two were found to contain more nutritive matter in the aftermath than in the first crop: thus 64 drs. of the

	First Crop. dr. gr.	Latter Crop. dr. gr.
Sweet-scented vernal grass yielded	1 3	2 1

In the vicinity of London most of the after-grass, or second crop, was formerly made into hay, and was considered of considerable value for the ewes of suckling lambs, and milch cows; but in harvesting this crop, so as to make it sell well, great nicety is requisite, the nature of after-grass being more soft, spongy, and porous than the first growth, and consequently more liable to be hurt by rains. The practice is therefore on the decline.

In the midland counties their management of the feeding off the after-grass is in general judicious. It is commonly suffered to get up to a full lute before it is broken, and not turned in upon as soon as the hay is off, or suffered to stand until much of it becomes improper for the food of animals. Farmers, however, make

a point of saving autumnal grass for spring feed, and contend that it is the most certain, and, on the whole, the best spring feed yet known. This would seem to be a wasteful practice, at least in respect to the more forward after-grasses. These ought certainly to be broken sufficiently early to be eaten, without waste, before winter sets in; and the latest, that is to say, the shortest, may be shut in for spring feed. If after-grass be too long and gross, it is apt to lodge, and rot upon the ground in winter; therefore, on rich lands, it ought always to be more or less off before Michaelmas, in order to prevent its being wasted or lost in the winter.

It is remarked by the author of "Practical Agriculture," that, "In some districts much of the after-grass is frequently cut and made into a green soft sort of hay, as has been already mentioned; but in others it is fed off by live stock in the autumn." And that "both modes may be useful under different circumstances. In situations where plenty of manure can be procured, as near large towns, and where the chief dependence is upon the sale of hay, or where lamb-suckling prevails, it may frequently be a beneficial practice to take a second crop of hay, as the first may by that means be more fully spared for sale, the after-crop supplying the cows or other cattle that may be kept on the farm. But in cases where manure cannot easily be obtained, and there is no local practice carried on which requires such sort of hay, it is better to let it be fed off by stock than run the risk of exhausting and injuring the ground by taking off repeated crops. There is also another circumstance," he says, "to be considered in this business, which is, that of the state of the land in respect to dryness, as where it is low, wet, and very retentive of moisture, it may be often more hurt by the poaching of the cattle in feeding off the herbage than by a second crop of hay." But that, "independent of these considerations, it may, in general, be a more safe and usual practice to eat off the after-grass by stock, and only take one crop of hay, as by such means a more abundant annual produce may be afforded, and the land sustain less injury."

It is, however, added, that "where a crop of rowen is made into hay, the most profitable application of it is probably in the foddering of such cows as are in milk; as it is well suited, by its grassy quality, and its not heating so much, when well made, as other sorts of hay in the stack, to afford a large flow of milk. It is this reason that induces the cow farmers to cut their grass so many times in the summer. Another beneficial application of this hay is, as has been seen, in the feeding of such ewes as are employed in the suckling of house-lambs during the winter season; the intention in this case is the same as in that of the preceding instance. There is another advantageous use to which this sort of produce may be applied, which is that of supporting young calves, and all sorts of young cattle that are kept as store stock." And that, "where sheep require the support of hay in the winter season, it is also well adapted to that use."

In the manner of feeding after-grass, there is

also much variety in different districts. "It has," the same author says, "been observed by a farmer in Middlesex, that the condition on which he rents his farm is that of taking out the cattle at Michaelmas, but that sheep remain till February." In that county the practice is to turn on the cattle immediately after mowing; but in the northern districts, this grass, to which they have given the name of *eddish*, is kept till November, or even a later period, for the purpose of furnishing fat stock, or for the pasturage of milch cows, from which a superior quality of cheese is made, and by which time it has attained a considerable head: however, this latter practice would seem to be attended with some loss, as has been shown from its being trodden and trampled under foot. In the stocking of after-grass, Marshall found the midland graziers of opinion, that one cow to an acre, on well-grown after-grass, was an ample stock. Good grass-land may, however, admit something more; and instead of pasturing of rowen, or after-grass, by heavy cattle in the autumn, to avoid poaching the ground, particularly at a late period in that or the winter season, it has been recommended by Dr. Wilkinson, "to confine the consumption of this grass principally to the support of sheep, unless in very favourable seasons, or where the soil is uncommonly dry; in which cases milch cows, or other heavy cattle, may be admitted without inconvenience."

In some places it is the practice, as "where there is a great scarcity of spring feed, to reserve after-grass in the autumn for spring use." Some, on the basis of experience, contend that it is the most certain, and, on the whole, the best spring feed yet known. It would seem, however, as has been shown, to be a wasteful practice, at least in respect to the more forward after-grasses. The forwardest ought certainly to be eaten without waste before winter sets in; and the latest, that is, the shortest, be shut up for spring feed. Arthur Young, it is stated, found, from repeated experiments, as suggested above, "that old after-grass feeds sheep that give milk better than turnips, which are more adapted to the fattening of stock; and that this grass holds to a period, if wanted, when most other resources fail, the last half of April and the first half of May—periods always of want and difficulty, where rye-grass is not sown." Marshall also assures us, that as a certain and wholesome supply of food for ewes and lambs in the early spring, the preserved pasture is to be depended on as "the sheet anchor, in preference to turnips, cabbages, or any other species whatever, of what is termed spring feed:" and the same thing has been experienced by Dr. Wilkinson, who has observed, that "this food with him afforded a more nutritive and healthful quality of milk from the ewes to their tender lambs than turnips, even in their best state." But however useful after-grass pastures may be under this management, there is evidently a great loss of food incurred by it, especially in severe winters. (*Sinclair's Hort. Gram.*; *Lowe's Prac. Agr.*)

AGARIC OF THE OAK. [Spunk, or touch-wood.] In farriery, a substance sometimes

employed for restraining the bleeding of small vessels.

AGARICUS. See *МУШКОМ*.

AGAVE. In botany, comprehends those plants which gardeners call American aloes.

AGE OF ANIMALS. The age of a horse may be ascertained by his mouth, and the examination of his teeth, till he is eight years old, after which the usual marks commonly wear out. These are usually forty in all; of which twenty-four are double teeth, and from their office, denominated grinders, four tushes, or corner teeth, and twelve fore-teeth.

The first which appear are the foal-teeth, which generally begin to show themselves a month or two after foaling; they are twelve in number, six above and six below, and are easily distinguished from the teeth that come afterwards, by their smallness and whiteness, having some resemblance to the incisores, or fore-teeth of man.

When the colt is about two years and a half old, he commonly sheds the four middlemost of his foal-teeth, two above and two below; but sometimes none are cast till near three years old. The new teeth are readily distinguished from the foal-teeth, being much stronger, and always twice their size, and are called the nippers or gatherers, being those by which horses nip off the grass when they are feeding in the pastures, and by which, in the house, they gather their hay from the rack. When horses have got these four teeth complete, they are reckoned to be three years old.

When they are about three and a half, or in the spring before they are four years old, they cast four more of their foal-teeth, two in the upper and two in the lower jaw, one on each side the nippers or middle teeth; so that when you look into a horse's mouth, and see the two middle teeth full grown, and none of the foal-teeth, except the common teeth, remaining, you may conclude he is four that year, about April or May. Some, indeed, are later colts, but that makes little alteration in the mouth.

The tushes appear near the same time with the four last-mentioned teeth, sometimes sooner than these, and sometimes not till after a horse is full four years old; they are curved like the tushes of other animals, only in a young horse they have a sharp edge all round the top and on both sides, the inner part being somewhat grooved and flattened, so as to incline to a hollow.

When a horse's tushes do not appear for some time after the foal-teeth are cast, and the new ones come in their room, it is generally owing to the foal-teeth having been pulled out before their time, by the breeders or dealers in horses, to make a colt of three years old appear like one of four that he may be the more saleable; for when any one of the foal-teeth have been pulled out, the others soon come in their places; but the tushes having none that precede them, can never make their appearance till their proper time, which is when a horse is full four, or coming four; and therefore one of the surest marks to know a four-year old horse is by his tushes, which are then very small, and sharp on the tops and edges.

At the time when a horse comes five. •

rather in the spring before he is five, the corner teeth begin to appear, and at first but just equal with the gums, being filled with flesh in the middle. The tushes are also by this time grown to a more distinct size, though not very large: they likewise continue rough and sharp on the top and edges. But the corner teeth are now most to be remarked; they differ from the middle teeth in being more fleshy on the inside, and the gums generally look rawish upon their first shooting out, whereas the others do not appear discoloured. The middle teeth arrive at their full growth in less than three weeks, but the corner teeth grow leisurely, and are seldom much above the gums till a horse is full five; they differ also from the other fore-teeth in this, that they somewhat resemble a shell; and thence are called the shell-teeth, because they environ the flesh in the middle half-way round; and as they grow, the flesh within disappears, leaving a distinct hollowness and openness on the inside. When a horse is full five, the teeth are generally about the thickness of a crown-piece above the gums. From five to five and a half they will grow about a quarter of an inch high, or more: and when a horse is full six, they will be near half an inch, and in some large horses a full half-inch above the gums.

The corner teeth in the upper jaw fall out before those in the under, so that the upper corner teeth are seen before those below; on the contrary, the tushes in the under gums came out before those in the upper.

When a horse is full six years old, the hollowness on the inside begins visibly to fill up, and that which was at first fleshy grows into a brownish spot, not unlike the eye of a dried garden-bean, and continues so till he is seven; with this difference only, that the teeth are gradually more filled up, and the marks, or spots, become fainter, and of a lighter colour. At eight, the mark in most horses is quite worn out, though some retain the vestiges of it a longer time; and those who have not had a good deal of experience may sometimes be deceived by taking a horse of nine or ten years old for one of eight. It is at this time only, when a horse is past mark, that one can easily err in knowing his age; such practices are used to make a very young horse or colt appear older than he really is, by pulling out the foal-teeth before their time, which may be discovered by feeling along the edges where the tushes grow, for they may be felt in the gums before the corner teeth are put forth; whereas, if the corner teeth come in some months before the tushes rise in the gums, we may reasonably suspect that the foal-teeth have been pulled out at three years old.

It is not necessary to mention the tricks that are used to make a false mark in a horse's mouth, by hollowing the tooth with a graver, and burning a mark with a small hot iron; because those who are acquainted with the true marks will easily discover the cheat by the size and colour of the teeth, by the roundness and jointness of the tushes, by the colour of the false mark, which is generally blacker and more impressed than the true mark, and by

other circumstances which denote the advanced age of horses.

After the horse has passed his eighth year, and sometimes at seven, nothing certain can be known by the mouth. It must, however, be remembered, that some horses have but indifferent mouths when they are young, and soon loose their mark; others have their mouths good for a long time, their teeth being white, even, and regular till they are sixteen years old and upwards, together with many other marks of freshness and vigour; but when a horse comes to be very old, it may be discovered by several indications, the constant attendants of age; such as his gums wearing away insensibly, leaving his teeth long and naked at their roots; the teeth also growing yellow, and sometimes brownish. The bars of the mouth, which in a young horse are always fleshy, and form so many distinct ridges, are in an old horse, lean, dry, and smooth, with little or no rising. The eye-pits in a young horse are generally filled up with flesh, look plump and smooth; whereas, in an old one, they are sunk and hollow, and make him look ghastly. There are also other marks which discover a horse to be very old, as gray horses turning white, and many of them being all over flea-bitten, except their joints. This, however, happens sometimes later, and sometimes sooner, according to the variety of colour and constitution. Black horses are apt to grow gray over their eyebrows, and very often

over a great part of their faces; and all horses, when very old, sink more or less in their backs; and some horses that are naturally long-backed, grow so hollow with age, that it is scarcely possible to fit them with a saddle.

The various progressive changes that take place in the appearance of the teeth of horses at different ages, from a few weeks old (marked *a* in *fig.*) to 1, 2, 3, 4, 5, 6, 7, 8, 10, 12, and 18 years, may be seen in the foregoing dental map, constructed by Mr. Blaine (*Encyc. of Rural Sports*, 273).

Age of Neat Cattle. The age of cows, oxen, and bulls, is known by the teeth and horns. At the end of about two years they shed their first fore-teeth, which are replaced by others, larger, but not so white; and before five years all the incisive teeth are renewed. These teeth are at first equal, long, and pretty white; but as the animals advance in years, they wear down, become unequal and black. When three years old, neat cattle also experience a considerable change in the structure of their horns, after which period these appendages, like the second or permanent teeth, preserve the same character. During the first year of the animal's age, two small, smooth, pointed, and neatly formed horns make their appearance attached to the head by a kind of button. This conformation continues during the first three years, after which the button moves from the head, being impelled by a horny cylinder. Thus the horns continue growing as long as the animal lives, as is indicated by the annual joints, which are easily distinguished in the horn, and by which the age of the creature may be easily known; counting three years for the point of the horn, and one for each of the joints or rings. Dishonest dealers sometimes obliterate these rings by shaving or filing the horns, in order to conceal the age of the beast.

Age of Sheep.—The age of these animals is known by their having, in their second year, two broad teeth; in their third year, four broad teeth; in their fourth year, six broad teeth; and in their fifth year, eight broad teeth before. After which, none can tell how old a sheep is while their teeth remain, except by their being worn down.

About the end of one year, rams, wethers, and all young sheep, lose the two fore-teeth of the lower jaw; and they are known to want the incisive teeth in the upper jaw. At eighteen months, the two teeth joining to the former also fall out; and at three years, being all replaced, they are even and pretty white. But as these animals advance in age, the teeth become loose, blunt, and afterwards black. The age of the ram, and all horned sheep, may also be known by their horns, which show themselves in their very first year, and often at the birth, and continue to grow a ring annually to the last period of their lives.

Age of Goats.—The age of these animals is known by the same marks as those of sheep, as, by their teeth, and the annular rings on their horns.

Age of Plants.—This, however difficult to ascertain, may be attempted in various ways, as from their general appearances and growth. The continuance of life is extremely different

in plants, and from this difference, they are generally divided into annual, biennial, and perennial.

The infancy of plants, like that of animals, is marked by the characters of weakness and tenderness; in the youthful state they acquire beauty and size, the vessels attract and convey their juices; the full growth is crowned with the robust fibre, and full exercise of all its functions; the fruit therefore ripens; but old age advancing, the vessels begin gradually to harden and lose their tone, they droop, the juices move no longer with equal celerity as in youth, the vital powers cease, and they die.

Age of Trees.—The age of some trees may be determined from the number of ligneous annuli or rings. In many sorts of trees it is, however, very difficult to distinguish these, and in others, utterly impossible. Some trees arrive to an astonishing age; thus, the cedars of Lebanon have existed for 2000 years. In England, the oak is the most durable.

Many instances of the extreme old age of trees exist in [England and elsewhere.] At Ellerslie, three miles from Paisley, at the birthplace of William Wallace, is an oak, in which, according to the tradition of the neighbourhood, that celebrated chieftain once sheltered himself with many of his followers. And many others either till lately or still abound in England; for instance, there was one at Langley Wood, near Downton (*Dodsley, An. Reg.*, 1758, p. 116), supposed to be of 1000 years' growth; then there is the oak of William Rufus, in the new Forest; the Fairlop oak of Hainault Forest; Fisher's oak on the road to Tonbridge; Hern's oak in Windsor Forest; Queen Elizabeth's oak at Heveningham, in Suffolk; the Whinfield oak, near Appleby, all of great antiquity. (*Phillip's Fruits; Withers on Planting.*)

At Ankerwyke, near Staines, is a yew tree, that has certainly been growing there since the time of King John; and at Fountain's Abbey, in Yorkshire, there are yew trees that are probably some centuries older; and the celebrated Spanish chestnut tree, growing in Lord Ducie's park, at Tortworth, in Gloucestershire, which in the reign of John was called the Great Chestnut of Tortworth, was certainly growing there in the days of William of Normandy.

At Trons, in the Grisons, there existed in 1798, a lime tree which was a celebrated plant in the year 1424, and which, when last measured, was 51 feet in circumference. The age of this specimen could not have been less than 580 years.

In the year 1776 there existed in the palace garden of Granada some famous cypresses, which were thought to have been at least 800 or 900 years old.

Some of the trees of oriental countries, however, attain to still greater ages than any of these: thus the Baobab trees of Africa, according to Adanson, are 5150 years old; and De candolle considers the deciduous cypress trees of Chapultepec in Mexico to be still older.

It would seem, that, after a certain age, all trees decrease in their rapidity of growth, a fact of some importance to be known to plant-

ers; the oak, for instance, between its fortieth and sixtieth years; the elm after its fiftieth; the spruce after its fortieth; the yew after its sixtieth: of this rate of growth, Decandolle has constructed an interesting table, showing the rate of increase in diameter of certain trees, such as the Oak, Larch, Elm, Spruce, Yew, every 10 years from 1 to 150 years.

Mr. Waistell has constructed tables respecting the growth of timber, showing every fourth year, from 12 to 100, the progressive annual increase in the growth of trees, and gradual decrease in the rate per cent. per annum, that the annual increase bears to the whole tree.

AGENTS. [In England.] Land agents, are very commonly persons of the legal profession, little conversant with the ordinary details of farming affairs. This is not always a desirable state of things—it often leads to oppression, to discord, and to very bad farming.

An agent cannot bind his principal beyond the extent of his limited authority (*Fenn v. Harrison*, 3 T. R. 575). For although a principal is bound by all the acts of his general agent, yet where he appoints an agent for a particular purpose, he is only bound to the extent of the authority given.

“Agreements for a lease, made with an agent who acts under a power of attorney, and a lease executed by such agent in pursuance of the agreement, shall bind the principal.” (*Hamillon v. Clunricarde*, 1 Bro. P. C. 341.)

AGISTMENT. A term seemingly from the the old law French word *giste*, which signifies a lying-place, and therefore, as applied to cattle, supposes pasturing. Agistment accordingly is the pasturing of cattle, the property of another, on the payment of a certain sum of money, or other valuable consideration; and the animals thus grazed are sometimes called *gistments*. “If,” says Blackstone, “a man takes in a horse or other cattle to graze and depasture in his grounds, which the law calls *agistment*, he takes them upon an implied contract to return them on demand to the owner. (*Cro. Car.* 271.) But he cannot like an innkeeper retain them till payment.” Agistment also means the profit arising from this practice. The tithe of agistment is the tenth part of the value for the keeping or depasturing such cattle as are liable to pay it; but it may be avoided by cutting the grass for stall-feeding.

AGREEMENT. A very considerable proportion of the lands of England are held by agreements between the landlord and the tenant. See LEASES.

These are best made in writing, although not absolutely necessary for terms not exceeding three years. (*Crosby v. Wordsworth*, 6 East, 602.) An agreement to make a lease is, in equity, a good lease. (*Hamillon v. Cardness*, 2 Bro. P. C. 125.) But whether an instrument shall amount to a present lease or only as an agreement for a future lease, will depend on the intention of the parties, to be collected from the instrument itself. (*Morgan v. Bissett*, 3 Taunton, 65. *Baxler v. Browne*, 2 W. Black. 973.) [See CUSTOMS OF COUNTIES.]

AGRICULTOR (Lat. a husbandman). The word in our language is modern, but is getting

into common use. It is, however, more generally written *agriculturist*, and is intended to imply one who is skilled in the art of cultivating the ground. (*Todd's Johnson*.)

AGRICULTURE, HISTORY OF (Lat. *agricultura*). The art of cultivating the ground; tillage, husbandry, as distinct from pasture. (*Todd's Johnson*.)

I shall, in the present article, limit myself to a brief historical sketch of agriculture, which became one of the sustaining arts of life as soon as man was ordained to earn his bread by the sweat of his brow. In the garden of Eden, whose fertile soil and genial clime appear to have combined in maturing a continued variety and unfailling succession of vegetable sustenance, agricultural operations were unknown; for that which came spontaneously to perfection required no assistance from human ingenuity; and where there is no deficiency there can be no inducement to strive for improvement. That period of perfection was but transitory; and the Deity that had placed man in the garden “to dress it and keep it,” eventually drove him thence “to till the earth from whence he was taken.” (*Gen.* ii. 15; iii. 23.)

From that time to the present, agriculture has been an improving art; and there is no reason to doubt but that it will go on advancing as long as mankind continues to increase.

Man, in his greatest state of ignorance, is always found dependent for subsistence upon the produce of the chase; but, as population increases, recourse must be had to other sources of food. And we find in the shepherd's life of the early ages, the first step to agricultural art, the domestication of animals, which it was found to be more convenient to have constantly at hand, rather than to have to seek precariously at the very time they were required. As the increase of population still went on, and the flocks and the herds had proportionately to be enlarged, one favourite spot would be found too small for the subsistence of the whole; and, as in the case of Abraham and Lot, they would have to separate and find pasturage in different districts. This separation into tribes could not proceed beyond a certain extent; and when the land was fully occupied, recourse would by necessity be had to means of increasing the produce of given surfaces of soil instead of enlarging their extent. With Abraham and Isaac it is very evident that wheat and the other fruits of the earth were the rare and choice things of their country; but when such nations once learned, as they might from the example of Egypt, the resource such products were in periods of famine, arising from mortalities among their cattle, they would soon pursue their interests by cultivating them. This completed, the acquirement of property in land for the space not only long occupied, but upon which the occupier had bestowed his labour, built his habitation, and had enclosed from injury by vagrant animals, would be acknowledged to be his without any one stopping to inquire what right he had to make the enclosure.

When once thus located, experience and observation would soon teach the employment

of manures, irrigation, times of sowing, and other necessary operations; and every generation would be wiser in the art than that which preceded it. This especially has occurred in these more northern climates, where art and industry has to compensate for a deficiency of natural advantages. "Enlarging numbers," observes Mr. Sharon Turner, "only magnify the effect; for mankind seem to thrive and civilize in proportion as they multiply; and, by a recurrent action, to multiply again in proportion as they civilize and prosper." In this manner improved modes of cultivation, the introduction of new species, and of more fruitful varieties of agricultural produce, have universally kept pace with an increasing population. This resting upon a basis of facts, vindicates the wisdom of Providence, and refutes Mr. Malthus's superficial theory of over-production. The agricultural produce of England has gradually increased from the insignificant amount that was its value in the time of the Roman invasion, to the enormous annual return of 200,000,000*l.*; and it is very certain that in this country, and much more in other parts of the world, the produce is a mere fraction of what the total soil is capable of returning.

Agriculture is the art of obtaining from the earth food for the sustenance of man and his domestic animals; and the perfection of the art is to obtain the greatest possible produce at the smallest possible expense. Upon the importance of the art, it is needless, therefore, to insist; for by it every country is enabled to support in comfort an abundant population. On this its strength as a nation depends; and by it its independence is secured. An agricultural country has within itself the necessaries and comforts of life; and, to defend these, there will never be wanting a host of patriot soldiers.

Of the pleasure attending the judicious cultivation of the soil, we have the evidence of facts. The villa farms sprinkled throughout our happy land, the establishments of Holkham, Woburn, &c., would never have been formed if the occupation connected with them was not delightful. We have an unexceptionable witness to the same fact in the late Mr. Roscoe, the elegant, talented author of the Lives of Lorenzo de Medici and of Leo the Tenth. Mr. Roscoe was the son of an extensive potato grower, near Liverpool. In the cultivation of that and other farm produce, he had been an active labourer; and he who thus had enjoyed the delights that spring from literary pursuits, and from the cultivation of the soil, has left this recorded opinion, "If I was asked whom I consider to be the happiest of the human race, I should answer, those who cultivate the earth by their own hands."

We have but little information to guide us as to the country in which man first cultivated the soil; nor of that in which he first settled after the deluge. Thus much, however, is certain, that we have the earliest authentic account of the state of agriculture as it existed among the Egyptians and their bond-servants, the Israelites. From the former, probably, the Greeks were descended. The Romans, at a

later period, were a colony from Greece; and from the Romans the other countries of Europe derived their earliest marked improvement in the arts.

Our brief history of the progress of agriculture, then, will be divided into, 1. The agriculture of the Egyptians and other eastern nations; 2. The agriculture of the Greeks; 3. The agriculture of the Romans; 4. The agriculture of the Britons, including a cursory notice of its present state among the chief nations of Europe.

I. THE AGRICULTURE OF THE EGYPTIANS, ISRAELITES, AND OTHER EARLY EASTERN NATIONS.

Every family of these primitive nations had its appointed district for pasturage, in it pursued a pastoral life; or its allotted enclosure, if it was occupied by tilling the earth. There was no distinction in this respect between the monarch and his people: each had a certain space of land from which he and his family were to derive their subsistence.

The Egyptians, as well as the Israelites, were flock-masters. The latter were particularly so; and, as Joseph's brethren said to Pharaoh, "their trade was about cattle from their youth." (*Gen.* xlvi. 34.) When, therefore, they came into Egypt, they desired the low-lying land of Goshen, as producing the most perennial of pasture. (*Gen.* lvii. 4.) It is true that the same authority says, "Every shepherd is an abomination unto the Egyptians;" but this was because, about a century before the arrival of Joseph among them, a tribe of Cushite shepherds from Arabia had conquered their nation, and held them in slavery; till, after a sanguinary contest of thirty years, they regained their liberty about twenty-seven years before Joseph was promoted by Pharaoh. That the Egyptians were flock-masters is certain, from many parts of the Scriptures. Thus, when Pharaoh gave permission to the Israelites to dwell in Goshen, he added, as he spoke to Joseph, "And if thou knowest any men of activity among them, then make them rulers over my cattle" (*Gen.* lvii. 6.); and when the murrain came into Egypt, it was upon their horses, asses, camels, oxen, and sheep. (*Exod.* ix. 3.)

The attention and care necessary to be paid to their domestic animals were evidently well known and attended to; for when they proposed to settle in a land, their first thought was to build "sheepfolds for their cattle." (*Numb.* xxxii. 16.) They had stalls for their oxen (*Hab.* iii. 17), and for all their beasts Thus King Hezekiah is said to have made "stalls for all manner of beasts, and cotes for flocks; moreover, he provided him possessions of flocks and herds in abundance" (*2 Chron.* xxxii. 28); and that this abundance exceeded the possessions of the greatest of our modern flock-masters, we may readily acknowledge, when we read that "Mesha, king of Moab, was a sheep-master, and rendered unto the king of Israel 100,000 lambs, and 100,000 rams, with the wool." (*2 Kings.* iii. 4.)

They prepared the provender for their horses and asses of chaff, or cut **stra** and

barley. (*Judges*, xix. 21; *1 Kings*, iv. 28.) Our translation does not explicitly state this, but it is clear in the Hebrew original. (*Dr. Kennicott's* xxivth Codex; *Harmer's Observations*, i. 423.) It is also certain, from the Hebrew original, that they tied up calves and bullocks for the purpose of fattening them (*Jerem.* xlvi. 21; *Amos*, vi. 4, &c., *Parkhurst's Hebrew Lexicon*, 673); and that they were acquainted with the arts of the dairy "Surely the churning of milk," says Solomon, "bringeth forth butter" (*Prov.* xxx. 31); and Samuel speaks of the "cheese of kine." (*2 Sam.* xvii. 29.) The chief vegetable products cultivated by these eastern nations were, wheat, barley, beans, lentils, rye, the olive, and the vine. (*Exod.* ix. 31; *Levit.* xix. 10; *2 Sam.* xvii. 28, &c.)

The scanty notices which we have of their tillage, give us no reason to doubt that they were skilful husbandmen. The name for tillage (*Obed*) emphatically expresses their idea of it; for it literally means to *serve the ground*. (*Parkhurst*, 508.) And that the cares and attention necessary were well sustained, is evidenced by the fact, that David, for his extensive estate, had an overseer for the storehouses in the fields; another over the tillage of the ground; a third over the vineyards; a fourth over the olive trees; two to superintend his herds; a seventh over his camels; an eighth to superintend his flocks; and a ninth to attend similarly to the asses. (*1 Chron.* xxvii. 25—31.)

Of their ploughing, we know that they turned up the soil in ridges, similarly to our own practice; for the Hebrew name of a husbandman signifies a man who does so. (*Parkhurst*, 93.) That they ploughed with two beasts of the same species attached abreast to the plough. (*Deut.* xxii. 10.) That the yoke, or collar was fastened to the neck of the animal; and that the plough, in its mode of drawing the furrows, resembled our own; for we read of their sharpening the coulter and the ploughshare. (*1 Sam.* xiii. 20, &c.) Ploughing was an operation that they were aware might be beneficially performed at all seasons; for Solomon mentions it as a symptom of a sluggard, that he will not plough in the winter (*Prov.* xx. 4); and that too much care could not be devoted to it, they expressed, by deriving their name for ploughing from a Hebrew root, which signifies *silent thought and attention*. (*Parkhurst*, 244.)

Their sowing was broadcast, from a basket (*Amos*, xi. 13; *Psalms* cxxvi. 6); and they gave the land a second superficial ploughing to cover the seed. It is true that harrowing is mentioned in our translation (*Job*, xxxix. 10); but Schultens and other Hebraists agree that harrowing was not practised by them. Russell, in remarking upon the mode of cultivation now practised near Aleppo, says, "No harrow is used, but the ground is ploughed a second time after it is sown, to cover the grain." (*Parkhurst*, 720.)

The after-cultivation apparently was not neglected; they had hoes or mattocks, which they employed for extirpating injurious plants. "On all hills," says the prophet, "that shall be dugged with the mattock, there shall not

come thither the fear of briers and thorns." (*Isa.* vii. 25.) In those hot climates a plentiful supply of moisture was necessary for a healthy vegetation; and the simile of desolation, employed by the same prophet, is "a garden that hath no water." (*Isa.* i. 30.) In Egypt they irrigated their lands; and the water thus supplied to them was raised by an hydraulic machine, worked by men in the same manner as the modern tread-wheel. To this practice Moses alludes, when he reminds the Israelites of their sowing their seed in Egypt, and watering it with their feet, a practice still pursued in Arabia. (*Deut.* xi. 10; *Niebuhr, Voyage en Arabie*, i. 121.)

When the corn was ripe, it was cut with either a sickle or a scythe (*Jer.* l. 16; *Joel*, iii. 13), was bound into sheaves (*Psalms* cxxix. 7; *Deut.* xxiv. 19, &c.), and was conveyed in carts (*Amos*, ii. 13), either immediately to the threshing-floor or to the barn. They never formed it into stacks as we do. These passages in the Scriptures (*Exod.* xxii. 6; *Judg.* xv. 5; *Job*, v. 26) refer exclusively to the thraves or shocks in which the sheaves are reared as they are cut. (*Harmer's Observ.* iv. 145, &c.) The threshing-floors, as they are at the present day, were evidently level plats of ground in the open air. (*Judg.* vi. 37; *2 Sam.* xxiv. 18—25, &c.) They were so placed that the wind might, at the time of the operation, remove the chief part of the chaff. They, perhaps, had threshing-floors under cover, to be used in inclement seasons; for Hosea (ii. 35), speaking of "the summer threshing-floors," justifies such surmise. The instruments and modes of threshing were various. They are all mentioned in these two verses of the prophet; "Fitches are not threshed with a threshing instrument, neither is a cart-wheel turned upon the cummin, but the fitches are beaten out with a staff, and the cummin with a rod. Bread-corn is bruised because he will not ever be threshing it, nor break it with the wheel of his cart, nor bruise it with his horsemen." (*Isaiah*, xxviii. 27, 28.) When the seed was threshed by horses, they were ridden by men; and when by cattle, although forbidden to be muzzled (*Deut.* xxv. 4), yet they were evidently taught to perform the labour. (*Hosea*, x. 11.) The "instrument" was a kind of sledge made of thick boards, and furnished underneath with teeth of iron. (*Isaiah*, xli. 15; *Parkhurst*, 242, 412.) The revolving wheels of a cart, and the various sized poles employed for the same purpose, need no further comment. To complete the dressing of the corn, it was passed through a sieve (*Amos*, ix. 9), and thrown up against the wind by means of a shovel. The fan was, and is still, unknown to the eastern husbandmen; and where that word is employed in our translation of the Scriptures, the original seems to intend either the wind or the shovel. (*Isaiah*, xxx. 24; *Jer.* xv. 7; *Parkhurst*, 183, 689.)

Of their knowledge of manures we know little. Wood was so scarce that they consumed the dung of their animals for fuel. (*Parkhurst*, 764.) Perhaps it was this deficiency of carbonaceous matters for their lands

that makes an attention to following so strictly enjoined. (*Levit.* xix. 23 ; xxv. 3 ; *Hosca*, x. 12, &c.)

The landed estates were large, both of the kings and of some of their subjects; for we read that Uzziah, king of Judah, "had much both in the low country and in the plains; husbandmen also, and vine-dressers in the mountains and in Carmel, for he loved husbandry" (*2 Chron.* xxvi. 10); that Elijah found Elisha with twelve yoke of oxen at plough, himself being with the twelfth yoke (*1 Kings*, xix. 19); and that Job, the greatest man of the east, had 14,000 sheep, 6000 camels, 1000 yoke of oxen, and 1000 she-asses. (*Job*, i. 3 ; xlii. 12.) In the time of Isaiah, the accumulation of landed property in the hands of a few proprietors was so much on the increase, that a curse was uttered against this engrossment. "Wo unto them," says the prophet, "that join house to house, that lay field to field, till there be no place, that they may be placed alone in the midst of the earth." (*Isaiah*, v. 8.)

II. THE AGRICULTURE OF THE GREEKS.

1. Ancient implement from a tombstone at Athens. 2. The Greek plough. 3. The spade. 4. and 5. Hoes.

Revelation has taught us to offer up our prayers and thanksgivings for all benefits to the one omni-beneficent Creator and provider of the universe. The less enlightened ancients, whose religion was mythological, equally convinced with ourselves of the existence of some divine first cause and providence, like us offered up their votive petitions and hymns of praise, though the objects of their worship were as many as the benefits or the evils to which man is subject.

Agriculture was too important and too beneficial an art not to demand, and the Greeks and Romans were nations too polished and discerning not to afford to it, a very plentiful series of presiding deities. They attributed to Ceres—as their progenitors, the Egyptians, did to Isis—the invention of the arts of tilling the soil. Ceres is said to have imparted these to Triptolemus, of Eleusis, and to have sent him as her missionary round the world to teach mankind the best modes of ploughing, sowing, and reaping. In gratitude for this, the Greeks, about 1356 years before the Christian era, established, in honour of Ceres, the Eleusinian mysteries, by far the most celebrated and enduring of all their religious ceremonies; for they were not established at Rome till the close of the fourth century. Superstition is a prolific weakness; and, consequently, by degrees, every operation of agriculture, and every period of the growth of crops, obtained its presiding and tutelary deity. The goddess, *Terra*, was the guardian of the soil; *Stercutius* pre-

sided over the manures; *Volulia* guarded the crops whilst evolving their leaves; *Flora* received the still more watchful duty of sheltering their blossom; they passed to the guardianship of *Lactantia* when swelling with milky juices; *Rubigo* protected them from blight; and they successively became the care of *Hos-tilina*, as they shot into ears; of *Matura* as they ripened; and of *Tutelina* when they were reaped. Such creations of polytheism are fables; but they are errors that should even now give rise to feelings of gratification rather than of contempt. They must please by their elegance; and much more when we reflect that it is the concurrent testimony of anterior nations, through thousands of years, that they detected and acknowledged a Great First Cause.

Unlike the arts of luxury, Agriculture has never been subject to any retrograde revolutions; being an occupation necessary for the existence of mankind in any degree of comfort, it has always continued to receive their first attention; and no succeeding age has been more imperfect, but in general more expert, in the art than that which has preceded it. The Greeks are not an exception to this rule; for their agriculture appears to have been much the same in the earliest brief notices we have of them, as it was with the nation of which they were an offset. The early Grecians, like all new nations, were divided into but two classes; landed proprietors, and *Helots*, or slaves; and the estates of the former were little larger than were sufficient to supply their respective households with necessaries. We read of princes among them; and as we dwell upon the splendid details of the Trojan war, associate with such titles, unreflectingly, all the pageantry and luxury of modern potentates, that are distinguished by similar titles. But in this we are decidedly wrong; for there was probably not a leader of the Greeks who did not, like the father of Ulysses, assist with his own hands in the farming operations. (*Homer's Odys.* l. xxiv.) Hesiod is the earliest writer who gives us any detail of the Grecian agriculture. He appears to have been the contemporary of Homer; and, in that case, to have flourished about nine centuries before the Christian era. His practical statements, however, are very meager; we have, therefore, preferred taking *Xenophon's Economics* as our text, and introducing the statements of other authors, as they may occur, to supply deficiencies or to afford illustrations.

Xenophon died at the age of ninety, 359 years before the birth of Christ. The following narrative of the Greek agriculture is from his "Essay," if not otherwise specified.

In Xenophon's time the landed proprietor no longer laboured upon his farm, but had a steward as a general superintendent, and numerous labourers, yet he always advises the master to attend to his own affairs. "My servant," he says, "leads my horse into the fields, and I walk thither for the sake of exercise in a purer air; and when arrived where my workmen are planting trees, tilling the ground, and the like, I observe how every thing is performed, and study whether any of these operations may be improved." After his ride, his

servant took his horse, and led him home, "taking with him," he adds, "to my house, such things as are wanted, and I walk home, wash my hands, and dine off whatever is prepared for me moderately." "No man," he says, "can be a farmer, till he is taught by experience; observation and instruction may do much, but practice teaches many particulars which no master would ever have thought to remark upon." "Before we commence the cultivation of the soil," he observes, that, "we should notice what crops flourish best upon it; and we may even learn from the weeds it produces, what it will best support."

"*Fallowing*, or frequent ploughing in spring or summer," he observes, "is of great advantage;" and Hesiod advises the farmer (*Works and Days*, 50) always to be provided with a spare plough, that no accident may interrupt the operation. The same author directs the ploughman to be very careful in his work. "Let him," he says, "attend to his employment, and trace the furrows carefully in straight lines, not looking around him, having his mind intent upon what he is doing." *Ibid.* 441—443.

Theophrastus evidently thought that the soil could not be ploughed and stirred about too much, or unseasonably; for the object is to let the earth feel the cold of winter and the sun of summer, to invert the soil, and render it free, light, and clear of all weeds, so that it can most easily afford nourishment. (*De Causis Plant.* lib. iii. cap. 2, 6.)

Xenophon recommends green plants to be ploughed in, and even crops to be raised for the purpose; "for such," he says, "enrich the soil as much as dung." He also recommends earth that has been long under water to be put upon land to enrich it, upon a scientific principle which we shall explain under IRRIGATION. Theophrastus, who flourished in the fourth century B. C., is still more particular upon the subject of manures. He states his conviction that a proper mixture of soils, as clay with sand, and the contrary, would produce crops as luxuriant as could be effected by the agency of manures. He describes the properties that render dungs beneficial to vegetation, and dwells upon composts. (*Hist. of Plants*, ii. cap. 8.) Xenophon recommends the stubble at reaping time to be left long, if the straw is abundant; "and this, if burned, will enrich the soil very much, or it may be cut and mixed with dung." "The time of sowing," says Xenophon, "must be regulated by the season; and it is best to allow seed enough."

Weeds were carefully eradicated from among their crops; "for, besides the hindrance they are to corn, or other profitable plants, they keep the ground from receiving the benefit of a free exposure to the sun and air." Homer describes Laertes as hoeing, when found by his son Ulysses. (*Odys.* xxiv. 226.)

Water-courses and ditches were made to drain away "the wet which is apt to do great damage to corn."

Homer describes the mode of threshing corn by the trampling of oxen (*Iliad*, xx. lin. 495, &c.) and to get the grain clear from the straw, Xenophon observes, "the men who have the care of the work take care to shake up the

straw as they see occasion, flinging into the way of the cattle's feet such corn as they observe to remain in the straw." From Theophrastus and Xenophon combined, we can also very particularly make out that the Greeks separated the grain from the chaff by throwing it with a shovel against the wind.

III. THE AGRICULTURE OF THE ROMANS.

1, 2, 3, Ploughs used by the Romans in different ages 4. The yoke for fixing the cattle. 5. The reaping hook 6. The scythe.

It is certain, that at a very early age Italy received colonies from the Pelasgi and Arcadians; and that, consequently, with them the arts of Greece were introduced; and we may conclude that there was then a similarity in the practice of agriculture in the two countries.

About 753 years before the nativity of Christ, Romulus founded the city of Rome, whose inhabitants were destined to be the conquerors and the improvers of Europe. The Roman eagle was triumphant in Egypt, Persia, Greece, Carthage, and Macedon; and the warriors who bore it on to victory, in those and other countries, being all possessors of land of a larger or smaller extent, naturally introduced, upon their return, any superior vegetable, or improved mode of culture, which they observed in those highly civilized seats of their victories.

Thus the arts of Rome arrived at a degree of superiority that was the result of the accumulated improvements of other nations; and

finally, when Rome became in turn the conquered, the victors became acquainted with this accumulated knowledge, and diffused it over the other parts of Europe.

Of the agriculture of the early Romans we know but little; but of its state during the period of their greatest prosperity and improvement, we fortunately have very full information. Cato in the second, and Varro in the first century before the Christian era, Virgil, at the period of that event, Columella and Pliny but few years subsequently, and Palladius in the second or fourth century, each wrote a work upon agriculture, which, with the exception of that by Columella, have come down to us entire.

From these various authorities we derive full information; and we are convinced that many of our readers will be surprised at the correct knowledge of the arts of cultivation possessed by that great nation.

1. *Size of the Roman Farms.*—When Romulus first partitioned the lands of the infant state among his followers, he assigned to no one more than he could cultivate. This was a space of only two acres. (*Varro*, i. 10; *Pliny*, xvii. 11.) After the kings were expelled, seven acres were allotted to each citizen. (*Pliny*, xviii. 3.) Cincinnatus, Curius Dentatus, Fabricius, Regulus, and others, distinguished as the most deserving of the Romans, had no larger estates than this. Cincinnatus, according to some authorities, possessed only four acres. (*Ibid.*; *Columella*, i. 3, &c.) On these limited spaces they dwelt, and cultivated them with their own hands. It was from the plough that Cincinnatus was summoned to be dictator (*Livy*, iii. 26); and the Samnian ambassadors found Curius Dentatus cooking his own repast of vegetables in an earthen vessel. (*Plutarch*, *in vita Cato. Cens.*)

Some of the noblest families in Rome derived their patronymic names from ancestors designated after some vegetable, in the cultivation of which they excelled, as in the examples of the Fabii, Pisones, Lentuli, Cicerones, and the like. (*Pliny*, xviii. 1.) In those days, "when they praised a good man, they called him an agriculturist and a good husbandman: he was thought to be very greatly honoured who was thus praised." (*Cato*, *in Præf.*) As the limits of the empire extended, and its wealth increased, the estates of the Roman proprietors became very greatly enlarged; and, as we shall see more particularly mentioned in our historical notices of gardening, attained to a value of 80,000*l.* (*Plutarch in vit. Marius et Lucullus.*) Such extensive proprietors let portions of their estates to other citizens, who, if they paid for them a certain rent, like our modern tenants, were called *Coloni* (*Columella*, i. 7; *Pliny*, *Epist.* x. 24) and *Politores*, or *Partiarii*, if they shared the produce in stated proportions with the proprietor. (*Pliny*, *Epist.* vii. 30, and ix. 37, &c.) Leases were occasionally granted, which appear to have been of longer duration than five years. (*Ibid.* ix. 37.)

2. *Distinction of Soils.*—Soils were characterized by six different qualities, and were described as rich or poor, free or stiff, wet or dry. (*Colum.* ii. 2.)

The best soil they thought had a blackish colour, was glutinous when wet, and friable when dry; exhaled an agreeable smell when ploughed, imbibed water readily, retaining a sufficiency, and discharging what was superfluous; not injurious to the plough irons by causing a salt rust; frequented by crows and rooks at the time of ploughing; and, when at rest, speedily covered with a rich turf. (*Virg. Georg.* ii. 203, 217, 238, 248; *Pliny*, xvii. 5.)

Vines required a light soil, and *corn* a heavy, deep, and rich one. (*Virg. Georg.* ii. 29; *Cato*, vi.)

3. *Manures.*—The dung of animals was particularly esteemed by the Romans for enriching their soil. "Study," says Cato, "to have a large dunghill." (*Cato*, v.) They assiduously collected it and stored it in covered pits, so as to check the escape of the drainage. (*Colum.* i. 6; *Pliny*, xvii. 9, and xxiv. 19.) They sowed pulverized pigeons' dung and the like over their crops, and mixed it with the surface soil by means of the sarel or hoe. (*Colum.* i. 16; *Cato*, xxxvi.) They were aware of the benefit of mixing together earth of opposite qualities (*Ibid.*), and of sowing lupines and ploughing them in while green. (*Varro*, i. 23.) They burnt the stubble upon the ground, and even collected shrubs and the like for the similar purpose of enriching the soil with their ashes. (*Virg. Georg.* i. 84; *Pliny*, xvii. 6, 25.)

Pliny also mentions that lime was employed as a fertilizer in Gaul, and marl in the same country and Britain; but we can only surmise hence that they were also probably employed by the Romans. (*Pliny*, xvii. 8, and xvii. 5.)

4. *Draining.*—The superfluous water of soils was carried off by means both of open and covered drains. (*Colum.* ii. 2, 8; *Pliny*, xvii. c.; *Virg. Georg.* i. 109.) Cato is very particular in his directions for making them. (*Cato*, xliiii. clx.)

5. *Crops.*—They cultivated wheat, spelt, barley, oats, flax, beans, pease, lupines, kidney-beans, lentils, tares, sesame, turnips, vines, olives, willows, and the like. To cite the authorities who mention each of these would be needless, for they are noticed in all the Roman writers upon agriculture. Of the relative importance or proportion in which the crops were profitable to the Romans, we have this judgment of Cato:—"If you can buy 100 acres of land in a very good situation, the vineyard is the first object if it yields much wine; in the second place, a well-watered garden; in the third, a willow plantation; in the fourth, an olive ground; in the fifth, a meadow; in the sixth, corn ground; in the seventh, an underwood, a plantation yielding stout poles for training the vine; and in the ninth, a wood where mast grows." (*Cato*, i.)

They made hay, and the process appears to have been the same as in modern times. After being cut it was turned with forks, piled into conical heaps, and finally into stacks or under cover. But the mowing was imperfectly formed; for, as soon as the hay was removed from the field, the mowers had to go over it again. (*Varro*; *Colum.* ii. 22.)

6. *Implements.*—The plough consisted of s-

veral parts : the beam to which the yoke of the oxen was fastened ; the tail or handle terminated in a cross bar, with which the ploughman guided the instrument ; it had a ploughshare, the share-beam to which it was fixed, and two mould-boards, a coulter, and a plough-staff for cleaning the ploughshare. (*Ovid. Pont. i. 8, 57 ; Virg. G. i. 170 ; Pliny, xvii. 18, 19.*) Some of their ploughs had wheels, and some were without coulters and earth-boards. Besides this, they had spades, rakes, hoes, with plain and with forked blades, harrows, mattocks, and similar implements.

7. *Operations.*—Ploughing was usually performed by two oxen, though three were sometimes employed. They were yoked abreast, and trained when young to the employment. (*Cicero, in Verr. iii. 21 ; Col. vi. 2, 10 ; Pliny, xviii. 18 ; Virg. G. iii. 163, &c.*) They were usually yoked by the neck, but sometimes by the horns. (*Pliny, viii. 45 ; Colum. ii. 2.*) There was but one man to a plough, which he guided, and managed the oxen with a goad. (*Pliny, Epist. viii. 17.*)

They sometimes ploughed in ridges, and sometimes not. They did not take a circuit when they came to the end of the field, as is our practice, but returned close to the furrow. They were very particular in drawing straight and equal sized furrows. (*Pliny, xviii. 19, s. 49.*)

They seem to have ploughed three times always before they sowed (*Varro, i. 29*) ; and to stiff soils even as many as nine ploughings were given. (*Virg. G. i. 47 ; Pliny, xviii. 20 ; Pliny, Epist. v. 6.*) The furrows in the first ploughing were usually nine inches deep. When the soil was only stirred about three inches, it was called *scarification*. (*Pliny, xviii. 17—19.*) They usually fallowed their land every other year. (*Virg. G. i. 71.*)

Sowing was performed by hand, from a basket ; and that it might be performed regularly, the hand moved with the steps. (*Colum. ii. 9 ; Pliny, xviii. 24.*) The seed was either scattered upon the land and covered by means of rakes and harrows, or more commonly by sowing it upon a plain surface, and covering by a shallow ploughing, which caused it to come up in rows, and facilitated the operation of hoeing. (*Pliny, xviii. 20.*) They were particular as to the time of sowing, the choice of seeds, and the quantity sown. (*Varro, i. 44 ; Pliny, xviii. 24, s. 55 ; Virg. G. i. 193, &c.*)

Weeding was performed by hoes, hooks, and by hand.

In dry seasons the crops were watered. (*Virg. G. i. 106.*) If they appeared too luxuriant they were fed off. (*Ibid. 193.*)

Reaping and mowing were the usual modes of cutting down the corn crops, but the ears were sometimes taken off by a toothed machine, called *batillum*, which seems to have been a wheeled cart, pushed by oxen through the corn, and catching the ears of corn between a row of teeth fixed to it, upon the principle of the modern daisy rake. In Gaul, the corn was cut down by a machine drawn by two horses. (*Varro, i. 50 ; Virg. G. i. 317 ; Colum. ii. 21 ; Pliny, xviii. 30.*) They do not seem to have ever bound their corn into sheaves. (*Colum. i.*)

Threshing was performed by the trampling of oxen and horses, by flails, and by means of sledges drawn over the corn. (*Pliny, xvii. 30 ; Colum. i. 6 ; Virg. G. iii. 132 ; Tibullus, i. 5, 22 ; Varro, i. 52.*) The threshing-floor was circular, placed near the house, on high ground, and exposed on all sides to the winds. It was highest in the centre, and paved with stones, or more usually with clay, mixed with the lees of the oil, and very carefully consolidated. (*Colum. i. 6 ; Varro, i. 2 ; Virg. G. i. 178 ; Cato, xci. and cxxix.*)

Dressing was performed by means of a seive or van, and by a shovel, with which it was thrown up and exposed to the wind. (*Varro, i. 52 ; Colum. ii. 21.*) It was finally stowed in granaries or in pits, where it would keep fifty years. (*Pliny, xviii. 30 ; Varro, i. 57.*)

8. *Animals.*—Oxen, horses, asses, mules, sheep, goats, swine, hens, pigeons, pea-fowls, pheasants, geese, ducks, swans, guinea-fowls, and bees, are mentioned by various authors as products of the Roman farms. Directions for breeding many of these are given in the third and fourth books of the *Georgics*.

Such is an outline of the Roman agriculture ; and in it our readers will doubtless find sufficient evidence to warrant them in agreeing with us, that it was but little different from that pursued by the present farmers of England. We are superior to them in our implements, and consequently in the facility of performing the operation of tillage ; we perhaps have superior varieties of corn, but we most excel them in our rotation of crops, and in the management of stock. We differ from them, also, in not practising the superstitious rites and sacrifices which accompanied almost all their operations (see *Cato, cxxxiv. c.*) ; but of the fundamental practices of agriculture, they were as fully aware as ourselves. No modern writer could lay down more correct and comprehensive axioms than *Cato* did in the following words ; and whoever strictly obeys them will never be ranked among the ignorant of the art. "What is good tillage ?" says this oldest of the Roman teachers of agriculture ; "to plough. What is the second ? to plough. The third is to manure. The other part of tillage is to sow plentifully, to choose your seed cautiously, and to remove as many weeds as possible in the season." (*Cato lxi.*)

Such is an epitome of their agricultural knowledge ; a knowledge which has since increased, and can only in future be added to by attending to this advice of another of their writers. "Nature," he observes, "has shown to us two paths which lead to a knowledge of agriculture—experience and imitation. Preceding husbandmen, by making experiments, have established many maxims ; their posterity generally imitate them ; but we ought not only to imitate others, but make experiments, not directed by chance, but by reason." (*Varro, i. 18.*)

IV. THE AGRICULTURE OF ENGLAND.

The historian of English agriculture has not the least trace of authority from which he can obtain information of its state beyond the pe

riod when the Romans invaded this island, and the annals of even that period are meager and unsatisfactory.

When Cæsar arrived in England, about 55 n. c., he describes the Cantii, or inhabitants of Kent, and the Belgæ, inhabiting the modern counties of Somerset, Wilts, and Hants, as much more advanced than the rest of the people in the habits of civilized life. They cultivated the soil; employed marl as manure; stored their corn unthreshed, and freed it from the chaff and bran only as their daily demands required. The interior inhabitants lived chiefly upon milk and flesh, being fed and clothed by the produce of their herds. "The country," adds Cæsar, "is well-peopled, and abounds in buildings resembling those of the Gauls, and they have a great abundance of cattle. They are not allowed to eat either the hen, the goose, or the hare, yet they take pleasure in breeding them." (*Cæs. v. c. 10*; *Strabo, iv. 305*; *Diodor. Sic. v. 301*; *Pliny, xvii. 4.*) Cicero, in one of his letters, says, "There is not a scruple of money in the island; nor any hopes of booty, but in slaves; (*Lib. iv. Ep. 17*); a description, that the industry and intelligence of succeeding ages has rendered singularly inapplicable. The first steps in that improvement were owing to the Romans themselves. Rutilius has elegantly and correctly said, that Rome filled the world with her legislative triumphs, and caused all to live in one common union, blending discordant nations into one country, and, by imparting a companionship in her own acquirements and laws, formed one great city of the world.

Agricola was the chief instrument in imparting to the Britons the improved arts and civilization of the Romans. "To wean them from their savage habits, Agricola held forth the baits of pleasure, encouraging the natives, as well by public assistance as by warm exhortations, to build temples, courts of justice, and commodious dwelling-houses. He bestowed encomiums on such as cheerfully obeyed; the slow and uncomplying were branded with reproach; and thus a spirit of emulation diffused itself, operating like a sense of duty. To establish a plan of education, and give the sons of the leading chiefs a tincture of letters, was part of his policy. By way of encouragement he praised their talents, and already saw them, by the force of their natural genius, rising superior to the attainments of the Gauls. The consequence was, that they who had always disdained the Roman language began to cultivate its beauties. The Roman apparel was seen without prejudice, and the toga became a fashionable part of dress. By degrees, the charms of vice gained admission to their hearts; baths, porticos, and elegant banquets grew into vogue; and the new manners, which in fact served only to sweeten slavery, were by the unsuspecting Britons called the arts of polished humanity." (*Tacitus, Agricola, xxi.*) Thus eloquently does Tacitus describe the diffusion of the Roman arts among the early natives of England; and that agriculture was one of those in which they so rapidly improved, is attested by the fact that in the fourth century the Emperor Julian, having erected here gra-

naries in which to store the tributary corn that he exacted from the natives, at one time sent a fleet of 600 large vessels to convey away the store they contained. Julian himself particularizes the transaction. "If," says Gibbon. "we compute those vessels at only seventy tons each, they were capable of exporting 120,000 quarters; and the country which could bear so large an exportation must have attained an improved state of agriculture." (*Dec. and Fall of Rom. Emp. c. xix.*)

Possessing this improved agriculture, England was successively subdued by the Saxons, the Danes, and the Normans; but as these all came to improve their fortunes, and to win the comforts of life, agriculture continued to flourish: her operations were interrupted, her products destroyed, in whichever direction swept the tide of war; but no sooner was peace restored than the inhabitants, though of varied extraction, united their knowledge in the pursuit of this art, on which not only their comfort, but their existence chiefly depended. A similar summary observation applies to all succeeding ages; and our agriculture has continued slowly to improve in spite of every obstacle that has occasionally delayed, or that has permanently retarded its advance.

1. *Tenures—Size of Estates.*—The native Britons, it is very certain, appropriated but small portions of the land for raising corn, or other cultivated vegetables, and the rest of the country was left entirely open, affording a common pasturage for their cattle, and *pannage* for their swine. Under the Roman government, we have seen that the extent of cultivated ground must have considerably increased, yet the oldest writers agree, that by far the greatest proportion of the country was occupied by heaths, woods, and other unclaimed wastes.

When the Saxons established themselves in the island, an almost total revolution in the proprietorship of the lands must have occurred. The conquest was only accomplished after a bloody struggle; and what was won by the sword was considered to possess an equitable title, that the sword alone could disturb. In those days it was considered that the lands of a country all belonged to the king; and on this principle the Saxon monarchs gave to their followers whatever districts they pleased, as rewards for the assistance afforded in the conquest, reserving to themselves certain portions, and imposing certain burdens upon each estate granted. (*Coke's Littleton, l. 58. 2*; *Blackstone's Comm. 45, &c.*) This was only a continuance of that feudal system that prevailed upon the Continent.

As this feudal system declined, and was finally extinguished in the twelfth year of Charles II., so proportionally did the landed interest increase in prosperity. Freed from the burden of furnishing a soldier and his armour for every certain number of acres, and all restrictions as to lands changing hands being removed, and the numerous impositions being got rid off, with which the lords oppressed their sub-tenants, it soon became a marketable species of property; and, as money and merchandise increased, and the

proprietor lived less upon his estate, it soon became the most eligible plan for both landlord and tenant, that the whole rent should be paid in money.

Of the size of these early farms we have no precise information; but, from the laws of Ina we may perhaps conclude that a hide of land, equal to about 100 or 120 acres, was the customary size; for, in speaking of the produce to be given to the lord for ten hides, the law speaks of the smallest division of each county of which it was particularly cognisant; namely, of ten families, or a *tithing*, as they were collectively called. Again, Bede expressly calls a hide of land *familia*, and says it was sufficient to support a family. It was otherwise called *mansum*, or *manerium*, and was considered to be so much as one could cultivate in a year.

War succeeded war, and chivalry and the chase were the engrossing occupations of the landed proprietors during the whole of the middle ages; yet amid all these convulsions, and all this neglect, agriculture continued to obtain a similar degree of attention, and its practitioners to occupy a similarly humble, yet more independent station of life. Bishop Latimer flourished in the first half of the sixteenth century; and his father was among the most respectable yeomen of his time, yet his farm evidently did not exceed 100 acres. "My father," says Latimer, "was a yeoman, and had no lands of his own; he had only a farm of three or four pounds by the year, at the utmost; and hereupon he tilled as much as kept half a dozen men. He had a walk for 100 sheep; and my mother milked thirty kine," &c. (*Latimer's Sermons*, p. 30.) But that this class of society was then not very refined, is proved by Sir A. Fitzherbert, in his *Book of Husbandry*, declaring, "It is the wife's occupation to winnow all manner of corn, to make malt, to wash and wring, to make hay, to shear corn, and in time of need to help her husband to fill the muckwain, or dung-cart; to drive the plough, to load corn, hay, and such other; and to go or ride to the market; to sell butter, cheese, milk, eggs, chickens, capons, hens, pigs, geese, and all manner of corn."

This race of farmers, and this extent of farm, continued much the same till the closing years of the eighteenth century. The wife, indeed, had long previously ceased to participate in the above-mentioned drudgery, but she still attended the dairy, and sold its products at market, as her husband still participated in the usual labours of his farm; but in the latter half of that century, and thence to the present time, a different class of men have engaged in the cultivation of the soil. The accumulation of wealth from the vast increase and improvement of manufactures and commerce, the diffusion of better information, and the increased population, have all contributed to this effect. Individuals engage in the pursuit whose education and habits require a larger income for their indulgence than can be afforded by the profits of a small farm; and, consequently, in districts having the most fertile soils, farms of from 300 to 500 acres are very common; whilst in less productive dis-

tricts they extend even to 1000 and 2000 acres. With the present expenditure of rent, tithe, taxes, rates, and labour, and the reduced prices of agricultural produce, farms, even of those extents, cannot yield a profit sufficient to support the farmer of refined habits. And if the present artificial system of corn laws is removed, we do not see any possible result but a return to smaller farms, and a more labouring class of tenants; for it admits of perfect demonstration, that small farms, having that manual labour, and that careful tillage which small plots obtain, return a more abundant produce than those which are too large to be so attentively cultivated.

Enclosure of Land.—It is a rule, founded upon general observation, that the most enclosed country is always the best cultivated: for, as Sir Anthony Fitzherbert observed, in the reign of Henry VIII., live stock may be better kept, and with less attendance, closes be better alternately cropped, and the crops better sheltered in inclement seasons, "if an acre of land," he concludes, "be worth sixpence an acre before it is enclosed."

We have seen, already, that hedges, ditches, and other fences, marked the boundaries of the early Saxon estates; and these were certainly not adventitious distinctions, for they are mentioned in most of the Saxon grants of which we are aware, and are strictly regulated and protected by law. If a tenant omitted to keep his farm enclosed, both in winter and summer, and to keep his gate closed, if any damage arose from his hedge being broken down, or his gate being open, he was declared to be legally punishable. (*Wilkins, Leges Sax.* 21.) If a freeman broke through another's hedge he was fined 6s. (*Ibid.*)

As woollen manufactures improved, the demand for broad cloths became excessive, not only in England but in the continental nations; and the consequent consumption of wool was so large, and the price was so enhanced, that self-interest dictated to the landed proprietors, even in the reign of Henry III., that the enclosure of their manorial wastes, on which to feed sheep upon their own account, or to let out as pasture farms, would be a source of extensive emolument. The statutes of 20 Hen. 3, 13 Edw. 1, and others, were consequently passed for sanctioning and regulating the practice. The demand for woollens continued, and became so great, that rapidity of manufacture was the chief consideration. "Yet as ill as they be made," says King Edward VI., in his private journal, "the Flemings do at this time desire them wonderfully." The consequences are depicted by the same genuine authority. "The artificer will leave the town, and for his mere pastime will live in the country; yea, more than that, will be a justice of the peace, and will scorn to have it denied him, so lordly be they now-a-days; for they are not content with 2000 sheep, but they must have 20,000, or else they think themselves not well. They must have twenty miles square their own land, or full of their farms: four or five crafts to live by is too little. Such hell-hounds be they." (*Edward the Sixth's Remains*, p. 101.) The rents of land were consequently enormously

raised, and the corn farmers were ruined. "They everywhere," says Roger Ascham, "labour, economize, and consume themselves to satisfy their owners. Hence so many families dispersed, so many houses ruined, so many tables common to every one, taken away. Hence the honour and strength of England, the noble yeomanry, are broken up and destroyed." (*Ascham's Epistles*, 293—295.) Bishops Story, Latimer, and others, raised their voices in their behalf, and hurled their invectives from the pulpit upon those who oppressed them. "Let them," said Latimer, in a sermon preached before the king, "let them have sufficient to maintain them, and to find them in necessaries. A plough land must have sheep to dung their ground for bearing corn; they must have swine for their food, to make their bacon of; their bacon is their venison, it is their necessary food to feed on, which they may not lack; they must have other cattle, as horses to draw their plough, and for carriage of things to the markets, and kine for their milk and cheese, which they must live upon, and pay their rents."

The short-sighted executive of that period endeavoured to prevent these enclosures by a prohibitory proclamation, as the legislature had done by the statutes 4 Hen. 7, c. 16, 19. There doubtless was great distress, and always will be upon any sudden change in the direction of the national industry, and in none more extensively than in the return from an agricultural to a pastoral mode of life. But, as is observed by one of the most impartial of our historians, "every one has a legal and social right of employing his property as he pleases; and how far he will make his use of it compatible with the comforts of others, must be always a matter of his private consideration, with which no one, without infringing the common freedom of all, can ever interfere. That no national detriment resulted from this extensive enclosure—no diminution of the riches, food, and prosperity of the country at large, is clear to every one who surveys the general state and progress of England with a comprehensive impartiality." (*Turner's History of Edward the Sixth, &c.*) "The landlord," he further observes, "advanced his rent, but the farmer also was demanding more for his produce."

The evil of converting arable to pasture land cured itself. The increased growth of wool in other countries, and the improvement of their manufactures, by degrees caused the production of it in England to diminish: and as dearths of corn accrued, and the consequent enormous increase of its value rendered its growth more lucrative, pasture-land gradually returned to the dominion of the plough.

Since that period enclosures have gone on with various, but certainly undiminished, degrees of activity. More than 3000 enclosure bills were passed in the reign of George III. The land so enclosed was, and is, chiefly dedicated to the growth of corn; but since the field culture of turnips was introduced in the seventeenth, of mangrel wurzel in the nineteenth century, and other improvements in agricultural practice, every farm is enabled to combine

the advantages of the stock and tillage husbandry.

Implements.—It is very certain that the state of any art is intimately connected with that of its instruments. If these are imperfect it cannot be much advanced; and this is so universally the case, that agriculture, of course, is no exception.

1. Norman plough, with the hatchet carried by the ploughman for breaking the clods. 2. Sowing, as represented by Strutt. 3. Reaping. 4. Threshing. 5. Whetting. 6. Beating hemp.

We find, in the earliest of our national records, that the *plough*, the most important implement of husbandmen, was then of a very rude construction. In general form it rudely resembled the plough now employed, but the workmanship was singularly imperfect. This is no matter of surprise; for among the early inhabitants of this country there were no artificers. The ploughman was also the ploughwright. It was a law of the early Britons that no one should guide a plough until he could make one; and that the driver should make the traces, by which it was drawn, of withs or twisted willow, a circumstance which affords an interpretation to many corrupt terms at present used by farming men to distinguish the parts of the cart harness. Thus the *womb withy* has degenerated into *wambtye* or *wantye*; *withen trees* into *whipping* or *whipple trees*; besides which we have the *tail withes*, and some others still uncorrupted. (*Leges Wollicæ*, 283—288.) We read, also, that Easterwin, Abbot of Wearmouth, not only guided the plough and winnowed the corn grown on the abbey lands, but also with his hammer forged the instruments of husbandry upon the anvil. (*Bede, Hist. Abb. Wearmoth*, 296.) Whether the early British or Saxon ploughs had wheels is uncertain, but those of the Normans certainly had such appendages. Pliny says that wheels were first applied to ploughs by the Gauls

The Britons were forbidden to plough with any other animal than the ox; and they attached any requisite number of oxen to the plough. The Normans had been accustomed, in their light soils, to employ only one, or at most two. (*Leges Wallicæ*, 288; *Montfaucon's Monumens de Monarchie François I. Planche*, 47; *Giraldus Cambrensis*, c. 17.)

The gigantic and universal impulse that seemed simultaneously to affect the human mind in the sixteenth century, tended to the improvement of sciences which could not be benefitted without agriculture sharing in the good. Metallurgy and its subservient arts, and applied mathematics, were thus assistant to improving the plough. It received the first improvement among the Dutch and Flemings in the sixteenth century; and still more so in Scotland in the following one.

The common wooden swing-plough is the state to which it was brought in the last-named country, in the eighteenth century, and still is known in many countries, as the *improved Scotch plough*. The first author of the improved form is differently stated. A man of the name of Lummis has by one writer this credit assigned to him, though he learned the improvement in Holland. He obtained a patent for his form of construction; but another ploughman, named Pashley, living at Kirkleatham, pirated his invention. The son of Lummis established a manufactory at Rotherham in Yorkshire, whence it is sometimes called the *Rotherham plough*; but in Scotland it was known as the *Dutch or Patent Plough*. On the other hand, the Rotherham plough is said to have been made at that town in 1720, or ten years before Lummis's improvements. The grandmother of the Earl Buchan, Lady Stewart of Goodtrees, near Edinburgh, is also named as an improver. She invented the *Rutherglen plough*, formerly much employed in the west of Scotland. Mr. Small, in 1784, and Mr. Bailey, in 1795, published upon the proper mathematical form of this implement. In the fourth volume of the *Transactions of the Highland Society*, and in the *Quarterly Journal of Agriculture* for February, 1829, there are also two valuable Essays upon the same subject. In 1811 this plough came very generally to be made of cast iron. (*Amos's Essay on Agricultural Machines, Survey of W. Riding of Yorkshire, &c.*)

Wheel ploughs have been commensurately improved. The objects to be attended to in the formation of a plough, and that is the best which attains to them most effectually, are, first, that it shall enter and pass through the soil with the least possible resistance; secondly, that the furrow-slice be accurately turned over; and, thirdly, that the moving power or team shall be placed in the most beneficial line of draught.

Scarifiers and horse hoes are implements which were unknown till within about a century ago. Hoeing by manual labour had, in very early ages, been partially practised; for the earliest writers, we have seen, recommended particular attention to the cutting down and destroying of weeds. But to Jethro Tull, is indisputably due the honour of having first demonstrated the importance of frequent

hoeing, not merely to extirpate weeds, but for the purpose of pulverizing the soil, by which process the gases and moisture of the atmosphere are enabled more freely to penetrate to the roots of the crop. The works of Tull appeared between the years 1731 and 1739.

Drills.—We noticed, when considering the Roman agriculture, that the Romans endeavoured to attain the advantages incident to row-culture by ploughing in their seeds. A rude machine is described in the *Transactions of the Board of Agriculture*, as having been used immemorially in India for sowing in rows. The first drill for this purpose introduced into Europe seems to have been the invention of a German, who made it known to the Spanish court in 1647. (*Harte's Essays on Husbandry.*) It was first brought much into notice in this country by Tull, in 1731; but the practice did not come into any thing like general adoption till the commencement of the present century. There are now several improved machines adapted to the sowing of corn, beans, and turnips. See *DRILLS*.

Draining, as we have seen, was attended to by the Romans, and it was unquestionably practised in Britain during the middle ages; for where lands were too retentive of moisture, or abounded in springs, the obvious remedy was to remove it by drains. This, however, and far simpler operations, are seldom performed in the most correct mode without a knowledge of the sciences connected with their success. Draining was never correctly understood till the scientific observations of Dr. Anderson, and the practical details of Mr. Elkington, about the year 1761, placed it upon a more enlightened and correct system. The important benefits that have arisen from the adoption of this system are very extensive; and the acknowledgment of 1000*l.*, voted to Mr. Elkington, was a just testimony that the landed interest appreciated the boon, and that the benefiter of this country is duly estimated by its legislature.

There are numerous kinds of drain ploughs. The *mole plough* was invented by a Mr. Adam Scott, and improved by a Mr. Lumley of Gloucestershire during the present century.

The past and the present century have also given birth to machines totally unknown in previous ages; of these are rollers, machines for haymaking, reaping, threshing, and dressing; and if to these be added the immense improvement that has taken place in the form and quality of all other agricultural implements, the saving of labour, and the power to pursue the necessary operations neatly and well, will be found to be incalculably promoted.

Crops.—It is probable that wheat was not cultivated by the early Britons; for the climate, owing to the immense preponderance of woods and undrained soil, was so severe and wet, that in winter they could attempt no agricultural employments; and even when Bede wrote, early in the eighth century, the Anglo-Saxons sowed their wheat in spring. (*Bede's Works*, p. 244.) The quantity cultivated in the reign of Henry III. does not appear to have exceeded the quantity necessary for the year's

consumption; for in a very wet, inclement year, 1270, wheat sold for six pounds eight shillings per quarter, which, calculating for the difference of the value of money, was equal to twenty-five pounds of our present currency. It continued an article of comparative luxury till nearly the 17th century commenced; for in the household books of several noble families it is mentioned that *manchets*, and other loaves of wheat flour, were served at the master's table, but there is only notice taken of coarser kinds for the servants. That the cultivation of wheat was very partial in the reign of Elizabeth is attested by Tusser, who, writing at that period, says,—

"In Suffolk again, whereas wheat never grew,
Good husbandry used, good wheat-land I knew."

As the climate has improved by the clearing and drying of the surface of the country, so proportionally, has the cultivation of wheat extended.

It was probably owing to the fickle and inclement climate of England rendering the successful completion of harvest a much rarer and more hazardous event than now, that our forefathers made on the occasion such marked and joyous festivities. We do not know the motive that actuated the farmer, but no dread of an uncertain harvest could have made him more prompt and vigorous, who, in 1289, cut and stored 200 acres of corn in two days. The account is given in "The History of Hawstead." About 250 reapers, thatchers, and others, were employed during one day, and more than 200 the next. The expenses of the lord on this occasion are thus stated:—Nineteen reapers, hired for a day at their own board, 4*d.* each; eighty men one day, and kept at the lady's board, 4*d.* each; 140 men, hired for one day, at 3*d.* each; wages of the head reaper, 6*s.* 8*d.*; of the brewer, 3*s.* 4*d.*; of the cook, 3*s.* 4*d.*; thirty acres of oats, tied up by the job, 1*s.* 8*d.*; three acres of wheat, cut and tied up by the job, 1*s.* 11*d.*; five pair of gloves," &c.

Barley is probably the grain which was most cultivated by the early Britons. The representation of it occurs upon their coins. (*Camden's Britannia*, by Gibson, lxxxviii.) It was not only the grain from which their progenitors, the Cymri, made their bread, but from which they made their favourite beverage, *beer*.

Oats being well-known and cultivated by the Germans and other continental nations when Pliny wrote, they were probably known also to this island in the earliest ages. In all periods, even to the present time, bread made of oatmeal has been a very prominent part of the food of the inhabitants of the northern parts of Britain. "In Lancashire," says Gerarde, in 1597, "it is their chiefest bread-corn, for jamrocks, haver-cakes, thorffe-cakes, and those which are called generally oaten-cakes; and for the most part they call the grain *haver*, whereof they do likewise make drink for want of barley." It is so hardy that it is admirably calculated for a cold climate, and there is scarcely any soil in which it will not be productive. In southern climates it will not flourish.

"Rye," says Gerarde, groweth very plentifully in the most parts of Germany and Polonia, as appeareth by the great quantity brought into England in times of scarcity of corn, as happened in the year 1596; and at other times, when there was a general want of bread-corn, by reason of the abundance of rain that fell the year before, whereby great penury ensued, as well of cattle, and all other victuals, as of all manner of grain. It groweth, likewise, very well in most places of England, especially towards the north."

Its hardiness probably rendered it a principal grain with the early Britons; but as it is a great impoverisher of the soil upon which it grows, and the grain makes very inferior bread, it is now cultivated to a very small extent.

Peas have been extensively cultivated in England from a very early period; but they have been much less since the bean has become a more general field crop, which it did not till within the present century. Lentils were brought to England about 1548. Gerarde says he had heard they were cultivated as fodder near Waterford. Maize, or Indian corn, was made known in England in 1562. It is commonly cultivated in the south of France as a field crop, and for the same purpose was tried in England in 1828, at the recommendation of Mr. Cobbett, but it has not succeeded. Tares, in 1566, according to Ray, were grown as a seed crop, and given to horses, mixed with oats and peas, though they were sometimes cut green as fodder. This is now their chief use.

Potatoes were introduced from South America, by Sir Walter Raleigh, about 1586. Sir Robert Southwell, President of the Royal Society, informed the Fellows, in 1693, that his father introduced them into Ireland, having received them from Sir Walter. (*MS. Journal of Royal Society*.) It long continued to be neglected by gardeners. In 1663, however, attention was drawn to its extensive culture. But notwithstanding the exertions of the Royal Society to effect this purpose, potatoes did not become a field crop till the early part of the last century. They became so in Scotland about 1730, a day-labourer of the name of Prentice having the honour of first cultivating them largely two years previously. Every county of England now grows them extensively. Lancashire and Cheshire are particularly celebrated for them. In the counties round London, especially in Essex, about two thousand acres are annually cultivated for supplying the metropolis with this root.

Turnips and clover, though known in England during time immemorial, were never much cultivated in the field before the early part of the seventeenth century, and we mention them together, because their introduction among the farmer's crops caused the greatest improvement in the art that it ever received. In 1684, it is observed as a modern discovery, "sheep fatten very well on turnips, these proving an excellent nourishment for them in hard winters, when fodder is scarce; for they will not only eat the greens, but feed on the roots in the ground, scooping them out even

to the very skin." This is the first notice we have of feeding off turnips; and the same authority adds, "ten acres sown with clover, turnips, &c., will feed as many sheep as one hundred acres would have done before." (*Houghton's Collections on Husbandry, &c.*, iv. 142—144.) Brown, Donaldson, and all other writers upon agriculture, agree, that the introduction of the improved mode of cultivating these crops revolutionized the art of husbandry. Previously, light soils could not be cropped with advantage; there was no rotation that the judgment could approve. Tusser, in the sixteenth century, in the following homely lines, tells us that two corn crops were grown consecutively and then a fallow; and many authorities could be quoted to show that some soils were fallowed on alternate years, so that they afforded only one crop in two years.

"First rie and then barlie, the champion saies,
Or wheat before barlie, be champion waies:
But drink before bread-corn, with Middlesex men,
Then laie on more compas, and fallow agen."

But now, by the aid of green crops, a fallow usually occurs but once in four years. "Clover and turnips," it has been observed, "are the two main pillars of the best courses of British husbandry; they have contributed more to preserve and augment the fertility of the soil for producing grain, to enlarge and improve breeds of cattle and sheep, and to afford a regular supply of butcher's meat all the year, than any other crops." It was previously a difficult task to support live stock through the winter and spring months; and as for feeding and preparing cattle and sheep for market during these inclement seasons, the practice was hardly thought of, and still more rarely attempted.

Mangel wurzel has only been cultivated by the farmer for a few years past. Its chief advantage is, that as it will succeed upon tenacious soils which will not produce turnips, it enables farms in which such soils predominate to support a larger quantity of live stock. Its cultivation seems on the increase, its fattening qualities being good, the produce heavy, and liability to failure small.

Hops, although indigenous to England, were little attended to, and never employed in brewing till the sixteenth century; and then, when they began to be more used, the citizens of London petitioned parliament to prevent them as a nuisance. "It is not many years since," says Walter Blith, writing in the year 1653, "the famous city of London petitioned against two nuisances, and these were Newcastle coals, in regard of their stench, &c., and hops, in regard they would spoil the taste of drink and endanger the people." (*English Improver Improved*, 3d ed. 240.)

There are many other crops occasionally cultivated by the farmer which may be enumerated here, and most of them first extensively cultivated within the last 150 years, but which in this place will require no further notice—such as the artificial grasses, rape, mustard, caraway, coriander, flax, hemp, buckwheat or brank, teasel, madder, saintfoin, lucerne, cabbage, carrots, and others.

General cultivation.—We have no informa-

tion as to whether the early inhabitants of Britain varied their modes of ploughing with the nature of their soil. They sometimes ploughed with two oxen, sometimes with more; some ploughmen, represented in very old pictures, evidently drove the team as well as guided the plough; but it was usual for them to have a driver. There is a very old Saxon dialogue extant, in which a ploughman, in stating his duties, says, "I go out at day-break, urging the oxen to the field, and I yoke them to the plough—the oxen being yoked, and the share and coulter fastened on, I ought to plough one entire field or more. I have a boy to threaten the oxen with a goad, who is now hoarse through cold and bawling. I ought, also, to fill the bins of the oxen with hay, and water them, and carry out their soil." (*Turner's Anglo-Saxons*, ii. 546, ed. 5.) Repeated ploughings and fallowings, to prepare the soil for wheat, was the common practice; for Giraldus Cambrensis, speaking of the Welsh, says, with astonishment, "they ploughed their lands only once a year, in March or April, in order to sow them with oats; but did not, like other farmers, plough them twice in summer and once in winter, to prepare them for wheat." (*Descript. Cambrix*, c. viii.)

In a law tract, called *Fleta*, and written early in the fourteenth century, are given several agricultural directions, especially upon dressing and ploughing fallows. In summer, the ploughing is advised to be only so deep as to bury and kill the weeds; and the manure not to be applied till just before the last ploughing, which is to be deep. (*Fleta*, lib. ii. c. 73.)

Sowing was anciently performed in all cases by hand. In the famous antique tapestry of Bayeux, a man is represented sowing. The seed is contained in a cloth fastened round his neck, is supported at the other extremity by his left arm, and he scatters the seed with his right hand.

All agricultural writers, from the earliest era to the present, have recommended the seed to be soaked in some medicament or other previously to sowing. Virgil recommends oil and nitre for beans; others direct the employment of urine; and Heresbachius, who wrote in 1570, mentions the juice of the houseleek. "Sow your ridges," says the same author, "with an equal hand, and all alike in every place, letting your right foot, especially, and your hand go together. Wheat, rye, barley, oats, and other large seeds must be sown with a full hand, but rape seeds only with three fingers." (*Googe's Heresbachius*, 246.)

The tapestry of Bayeux, already mentioned, represents a man harrowing; one harrow only being employed, and one horse. In the time of Heresbachius, though harrowing was the usual mode of covering the seed, yet he says, "in some places it is done with a board tied to the plough." Rakes seem to have been employed by the Anglo-Saxons; for the accurate researches of Mr. Turner do not appear to have discovered any mention of other implements that were employed by them for the purpose. (*Hist. Anglo-Sax.* ii. 544.)

We find no very early mention made of hoeing by any English agricultural writer.

Though there is generally some directions for "plucking up the naughty weeds." Heresbachius is the first that we have met with who notices the advantage of loosening the surface of the soil about growing crops. "Sometimes," he says, "raking is needful, which, in the spring, loosens the earth made clung by the cold of winter, and letteth in the fresh warmth. It is best to rake wheat, barley, and beans twice. Moreover, they break asunder with a roller the larger and stiffer clods." (*Googe's Heresbachius*, [printed in 1578,] 256.) It was not till the time of Tull, 1731, that the due importance of this was appreciated.

Of the other operations of agriculture, as reaping, mowing, stacking, and the like, there seems no need of making mention: they were performed much in the same way as now. "Corn," says the author last quoted, "should be cut before it is thorough hard; experience teacheth that if it be cut down in due time, the seed will grow to fulness as it lieth in the barn." (*Googe's Heresbachius*, 406.) According to Henry, the practice with our ancestors was for the women to thresh and the men to reap. (*Hist. of Britain*, vi. 173.)

Irrigation seems to have been practised in a few places in Britain from the time of the Romans, there being meadows near Salisbury which have been irrigated from time immemorial. Lord Bacon mentions it as a practice well understood in his time (1560—1626); and at the same period, 1610, appeared a work by Robert Vaughan, detailing the mode of "summer and winter drowning of meadows and pastures, thereby to make those grounds more fertile ten for one." It was not, however, till the close of the last century that the attention of agriculturists was much aroused to the subject. The writings of Boswell, Wright, Western, and others, between the years 1780 and 1824, partially awakened the farmers to the importance of the practice. The best examples of it are to be observed in Gloucestershire and Wiltshire; but it is now one of the practices of farming that is the most undeservedly neglected. Mr. Welladviser was its great promoter in Gloucestershire.

Live Stock.—Cattle and sheep were the chief riches of the Britons when they became first known to the Romans (*Cæsar*, v. c. x.), and they are still a great source of our agricultural riches.

Sheep.—In a very early Anglo-Saxon MS. a shepherd is represented as saying, "In the first part of the morning I drive my sheep to their pasture, and stand over them in heat and in cold with dogs, lest the wolves destroy them. I lead them back to their folds, and milk them twice a day; and I move their folds and make cheese and butter." (*Turner's Anglo-Sax.* ii. 546.)

This attention to sheep was attended with so much success that they became an object of acquirement by the continental nations; and in the reign of Edward IV. at the time a treaty of peace was concluded with Spain (1466), a license was granted by that monarch "for certain Coteswold sheep to be transported to Spain, as people report, which have there so multiplied and increased, that it hath turned

the commodity of England much to the Spanish profit, and to the no small hinderance of the gain which was beforetimes in England raised of them." (*Hall's Chronicle*, 266. *Holinshed*, 668.) The sheep thus exported were probably improved by attention and climate till they had become that breed of Merinos which was re-imported to this country early in the present century. The statute 3 H. 6, c. 2, forbids the exportation of sheep. The fears which old chroniclers may have ignorantly entertained, that the exporting of sheep would be injurious to our native commerce, have in all succeeding years been proved to be fallacious. The demand for our wool was so large, and the consequent increase of the breed of sheep was so great, that an impolitic legislature in 1533 endeavoured to check it. The preamble of the act states, that "divers of the king's subjects, to whom God of his goodness hath disposed great plenty and abundance of moveable substance, now of late, within few years, have daily studied, invented, and practised ways and means to accumulate into few hands, as well great multitudes of farms as great plenty of cattle, and in especial sheep, putting such lands as they can get to pasture and not to tillage, whereby they have not only pulled down churches and towns, and enhanced the old rates of the rents, and that no poor man is able to meddle with it, but also have raised the prices of all manner of corn, cattle, &c., almost double above the prices accustomed, to the great injury, &c., of his majesty's subjects; and as it is thought that the greatest occasion of this accumulation is the profit that cometh of sheep, which now be come to a few persons' hands of this realm, that some have 24,000, some 20,000, &c., by which a good sheep for victual, that was accustomed to be sold for 2s. 4d., &c., is now sold for 6s., &c.; which things thus used be principally to the high displeasure of Almighty God, to the decay of the hospitality of this realm, to the diminishing of the king's people, and to the let of cloth-making," &c. It then enacts, that no one shall have more than 2000 sheep; though, as a subsequent section declares every hundred to consist of six score, the limited number was 2400. And it further enacts, that no man shall have above two farms. (25 H. 8, c. 13.)

Harrison, who died in 1593, describes our sheep as very excellent, "sith for sweetness of flesh they pass all other. And so much are our wools to be preferred before those of Milesia and other places, that if Jason had known the value of them that are bred and to be had in Britain, he would never have gone to Colchis to look for any there." (*Description of England, prefixed to Holinshed*, 220.) Heresbach, who was a contemporary, gives such a description of the best form and qualities of sheep, that it is evident that the excellence of the breed was not the mere effect of chance. (*Googe's Heresbach*, 1376.) From that period till the latter half of the eighteenth century, we are not acquainted with any efforts further to improve it. This last-mentioned period was the era of the improvements effected by Mr. Bakewell and his pupils, the Messrs. Cullley.

Bakewell was born in 1726, at Ditchley in

Leicestershire, and about the year 1755 commenced those experiments which finally effected a greater improvement in our sheep than was ever effected in any species of agricultural produce by the exertions of one individual. He travelled over England, Ireland, Holland, and other places, for the purpose of examining the various breeds of cattle, and by careful selections, and judicious crosses, succeeded in procuring a stock that obtained for the Ditchley sheep a previously unheard of excellence. Fortunately the English agriculturists appreciated the importance of his success; and it is a fact that, in 1789, three of his rams, the produce of one birth, were let for the breeding season, for 1200 guineas, and the whole produce of his letting was at least 3000 guineas. One of his rams obtained for Mr. Bakewell, in one season, 800 guineas; and when it is taken into the calculation, that the same animal served for his own flock, it produced for its owner in that year 1200 guineas. Mr. Bakewell died in 1795.

Messrs. Culley introduced these improvements into Northumberland, and the other northern counties of this island. When they first settled in that district, the sheep kept there were large, slow-feeding, long-woolled animals; and a breed between those and the Cheviot sheep. These breeds rarely became fat before they were three years old; but the Leicesters introduced by the Messrs. Culley were sold fat at little more than a year old. They at first met with much opposition; but as it was soon seen they were improvers, and not mere innovators, the flocks have generally been made to improve by their example. They became the general patrons of improvement, and their great attention to minutiae, unremitting industry, and superior cultivation, gave birth to a spirit of emulation, and their own merits were rewarded with a liberal success. For several years they occupied farms to the amount of about 8000*l.* per annum. They had pupils with liberal premiums from all parts; and these again were the means of making known, not only their enlightened husbandry, but the encouraging illustration they afforded of industry, economy, and intelligence duly rewarded.

Merino sheep were imported by George III. in the years 1788 and 1791. This breed attracted much attention in 1804, when his majesty commenced his annual sales. Dr. Parry, Lord Somerville, and others have paid considerable attention to them; but the climate of England has a considerable effect in deteriorating their fleeces, and the flesh is too indifferent to permit them to be much encouraged in a country where mutton is so considerable an article of food. (*Hunt's Agricultural Memoirs; Gent's Magazine; Enc. Brit.*)

Mr. Ellman, of Sussex, during an enlightened practice of more than fifty years has brought the South Down variety of sheep to a state of the highest improvement. Perhaps the best description of the varieties of the sheep reared in England has been written by this gentleman for "*Baxter's Agricultural Library.*"

Cattle, as we have already noticed, have al-

ways been a prominent production of Great Britain. They were mentioned by Cæsar, Strabo, and other ancient writers. They have ever since continued, more or less, particularly to engage the attention of the husbandman, not only for the dairy and the plough, but also as a source of food. The breeding of cattle, however, had been so much neglected for the more profitable pasturage of sheep, that in 1555, an act of parliament was passed to remedy the evil. The preamble states that, "Forasmuch as of late years a great number of persons in this realm have laid their lands, farms, and pastures, to feeding of sheep, oxen, runts, scrubs, steers, and heifers, &c., having no regard or care to breed up young beasts or cattle, whereby is grown great scarcity of cattle and victual;" and, therefore it is enacted that a cow shall be kept wherever are sixty sheep, and a calf reared where there are one hundred and twenty, &c. (2 & 3 *Phil. & Mary*, c. 3.) Many other legislative enactments occur in the records of that and contiguous periods; but reason and interest are better promoters of improvement than acts of parliament. A due attention to the breeding of cattle was first aroused by Mr. Bakewell, who has just been mentioned as an improver of sheep. He let bulls for 150 guineas during four months, and 5 guineas per cow was no uncommon charge. Pedigrees have been preserved of different animals with as much care as those of race-horses. The attention and care that have thus been paid to their breeding have met with an appropriate recompense. In no other country is there to be found such breeds of cattle; and that none are so highly estimated, is proved by the prices that have been given for individuals. (*Marshall's Midland Counties*, i. 334; *Parkinson on Live Stock*, ii. 469.)

Horses.—That the ancient Britons had horses with which they impelled their war chariots, we know upon the authority of those who had seen them—Cæsar, Strabo, and others. In the epitome of Dion Cassius, by Xiphelin, those horses are described as small and swift. They appear not to have been usually employed in the operations of agriculture; and their employment was not considered desirable; for in the old Cambrian laws, oxen are exclusively directed to be employed. (*Leges Wallicæ*, 288.) Under the Saxons, and still more under the Normans, who flourished here in an age that, from its excelling in noble horsemanship, has been distinguished as the *chivalric*, the breed of horses was undoubtedly improved. "Richard De Rulos, Lord of Brunne and Deeping, was much addicted to agriculture, and delighted in breeding horses and cattle." (*Ingulphus's Chron.* lib. i.)

In the year 1494, the exportation of horses was so extensive, and the price of them so much enhanced, that an act of parliament ordained that none should go out of the realm without the king's license (2 *H.* 8, c. 6; 32, c. 13; 33, c. 5); but these being evidently intended for the improvement of war horses, "for the defence of the realm," would only collaterally benefit those employed by the husbandman. It was provided by the second of the acts just quoted, that no stallion should be kept that did

not measure fifteen hands from the sole of the hoof to the highest part of the wither; each hand to be four standard inches. We find, however, that at this period draught horses were fine and powerful animals, for Harrison, who lived at this era, and whose appendix to Holinshed we have before quoted, after expressing his admiration of them, says, that five or six of them would draw with ease three thousand weight of the greatest tale for a long journey. We must remember, too, that in those days the roads were totally different from what they are at present. It is within the memory of persons still living in the hundreds of Essex, that no more than a load of wheat was ever sent out in a wagon, the roads there being, until within less than a half a century, exceedingly bad.

We have already noticed that in the tapestry of Bayeux a man is represented harrowing with a horse. This tapestry was woven in the year 1066, and this representation is the first notice, of which we are aware, of the horse being employed in agriculture. The first attempt that historians notice, to improve the breed of our husbandry horses, was in the reign of King John. Tyrant and despot as he was, yet his evil qualifications gave two benefits to England. His tyranny gave birth to Magna Charta; and his pride, rendering it hateful to him to see foreigners surpass him in the excellence of their horses, induced him to import 100 stallions from Flanders; and from that era may be dated the improvement of our draught horses. His object did not entirely succeed; for a century subsequently, in the reign of Edward II., we find that horses were still imported from Lombardy and Flanders. We have already noticed some of the enactments to improve the breed of horses, but these shared the fate of most other compulsory measures; for when Elizabeth summoned her forces to defend her realm, in the prospect of a Spanish invasion, she could obtain no more than 3000 cavalry.

Sir A. Fitzherbert, who wrote in the reign of Henry VIII., says, in his *Booke of Husbandry*,—"A husbände may not be without horses and mares, and specially if he goe with a horse-plough, he must have both; his horses to droive, and his mares to brynge colts to upholde his stocke, and yet at many times these may droive well if they be well handled." The roguery of horsedealers was an early sin; for one of the old Cambrian laws provides, that the purchaser of a horse shall have three nights to ascertain whether he is infected with the *staggers*; three months to prove his *lungs*; and twelve months to discover whether he is infected with the *glanders*. For every blemish not discovered before purchasing, if it was not in the ears or tail, one third of the price was to be returned. (*Laws of Howell Dhu.*) The deceptions practised by the dealers in horses is still proverbial; and there does not appear with their fraternity to have been any intermediate age of innocence; for Sir A. Fitzherbert says, "Thou grayser, that mayest fortune to be of myne opinion or condytion to love horses, and young coltes and foles to go among

thy cattle, take hede that thou be not beguiled as I have been a hundred times and more. And first, thou shalt knowe that a good horse has fifty-four properties; that is to say two of a man, two of a badger, four of a lion, nine of an oxe, nine of a hare, nine of a fox, nine of an asse, and ten of a woman."

Since the days of Elizabeth, every variety of horses has been gradually improving, in England, and four kinds, the Suffolk Punch, the Cleveland bays, the Clydesdale, and the Lincolnshire or dray, are surpassed by no country in the world. The numerous cart stallions attending every market town during the covering season, is an attestation that this care is not on the decrease. It is stated, as a further proof, that a few years since a Suffolk cart-mare and her offspring sold at Woodbridge Lady-day fair for 1000*l.*

Pigs have been among the usual animals fostered by the farmer in times at least as early as the Anglo-Saxons. In those days they were evidently the most numerous of their live stock; scarcely an estate is mentioned without its being stated that it afforded *pannage*, or mast in its wood, for such a number of swine. They were a very prominent portion of their wealth; and, indeed, a chief necessary, for they were in winter obliged to use almost exclusively salted meat, and the great preponderance of woodland supported best this kind of stock. (*Turner's Anglo-Saxons*, iii. 22.) Heresbach is particularly earnest in commending the pig; and after mentioning it as abominable to the Jews, says, with a boastful feeling that made him forget its impiety, "I believe, verily, they never tasted the fitches of Westphaly."

Enactments occur in our statute book, in 1225 and 1534, regulating the pannage of swine. There are now a great many varieties of pigs, every district of England varying in the size and qualities of those it prefers. Some attention has of late years been paid to improve the stock, but in general they have been too much neglected. We have not particularized the progress of husbandry in Scotland, because previously to the time of its union with this country, Lord Kames and Mr. Fletcher agree that its agriculture was deplorable; and since then the improvement of the art in that most generally enlightened part of the island has, in many districts, outstripped, and, in most, at least kept pace with that of England; and its future advance will probably surpass that of England, because good education is more completely diffused among its inhabitants.

Ireland is in general deplorably behind in all the arts of life; nor will this be obviated until the effect of education and wealth is more generally felt and appreciated by its generous and hospitable, but far from wealthy inhabitants.

Wales, for the most part, has an agriculture as bad as that of Ireland; and we cannot have much hope of its improvement, when Mr. Adam Murray, in his evidence before the Committee of Agriculture in 1833, stated that the Welsh have a great antipathy against u-

Saxons, or *Sassenachs*; and that they take every advantage of any *Englishman* that settles among them.

V. CONTINENTAL AGRICULTURE.

We have now brought to a conclusion our sketch of the progress of agriculture. The limits of our work preclude us from giving here more of the ample details that have come under our notice in the research for the materials, of which we have given the abstract. We have not withheld our attention from the husbandry of other nations, but have found little concerning the history of their progress in the art; and the examination of their present operations made it so apparent, that with the exception of Flanders, they were all so much behind in general practice, that the conviction is forced upon us, that little instruction could be obtained from its detail. Several of them, however, excel us in some particular points: and in noticing these we shall avail ourselves of the opportunity to enforce the importance of extra attention to them upon our own agriculturists.

Flanders.—This country was certainly the first of modern countries to improve the practice of agriculture. Its farmers were the first tutors of England; and from the time of Sir Richard Weston, who published an account of their husbandry, in 1645, till that of the Rev. T. Radcliff in 1819, the Flemish husbandmen have continued models of neat and economical farming. In this respect we fall short of them. It is a leading principle with them to make their farms closely resemble gardens. Consequently, to effect this, they have small farms, and devote their efforts to these three grand points—the accumulation of manure—the destruction of weeds—and the frequent and deep pulverization of the soil. We recommend for the perusal of our readers the work (*Tour in Flanders*) published by Mr. Radcliff, and the *Flemish Husbandry* of the Society for the Diffusion of Useful Knowledge, and we are convinced that they will benefit by the time so occupied. We do not expect that they will induce them to try to cultivate a large surface of land with the minute accuracy of a garden; but it might persuade them to adopt that more cleanly system of cultivation which is the only one that is permanently profitable.

We shall only remark more particularly upon the assiduous care the Flemish farmers bestow upon the collection of manures.

They were the first among the moderns to raise crops for the sake of ploughing them in whilst growing; and they continue it more extensively than any other nation. This practice, we may say, is entirely neglected by our farmers; but if they knew sufficient of chemistry to understand how much fertilizing materials such green crops impart to the soil, it would be a practice more extensively adopted. Every fragment of animal and vegetable matter is preserved by the Flemish farmers for the fertilizing of their lands; and the ready sale which all such decomposable substances meet, is one cause of the broom and the bar-

succeeding in keeping their town so scrupulously neat.

Saw-dust, chips, and similar refuse all tend to increase their composts; and on their barren lands trees are frequently planted for the purpose of creating in time a fertile soil by the agency of their falling leaves.

Their dunghills are so constructed that all the drainage is collected in cisterns, with which liquid is mixed the emptyings of privies, pulverized rape cakes, and the like; and this most fertilizing compound is conveyed to their fields by means of barrels fixed on wheels, and is spread by means of a scoop, 2840 gallons per acre being allowed for their flax crop. (*Johns. on Liq. Manure.*)

The slovenly management of his dunghill is one of the most general specimens of the ignorance or carelessness of a farmer. He allows the most soluble and valuable portions to drain away; and treats with ridicule the idea of carrying out manure in a liquid form. As this arises from ignorance and bigoted attachment to old practice, it should excite our pity more than our anger. Liquid manures, notwithstanding stupidity and prejudice, are amongst the best of fertilizers, and will, in a coming age, be generally employed, since it is a fallacy to argue that they cannot be employed on a large scale; for the comparative expense of preparation and application is unquestionably smaller on a large scale than on a less.

Holland.—The husbandry of this country is almost exclusively confined to the dairy and to stall feeding. There are two points in their practice in which other farmers would do well to imitate them.

It is a common prejudice that a cow for the dairy should never be fat. This is thus far true, namely, that if a cow inclines to fatten easily, she does not yield so much milk as one that generates fat less readily. But a good dairy cow, that is, one that secretes milk abundantly, will not fatten whilst in that condition, and therefore the abstaining from giving them nutritive food is an erroneous conclusion. The Hollanders know that the contrary is the correct practice, and once a day, or oftener, they give their cows rape cake, and other nutritious preparations. The ignorance of the common English practice is evident from this fact, that without one exception, other animals, when suckling, are always kept much higher than at other periods.

The other point of their practice that merits imitation is the cleanliness with which they keep all their animals. It will excite a laugh with some of our agricultural readers, when we recommend not only the most scrupulous daily cleaning and washing out of cow-sheds, pig-styes, and the like, but that the animals themselves should be cleaned. This, however, is not a mere speculative precept, for the national example of Holland attests its utility. We have known the beneficial effects of such treatment upon the health of cows and pigs in this country. But in the absence of all facts, if the farmer would but allow his own common sense to direct him; if he would but reflect that no animal will thrive that is not healthy; that his horse becomes diseased if not kept clean; and that by no possibility can it be

otherwise but that fetid stench, and encumbering filth must tend to breed disease, he would not allow so baleful a neglect to continue. It is futile to urge that where stock is large, the attendance to such treatment is impossible; for if it is beneficial it will pay to adopt it; and no one should engage in a larger concern than he can manage in the most beneficial mode.

Germany.—The inhabitants of the different districts of this extensive empire pay particular attention to the cultivation of timber trees. The number of German books on the subject is excessive.

It is a subject which has of late years been gaining much attention also in England, and planting will probably be still further extended over many of the poorer soils that at present will not pay whilst producing corn.

The careless and ignorant manner in which the labourer is allowed to mutilate timber trees that grow upon most farms, cannot be too severely deprecated. To train trees correctly, requires as much judgment as any operation in which the gardener or forester is concerned. Not an unnecessary wound should be inflicted upon them; for the process of healing each wound not only deducts so much from the growth of the tree, but is usually the introducer of decay. Yet the hedger, with no other instrument than his bill, is generally allowed an unguided use of so unfit and mutilating a tool.

Lombardy.—In this, and most of the other Italian states, all rivers, and in some, even all springs, are considered to be the property of the government, for they are the source of a considerable revenue. Any one desiring a canal from a river has to pay for it to the government; and he may cut it through another person's ground without the latter having the power to prevent it, upon paying the value of the land. Such canals are considered as improving the value of an estate, for they irrigate not only their grass lands, but their corn, vines, and other crops, numerous little channels being cut for the purpose down the ridges. The water from a river is purchased at a certain price for so many hours' or days' run in the year, through a sluice of a stated dimension. Arthur Young mentions that the fee-simple of an hour's run per week through a particular sized sluice at Turin, sold in 1788, for 1500 livres. Watered lands usually let for one third more than lands that are unwatered.

We have already noticed, and shall again have to recur to the subject of irrigation; but we could not but notice the above national evidence in favour of what we know to be one of the most beneficial practices neglected by our agriculturists.

Tuscany.—Sismondi informs us that it is the practice in this country, where he was himself for five years a cultivator, to trench one-third of the farm every year with the spade, bringing the lower soil to the top. This mode of culture bringing a new soil for the promotion of vegetation, for it has been in a manner lying two years fallow, is sanctioned by reason as well as confirmed by practice. We are not the advocates of a general system of spade

husbandry. There are objections to it that at present are insuperable. But we do recommend, and that from our own experience, its partial adoption. There is no parish in England in which many of the labourers are not out of employ during a considerable portion of the year. Perhaps the average of the poor's rates were 10s. in the pound upon the farmer's rental; and this might have been reduced more than one half, if every farmer had employed one man in spade husbandry for every thirty acres he cultivated. Thus he would have had some return for the money he expended; and the saving of horse labour, and the benefit of the extra cultivation, would have turned the balance in his favour, and he would thus have got rid, in a great degree, of the worst of all outlays—an outlay without a possibility of a return.

I have searched various statements of the agriculture of the other European countries; but though I am gratified by the conviction that they are all more or less improving, yet in almost all their practices, except the culture of the vine, they are very far behind England. For that reason I leave them unnoticed, because there is no instruction to be extracted from a detail of deficiencies that have already been overcome. Upon a revision of the whole, I may remark that agriculture, in common with all other kinds of knowledge, is always flourishing, in proportion to the freedom of the people. Spain, subjugated by its despotic monarchy and priesthood, has an agriculture imperfect and degraded beyond that of any other European nation. Flanders has always had a liberal government, and its agriculture improved before our own, and is its equal now.

By freedom, I mean security of property and person, unrestricted discussion of every virtuous opinion, and an untainted distribution of justice. With us, the era that introduced such freedom into England was that of the Reformation, confirmed and strengthened by the exclusion of the Stuarts in 1688.

The introduction of the scholastic philosophy, which revived that activity of mind which the Grecian vanity had so much abused, and the Romans, by their gross habits, had so long paralysed; the mathematical sciences which the Grecians had imported from Alexandria and had forgotten; that natural and experimental knowledge which neither the Grecians nor Romans had ever much or permanently pursued; the reformation of religion, which removed from the mind that incubus that forbade man to trust to his own reason, but made it the bond-slave of interested ignorance—the invention of printing, which became the mighty engine of diffusing accumulated knowledge; were all events that preceded the seventeenth century, and rendered it an era splendid by the general improvement which it afforded in all the arts and sciences. These have justly been represented as forming a circle, for they are so united, so blended together, and so co-assistant, that one cannot be improved without the benefit being shared in some way by the others.

Agriculture participated in the general pro-

gress; and the impetus that was given to the human mind, tutoring it to follow reason rather than habit, was felt by the cultivators of the soil. The eighteenth and present centuries have been those in which the improvement has been marked, and the instances of which have already been noticed. The reason of this is to be found in its having then very generally engaged the attention of a more enlightened class of society. The noblemen, the gentry, and even the monarch of England, became practical agriculturists; and under the patronage of George III., the Duke of Bedford, Lords Sheffield, Suffield, and Albemarle, Coke, Western, and many others, it was sure to obtain the benefit of all the improved knowledge of the day. In 1723 was instituted the Society of Improvers in the Knowledge of Agriculture in Scotland; in 1749, the Dublin Agricultural Society; in 1777, the Bath and West of England Society; in 1784, the Highland Society of Scotland; in 1793, the London Board of Agriculture, and the Royal Agricultural Society of England in 1838. The last chiefly through the exertions of Mr. W. Shaw and Mr. Handley, Lord Spencer and the Duke of Richmond. This, although supported entirely by voluntary subscriptions, promises to be of the highest advantage to agriculture, and by its excellent arrangements, of which carefully avoiding all political discussions is a prominent feature, it now includes in its copious list of members, men of all parties, who are united not for the sake of indirectly forwarding party objects, but for the improvement in all its important branches of practical agriculture. The fate of the Board of Agriculture, which expired about the year 1812, from the withdrawal by government of the annual parliamentary grant for its support, should operate as a warning to all other agricultural societies; for this society failed, not from a want of talent or of industry, but from its efforts being paralysed, and its resources curtailed by its being considered the society of a party, and made the arena for the discussion and promulgation of political doctrines. From none of these have arisen any splendid discoveries, for such are not to be made in agriculture: there can never arise, so far as we can foresee, any Newton or Watt in this art; but they have effected and are accomplishing all that such associations can be expected. They have occasioned the collision of opinion, they have stimulated the desire of improvement, and they have promoted the general communication of its acquirements. The general improvements introduced into agriculture, under the auspices of these valuable societies, have been, amongst several others, 1. The general introduction of green crops; 2. The improvement of agricultural machinery, such as the drill, the thrashing-machine, the plough, &c.; 3. Better breeds of all kinds of live stock; 4. Better and more numerous varieties of seeds.

Of the benefits conferred by other sciences upon agriculture, by chemistry, botany, and physiology. I shall hereafter have much to say. They are branches of knowledge hitherto seldom combined with practical skill to

have yet accomplished much; but of what they are capable of achieving, an estimate may be formed from the perusal of De Candolle's *Physiologie Végétale*. "It is certain," as the writer of this has elsewhere observed, "that a cultivator of the soil should have a knowledge of botany and of chemistry. Without the first he will be unable to understand terms and observations that must occur in every well-written work on his art; unable to comprehend the nature and habits of the objects of his culture, or to render observations which he makes intelligible to others or even to himself. Chemistry is of as much, if not greater, importance to him. The nature of soils, of manures, of the food and functions of plants, would all be unknown but from the analyses which chemists have made. Science can never supersede the dung-hill, the plough, the spade, and the hoe; but it can be one of their best guides—can be a pilot even to the most experienced." (*Baxter's Agricultural Library*, 140.)

Of the literature of agriculture, I have little to say in this place. From the days of Hesiod until the sixteenth century, the authors upon this art were very few; but from that period to the present, they have continued to increase; and its literature, if now collected, would form a copious library.

There have been professorships of agriculture for some time proposed at the Universities of Oxford and Cambridge. There was one appointed at Edinburgh in 1790, and the chair is now (1841) filled by Mr. Low; another at Oxford in 1840, of which Mr. Daubeny is the present holder.

A prejudice too generally existed amongst farmers against the agricultural knowledge contained in books; but now they are generally better educated, this prejudice will cease. Ignorance is always bigoted and obstinate; and it is the same mental sterility which made them jealous of all new practices, that made the Irish persist in fastening their horses to the plough by their tails, until it was absolutely prohibited by the government. The Irish said in defence of their practice what some English farmers say in defence of theirs, however erroneous, "My grandfather did well enough this way." Such foolish observations amount to no more than this, "We will not try to improve." This race of stagnant cultivators is gradually disappearing; and those who are succeeding them, we see reason to believe, are more enlightened, and consequently more ready to adopt improvements. We most heartily rejoice at this; and we hope to see them more and more a class of reading men. Practice must ever be their chief tutor, as in all other arts; but likewise, as in all other arts, that practice will always be the most correct in its details which is founded upon scientific knowledge. (*G. W. Johnson. Miller's Gard. Dict. by Orr & Co.*)

[AGRICULTURE IN THE UNITED STATES.]

A glance into the agricultural history of the United States has been given in the introduction to this work. It will not therefore be

necessary to say much upon that topic here, where the agricultural resources of the Republic will be mainly dwelt upon.

Notwithstanding the desolation to which a scourging course of tillage has reduced so many of the once rich acres in the Atlantic states, the agricultural productions of the country are exceedingly abundant. Until very recently, the value of these products has been a subject for conjecture and approximate computation. The act of Congress for taking the Census of 1840, provided that the persons engaged in enumerating the population, should collect facts so as to show the amount of the products of husbandry, as well as of every other branch of industry pursued throughout the country. A fund of authentic information of the highest interest has been thus obtained, exhibiting not only the aggregate value, but the relative proportions the several products of agriculture, commerce, the forests, and the manufactures, bear to each other.

As the agriculture of the country yields the immediate means of subsistence, so does it furnish the basis of commerce, and the various branches of industry, all of which must prosper or languish according to the good or bad success attending rural affairs.

"Land and trade," says a quaint old English writer, "are twins, and ever will wax and wane together. It cannot be ill with trade but lands will fall, nor ill with lands, but trade will feel it." (*Sir Joseph Child.*)

"In the pursuit of agriculture," says a sensible writer in Hunt's Magazine, "we are, in effect, advancing the other great interests of the country, a fact which we are too apt to forget in discussing any single interest with ex-parte views. We will take the mere subject of commerce, which is supposed to be inimical to the other interests of the nation, and what a mighty spring is given to the internal trade of the country by agricultural enterprise, looking at the actual condition of the transportation of agricultural products upon the principal lines of commercial communication, both at the east and west. How large a portion of the freights is furnished by the agriculture of the south to the ships which are continually plying from its ports to the inland ports of our own territory, and to the prominent cotton markets abroad. Of the vessels that are daily taking in their cargoes in the harbours of Charleston and New Orleans, and the intervening ports, it is safe to say that the principal portion of those freights is derived from the cotton, sugar, tobacco, and rice, as well as the other agricultural staples of the surrounding territory. The same is the case with the commerce of the Mississippi: and we find the numerous steam ships and flat boats which ply upon that river during the season of navigation, are laden with the agricultural products of the states that border its banks, or that are sent down through the interior by the Ohio. The commerce of the lakes is maintained, moreover, in a great measure by the transportation of the agricultural produce of the great states of Ohio, Illinois and Michigan, lying upon their borders, to the eastern markets: and the same may be said of the canal and rail-road trans-

portation of the greater number of the states as well as our coastwise trade. Furthermore, if we examine the decks and holds of the ships which are constantly setting sail from our commercial towns both at the east and south, we find that agriculture supplies the great bulk of the cargoes which are exported abroad. It is agriculture indeed which gives life-blood to the trade and commerce of the country, and is doubtless as important to the solid vigour of commercial enterprise as nutritious food to the health of the human body. Withdraw this resource from our commerce, and the veins and arteries of the commercial system would sink into a state of collapse, exhibiting the cadaverous and pallid hue of disease and starvation. Of the amount of the several species of agricultural products yielded by the country, we are furnished with the following statements, made in one of the late reports of the United States Commissioner of Patents.

An Estimate of the products of labour and capital in the United States for the year 1848.

Articles.	Quantities	Prices.	Value.
<i>Agricultural Products.</i>			
	<i>Bushels.</i>	<i>Dollars</i>	<i>Dollars.</i>
Wheat (a)	126,364,600	1 15	145,319,290
Indian corn.....	583,150,000	59	344,058,500
Barley	6,222,050	65	4,044,332
Rye	32,951,500	65	21,418,475

			2,323,564,756

(a) The estimates above given by the Commissioner of Patents, for 1848, are founded upon the bases furnished in the census returns for 1840, with the addition of 22 per cent., that being the computed increase of population since that period. The prices are generally the average prices of the different articles in the New York market. The quantities and values of hemp, flax, hops, beeswax, molasses, wine, products of orchards

and nurseries; have 25 per cent. allowed for increase, except where later information justifies a departure from this rule.

(b) The census of 1840 contains no returns of honey. Bevan estimates 30 pounds of honey for each pound of wax produced, and this is taken as the basis of the present estimate.

(c) A little more than 45 gallons of molasses are allowed by authors treating on the subject of sugar-growing and manufacture, for every 1000 lbs. of cane sugar.

(d) In France 11½ per cent. upon the value of the products of the land and forest is allowed for the refuse of crops. From the returns of estimates made by farmers in various parts of the Union in 1848, it appears that many allow 1 ton of straw to 20 bushels of wheat and other small grain produced, and 1 ton of fodder for about 25 bushels of Indian corn. The straw is valued at \$2.50, and the fodder at \$2 per ton: very low prices. If to these be added the refuse of the cotton, sugar, rice, and other crops, it will make the total value exceed \$100,000,000. In England, the annual value of straw alone, used for thatching, &c., is, estimated at about \$40,000,000.

(e) The average price of manure in the present estimate is 66⅔ cts. per cord. The value of the manure produced in England was computed, in 1835, at 329,300,000 loads, valued at about \$295,000,000, exclusive of the droppings from grazing stock, equal to about ⅓ more.

(g) See FOOD and VENTILATION.

[AGRICULTURAL PRODUCTS, CONSUMPTION OF. To one who examines statements of the agricultural products of various kinds every year yielded in such immense quantities, it seems, at first glance, difficult to imagine how these can all be consumed, before fresh crops would glut the markets and do away, for a time, with the labours and profits of the husbandman. It is, however, only necessary for one to inquire into the consumption of the products of the soil constantly going on in some of the most populous countries and cities, to give him courage to persevere in his productive efforts, even with renewed ardour. It has, for example, been estimated that the daily consumption of corn in England and Ireland, is, 1,238,096 bushels of wheat and barley; besides annually, 100,000 bags of rice, and 450,000,000 lbs. of sugar. The immediate products of the grasses, which, consumed by animals, forms the food of man, constitutes an amount almost inconceivable. In London alone there is annually consumed 155,000,000 lbs. of butcher's meat. Of cheese, another production of grass, 11,500 tons are annually introduced into London, from Cheshire, about 20,000 tons from Warwickshire, besides that imported from many other countries. Of butter, the annual consumption is about 50,000,000 lbs., the produce of 300,000 cows; and in London, between 9 and 10,000 cows are kept for the supply of milk to the inhabitants, which produce annually about 30,000,000 qts. (*Johnson's Lectures on Botany.*)]

AGROSTIS. The bent grass. An extensive genus of grasses, which, from the marshy soil on which they flourish best, are of comparatively small value to the farmer.

Agrostis alba, or white bent, in England flowers in the first week in August, and the

seed is ripe about the beginning of September. This grass is late, unproductive, and contains but little nutritive matter. Its creeping roots greatly exhaust the soil; in this variety they are smaller than in the other varieties of *Agrostis*, but equally difficult to extirpate when once in possession of tenacious clays. This property of the roots is the best character of distinction for the purpose of the agriculturist, as it may be found at any season or stage of growth of the plant.

The *Agrostis canina*, var. *mutica*, Awnless variety of brown bent; *Trichodium caninum muticum* (Schrader), Creeping-stalked brown bent, is the most common grass on deep bogs, even where they are subject to be under water for six months in the year. It is a diminutive plant, very unlike the produce of such soils: the leaves seldom attain to more than two or three inches in length. The smallness of the produce, even when cultivated in the most favourable circumstances, affords a sufficient proof of its unworthiness to be regarded by the farmer in any other light than that of a weed which indicates a soil capable of being improved, so as to produce the most valuable grasses by irrigation. It differs but little from the *Agrostis nivea*, except in the want of awns and the length of the culms. The structure varies almost imperceptibly in the *Agrostis canina*, *Agrostis nivea*, and in this species. The like gradual shades of difference may be perceived in the colour of the plants; the *canina* is of a brownish-green colour; this awnless variety is of a pale green; the *nivea* of a greenish straw colour. The knots or bundles of leaves attached to the decumbent shoots show it to be connected with the *Agrostis canina fascicularis*. It flowers in England the second and third weeks of July, and ripens the seed about the middle of August.

Agrostis canina capillaris. Fine-panicked brown bent. This variety is nearly akin to the *Agrostis canina fascicularis*, bundle-leaved bent; tufted bent. In old pastures, or light soils, this bent may be readily distinguished in the autumn by its shoots, which are furnished with leaves in tufts or bundles, that generally run along on the surface of the rest of the herbage, and is occasioned, apparently, by the cattle, which eat the other herbage, and leave the scattered shoots of the tufted-leaved bent untouched. It is a very common grass on poor, light, but moist soils, incumbent on clay, that have long been under pasture. This and the woolly soft grass in some parts of England are termed *winter fog*. From the above details it will appear to be the least valuable of the bent grasses that have been mentioned. The cultivation of a grass of this value is out of the question; the point of most importance to be ascertained respecting it is, how to remove it from the soil, and to substitute more valuable grasses in its place. I have witnessed the beneficial effects of coal ashes, as a top dressing, when spread on the pasture in sufficient quantity. The ashes favour the growth of the superior grasses, and the pasture being in consequence closely cropped by the cattle, which now find the pasture more palatable, the tufted bent disappears; it will, how-

ever, be found by no means destroyed, but only checked in its growth. This grass flowers in England the first and second weeks of August, and ripens the seed in the end of the same month.

Agrostis lobata. Lobed bent; sea-side bent. The general appearance of this plant indicates its inferior comparative value. It appears, according to the information afforded by Mr. Curtis, to be chiefly confined to the sea coasts. It grows wild on a stiff wet, clayey loam, part of the London blue clay, in the parish of Cuddington, near Epsom, Surrey. It does not appear to be of much value to the agriculturist, although its nutritive powers are far from being inconsiderable.

Agrostis mexicana, the Mexican bent grass, is, as its name implies, a native of South America, and was introduced into England, by Mr. Gilbert Alexander, in 1780. It delights more in calcareous or clayey soils than in those that are of a silicious sandy nature. It perfects an abundance of seed, which when sown produces plants that soon arrive at perfection. So far, therefore, it possesses the requisite properties of a grass adapted for the alternate husbandry; but it is late in the produce of foliage in the spring, and that herbage is not distinguished by any superior nutritive powers. It is perfectly hardy. Being a native of a warmer climate, its defects may possibly be greatly lessened by being naturalized, and by frequently raising it from seed successively ripened in England. At present it does not offer any strong reasons to recommend it further to the notice of the agriculturist. It flowers in the third week of August, and the seed is ripe towards the end of September.

Agrostis nivea. Snowy bent; straw-coloured bent grass.

Agrostis palustris, or marsh bent. This is considered only a variety of the *Agrostis stolonifera*. This grass is properly a sub-aquatic: it will grow on tenacious clays, but it seems only to thrive in very moist soils, or in such as are for the most part covered with water. In moist woods it is more frequent than any other of the creeping-stemmed bent grasses: here the culms often attain to five feet in height, when supported by bushes. The above details show the inferior nature of this grass compared to the larger, and even to the lesser leaved varieties of the *Agrostis stolonifera*. It cannot, therefore, as yet be considered in any other light than a weed that chokes up drains and underwoods.

Agrostis ramosissima. Lateral-branching bent grass. This is nearly allied to the *Agrostis mexicana*, and is one of the latest flowering grasses. It is remarkable for the number of branches that issue from the joints of the stem; and the woody substance of the culms makes it approach to the nature of a shrub. It affords little herbage till the beginning of summer, and flowers at so late a period of the season (the first or second week in October), that, the frost generally destroys the panicles before the seed is perfected. The herbage is killed by frost, but the roots suffer nothing from its effects; it is propagated by parting and planting the roots early in the spring or

late in the autumn. It is neither very productive nor nutritive.

Agrostis repens. Creeping-rooted bent; white bent. The *Agrostis nigra*, or black couch grass of Withering. Though a later growing grass, it is less productive than the *Agrostis alba*. It is subject to the rust, a peculiar disease which dries up the extremities of the leaves and gives it an unsightly appearance. Simple ploughing will be found ineffectual to root out this weed in clayey soils. It will be found ultimately the cheapest and most expeditious mode of extirpating it to follow the plough and fork out the roots. Burning, under such circumstances of soil, would doubtless be highly beneficial, but the roots of this couch grass penetrate so deep that a considerable part of them would escape; and the least particle of the root soon produces a plant. It flowers in England the second week of August, and the seed is ripe about the latter end of September.

Agrostis stolonifera aristata. Awned-creeping bent. This variety of creeping bent, which is allied to the *Agrostis Canina* or awned var. *Agr. vulgaris* of Dr. Smith, is greatly inferior to the larger-leaved variety (*Agrostis stolonifera latifolia*, or fiorin); for the weight of nutritive matter per acre afforded by the *latifolia* is two-thirds greater than that of the awned variety. Cattle appear to eat this grass in common with the rough-stalked meadow-grass and meadow fox-tail grass. It flowers about a week later than the fiorin, but the seed is ripe about the same time.

Agrostis stolonifera angustifolia. Smaller-leaved creeping bent. This is the most common variety of the creeping bent, on damp, tenaceous, clayey soils, and in moist woods. It stands next in value to the longer-leaved variety of creeping bent; but appears from all the observations that have been made on it, when growing in natural pastures, to be entirely neglected by cattle, while any of the superior pasture grasses presented a sufficiency for a bite. It flowers in the second and third weeks of July, and ripens the seed about the end of August.

Agrostis stolonifera (var. 1 *latifolia*). Longer-leaved creeping bent; fiorin. [See Plate 5, n. Hay Grasses.]

The Rev. Dr. Wm. Richardson has introduced this variety of the *Agrostis stolonifera* to the agricultural world, under the name of Fiorin, and has shown its merits and properties, deduced from his own experiments, in a variety of publications on the subject, to which the reader is referred. It is greatly superior in point of produce and nutritive powers to the other varieties of *Agrostis stolonifera*.

On comparing the specimens of these different varieties, their resemblance to each other is so great, that they may be easily mistaken for each other, without a close inspection, and some knowledge of botany to assist it. This variety appears to be confined to rich ancient pasture land, as its natural place of growth, and the other varieties to various soils and situations; and that when taken from these different soils, and cultivated together under the same circumstances, they retain their discriminating characters. On damp, clayey

soils, the second variety (smaller-leaved, creeping bent) is the most common. To moors and bog soils, the third variety (awned creeping bent grass) is chiefly or altogether confined. To light sandy soils, particularly when more or less shaded, the fourth variety (wood creeping bent grass) is peculiar; and the fifth variety (marsh creeping bent grass) is seldom found but in the bottoms of ditches, or by the side of rivulets. The first variety being therefore scarce, and the others very common, there is little room for surprise at the contradictory results of experiments that have been made, on one or other of these inferior varieties, by gentlemen equally eminent for agricultural knowledge under the conviction of their being one and the same grass as recommended by Dr. Richardson under the name of fiorin: whereas, though they agree in the general habit of Dr. Richardson's variety, and indeed in every respect except in the characters before described, their inferiority in every agricultural merit is so great, as to justify the opprobrious epithets that have been bestowed upon them, by those who, from the above causes have differed from Dr. Richardson's statements of the merits of the first variety of fiorin, and prevented that justice being done to the discovery which it may have deserved.

The above details will assist the farmer in deciding on the comparative merits of this grass as a constituent of a mixture of grasses for permanent pasture; from which it will doubtless appear worthy of attention, but its value not so great as has been supposed, if its habits or manner of growth be impartially taken into the account, when compared with the produce and nutritive powers of the other grasses. The chief advantage of this grass, in permanent pasture, is its late growth. It remains in a degree inactive, till other grasses have attained to perfection, and when their productive powers become exhausted, those of fiorin and its varieties begin; and it will be found, on inspection, that the latest mouthful of herbage, and sometimes the earliest, in those pastures, is principally afforded by this grass.

There has been much prejudice existing against the different species of *Agrostis* in general; but let the proprietor of a rich ancient pasture divest a part of it of this grass entirely, and the value of the plant will be demonstrated in the comparative loss of late and early herbage. The cock's foot grass is superior to the larger variety of the creeping bent, in the proportion nearly of 11 to 9. The meadow fescue is also superior to fiorin in nearly the like proportion as cock's foot. The meadow fox-tail grass is inferior to fiorin in the proportion nearly of 6 to 7. When cultivated separately, for the purpose of green food or hay, fiorin requires to be kept perfectly clear of weeds, its couchant habit of growth affording great encouragement for the health of upright growing plants—under this circumstance, weeds. It flowers in England about the second and third weeks of July, and the seed is ripe about the second and third weeks of August. The mode of converting fiorin into hay, during the winter months, is amply detailed in Dr. Richardson's publications on Fiorin. Full information will there

be likewise found on the productive powers, uses, modes of cultivation, &c., of this grass, deduced from the Doctor's own experiments.

Agrostis stricta. Rock bent; upright bent. *Trichodium rupestre* (Schrader). This species being inferior to the common bent in most points, its value to the agriculturist can be but little. The only property that renders it worthy of notice is, the small degree in which it impoverishes the soil: when cultivated on a poor, silicious, sandy soil, the produce, though somewhat inferior, continued for six years, without diminishing in the yearly quantity, and without any manure being applied; a circumstance which was not manifested in any other species of grass.

Agrostis vulgaris canina. Awned fine bent. (Brown bent, or *Agrostis canina*, Wither. Arr. *Smith's Engl. Flora. Agrostis vulgaris* var. β . Do. var. 1.) As this is a much less common plant than the variety of *Agrostis vulgaris* before described, and as it differs so much from that variety in the properties which constitute the farmer's distinguishing characters of grasses, the name *canina* is here added. The *vulgaris mutica* is more common to sandy soils; the *v. canina* to clayey soils. The weight of nutritive matter in which the produce of one acre of the awnless variety of *Agrostis vulgaris canina* exceeds that of the awned variety is 151.8. The comparative merits of the *Agrostis vulgaris* exceed those of the *Agrostis vulgaris canina* nearly as 2 to 1. The crop of the awnless variety is greater than that of the awned, but it is much less nutritive, being as 10 to 7; the spring and autumn produce is

likewise superior. Neither of these varieties appears to be of much value to the farmer. The rust attacks the culms and leaves of both varieties which gives the plants a dirty brown appearance; the *Agrostis vulgaris* is always free from this disease. The brown bent flowers in the second and third weeks of July, and ripens the seed in the end of August.

Agrostis vulgaris mutica. Common bent; fine bent grass. [See Plate 6, *d*, of Hay Grasses.] This species has four varieties, according to Dr. Schrader. The first is distinguished by being awned (see *Agrostis vulgaris canina*, and *Trichodium caninum*); the second by awnless and diseased flowers (see *Agrostis pumila* of Willd. Spec. Plant. i. p. 371); the third by its diseased awned flowers; the fourth, by having the flowers viviparous, *Agrostis sylvatica*.

The common bent is one of the earliest of the bent grasses; in this respect it is superior to every other of this family; but inferior to several of them in the quantity of produce it affords, and the nutritive matter it consumes. It is the most common grass on natural sandy pastures; and even on more tenaceous soils, that are elevated and exposed, it is frequent. It flowers from the third week of June till the second week of July, and the seed is ripe the beginning of August.

The following tabular arrangement shows at a glance the proportional value of the several varieties of *Agrostis*, in seed and in flower, and their yield per acre of green and dry produce on various soils, and comparative qualities of nutrition.

Description.	Soil.	Green Produce per Acre.		Dry Produce per Acre.		Produce per Acre of Nutritive matter.

— <i>vulgaris canina</i>	Sandy loam	6,125	10 0	2,603	6 4	239	4 8

This family of grasses has been held in little esteem by farmers, principally on account of their lateness of flowering. (*Sinclair's Hort. Gram.*; *Smith's Eng. Bot.*)

[Several of the species thus enumerated, as existing in England, have found their way to America, doubtless introduced mixed in grain and grass seeds. They are, however, so dry and wiry as to be esteemed of little or no

value to the farmer. Among these are, the — *A. vulgaris*, which Pursh, the celebrated botanist, says, is common in all grassy field., flowering in July. This is doubtless the species which gives name to the genera, derived from *Agros*, a Greek word signifying a field. Dr. Darlington says it is the grass extensively known in the Middle States as *Herds* or *Red-top*, and sometimes in the Eastern States

called *Foul Meadow Grass*. The last name being evidently derived from the great difficulty with which it is eradicated when it has once obtained a footing. The grass called *white-top*, appears to be a variety of Herds. There seems to be considerable obscurity and confusion in the descriptions given of this grass. The common characteristics of the plant, as seen in the meadows of Pennsylvania, Dr. Darlington says, resemble those of the *A. alba*, the White or Yellow Tops of the Eastern States. It affords a tolerably good pasture for cattle, and is valuable in swampy grounds, which its roots tend to consolidate; but it is not much esteemed for hay, and is now seldom, if ever, an object of special cultivation in the Middle States. The Pennsylvania farmers are so opposed to having Herds grass rooted in their fields and meadows that they reject clover and every other grass seed in which the least Herds appears. Among the species found in the United States, are the following—

A. pungens, or *Virginian Agrostis*, frequenting dry, sandy banks, and road-sides, flowering in the southern part of Pennsylvania, in August. This species differs much, in habit, from most others.

A. cinna, common on rivers and islands below tide-water, from Canada to the Carolinas, flowering in June, &c.

A. juncea, found in barren, sandy places, from New Jersey to Florida; flowering from July to August.

A. luterifolia, found in rich soil on the edges of woods from New York to Florida, especially in the western countries, where it appears to be of more value. In the southern parts of Pennsylvania it affords an indifferent pasture in the latter part of summer, but is not regarded as of much consequence, which may indeed be said of most, if not all, of the American species of agrostis.

The late Judge Peters introduced the fioriu into Philadelphia county, in 1812, by importing a quantity of the strings or layers from which it is always propagated in Ireland. For some reason its cultivation has not been kept up, and at present it is difficult to be found in America. When once it has obtained a footing in a suitable soil, it is scarcely to be eradicated, for which reason it is not adapted to the alternate system of husbandry.]

AIR (*Air*, French, *aër*, Lat). The element or thin medium in which terrestrial animals move and breathe, and which surrounds the earth to a considerable height. See ATMOSPHERE and GASES.

AIRA. A genus of grasses, of which there are but few species capable of being cultivated to advantage as field grasses.

Aira aquatica. Water hair-grass. This plant is an aquatic, found naturally growing in the mud of standing pools, or running waters in England. It is, therefore, unfit for cultivation. Mr. Curtis says, that it is the sweetest of the British grasses; but there are several species which contain more sugar, in proportion to the other ingredients which compose their nutritive matter, as the *Glyceria fluitans*, *Elymus arenarius*. *Poa nemoralis* var. *angustifolia*, *Poa aquatica*

Aira cæspitosa. Turfy hair-grass; hassock grass. [See Plate 6. of PASTURE GRASSES, m.] This grass is of a very innutritious nature; but even if it had greater nutritive powers, the extreme coarseness of the foliage would render it unfit for cultivation. It delights in moist clayey soils, where the water stagnates; but is found in almost every kind of soil, from the dry sandy heath to the bog. It forms dense tufts in pastures very disagreeable to the sight, which are termed hassocks, bull's faces, &c., by farmers. It is a most difficult plant to extirpate, when in considerable quantity. Some persons, to get rid of it, dig up the tufts, and fill up the holes with lime compost; this, no doubt, would answer the end, at least for a few years, if all the roots were destroyed; but this is never the case: a circle of roots is left, which, in one or two seasons, produce larger hassocks than before; and besides, when the hassocks are numerous, the expense attending this process is considerable. Others depend on occasional mowings to keep the hassocks under; but this is productive of little good, particularly if the mowing of the tufts be deferred till the autumn, which I believe is the common practice. I have found no treatment weaken or retard the growth of grass so much as cutting it closely, before and after the first tender shoots appear in the spring. But the only effectual and most profitable mode of extirpating this grass is by first paring and burning the surface of the land, and by making proper drains, to correct, as much as possible, the tenacious nature of the soil; in this case surface-drains are as necessary as those termed hollow. Sand should likewise be applied during the course of crops taken previous to returning the land again to permanent pasture, if such should be desirable, from its local situation; as that, for instance, of a park or policy. This grass flowers about the third week in July, and the seed is ripe towards the end of August.

Aira cristata. Crested hair-grass. *Poa cristata*. Crested meadow-grass. *Host.* ii. p. 54, t. 75. This native grass was formerly ranked by botanists under the genus *Poa*, but has since been referred to that of *Aira*, to which it is more closely allied. The produce of this species, and the nutritive matter it affords, are equal to those of the *Festuca ovina* at the time the seed is ripe; they equally delight in dry soils, though the *Aira cristata* will thrive well and remain permanent in soils of a moist and clayey nature, which is different from the *Festuca ovina*. The greater bulk of the produce of the *Aira cristata*, in proportion to its weight, makes it of inferior value to the *Festuca ovina*. In some parts of the country it grows on dry pastures plentifully, where it appears to be but sparingly eaten by cattle, particularly if the pasture be not overstocked. Rye-grass (*Lolium perenne*), sheep's fescue (*Festuca ovina*), yellow oat-grass (*Avena flavescens*), crested dog's tail (*Cynosurus cristatus*), meadow barley (*Hordeum pratense*), flexuose hair-grass (*Aira flexuosa*), are all preferred by cattle to the crested hair-grass. The nutritive matter of this grass differs but little in its composition from those of the above: it approaches nearest

to that of the *Aira flexuosa*, differing only in having less bitter extractive matter and of more tasteless mucilage; but the soft hairy foliage of the grass appears at once the cause of this dislike in cattle to eat it. It flowers about the first week in July, and the seed is ripe about the beginning of August.

Aira flexuosa. Zig-zag hair-grass; wavy mountain hair-grass. The *Aira flexuosa* is much more productive on its natural soil than the *Festuca ovina*; but it requires a deeper soil though not a richer. The *Festuca ovina* is more common among heath, the *Aira flexuosa* among furze, though both grasses frequently grow intermixed on the same soil. To those who attempt the improvement of such soils in

a secondary manner only, this species of hair-grass appears to be the best of those grasses natural to the soils in question, and may form a principal part of a mixture of seeds for that purpose of improvement. The produce of this grass on a heath soil is superior to that on a clayey loam in the proportion of 2 to 1. The proportional value in which the grass at the time of flowering exceeds that of the latter, is as 8 to 7. Flowers in the first week of July. Seed ripens in August.

In England the proportionate value of the different varieties of *Aira* as deduced from experiments may be ascertained by reference to the following classified table of results:

Description.	Soil.	Green Produce per Acre.			Dry Produce per Acre.			Produce per Acre of Nutritive Matter.		
		lbs.			lbs.			lbs.		
<i>Aira aquatica</i> , in flower	{ Mud covered with water }	10,890	0	0	3,267	0	0	382	13	10

(Sinclair's Hort. Gram. Wob.)

AIRING. In the management of horses, implies the exercising them in the open air, which is of the greatest advantage to them when performed with moderation, and according to the circumstances or state in which they are in respect to their health and the nature of their keep. By this means their legs are prevented from swelling, their stomachs improved, and their wind rendered more free and perfect.

AIR VESSELS, of vegetables, are certain horizontal vessels of large diameter, that pass through the bark of trees to the alburnum, [or white internal bark.] These horizontal vessels Dr. Darwin supposes to contain air, enclosed in a thin moist membrane, which may serve the purpose of oxygenating the fluid in the extremities of some fine arteries of the embryo buds, in the same manner as the air at the broad end of the egg is believed to oxygenate the fluids in the terminations of the placental vessels of the embryo chicken.

ALBUMEN is the name given by chemists to the impure glossy viscid liquid, which forms the white of an egg. This white is composed chiefly of albumen mixed with some mucus, soda, and sulphur

Albumen unites readily with water, and when heated to 165° it coagulates into a white solid mass; but when mixed with ten times its weight of water, it no longer is coagulated by heat. It is composed, according to the analysis of MM. Gay Lussac and Thénard, of

Carbon	-	-	-	-	-	52.883
Oxygen	-	-	-	-	-	23.872

Azote	-	-	-	-	-	15.705

(Rech. Phys. Chem. ii. 332.)

100.000

Albumen (which is nearly identical in composition with the gluten of vegetables), is one of the most important and common of all the animal substances. It abounds in bones, mus-

cle, the membrane of shells, sponges, &c.; and, according to the experiments of Hatchett, cartilage, nails, horns, hair, &c., are almost entirely composed of it. (Thomson, vol. iv. p. 407.)

ALBURNUM. An integument composed of a soft white substance, scarcely perceptible in some sorts of trees, situated between the liber and the wood. In the oak and elm it is hard and very conspicuous. It is as it were an imperfect wood, not having acquired that state of consistence necessary to perfect wood; hence it may be compared to the cartilage in animals, which at length becomes bone. This state must necessarily be passed through before wood can be formed. The hardness of this substance is in proportion to the vigour of the plant or tree.

The vessels of the alburnum in their living state possess the property of conveying the sap-juice, which is propelled upwards in the early spring, by the absorbent terminations of the roots, as visible in decorticated oaks, the branches of which expand their buds like those of the birch and vine in the bleeding season. That the vessels of the alburnum in their living state occasionally act as capillary syphons, through which the sap-juice is first pushed upwards by the absorbent extremities of the roots, and afterwards returns downwards, partly by its gravitation, in branches bent below the horizon, appears from an experiment of Dr. Walker; and lastly, that the vessels of the alburnum, after their vegetable life is extinct, possess a power of capillary attraction of the sap-juice, or of permitting it to pass through them occasionally, appears from the following experiment:—A branch of a young apple-tree was so cankered, that the bark for about an inch round it was totally destroyed. To prevent the alburnum from becoming too dry by exsiccation, this decayed

part was covered with thick white paint: in a few days the painting was repeated, and this three or four times, so as to produce a thick coat of paint over the decayed part, or naked alburnum, extending to the ascending and descending lips of the wound; this was in spring, and the branch blossomed and ripened several apples.

ALCOHOL is the name first given by the alchemists (it came originally from Arabia) to the liquid obtained by the distillation of wine, beer, and other fermented spirits. These seem to have been known in the earliest ages: Noah, who planted a vineyard, drank wine; and the heathen writers deemed the invention worthy of being ascribed to their greatest kings and heroes. Beer, there is little doubt, was invented by the Egyptians. They certainly used it in the days of Herodotus. The Germans drank it extensively when Tacitus wrote. These were probably the purest varieties of alcohol then generally made; although they were *known* in the dark ages, and it is probable have been employed in the North of Europe from a very remote period. The process, however, of separating the impure alcohol from these is very easy: upon subjecting the wine or *wash* to a moderate heat, the spirit arises, and is easily collected in a worm surrounded by cool water. It is in this way that gin is procured from the distillation of fermented barley or other grain; rum from molasses; brandy from wine. It must not be supposed, however, that the product of these distillations is pure alcohol, for even the strongest brandy contains between forty and fifty per cent. of water. The first who procured alcohol in a state of tolerable purity is supposed to have been Arnold of Villa Nova, a celebrated alchemist of the fourteenth century. When impure alcohol is concentrated by repeated distillations, and by mixing it with some salt, like the salt of tartar, that has a strong attraction for water, it gradually parts with a considerable portion of its water, and becomes reduced in specific gravity to about 0.820; that of commerce, however, is rarely of less specific gravity than 0.8371. At the greatest strength, however, at which it has been observed, such as that of 0.792, which M. Lowitz obtained by repeatedly distilling rectified spirits from potash, it possesses the following properties:—it is transparent, colourless, of a strong agreeable penetrating taste, and produces when swallowed intoxication. It does not freeze, even by exposure to the most intense cold; it is very volatile, boiling at 176° of Fahrenheit, and in a vacuum at 56°. It unites with water in all proportions, and is entirely combustible, burning without leaving any residuum. Alcohol, according to the analysis of M. Saussure, is composed of

The spirits distilled from different fermented liquors, says Davy, differ in their flavour, for peculiar odorous matters or oils rise in most cases with the alcohol. The spirit from malt usually has an empyreumatic taste, like that of oil formed by the distillation of vegetable substances. The best brandies seem to owe their flavour to a peculiar oily matter, formed probably by the action of tartaric acid upon alcohol; and rum derives its characteristic taste from a principle in the sugar cane. The cogniac brandies contain prussic acid. (*Davy, Chem. Phil.* 135.)

ALCOVE (Span. *alcoba*; Dan. *alkove*; but originally from the Arab. *alkabba*). A recess in gardens or pleasure-grounds.

ALDER TREE (*Alnus glutinosa*, Gærtner; *Betula Alnus*, Linn.). The common Alder [of England] appears generally as a shrub; but if allowed to attain maturity it will grow to a stately tree. The bark in old trees is blackish, and full of clefts; on the young shoots it is smooth, and of a purplish hue. The leaves have a dark green colour, and roundish shape, resembling those of the hazel, nicked on the margin, smooth, and clammy to the touch. The foot-stalk is about an inch long; the leaf-ribs on the under side have spongy balls at the angles, as in the leaves of the lime tree. The male catkins are cylindrical, appear in autumn, and remain on the tree till spring. The female catkins are of a short conical form, like a small fir cone.

[In England] the alder is often planted as a coppice-wood in wet and boggy places where no other trees will thrive, and cut down every

tenth or twelfth year for poles. It may also be often used to advantage on swampy ground for fences, and may be conveniently trained to any desired height. The young trees may be planted to great advantage for securing the banks of water-courses from the torrents. We certainly know of no tree so well adapted to this purpose as the alder; for, on account of the numerous suckers which it constantly sends up from the bottom, and the very fibrous nature of their roots, the banks become in time one mass of strongly interwoven roots.

Wherever it may be desirable to complete a prospect by extending plantations over sterile cold ground, water-galls, or boggy swamps, no tree we know of is equal to the alder, even in a picturesque point of view.

The generality of trees acquire picturesque beauty by age. Some of the largest alders to be seen in England are growing in the Bishop of Durham's park at Bishop-Auckland, and some very fine ones are to be found in his Grace the Duke of Northumberland's grounds at Sion House. Mr. Beever mentions an alder in his garden, which, at four feet from the ground, measured upwards of sixteen feet in circumference.

Sir Thomas Dick Lauder says, "In very many instances we have seen the alder put on so much of the bold resolute character of the oak, that it might have been mistaken for that tree except for the intense depth of its green colour.

The wood of the alder is used [in Europe] for making charcoal and heating ovens, and is valuable for piles, pumps, sluices, and in general for all works under water; "because," says Pliny, "it will endure for many years." It is said to have been used under the Rialto at Venice; and we are told that the morasses about Ravenna were piled with it in order to lay foundations for building upon. In Flanders and Holland it is raised in great quantities for this purpose. It serves also many domestic and rural uses, such as for cart-wheels, spinning wheels, milk-vessels, bowls, spoons, and other turnery ware, troughs, handles of tools, clogs, pattens, and wooden heels. The roots and knots furnish a beautiful veined wood for cabinets. The Scottish Highlanders often made chairs of it, which are very handsome, and of the colour of mahogany.

Sir Thomas Dick Lauder tells us that the old trees, which are full of knots, cut up into planks, make very handsome tables. "We have seen some of these," says the baronet, "made from some enormous trees that grew at Dalwick, on the property of Sir John Nasmyth, in Peebleshire; and no foreign wood we have ever seen can match them for beauty."

The bark, though nearly superseded by logwood, is used by dyers, tanners, and leatherdressers; and also by fishermen for dyeing their nets. Both the bark and young shoots dye yellow, and with a little copperas, a yellowish grey, very useful in the demitints and shadows of flesh colour in tapestry. The shoots cut in March will dye a cinnamon colour; and a fine tawny, if they be dried and powdered. The fresh wood yields a dye the colour of rappee snuff. The catkins dye green,

and the bark is used as a basis for black. The bark and leaves have been sometimes employed in tanning leather, the whole tree being very astringent.

The alder delights in a very moist soil, where few other trees will thrive:—

"The Alder, owner of each waterish soil,"

Fairfax's Tasso.

It is also an old opinion that it does not injure grass, but rather nourishes its growth:—

"The Alder, whose fat shadow nourisheth;

Each plant set neere to him long flourisheth."

W. Browne.

Marshall is of a very different opinion. "In low swampy situations," he says, "where the ground cannot be drained but at too great an expense, the alder may be planted with propriety and advantage; but wherever the soil is or can be made pasturable, the alder should by no means be allowed to gain a footing. Its suckers and seedlings poison the herbage; and it is a fact well known to the observant husbandman, that the roots of the alder have a peculiar property of rendering the soil they grow in more moist and rotten than it would be if not occupied by this aqueous plant. Plantations of alders should therefore be confined to swampy, low, unpasturable places; except when they are made for the purpose of ornament; and in this case the native species ought to give place to its more ornamental varieties, of which Hanbury makes five, namely, the log-leaved alder, the white alder, the black alder, the hoary-leaved alder, and the dwarf alder." (*On Planting*, ii. 37.) The cut-leaved is a pretty variety.

It is propagated by layers, cuttings, or truncheons, about three feet in length. Such truncheons are often employed for securing the banks of rivers, either by planting them very close, or crosswise. For general purposes, however, we approve of raising the young trees by layers.

The distance at which these trees should be placed, if intended for a coppice, is a yard square; and at the expiration of seven years, when they may be felled for poles, every other stool may be taken away; and if the small lateral shoots be taken off in the spring, it will very much strengthen the upright poles, provided a few small shoots be left at certain distances upon the trunk, to detain the sap for the increase of its bulk.

The alder may be raised from seeds sown in beds in the same way as is usual for birch, but propagation by truncheons or layers is the most speedy process for obtaining young plants.

The best time for planting alder truncheons is in February or March. They should be about three feet in length, sharpened at one end, and the ground loosened with an instrument before they are thrust into it, lest the stiffness of the soil the bark should be torn off, which may prevent their growing. They should be put into the earth about two feet, to prevent their being blown out of the ground by strong winds. After they have made stout shoots, the plantations should be cleared from all such weeds as grow tall, otherwise they will overbear the young shoots; but when they hav

made good heads, they will keep down the weeds, and will require no further care.

If they be raised by laying down the branches, it must be performed in October; and by the October following, they will have taken root sufficiently to be transplanted out; which must be done by digging a hole, and loosening the earth in the place where each plant is to stand, planting the young trees at least a foot and a half deep, cutting off the top to about nine inches above the surface, which will occasion them to shoot out many branches.

Mr. South, in the sixth volume of the *Letters and Papers of the Bath and West of England Society*, has stated, that, on planting a wagon-load of truncheons in such situations as have been described above, they all appeared to succeed by throwing out strong shoots the first summer, but that the year following they all died, not having struck a single root. Concluding that this did not depend on any defect in the soil, he planted it again with small-rooted slips, taken from old stubs, few of which failed, most of them having been since repeatedly cut for brush-wood, poles, and other purposes; and of those planted single, he observes, one has formed a conical top of great beauty, and that its bole is three feet seven inches in circumference midway between the branches and the ground. From this statement it would seem, that the best mode of securing the growth of those trees is the planting of the rooted slips, which can be easily done, as great quantities of young shoots are annually thrown out from about the roots of this sort of trees.

Where there are plantations, or much of this sort of wood on a farm, Arthur Young advises that it should be cut when the bark will peel, and be immediately soaked in a pond for two months, as by this means the wood is so much hardened as to be greatly improved in its quality.

[Among the species of alder found in the United States Michaux describes only two species, the *Alnus serrulata*, or Common Alder, abounding in the Northern, Middle, and Western States on the borders of streams and especially in places covered with stagnant water. Its ordinary size is eight or ten feet in height, seldom attaining more than two inches in the diameter of its stem. It blooms in January, the sexes being separate on the same stock. The barren flowers resembling those of the birch. The common alder is too small to be applicable to any use in the arts, and from its inferiority of size, it will probably one day give place to the European Alder.

The *Alnus Glauca*, or Black Alder, is one of the most beautiful species of the genus. It is unknown in the Southern, rare in the Middle States, and in the North-eastern States, where it is more frequently found, much less multiplied than the common alder. It grows a third taller than the latter species, attaining sometimes eighteen or twenty feet in height and eight inches in diameter. Its leaves are similar in shape, but a third larger. The bark of the trunk and of the secondary branches is smooth, glossy, and of a deep brown colour sprinkled

with white. It is employed by hatters for dying black. (*North American Sylva.*)

ALDERNEY COWS. This admired breed of cows is in general fine-boned, but small and ill-made, and of a light red or yellowish colour. Cows of this breed are most frequently met with in England about the seats of the opulent, from their milk, though smaller in quantity, being more rich in quality than that of most other kinds, and yielding from the same measure a larger proportion of cream and butter, which is of a beautiful yellow colour and fine flavour. They are much inclined to fatten, and their beef has a very fine grain, and is well tasted, but rather more yellow or high-coloured than that of other sorts.

Mr. Lawrence in his general treatise on cattle, however, supposes, "that the cattle of the islands on the French coast are collectively known by the name of Alderney;" and that "these are a variety of, and smaller than, the Norman; light red, yellow, dun, and fawn-coloured; short, wild-horned, deer-necked, with a general resemblance to that animal; thin, hard, and small-boned; irregular, often very awkwardly shaped." But he considers this description to refer chiefly to the cows. He thinks "they are amongst the best milkers in the world as to quality, and in that respect are either before or immediately next to the long horn, but that in weight of butter for inches they are far superior to all. He has been assured by a respectable friend, that "an Alderney strayed cow during the three weeks she was kept by the finder made nineteen pounds of butter each week; and the fact was held so extraordinary, as to be thought worth a memorandum in the parish books." And it is added, that "the Norman and island cattle make fat very quick, and for their bulk arrive at considerable weight. The beef," in his opinion, "is of the first class, very fine grained, in colour yellow, or of a high colour, with a bluish cast and elastic feel, which denotes the closest grained, most savoury, and finest meat." It is in his recollection, that, "some years since, a heifer, bred between Alderney and Kentish home-bred stock, and fattened on cabbages and carrots, made one hundred and fifty stone, dying uncommonly fat." On this ground he supposes, that "this species is, in course, a proper cross for the large and coarse-boned, but in that view he would prefer the real Normans from the Continent, as generally better shaped than the islanders." He likewise states, that "many persons near the metropolis, and along the south and western coast, make a trade of importing these cattle, which are extremely convenient for private families, and make a good figure in parks and lawns."

Mr. Culley, however, remarks, that they are a breed of cattle too delicate and tender to be much attended to by the British farmer, and not capable of bearing the cold of this island, especially the northern parts of it.

By an experiment which is stated in the *Report for the County of Kent*, made between a large home-bred cow of eight years old and a small Alderney of two years old, it appears that the home-bred cow in seven days gave thirty-five gallons of milk, which made ten

pounds and three ounces of butter, and the Alderney cow, in the same length of time, gave only fourteen gallons of milk, but which made six pounds and eight ounces of butter.

Very useful cattle may be bred by crossing these cows with short-horned bulls. The late Mr. Hunter also produced a very beautiful cow from the Alderney by a buffalo, which is said, in the *Middlesex Report*, to have kept plump and fat, both in summer and winter, on much less food than would be sufficient to support a beast of the same size of the ordinary breed.

ALE (Sax. eale). A liquor obtained from the infusion of malt and hops by fermentation. Ale differs from beer chiefly by having a smaller proportion of hops. There are different sorts of ale brewed, such as strong ale, table ale, pale ale, and brown ale. The pale ale is made from malt which has only been slightly dried, and is generally considered as of a more viscid quality than the brown ale, which is produced from malt that has been roasted, or very hard dried. (*Miller.*) See **BEER** and **BREWING**. The fertility of the soil in grain, and its being not proper for vines, put the Egyptians upon drinking *ale*, of which they were the inventors. (*Arbutnot.*)

A liquor made from fermented barley is mentioned by Herodotus (l. ii. c. 77): the earliest manufactured kind of intoxicating liquid was probably, however, mead. Tacitus notices the use of beer by the Germans. Pliny describes it as common to all the nations of the west. It has long been a favourite beverage of the inhabitants of England. Our Saxon and Danish forefathers drank beer to excess. They regarded it as the drink allotted to those admitted into the Hall of Odin. Ale is named amongst the laws of King Ina; and it was long the custom, when the Norman princes were on the throne, to regulate its price by statute; thus, in 1272, it was ordained that a brewer should sell two gallons of ale in a city for a penny, or three or four gallons for the same price in the country.

Hops were apparently first used for beer in Germany, and in the Dutch breweries about the year 1400; but they were not used generally in England until about the year 1600. Henry VIII., in 1530, even forbade the brewers to mix hops in their beer; and yet, according to Beckmann (*Hist. of Inv.* vol. iv. p. 336), plantations of hops had begun to be formed in England, A. D. 1552: The distinction between ale and beer is thus stated by Dr. Thomson: "Both are obtained by fermentation from the malt of barley, but they differ from each other in several particulars, ale is light-coloured, brisk, and sweetish, or at least free from bitter; while beer is dark-coloured, bitter, and much less brisk. *Porter* is a species of beer, and is what was formerly called strong beer. The original difference between ale and beer was owing to the malt, from which they were prepared. Ale malt was dried at a very low heat, and consequently was of a pale colour; while beer or porter malt was dried at a higher temperature, and had in consequence acquired a brown colour. This incipient charring had developed a peculiar, and agreeable bitter taste, which was communicated to the beer

along with the dark colour. This bitter taste rendered beer more agreeable to the palate, and less injurious to the constitution than ale. It was manufactured in larger quantities, and soon became the common drink of the lower ranks in England. When, during the wars of the French Revolution, the price of malt was very materially increased, the brewers found out that a greater quantity of wort of a given strength could be procured from pale malt, than from brown malt; the consequence was, that pale malt was to a considerable extent substituted for brown malt in the brewing of porter and beer. The wort now, however, was paler, and wanted that agreeable bitter flavour which characterized porter. The porter brewers endeavoured to remedy these defects by several artificial additions, such as burnt sugar, quassia, &c., and most of which the chief London porter brewers have, I believe, long since discontinued." Brewers are obliged, under the 6 Geo. 4, c. 81, to take out an annual license, for which they pay, if brewers of strong beer,

	Barrels.	L. s.
Of not exceeding - - - - -	20	0 10
Of exceeding 1,000 and not exceeding -	2,000	3 0
— 10,000 —	20,000	30 0
— 30,000 —	40,000	60 0
Exceeding - - - - -	40,000	75 0

Considering the increase of population in England, the consumption of beer has not materially increased since 1787, as the following table of the beer brewed in this country in various years will show.

Years ending 5th July.	Strong Beer.	Table Beer.
	Barrels.	Barrels.
1787	4,426,482	485,620
1797	5,839,627	584,422
1807	5,577,176	1,732,710
1817	5,236,048	1,453,960
1825	6,500,664	1,485,750

The number of barrels of beer exported from England is considerable and increasing, amounting in the years ending the

5th of January, 1826 to 53,013 barrels.

— 1828 — 59,471 —

— 1830 — 74,902 —

(*M'Culloch's Dict. of Com.*)

ALEHOOF (*Hedera terrestris*. From *ale*, and *hooff*, head). Ground-ivy, so called by our Saxon ancestors, as being their chief ingredient in ale. This wild plant creeps upon hedge banks, at the foot of trees, and in every shady place, flowering in spring. It takes root at every joint, like the strawberry runners, and its leaves are roundish and notched at their edges, becoming a purple colour as the spring advances. Its flowers are blue, and its roots fibrous. This plant has a peculiar and strong smell; and it is best gathered when in flower. It is an excellent vulnerary or wound-herb, applied outwardly, and taken inwardly. An ointment made from alehoof, or ground-ivy, is very healing to ulcers and fistula. The decoction of the herb drank daily for a continuance is deemed useful for cleansing the stomach, promoting the proper secretions, and sweetening the blood. [The old writers are full of commendations of the medical virtues of ground-ivy, which are extolled for a great

variety of ailments and "griefs," operating as a diuretic, and being excellent in disorders of the lungs and breast.] It obtained its name of Alehoof among the poor, who infuse it in ale or beer, and drink it warm for all internal ailments. (*L. Johnson.*)

ALEXANDER (*Hipposelinum*). This garden vegetable has been superseded by celery, yet it is an excellent vegetable, and grows abundantly wild almost everywhere in England. The seeds and root are hot and dry like those of parsley, and preparations of them are much in use as a popular medicine.

[Some wild species of Alexander are known in the United States. (*See Flor. Ces.*)]

ALIMENT (Lat. *alimentum*). That which nourishes, nutriment or food.

Of *alimentary* roots, some are pulpy and very nutritious, as turnips and carrots. These have a fattening quality. (*Arbuth. on Aliments.*)
See **GASES, EARTH, WATER, &c.**

The food of animals, whether of a solid or liquid kind, should be adapted to their different organs both in quantity and quality, in order that they may exist in the most perfect state. It is observed, that nature directs every animal, instinctively, to choose such substances for food as are best adapted to its health and support; but as some are withdrawn from their natural condition for the convenience of man, and, in their domesticated state, are fed on artificial productions, not of their own choice, it becomes a matter of serious importance to the owners of cattle, horses, &c., to make themselves acquainted with their nature and habits, and also with the qualities of those substances which are usually designed as food for them, since there is no doubt but errors in the choice of the latter must be a fruitful source of disease. Besides, in the view of the grazier, some sorts of food may be much more advantageous in the quality of fattening animals than others—a circumstance of vast importance. See **Food.**

ALKALI. The word *alkali* comes from an herb called by the Egyptians *kali*; by us glasswort. This herb they burnt to ashes, boiled the ashes in water, and after having evaporated the water, there remained at the bottom a white salt—this they called *sal kali* or *alkali*. (*Todd's Johnson.*) The word is of Arabic origin; according to Albertus Magnus it signifies "the dregs of bitterness." (*Thomson*, vol. ii. p. 49.)

The chief alkalies found in plants are potash and soda; ammonia, it is true, is produced by the distillation of certain vegetables, but it is a product of the distillation; and again, morphia is obtained from opium, quinia from the Peruvian bark, &c.; but these alkaline substances are but rarely met with by the cultivator, and do not involve any very important facts of vegetable chemistry.

Potash is found in all vegetables growing at a distance from the sea; that of commerce is procured by merely burning the vegetable, washing the ashes in water, and evaporating the solution of potash thus obtained to dryness. In this manner the potash of commerce is made. The proportion, however, of potash, existing in plants varies very considerably, as

may be seen from the following table of the quantities of ashes and potash obtained from 100 parts of various plants:—

	Ashes.	Potash.

Thomson's Chem. iv. 189.

The potash thus obtained, however, must not be regarded as a pure alkali, for it contains almost always a small portion of various salts, such as the sulphate of potash, muriate of potash, sulphate of lime, phosphate of lime, &c.

Soda abounds in marine plants generally to a much greater extent than potash does in the vegetables of inland districts; the barilla of Spain is extracted from the *salsola sativa* and *vermiculata*, and some of these plants yield nearly 20 per cent. of ashes, which contain about 2 per cent. of soda.

The union of alkalies with acids forms the class of bodies known as the alkaline salts.

[Plants, in their growth, derive certain elements for their subsistence from the atmosphere, namely, carbonic acid, water, and ammonia, the decomposition of the last furnishing their nitrogen. They, however, require other materials for the perfection of certain organs or parts appropriated to the performance of special functions, such, for example, as the perfection of the seed, which is destined to renew the plant. These elements are furnished by the soil, and consist of salts or alkaline substances, such as potash, soda, lime, alumine, magnesia, metallic oxids, and phosphates. The proportion of these contained in soils regulate, in a great degree, their capacities for the production of different plants.]

Connected with agricultural philosophy, the alkalies are subjects of the deepest interest.

The salts of potash and soda, and of the alkaline earths or minerals, lime, alumine, and even magnesia, can be obtained, by burning and certain chemical processes, from parts of the structure of all plants. This shows the great importance of alkalies, and alkaline substances, to the growth and welfare of every product of the soil. It follows also that with every crop removed, a portion of the potash, etc., must be removed from the land. To compensate for such losses, ashes, farm-yard manure, &c., supply alkalies to the soil, along with other fertilizing substances. In rocky districts of country natural sources exist from whence the soil derives a regular supply of potash, namely, the disintegration of granite, and decomposition of its felspar and mica, both of which contain this alkali.

A few years after gypsum was introduced into general use, farmers began to observe a diminution of their hay crops, and to condemn it as an exhauster of the soil. But this charge against plaster was not well founded, at least in the sense it was made.

The numerous instances given by Liebig, of the importance of the alkalies and metallic oxides on vegetation, show that their influence has been too much overlooked. It has been thought remarkable by some vegetable physiologists, that those cereal grasses which furnish food for man, should, as it were, follow him wherever he goes. The reason is to be found in the fact, that none of our grain plants can produce perfect seeds, or seeds yielding farina, without a greater supply of phosphate of magnesia and ammonia than can be found in regions where these salts, resulting from organized vitality, are less abundant. (*Cultivator.*)

Plants growing on a soil, containing a due mixture of earthy ingredients, always select a proportion of each, according to their several capacities or wants. It is a fact of the highest practical value to the agriculturist to know, that where a soil which originally contained all the elements essential to the production of a crop, becomes exhausted of one alkaline or earthy element, another may be substituted so as to compensate for the privation. Where, for example, there is a deficiency in a soil of the alkaline earth—lime, the addition of potash, soda or magnesia, all of which exist in the ashes of wood and other vegetable substances, may be resorted to for the purpose of making it up. Thus, plants when growing in a soil where there is no potash will make up the deficiency by taking up soda, if this last alkali be present.

Plants which grow on or near the sea-shore assimilate or take up soda instead of potash. Sea-salt consists almost entirely of soda, and the sea is therefore to be regarded as the great source of this alkali. It is, however, found in England and many other countries in the form of native rock salt, and also exists in most soils combined with potash. The soda of commerce is usually obtained from the ashes of plants growing on the sea coast, just as potash is procured from the ashes of trees and other vegetables growing inland. (*See Soda, Kelp, &c.*)

The sowing of the earth with salt has from the earliest times been deemed an infallible means of producing total barrenness, and the excess of any salt in a soil is still known to be destructive of fertility.

The perfect development of a plant is, nevertheless, according to Liebig, dependent on the presence of due proportions of the alkalies or alkaline earths, since, when these substances are totally wanting, its growth will be arrested, and when they are only deficient it must be impeded. "Let us compare," says this eminent chemist, "two kinds of trees, the wood of which contains unequal quantities of alkaline bases, and we shall find that one of these grows luxuriantly in several soils, upon which the others are scarcely able to vegetate. For example, 10,000 parts of oak wood yield 250

parts of ashes, the same quantity of fir-wood only 83, of linden-wood 500, of rye 440, and of the herb of the potato-plant 1500 parts.

"Firs and pines find a sufficient quantity of alkalies in granitic and barren sandy soils, in which oaks will not grow; and wheat thrives in soils favourable for the linden-tree, because the bases, which are necessary to bring it to complete maturity, exist there in sufficient quantity. The accuracy of these conclusions, so highly important to agriculture and to the cultivation of forests, can be proved by the most evident facts.

"All kinds of grasses, the *Equisetaceæ*, for example, contain in the outer parts of their leaves and stalk a large quantity of silicic acid and potash, in the form of acid silicate of potash. The proportion of this salt does not vary perceptibly in the soil of corn-fields, because it is again conveyed to them as manure in the form of putrefying straw. But this is not the case in a meadow, and hence we never find a luxuriant crop of grass on sandy and calcareous soils which contain little potash, evidently because one of the constituents indispensable to the growth of the plants is wanting. Soils formed from basalt, grauwackè, and porphyry are, *cæteris paribus*, the best for meadow land, on account of the quantity of potash which enters into their composition. The potash abstracted by the plants is restored during the annual irrigation.* That contained in the soil itself is inexhaustible in comparison with the quantity removed by plants.

"But when we increase the crop of grass in a meadow by means of gypsum, we remove a greater quantity of potash with the hay than can, under the same circumstances, be restored. Hence it happens, that after the lapse of several years, the crops of grass on the meadows manured with gypsum diminish, owing to the deficiency of potash. But if the meadow be strewed from time to time with wood-ashes, even with the lixiviated ashes which have been used by soap-boilers, (in Germany much soap is made from the ashes of wood,) then the grass thrives as luxuriantly as before. The ashes are only a means of restoring the potash.

"A harvest of grain is obtained every thirty or forty years from the soil of the Luneburg heath, by strewing it with the ashes of the heath-plants (*Erica vulgaris*) which grow on it. These plants during the long period just mentioned collect the potash and soda, which are conveyed to them by rain-water; and it is by means of these alkalies, that oats, barley and rye, to which they are indispensable, are enabled to grow on this sandy heath.

* A very high value is attached in Germany to the cultivation of grass as winter provision for cattle, and the greatest care is used in order to obtain the greatest possible quantity. In the vicinity of Liegen (a town in Nassau), from three to five perfect crops are obtained from one meadow, and this is effected by covering the fields with river-water, which is conducted over the meadow in spring by numerous small canals. This is found to be of such advantage, that supposing a meadow not so treated to yield 1,000 lbs. of hay, then from one thus watered 4,500 lbs. are produced. In respect to the cultivation of meadows, the country around Liegen is considered to be the best in all Germany.—L.

"The woodcutters in the vicinity of Heidelberg have the privilege of cultivating the soil for their own use, after felling the trees used for making tan. Before sowing the land thus obtained, the branches, roots, and leaves are in every case burned, and the ashes used as a manure, which is found to be quite indispensable for the growth of the grain. The soil itself, upon which the oats grow in this district, consists of sandstone; and although the trees find in it a quantity of alkaline earths sufficient for their own sustenance, yet in its ordinary condition it is incapable of producing grain.

"The most decisive proof of the use of strong manure was obtained at Bingen (a town on the Rhine), where the produce and development of vines were highly increased by manuring them with such substances as shavings of horn, &c., but after some years the formation of the wood and leaves decreased to the great loss of the possessor, to such a degree, that he has long had cause to regret his departure from the usual methods. By the manure employed by him, the vines had been too much hastened in their growth; in two or three years they had exhausted the potash in the formation of their fruit, leaves, and wood, so that none remained for the future crops, his manure not having contained any potash.

"There are vineyards on the Rhine, the plants of which are above a hundred years old, and all of these have been cultivated by manuring them with cow-dung, a manure containing a large proportion of potash, although very little nitrogen. All the potash, in fact, which is contained in the food consumed by a cow is again immediately discharged in its excrements.

"The experience of a proprietor of land in the vicinity of Göttingen offers a most remarkable example of the incapability of a soil to produce wheat or grasses in general, when it fails in any one of the materials necessary to their growth. In order to obtain potash, he planted his whole land with wormwood, the ashes of which are well known to contain a large proportion of the carbonate of that alkali. The consequence was, that he rendered his land quite incapable of bearing grain for many years, in consequence of having entirely deprived the soil of its potash.

"The leaves and small branches of trees contain the most potash; and the quantity of them which is annually taken from the wood, for the purpose of being employed as litter, contain more of that alkali than all the old wood which is cut down. The bark and foliage of oaks, for example, contain from 6 to 9 per cent. of this alkali; the needles of firs and pines 8 per cent.

"With every 2650 lbs. of fir-wood, which are yearly removed from an acre of forest, only from 0.114 to 0.53 lbs. of alkalies are abstracted from the soil, calculating the ashes at 0.83 per cent. The moss, however, which covers the ground, and of which the ashes are known to contain so much alkali, continues uninterrupted in its growth, and retains that potash on the surface, which would otherwise so easily penetrate with the rain through the

sandy soil. By its decay, an abundant provision of alkalies is supplied to the roots of the trees, and a fresh supply is rendered unnecessary.

"The supposition of alkalies, metallic oxides, or inorganic matter in general, being produced by plants, is entirely refuted by these well-authenticated facts.

"It is thought very remarkable, that those plants of the grass tribe, the seeds of which furnish food for man, follow him like the domestic animals. But saline plants seek the sea-shore or saline springs, and the *Chenopodium** the dunghill from similar causes. Saline plants require common salt, and the plants which grow only on dunghills, need ammonia and nitrates, and they are attracted whither these can be found, just as the dung-fly is to animal excrements. So likewise none of our corn-plants can bear perfect seeds, that is, seeds yielding flour, without a large supply of phosphate of magnesia and ammonia, substances which they require for their maturity. And hence, these plants grow only in a soil where these three constituents are found combined, and no soil is richer in them, than those where men and animals dwell together; where the urine and excrements of these are found corn-plants appear, because their seeds cannot attain maturity unless supplied with the constituents of those matters.

"When we find sea-plants near our salt-works, several hundred miles distant from the sea, we know that their seeds have been carried there in a very natural manner, namely, by wind or birds, which have spread them over the whole surface of the earth, although they grow only in those places in which they find the conditions essential to their life.

"The first colonists of Virginia found a country, the soil of which was similar to that mentioned above; harvests of wheat and tobacco were obtained for a century from one and the same field without the aid of manure, but now whole districts are converted into unfruitful pasture land, which without manure produces neither wheat nor tobacco. From every acre of this land, there were removed in the space of one hundred years 1,200 lbs. of alkalies in leaves, grain, and straw; it became unfruitful, therefore, because it was deprived of every particle of alkali, which had been reduced to a soluble state, and because that which was rendered soluble again in the space of one year, was not sufficient to satisfy the demands of the plants. Almost all the cultivated land in Europe is in this condition; fallow is the term applied to land left at rest for further disintegration. It is the greatest possible mistake to suppose that the temporary diminution of fertility in a soil is owing to the loss of humus; it is the mere consequence of the exhaustion of the alkalies.

"Let us consider the condition of the country around Naples, which is famed for its fruitful corn-land; the farms and villages are situated from eighteen to twenty-four miles distant from one another, and between them there are no

* *Chenopodium album*, called in the United States Lamb's Quarter, a troublesome weed about gardens and houses.

roads, and consequently no transportation of manure. Now corn has been cultivated on this land for thousands of years, without any part of that which is annually removed from the soil being artificially restored to it. How can any influence be ascribed to humus under such circumstances, when it is not even known whether humus was ever contained in the soil?

"The method of culture in that district completely explains the permanent fertility. It appears very bad in the eyes of our agriculturists, but there it is the best plan which could be adopted. A field is cultivated once every three years, and is in the intervals allowed to serve as a sparing pasture for cattle. The soil experiences no change in the two years during which it there lies fallow, further than that it is exposed to the influence of the weather, by which a fresh portion of the alkalies contained in it are again set free or rendered soluble. The animals fed on these fields yield nothing to these soils which they did not formerly possess. The weeds upon which they live spring from the soil, and that which they return to it as excrements, must always be less than that which they extract. The field, therefore, can have gained nothing from the mere feeding of cattle upon them; on the contrary, the soil must have lost some of its constituents.

"Experience has shown in agriculture, that wheat should not be cultivated after wheat on the same soil, for it belongs with tobacco to the plants which exhaust a soil. But if the humus of a soil gives it the power of producing corn, how happens it that wheat does not thrive in many parts of Brazil, where the soils are particularly rich in that substance, or in our own climate, in soils formed of mouldered wood; that its stalk under these circumstances attains no strength, and droops prematurely? The cause is this,—that the strength of the stalk is due to silicate of potash, and that the corn requires phosphate of magnesia, neither of which substances a soil of humus can afford, since it does not contain them; the plant may indeed, under such circumstances, become an herb, but will not bear fruit.

"Again, how does it happen that wheat does not flourish on a sandy soil, and that a calcareous soil is also unsuitable for its growth, unless it be mixed with a considerable quantity of clay? It is because these soils do not contain alkalies in sufficient quantity, the growth of wheat being arrested by this circumstance, even should all other substances be presented in abundance.

"Trees, the leaves of which are renewed annually, require for their leaves six to ten times more alkalies than the fir-tree or pine, and hence, when they are placed in soils in which alkalies are contained in very small quantity, do not attain maturity.* When we see such trees growing on a sandy or calcare-

ous soil,—the red-beech, the service-tree, and the wild-cherry, for example, thriving luxuriantly on limestone, we may be assured that alkalies are present in the soil, for they are necessary to their existence. Can we, then, regard it as remarkable, that such trees should thrive in America, on those spots on which forests of pines which have grown and collected alkalies for centuries, have been burnt, and to which the alkalies are thus at once restored; or that the *Spartium scoparium*, *Erysimum latifolium*, *Blitum capitatum*, *Senecio viscosus*, plants remarkable for the quantity of alkalies contained in their ashes, should grow with the greatest luxuriance on the localities of conflagrations.*

"Wheat will not grow on a soil which has produced wormwood, and, *vice versâ*, wormwood does not thrive where wheat has grown, because they are mutually prejudicial by appropriating the alkalies of the soil.

"One hundred parts of the stalks of wheat yield 15.5 parts of ashes (*H. Davy*); the same quantity of the dry stalks of barley, 8.54 parts (*Schrader*); and one hundred parts of the stalks of oats, only 4.42;—the ashes of all these are of the same composition.

"We have in these facts a clear proof of what plants require for their growth. Upon the same field, which will yield only one harvest of wheat, two crops of barley and three of oats may be raised.

"All plants of the grass kind require silicate of potash. Now this is conveyed to the soil, or rendered soluble in it by the irrigation of meadows. The *equisetaceæ*, the reeds and species of cane, for example, which contain such large quantities of siliceous earth, or silicate of potash, thrive luxuriantly in marshes, in argillaceous soils, and in ditches, streamlets, and other places, where the change of water renews constantly the supply of dissolved silica. The amount of silicate of potash removed from a meadow, in the form of hay, is very considerable. We need only call to mind the melted vitreous mass found on a meadow between Manheim and Heidelberg after a thunder-storm. This mass was at first supposed to be a meteor, but was found on examination (by *Gmelin*) to consist of silicate of potash; a flash of lightning had struck a stack of hay, and nothing was found in its place except the melted ashes of the hay.

"Potash is not the only substance necessary for the existence of most plants, indeed it has been already shown that the potash may be replaced, in many cases by soda, magnesia, or lime; but other substances, besides alkalies, are required to sustain the life of plants.

The soil in which plants grow furnishes them with phosphoric acid, and they in turn yield it to animals, to be used in the formation of their bones, and of those constituents of the brain which contain phosphorus. Much more

* One thousand parts of the dry leaves of oaks yielded 55 parts of ashes, of which 24 parts consisted of alkalies soluble in water; the same quantity of pine leaves gave only 29 parts of ashes, which contained 4.6 parts of soluble salts. (*De Saussure*.)

* After the great fire in London, large quantities of the *Erysimum latifolium* were observed growing on the spots where a fire had taken place. On a similar occasion, the *Blitum capitatum* was seen at Copenhagen, the *Senecio viscosus* in Nassau, and the *Spartium scoparium* in Languedoc. After the burnings of forests of pines in North America poplars grew on the same soil. (*Franklin*.)

phosphorus is thus afforded to the body than it requires, when flesh, bread, fruit, and husks of grain are used for food, and this excess in them is eliminated in the urine and the solid excrements. We may form an idea of the quantity of phosphate of magnesia contained in grain, when we consider that the concretions in the œcum of horses consist of phosphate of magnesia and ammonia, which must have been obtained from the hay and oats consumed as food. Twenty-nine of these stones were taken after death from the rectum of a horse belonging to a miller in Eberstadt, the total weight of which amounted to 3 lbs.; and *Dr. F. Simon* has lately described a similar concretion found in the horse of a carrier, which weighed $1\frac{1}{2}$ lb.

"It is evident that the seeds of corn could not be formed without phosphate of magnesia, which is one of their invariable constituents; the plant could not under such circumstances reach maturity." (*Organic Chemistry.*)

ALKANET (*Anchusa*, Lat.). This plant is a species of bugloss with a red root, brought from the southern parts of France, and used in medicine. It grows wild in Kent and Cornwall, but in other counties only in gardens. It flowers in summer, and its root becomes red in Autumn. The root is astringent: the leaves not so much so. [The puccoon (*Batschia Canadensis*) is called alkanet in the United States. See *Flor. Ces.* p. 118, obs.]

ALLIUM. See ONION, GARLIC, LEEK, SHALLOT, CHIVES, &c.

ALLOTMENT SYSTEM. This designation has been applied in England to a plan for bettering the condition of the poor, by allotting to each family in a parish an extent of ground for the purpose of cultivation with the spade.

Under the article AGRICULTURE it is noticed, that in England, during the feudal times, an allotment system existed. Its object, however, was different; the lords of the soil, having an interest in obtaining as many tenants as they could, for their power was proportionate to their number, portioned their estates into as many small allotments as they could obtain family tenants, receiving in return certain days of military or other service.

When the feudal system was destroyed, the lords let their lands in a similar manner, receiving as rent certain quantities of labour from the tenant, or produce of the land he rented; although, it not being now an object to maintain the number of their tenants, but rather to acquire an increased return of produce, and to obtain a prosperous tenantry, no obstacle was thrown in the way of increasing the size of farms. Land was left like any other subject of investment, and a man obtained as much as his means of cultivating permitted, or as he found to be profitable. These were powerful limitations, for money was scarce, and the agriculturists were chiefly tenants, labourers for hire being few.

In the fourteenth century occurred the greatest revolution that ever happened to the agriculture of England. The increased demand for wool in the Netherlands and at home, rendered the breeding of sheep much more profitable than the growing of corn, and conse-

quently the arable lands were converted into pastures. England had been very closely cultivated, and the small or cotter farms were extremely numerous. These were now generally exterminated, and the land proprietor becoming a great flock-master, converted them all into one breadth of grazing land. "Your sheep," says Sir Thomas More in his *Utopia*, "that were wont to be so meek and tame, and such small eaters, are now become such great devourers, and so wild, that they eat up and swallow down the very men themselves."—"One covetous and unsatiable cormorant, and very plague of his native country, compasses about and encloses many thousand acres of ground together within one pale or hedge, the husbandmen are thrust out of their own, or else, either by covin and fraud, or by violent oppression, they are put beside it, or by wrongs and injuries they be so wearied that they be compelled to sell all; by one means or other, either by hook or by crook, they must needs depart away, poor, silly, wretched souls, men, women, husbands, wives, fatherless children, widows, woful mothers and their young babes, and their whole household, small in substance and much in number, as husbandry requireth many hands. For one shepherd or herdsman is enough to eat up that ground, to the occupying whereof about husbandry many hands were required."

Some few of the cotter farmers were reduced to the grade of hired shepherds; others became artisans, a still smaller number retained a plot of land, but a large portion (for even monastic support was now abolished) became beggars, who, as all records agree, infested England. This gave birth to the poor laws, and the same reign of Elizabeth was the era of an effort to remedy the evils which had arisen from this destruction of small farms.

It had been experienced that though the tenants of those small farms had been poor, yet none of them were paupers; it was therefore thought that every mode of recurring to such a system must be beneficial; and in accordance with this opinion an act of parliament was passed, commanding that to every cottage that should be erected, four acres of ground should be allotted. This first suggestion of the allotment system failed. The quantity of ground allotted was too large, and from its interfering with the just liberties of the landed proprietors, this act was repealed in the last century.

As the value of all farming produce increased from various causes, the profits becoming commensurately large, cultivators required more extensive forms, consolidation proceeded, and in 1709 the first enclosure act passed; and from that time to the present the small occupiers have gradually further diminished, as their right of commonage and the like was taken away by the four thousand enclosure bills that have since been enacted.

When small farmers are deprived of their tenements, they become, if they continue agriculturists, farming labourers. It becomes a subject of very great political importance, therefore, to ascertain how the character

and comfort of these, who are now by far the most numerous class in society, can be best promoted. It would be here misplaced to examine how the system of poor laws has served in various ways to debase and depress them; our present object must be to consider how the allotment system may be the best made to promote contrary effects.

This system, we have noticed, suggested itself to the legislature in the reign of Elizabeth, but it was of very limited operation.

On the Continent, a system of larger allotments was partially adopted in the year 1707, in the Duchy of Cleves, but we are not aware that the example was followed, till, after the lapse of more than a century, the Dutch government, in 1818, divided tracts of poor soil at Frederick's Oord, and other places, into allotments of seven acres. The government provided overseers to notice the moral conduct and industry of the tenants; advanced capital when needed, which was to be repaid; and an annual rent was to be returned. Manual labour was exclusively adopted. The expense of establishing each individual was 22*l.* 6*s.* 4*d.*; and the annual excess of produce over the subsistence of the family, after deducting the rent, twelve shillings per acre, was 8*l.* 2*s.* 4*d.* (*M. de Kirchoff. Jacob on the Corn Trade, &c.*)

About the year 1800, Dr. Law, Bishop of Bath and Wells, commenced the allotment system; Sir H. Vavasour communicated to the Board of Agriculture, about the same period, some experiments demonstrating the great benefit of "the Flemish," or "field-gardening husbandry;" and, in 1802, Charles Howard, Esq. followed the example.

"On Pulley Common, in Shropshire," says Sir W. Pulteney, "there is, at least there was, a cottager's tenement of about 512 square yards, somewhat more than one-ninth of an acre. The spade and the hoe are the only implements used, and those chiefly by his wife, that he may follow his daily labour for hire. The plot of land is divided into two parcels, whereon she grows wheat and potatoes alternately. In the month of October, when the potatoes are ripe, she takes off the stalks of the plants, which she secures to produce manure by littering her pig. She then goes over the whole with a rake, to collect the weeds for the dunghill. She next sows the wheat, and then takes up the potatoes with a three-pronged fork; and by this operation the wheat seed is covered deep. She leaves it quite rough, and the winter frost mellows the earth; and by its falling down in the spring it adds vigour to the wheat plants. She has pursued this alternate system of cropping for several years without any diminution of produce. The potato crop only has manure. In 1804, a year very noted for mildew, she had fifteen Winchester bushels of wheat from 272 square yards, being four times the general averaging crop of the neighbouring farmers. It is to be wished such instances of cottage industry were more frequent; and more frequent they would be, were proper means made use of to invigorate the spirit of exertion in the labouring class."

Since that period the patrons of the system have been very numerous. The clergy have been especially promoters of this system.

Where this system, well regulated, has been tried, and the experience is now very extensive, the results have been most happy. The condition of the poor has been ameliorated; by rendering them more independent, they have become more contented and more careful; better as citizens, and better as individuals.

If the allotments much exceed a quarter of an acre, or in any way approach to the nature of cotter farms, a proportionate blow is made at that employment of capital and talent in agriculture which has raised it to its present improved state.

"The advantages attending this system," says a clerical writer in the *Christian Observer* for 1832, "besides the comfort of the poor man, are the diminution of the poor's rate, and the moral improvement of the labourer. Since this plan has been in operation, the poor-rate has been steadily declining from about 320*l.* to about 180*l.* per annum, with the prospect of still further diminution. When the farmer's work is scarce, the poor man finds profitable employment on his patch of ground, which if he had not to occupy him, he would be sent to idle upon the roads at the expense of the parish. The system has the further and very important effect of improving his character. When the labourer has his little plot of ground, from which he feels he shall not be ejected as long as he conducts himself with propriety, he has an object on which his heart is fixed; he has something at stake in society; he will not hang loose on the community, ready to join those who would disturb it; so much so, that in the late riots, no man in the parish showed any disposition to join them."

From the year 1828 to the present time, numerous pamphlets upon this subject have appeared, and for further information readers are referred to those of Dr. Law, and of Messrs. Scobell, Scrope, Banfill, Denson, Blackiston, Withers, &c.

ALLOWANCES TO TENANTS. Such as are agreed to be made to them on their quitting farms, or under any other circumstances. See *Customs of Counties and Appraisement*.

ALLUVIUM, or ALLUVION (from the Latin *Alluvio*, "an inundation"), is a term which, in the English language, has no very defined meaning. Some authors use it to designate all those rocks which have been formed by causes now acting on the surface of the earth, including those of volcanic origin; while others, adhering to the literal meaning of the original term, confine its application to deposits, whatever be their character, that have resulted from inundations. Neither of these definitions convey the same meaning as is usually attached to the word, the one including too much, the other too little. The term has been badly selected, but is used in its proper application to designate all those deposits recently formed, or now forming, by the agency of water, whether from an uninterrupted and constant stream, or from casual inundation.

All streams, lakes, rivers, seas, and the

ocean itself, hold a large quantity of earthy matter in mechanical solution, which they deposit in their beds. The character of the sediment is governed by the nature of the rocks over which the waters flow; and the quantity depends partly upon the constitution of the rocks, and partly upon the power of the water. If the rock be easily destroyed, and a large body of water flow over it with a considerable velocity, the destructive effect will be great, and much worn materials (*detritus*) being formed, the stream will have a thick and turbid appearance. The same effect is frequently produced by the discharge of a number of tributary streams into a river, all of which accumulate a greater or less quantity of the earths over which they flow.

The distribution of water at the present time, and I more particularly refer to rivers, is very different from that of former periods. The majority of the valleys through which rivers are now flowing, have been produced by the action of water, which, running from higher lands, has not only scooped them out, but has spread over them the worn material which it accumulates in its passage. By the operations which have since been going on, the waters have been collected together in comparatively narrow channels of considerable permanency. On this account, the influence of water that flows over the portions of the earth inhabited by terrestrial animals is greatly restricted; and the production of new beds of rock or soil is rather an accidental than a necessary consequence.

But, although the influence of water has been thus confined, all lands, and especially the surfaces of mountainous districts, are undergoing change, and the superficial covering of one district is conveyed to another. The showers of heaven are constantly sweeping away the soil and decomposed rocks of the uplands into the valleys, over which they are transported by streams and rivers, the larger and heavier particles falling to the bottom, the smaller being united with the water in mechanical mixture. That portion of earthy matter which is carried away from a district by the running water, is, as far as the district itself is concerned, the most valuable, being the superficial covering or soil, and would be forever lost to that portion of the earth inhabited by man, were it not arrested in its passage to the ocean, by deposition in the bed of the river, or on those lands which the waters may happen to overflow.

It is well known to those who have visited elevated districts, that many mountains are already deprived of their soils, and are but the skeletons of the earth, without covering or life. By this action the valleys are in the process of elevation, and the mountains of depression; and if we could conceive it to proceed without limitation, we may imagine a time when all the varieties of elevation and depression, which now give beauty to the surface, will be destroyed, and an entirely different condition of the distribution of land and water will be established. But, at the same time, it cannot be denied that these changes, as far as they have hitherto proceeded, have been advanta-

geous to man, whatever might be their result under the conditions to which we have alluded. The mountainous regions are, from their elevation, less suited to the progression of society, so intimately connected with agricultural prosperity, than the plains. As we rise above the level of the sea, the atmosphere becomes more rarified, and the cold more intense, both of which are injurious to vegetation in general, and unsuited to promote the comfort of animal life. The plains are, therefore, preferred by men when they congregate together, and form societies. It cannot be considered an unwise or unfit result, that the lowlands should be enriched with alluvial soils, produced by the destruction of the rocks and natural soils of mountainous regions. It is reported of Dioclesian, that he told his colleague, Maximilian, he had more pleasure in the cultivation of a few potherbs which, in the gardens of Spalatro, grew in the soil that on the top of Mount Hæmus had only produced moss and dittany, than in all the honours the Roman empire could confer. From the definition I have given of the word "alluvium," I must include the gravels and sands that are of recent formation among the alluvial deposits; but our attention is chiefly directed to the soils, or those beds which are suited to sustain vegetable life. It is true that the gravels may be made available for the cultivation of some plants, but the beds which are so used belong rather to that class of rocks denominated *diluvial* by geologists, than to the deposits of which we are speaking.

If we trace the circumstances under which alluvial soils are formed to their cause, we shall find that they have their origin in the fall of heavy rains, and the melting of snows, in mountainous regions. The water, in its passage to the valleys, collects the superficial soil and decomposed earthy material that lies in its path, and transports them into the channels towards which it flows. The streams that are formed on the mountain slopes are generally united together before they reach the plains, and form impetuous torrents, overcoming all obstacles, until their velocity is lost, when, in their winding courses, they meet each other, and form rivers.

Rivers, in every part of their course, are subject to inundation; when, throwing their waters over a considerable space, they deposit the earthy materials they have accumulated. If such inundations had not occurred, the accumulated worn materials (*débris*) would have been deposited in the bed of the river, or carried into the lake or sea where the waters themselves are discharged. There are abundant instances on record of the filling up of rivers by the worn materials (*detritus*), which have been carried into their courses; and any river of our own country will afford a limited example of this result. Many rivers and estuaries, which a few years since were navigable, have ceased to be so on account of the large amount of alluvial matter deposited in their beds; and many of our towns, which were once populous and wealthy, have on this account become poor and almost deserted. If we would see the effect of the transport of worn

materials into lakes, we cannot have a more favourable opportunity than in Switzerland. Many of the lakes of this sublime and majestic country are rapidly filling from this cause; and in some of them water plants are seen above the surface of the water. But when a river suffers inundation, the earthy matter, which is held in mechanical mixture, is arrested, and deposited on the land that is overflowed, and a richly productive soil is formed. One or two examples may illustrate these remarks.

The Ganges annually overflows its banks, and deposits a rich alluvial soil over the country it inundates. This magnificent river was supposed to take its rise on the northern side of the Himalaya mountains, until it was proved, in 1819, by Lieutenant Webb, that all the streams which unite to give its existence, take their rise on the south side of the Hindoo Coast, or Snowy Mountains. The melting of the snows, and the heavy periodical rains augment the volume of the water, and by the end of June, before the rainy season has commenced in the low country, the river has generally risen fifteen feet; but after the rains in Bengal it usually attains a height of thirty-two feet above its ordinary level. By the end of July all the low countries adjoining the Ganges and the Burrampooter are overflowed, and nothing but houses and trees are seen for many miles inward. The province of Bengal is divided into two nearly equal parts by the Ganges; and as a large portion of the country on the banks of the river is low, it is especially exposed to inundation, from which circumstance it probably derives its name, such districts being called *beng*. A deep bed of rich soil is deposited during the period of the overflow, and the vegetable productions are of the most varied and luxuriant character. Rice, wheat, barley, tobacco, indigo, cotton, the mulberry, and the poppy, are all cultivated with success on the alluvial soils.

It is well known that Egypt has been from time immemorial indebted to the overflow of the Nile for a rich alluvial soil, as well as for the means of irrigating the land. The ancients seem to have been altogether at a loss to account for the periodical overflow of this river; and when we consider the appearances before them, we are not surprised at the difficulties they experienced. They observed it in a country that was not moistened by a drop of rain, and where it was unaided by a single stream, and yet, at its stated period, it began to lift its waters from their bed, and rising higher and higher, overflowed its banks, and spread itself like a sea over Lower Egypt, refreshing the parched earth with moisture, and aiding its productiveness with the formation of a superficial covering of rich loam. The philosophers speculated without success upon its cause; but while they were disputing as to the origin of the phenomenon, year by year the Nile rose, and left the evidence of its beneficial sway in the richness of the crops and the luxuriance of the country. From the investigations that have now been made, we know that the rise of the Nile is occasioned by the rains which fall on the high mountains

in the interior and tropical regions, and not, as many of the ancients supposed, from the Etesian winds, which, blowing periodically from the north, prevent the waters from reaching the sea.

The great importance of rivers, as agents in the production of alluvial soils, cannot be more strongly proved by any positive evidence than by a consideration of the state of Australia, a country remarkable for the fewness of its rivers, and the general poverty of its soil. Contrary to all precedents, the richest soils in this land, excepting the alluvial, are found on the summits of hills. The fires which so frequently happen on the plains, the peculiar character of the vegetation (chiefly consisting of ever-greens), and the sparing distribution of water, are the principal causes of the sterility of this otherwise desirable country. There are, however, spots which, covered with alluvial soil, can rival the richest and most cultivated districts of England; and the comparison of these with other lands impresses the observer the more strongly with the great importance of the natural provision for the restitution of that portion of the earth inhabited by man, by the deposition of new earthy matter and a virgin soil. The alluvial flats of the Nepean, the Hawksbury, and the Hunter rivers, are spoken of by all writers as remarkable for their fertility. The rich valley in which the Lake Alexandrina is situated may be noticed as another example of the influence of alluvial soils. The country around this lake appears to be one of the most beautiful and fertile in Australia; and a glance at the map will immediately inform the inquirer of the cause. It is so situated as to receive the worn materials of the mountain chain that ranges along the promontory of which Cape Jervis is the southern point, and also to obtain moisture at all times from the lake, and a renovating soil whenever it may overflow its banks.

Alluvial soils are produced by the discharge of mountain streams into valleys, as well as by the overflow of rivers. We have already explained the manner in which they collect the superficial covering of mountainous districts, and being charged with earthy matter, bring it into the plains. This may be deposited before the streams are united together in an individual channel as well as after, and should this be done, the valley may be covered with alluvial products. The formation of a river is a process which requires time, and many changes must happen before the flowing waters can form for themselves a local habitation; obstacles must be removed, a bed must be scooped out, and an outlet must be formed, in the performance of which earthy matter must be accumulated, and extensive deposits be formed.

A third cause in the production of alluvial deposits may be mentioned. The sea is making great inroads upon many of its shores, carrying on a destructive war against the cliffs that vainly endeavour to oppose its force; while on the other hand it is in some instances receding from the shores against which it once beat; and thus, as though to recompense man for what it takes away, gives to him a portion

of its own territory. Those districts which are thus added to the land are usually superposed by a fine rich alluvial soil, as also are those which have at a former period been covered by the sea, and would be at the present day, were it not for the ingenuity and works of man.

The districts in which are situated New Orleans in America, and Missolonghi in Greece, are chiefly alluvial, and nearly the whole of Holland has the same character, and can only be described as a district of which man has robbed the ocean. That part of the coast of Germany which is bordered by the North Sea is alluvial, and additions are constantly made to the shores by the gradual depositions of earthy matter upon the immense flats which extend along them. The first sign of vegetation on these lands is the appearance of the saltwort (*Salicornia maritima*), which is succeeded by the sea grass (*Poa maritima*), and when the land is very rich, by the marsh starwort (*Aster Tripolium*). The land is afterwards dyked, and used as pasture for sheep and cattle; so that the spot over which the sea has perhaps for ages exercised an undisputed control, is brought under the power of man in a state most admirably adapted to suit his wants.

In Lincolnshire and other parts of the English coast, where the land is beneath the level of high-water mark, unfruitful districts are often restored to a state of fertility by the removal of the artificial banks that prevent the sea-water from flowing over it. In this way the land is thrown open to the sea, and as the tide rises, it is covered by water, which, being overcharged with earthy matter, deposits in two or three years a bed five or six feet thick of rich soil, which may be brought under cultivation by the exclusion of the agent that was instrumental in its production. (See WARPING.)

But it may be asked, whence does the sea obtain the earthy matter with which it abounds? Rivers discharge themselves into the ocean, and it has been already stated that their waters are charged, more or less, with the superficial soil of mountainous countries, and the destroyed materials of rocks. A part of this may be arrested by occasional or periodical inundations, and by deposition in the bed of the river, but a large quantity must still be carried into the ocean. It must also be remembered that the water which is conveyed in a channel is constantly endeavouring so to arrange its course as to suffer the least possible resistance. In this attempt, it attacks the banks that confine it, and widens its course, precipitating much earthy matter into the stream, to be removed by the flowing water. It frequently happens, and especially after the fall of heavy rains, that the water at the mouths of rivers is thick and turbid from the quantity of alluvial matter it holds in solution, and very many large rivers are rendered unsafe for navigation by the existence of large bars of sand or clay at their outlet.

But the sea is not merely a passive recipient of the product of destructive causes, but is itself a cause. Sea coasts are constantly suffering depredation by the action of the waves that beat upon them. Whether we look

at the soft and almost unresisting rocks of the eastern coast of England, or the hard primary rocks of Devonshire, Cornwall, and the Shetland Isles, the same results will be observed. During the stormy months of winter, when the waves are tossed upon the coasts with an almost uncontrolled violence, no rock is sufficiently hard to resist its energy, and when unruffled by a passing breeze in the months of summer, its influence upon the softer rocks is hardly less destructive, though more insidious, for it then attacks the base of the cliffs, and removing the support of the superincumbent mass, causes the precipitation of large portions into the sea. By these two causes the sea is provided with the materials for the formation of alluvial soils. Some estimate may be formed of the violence and extent of these causes, by an examination of the present state of the German Ocean, one fifth of which is covered by banks that appear to have been produced in the same way as the alluvial soils on the northern coast of Germany.

Water, then, is a most powerful agent in the destruction and production of rocks, and were there no conservative principle, the changes that are going on would be more extensive than they are in the present day. The floods to which some rivers are subject are so impetuous that they frequently sweep away all opposing objects, and involve an entire district in ruin. These effects, however, are much more common in countries that are thinly covered by vegetation than in those where it is luxuriant, for it acts as a conservative agent, increasing the power of the resistance, by binding the soil more closely together. This, therefore, will account for the diminished influence of floods upon lowlands, and for the frequent deposition of rich and fertile alluvial soils.

The composition of the alluvial soils that have been brought under cultivation is exceedingly various; but they are generally remarkable for their fertility, and are admirably suited for pasture lands. "In general," says Sir Humphry Davy, "the soils, the materials of which are most various and heterogeneous, are those called alluvial, or which have been formed by the deposition of rivers; many of them are extremely fertile. I have examined some productive alluvial soils, which have been very different in their composition. A specimen from the banks of the river Parret in Somersetshire, afforded me eighty parts of finely divided matter, and one part of silicious sand; and an analysis of the former gave the following result;

Carbonate of lime	-	-	-	-	-	360 parts.
Alumina	-	-	-	-	-	25
Silica	-	-	-	-	-	20
Oxide of iron	-	-	-	-	-	8
Vegetable, animal, and saline matter	-	-	-	-	-	19

"A rich soil from the neighbourhood of the Avon, in the valley of Evesham, in the Worcestershire, afforded me three-fifths of fine sand and two-fifths of impalpable matter. This last consisted of—

Alumina	-	-	-	-	-	41 parts.
Silica	-	-	-	-	-	42
Carbonate of lime	-	-	-	-	-	4
Oxide of iron	-	-	-	-	-	5
Vegetable, animal, and saline matter	-	-	-	-	-	8

"A soil yielding excellent pasture, from the valley of the Avon, near Salisbury, afforded one eleventh of coarse silicious sand, and the finely divided matter consisted of—

Alumina	-	-	-	-	-	-	7	parts.
Silica	-	-	-	-	-	-	14	
Carbonate of lime	-	-	-	-	-	-	63	
Oxide of iron	-	-	-	-	-	-	2	
Vegetable, animal, and saline matter	-	-	-	-	-	-	14	"

Another striking cause of the fertility of alluvial soils will come more properly under IRRIGATION.—(*Miller's Dictionary.*)

ALMOND, *Silver-leaved* (Lat. *Amygdalus argentea*). A beautiful shrub originally from the Levant. It grows from eight to ten feet high, and blows rose-coloured flowers in April. Its leaves are covered on both sides with a silvery-coloured down, but they do not appear till the flowers are gone. All the almond tribe are hardy, and will bear any situation, if the soil is tolerably good. Propagate by grafting upon the bitter almond or a plum stock. The *double dwarf almond*, Lat. *Amygdalus pumila*, is a smaller shrub, with pale, rose-coloured double flowers, blowing in May, and again in September. The *common dwarf almond*, Lat. *Amygdalus nana*, grows only three feet high, and is a native of Russia. It blows its pink flowers in March and April. Propagate by seed, or grafting upon the bitter almond or plum stocks. Trim away dead wood, but prune seldom, they rarely require pruning. (*L. Johnson.*)

ALMOND TREE (*Amygdalus*, Linnæus; *amand*, Fr.). Derived by *Menage* from *amandala*, a word in low Latin; by others from *Allemand*, a German, supposing that almonds came to France from Germany. But the Spanish have *almendra*; and perhaps *amand*, *amandola*, and this, are all referable to *amygdalum*, as that is to ἀμυγδαλίον. (*Todd's Johnson.*) More than one species, and several varieties of this well known genus are cultivated in England, chiefly for the beauty of their early spring flowers.

The common almond tree (*Amygdalus communis*, Linnæus) is a native of northern Africa, and so late as the time of Cato had not been introduced into Italy, as he calls the fruit Greek nuts (*nucæ Græcæ*). It was introduced into Britain about 1548. It will grow to the height of twenty or thirty feet, dividing into a head of numerous spreading branches. The leaves very much resemble those of the peach, but they proceed from buds both above and below the flowers. There are also small glands on the lower saw-toothing of the leaves. The form of the flowers is not very different from those of the peach, but they come out usually in pairs, and vary more in their colour, from the fine blush of the apple blossom to a snowy whiteness. The chief obvious distinction is in the fruit, which is flatter, with a leather-like covering, instead of the rich pulp of the peach, and the nectarine, and it also opens spontaneously when the kernel is ripe. The shell of the almond is never so hard as a peach stone, and is sometimes even tender and exceedingly brittle. It is flatter, smoother, and the furrows or holes are more superficial than those of the peach stone.

Varieties of the common almond.—1. The nuts

about an inch and a quarter long, with a hard smooth shell; the kernel not valuable. The seedlings are used in France to bud peaches upon.

2. Bitter: fruit of a large size.
3. Bitter: with a tender shell; fruit of a large size.
4. Bitter: with a hard shell; fruit of a large size.
5. Sultan: fruit of a small size.
6. Grand Sultan: fruit of a small size.
7. Sweet: with a tender shell, or tender-shelled Sultan; fruit of a moderate size.
8. Sweet: with a half hard shell.
9. Sweet: with a hard shell.
10. Long-fruited: hard-shelled; fruit of a large size.
11. Peach almond: fruit of a large size.
12. Brittle: fruit of a moderate size.

We are not certain whether the French varieties, called, 1. *Amande douce à coque dure*; 2. *Amande douce à coque tendre*; 3. *Amande des dames*; and 4. *Amande princesse*, coincide with any of the preceding.

The whole of the varieties generally produce a profusion of blossoms, which vary a little in colour from a fine rose to a pale blush. They closely resemble each other in foliage, the principal distinction being in the fruit, which differs either as to its form, its size, or its taste.

In the south of Europe, as in France, Spain, Portugal, and Italy, the almond is cultivated very extensively as a standard fruit tree, the varieties there being very numerous. They export the fruit to every quarter of the globe. The kernel of the almond is the part used, and when it is green, ripe, or dried, it furnishes a most agreeable addition to the dessert. It is also used to a very great extent in confectionary, perfumery, cookery, and medicine.

The general purpose of introducing the tree into gardens and pleasure grounds in England is for the great beauty of its blossoms, which are not only handsome, but being produced in such profusion as they usually are at so early a period of the spring season, before the foliage appears, become extremely conspicuous and highly ornamental; a circumstance which renders the tree a most desirable shrubby plant.

The common almond, and its varieties, blossom earlier than the dwarf kinds, from which circumstance the blossoms of the latter are very rarely damaged by spring frosts, but the other kinds, when planted in situations sheltered from the east winds, are generally preserved from sustaining damage.

Propagation.—All the species and varieties are propagated by seeds, budding, grafting, layers, and occasionally they will produce suckers, which may be successfully planted out. When stocks for budding or grafting upon are wanted, or new varieties desired, these are obtained by sowing the fruit stones, though they may be budded or grafted on mussel-plum stocks.

The stones of the last season's produce should be sown in October, upon a bed of light rich soil, about three inches apart, and covered four inches deep with fine soil. This is indispensable; for when the soil is left in lumps, the

shoots are often forced into a crooked direction, and this causes the trunk to be deformed, and unfit to become a fine tree. When the surface of the seed-bed has been smoothed, a covering of rotten tanner's bark, or leaf mould, to the depth of two inches, must be laid upon it, which being light, prevents the fruit-stones from being damaged by any severity of winter. At the beginning of May this covering of bark or leaves must be raked clean off the bed. The stones might be reserved till spring, and be sown at the end of March, but the plants do not come so certainly as when sown in autumn. An additional advantage of an autumn sowing is, that the plants come up about six weeks or two months earlier than those sown in spring; consequently the plants become vigorous and well rooted the first year, and thereby not liable to be thrown out of the ground by thaws succeeding frost in the following winter.

During summer, care must be taken to pull up all weeds, when very young, for if they be allowed to get strong before pulling out, this operation is apt to injure the roots of the almond plants.

When almond stones have been sown in spring, it will be necessary at the approach of the succeeding winter to have the beds covered with rotten tanner's bark, or leaf mould, scattering it an inch deep, or more, amongst the plants, a covering which will tend to prevent the plants being injured or thrown out by frost.

In the second spring after the sowing, the plants should be taken up, carefully preserving all the fibrous roots, a care which, as they are but sparingly produced, will be essentially necessary. The plants must be transplanted in rows, at two feet apart, row from row, and a foot and a half distant in the rows. Here they may be trained to form standards, half standards, or dwarfs, and be regulated and prepared either for wall training or shrubbery plantations. For both purposes, attention will be requisite during summer and winter, to thin out the branches, reserving only a suitable number for the future limbs of the tree, and these so far apart that they may not, in any future stage of growth, be liable to rub against each other, which standard trees would be liable to; for if this be not avoided, gum would be exuded at such injured parts, and the speedy decay of the tree be the consequence.

Almond plants intended for training against walls should have some stakes fixed in the form of a trellis, to which the branches should be secured in a proper form, so that they may be suited to the position of the wall on their final removal. (*Miller's Dictionary.*)

[In many parts of the Middle and Southern United States, the climate admits the almond tree to mature its fruit. The kind with a hard and smooth shell will ripen in New Jersey and the southern part of Pennsylvania, near Philadelphia. A communication published in the 15th vol. of the *American Farmer* states that the more tender and valuable soft-shell kind have been brought to perfection at Cambden, Kent County, Delaware, which is about eighty miles south of Philadelphia.]

ALOPECURUS. A genus of grasses of the foxtail kind, of which there are several species, some of which may be cultivated to advantage in the field.

Alopecurus agrestis. Slender foxtail-grass. (*Alopecurus myosuroides*, Curt. Lond.) One of the most inferior species of this grass. The herbage it produces is comparatively of no value whatever. It appears to be left untouched by every description of cattle. The seed is produced in considerable abundance, and is eaten by the smaller birds, as well as by pheasants and partridges. This annual species of foxtail-grass is distinguished from the perennial meadow foxtail (*Alopecurus pratensis*) by the total want of woolly hairs on the spike, so conspicuous in that of the *A. pratensis*. The Rev. G. Swayne observes, that it is a very troublesome weed in many places among wheat, and execrated by farmers under the name of black bent.

"I have always," says Mr. Sinclair, "found it prevalent in poor soils, particularly such as had been exhausted by avaricious cropping. It is most difficult to extirpate when once in possession of the soil; for it sends forth flowering culms during the whole summer and autumn, till frost arrests it; so that it can bear to be repeatedly cut down in one season, without suffering essentially by the process. Indeed, it will be found a vain and unprofitable labour to attempt the removal of this grass by any other means than the opposite to that which gave it possession of the soil, which is judicious cropping. To return land, in this state, to grass, in the hope of overcoming this unprofitable plant, will be found of little avail. I have witnessed this practice, and the slender foxtail, instead of disappearing in these instances, re-appeared with the scanty herbage, and in greater health and abundance. The soil must first be got into *good heart* by very moderate and judicious cropping, which includes the proper application of manure, a skilful rotation of crops, and the most pointed attention to the destruction of weeds; which last can only be effected, in this sense, by adopting the drill or row culture for the crops. After this the land may be returned to grass for several years with every prospect of success. It flowers in the first week of July, and successively till October.

Alopecurus arundinaceus. Reed-like foxtail-grass. The substance of the culms and leaves of this grass is coarser than that of the *Alopecurus pratensis*; and the root is so powerfully creeping as to render its introduction into arable land a matter of great caution. The produce and nutritive powers are very considerable: it is an early grass, producing culms at an early period of the spring, and continuing to vegetate vigorously through the summer and autumn. It cannot be recommended as a constituent of permanent pasture; but as a grass to cultivate by itself, to a certain extent, for green food, or for hay, it offers advantages in the superior produce and nutritive powers above stated. It grows stronger, and attains to a greater height, than the *A. Tauntoniensis*; but, owing to the roots spreading wide, being large, and requiring a consequent greater sup-

ply of nourishment from the soil, the produce stands thinner and proves less weighty than the crops afforded by that variety. It flowers in April or early in May, and continues to produce flowering culms until the autumn.

Alopecurus bulbosus geniculatus. Bulbous-rooted, knee-jointed, foxtail-grass. The produce and nutritive powers of this perennial grass are so inconsiderable as to justify a conclusion that it is comparatively of no use to the agriculturist. I have found it but seldom in a wild state. It grows on a soil of a drier nature than the fibrous-rooted variety, to be spoken of hereafter. When raised from seed on a moist soil, it still retains the bulbous root, which goes the length to prove, that if it is not a distinct species, it is at least a permanent variety.

Alopecurus geniculatus. Knee-jointed, foxtail-grass. There are two varieties of this species of foxtail-grass: the present, which is by far the more common, is distinguished from the other by its fibrous root and greater size; the less common variety has a bulbous root. The *A. bulbosus* may be distinguished from the bulbous-rooted variety of the knee-jointed species, by its upright culms, which want the knee-jointed form so conspicuous in the culms of the former. (*Sm. Engl. Flora.*) It is a perennial, and grows commonly in surface drains, and at the entrance of cattle ponds, particularly where the soil is clayey. It does not appear to be eaten with much relish by either cows, horses, or sheep. Its nutritive powers are not considerable, and its sub-aquatic natural place of growth excludes any recommendation of it for cultivation. Flowers in the first week of June, and during the summer. [This species is designated by Professor Dewey as the true foxtail-grass, which in Massachusetts grows in wet, muddy bottoms, flowering in July.]

Alopecurus pratensis. Meadow foxtail-grass. [See Plate 5, of PASTURE GRASSES, g.] This grass is a native of Britain and most parts of Europe, from Italy, through France, Germany, Holland, to Denmark, Norway, Sweden, and Russia.

Under the best management, it does not attain to its fullest productive powers from seed till four years; hence it is inferior to the cock's-foot grass for the purposes of ultimate cropping, and to many other grasses besides. The herbage, however, contains more nutritive matter than that of the cock's-foot, though the weight of grass produced in one season is considerably less. It thrives well under irrigation, keeping possession of the crowns of the ridges; and is strictly permanent. Sheep are very fond of it; when combined with white clover only, the second season on a sandy loam, it is sufficient for the support of five couple of ewes and lambs per acre. As it only thrives in perfection on lands of an intermediate quality as to moisture and dryness, and also being somewhat longer in attaining to its full productive state than some other grasses, its merits have been misunderstood in many instances; and in others, as in the alternate husbandry, it has been, by some persons, set aside altogether.

In many rich natural pastures, it constitutes the principal grass. Though not so well adapted, therefore, for the alternate husbandry, it is one of the best grasses for permanent pasture, and should never form a less proportion than one-eighth of any admixture of different grasses prepared for that purpose; its merits demand this, whether in respect to early growth, produce, nutritive qualities, or permanency. It has been observed by the Rev. Mr. Swayne, (in his *Gramina Pascuæ*, a work which contains much valuable information on the subject of grasses), that nearly two-thirds of the seed is constantly destroyed by insects: according to my experiments, this evil may be almost entirely obviated by suffering the first culms of the season to carry the seed. It flowers in April, May, and June, according as it may have been depastured earlier or later. Seed ripe in June and July, according to the season of flowering. The meadow-foxtail constitutes part of the produce of all the richest pastures I have examined in Lincolnshire, Devonshire, and in the vale of Aylesbury. In Mr. Westcar's celebrated pastures at Creslew I found it more prevalent than in those of Devonshire and Lincolnshire.

Experiments tend to prove that there is nearly three-fourths of produce greater from a clayey loam than from a silicious sandy soil, and that the grass from the latter soil is of comparatively less value in the proportion of 3 to 2. The culms produced on the sandy soil are deficient in number, and in every respect smaller than those from the clayey loam; which satisfactorily accounts for the difference in the quantity of nutritive matter afforded by equal quantities of the grass. It is not the strength and rankness of the grass that indicates the fitness of the soil for its growth, but the number and quality of the culms. The proportionate value in which the grass of the latter-math exceeds that of the flowering crop is as 4 to 3; a difference which appears extraordinary when the quantity of flowering culms is considered. In the *Anthoxanthum odoratum* the proportional difference is still greater, the latter-math being to the flowering crop in nutriment nearly as 9 to 4. In the *Poa trivialis* they are equal; but in all the later-flowering grasses that have culms resembling those of the meadow-foxtail and sweet-scented vernal, the greater proportional value is always, on the contrary, found in the grass of the flowering crop. Whatever the cause may be, it is evident that the loss sustained by taking these grasses at the time of flowering is considerable. In ordinary cases, this seldom happens in practice, because these grasses perfect their seed about the season when hay-harvest generally commences, unless where the pasture has been stocked till a late period in the spring, which cannot, in this respect, be productive of any ultimate advantage, but rather loss. The proportional value which the grass, at the time the seed is ripe, bears to that at the time of flowering is as 3 to 2. The superiority of the produce from a light loam over that from a clayey soil is as 4 to 3.

Alopecurus Tauntonensis Taunton's meadow

foxtail-grass. This holds a middle station between the *Alopecurus pratensis* and *Alopecurus arundinaceus*.

The produce and nutritive powers of the se-

veral species of *Alopecurus*, may easily be seen by a reference to the following analytical classification (*Sinclair's Hort. Gram.*):—

Description of Grass.	Soil.	Green Produce per Acre.		Dry Produce per Acre.		Produce per Acre of Nutritive matter	
		lbs.		lbs.		lbs.	
<i>Alopecurus agrestis</i> , in flower	Sandy loam	8,167	8 0	3,164	14 8	223	5 4

ALPACA. A peculiar breed of Peruvian sheep, for whose introduction into England considerable efforts have been recently made. A very excellent "Memoir" upon these interesting animals has recently (1841) been published by Mr. William Walton, from whose work are gathered the following interesting facts:—"When the Spanish adventurers under Pizarro crossed the isthmus of Panama and reached the shores of the Pacific, they bent their steps towards Peru, and arriving there found the inhabitants in possession of two domestic animals, the beauty and utility of which excited their admiration. They also ascertained that two others, alike in species, although varying in properties, existed in a wild state. Struck with the analogy, and always disposed to see objects of comparison with the productions of their own land, the Spaniards called this new breed of cattle *Carneros de la tierra*, or country sheep, and in their use of them imitated the natives. Acosta, one of the earliest naturalists who embarked for the New World, wrote an account of these interesting animals, derived from personal observation; and that account, which made its appearance in 1590, is perhaps the best ever penned. He says (*Historia Natural y Moral de los Indias*, lib. iv. c. 41), "There is nothing in Peru more useful, or more valuable, than the country sheep called llamas, and they are as economical as they are profitable. From them the natives obtain both food and clothing, as we do in Europe from sheep, and besides use them as beasts of burden. They require no expense in either shoeing, packsaddles, bridles, or even barley, serving their masters gratuitously, and being satisfied with herbage picked up on the wastes. Thus did Providence provide the Peruvians with sheep and beasts of burden united in the same animal, and on account of their poverty, seems to have wished that they should enjoy this advantage, free from expense, as pastures in the highlands are abundant. These sheep are divided into two kinds; the one called *paco* bears a heavy fleece of wool, while the others have only a short coat, and are better adapted for carrying burdens. They have a long neck, similar to the camel, and this they require; for being tall and upright, they stand in need of an elongated neck to reach their food. The colours of both animals vary, some being entirely white, others entirely black, and occasionally particoloured. The meat is good, that of the fawn is best and most delicate, although the Indians use it spa-

ringly, their principal object in rearing this breed of cattle being to avail themselves of its wool for clothing and of its services to carry loads. The wool they were accustomed to spin and weave into garments, one of their kinds of cloth, called *huasca*, being coarse and in more general use; while the other, known by the name of *cumbi*, was of a finer and more delicate quality. Of the latter they still make mantles, table-covers, quilts, and various articles of ornamental dress, which are durable, and have a gloss upon them, as if partly made of silk. Their mode of weaving is peculiar to themselves, each side of the web being alike; nor in a whole piece is it possible to discover an uneven thread or a knot. The Peruvian incas, or emperors, kept experienced masters to teach the art of making the *cumbi*, or superfine cloth, the principal part of whom resided in the district of Capachica, where they had public establishments, and with the aid of plants gave to it various colours, bright and lasting. The men and women in the highlands were mostly manufacturers, having looms in their own houses, which precluded the necessity of going to market to purchase clothing."

"The Indians still possess large droves, consisting of 400, or 1000 head each, which they load, and with them perform journeys, travelling like a string of mules and carrying wine, coca, corn, chuño (a nutritive food made from potatoes, first frozen, and afterwards reduced to powder), quicksilver, and other articles of merchandise, and more especially that which, of all others, is the most valuable, viz., silver, ingots of which they bear from Potosi to Arica, a distance of seventy leagues, as they formerly did to Arequipa, more than twice as far. Often have I been astonished at seeing these droves carrying 1000 or 2000 ingots, valued at more than 300,000 ducats, journeying slowly on with no other guard than a few Indians, who chiefly served to load and unload, or, at most, two or three Spaniards. They sleep in the open country; and though the journey is long, and the protection afforded so extremely weak, no part of the silver is ever missing. The load usually carried by each animal is from four to six *arrobas*, (each *arropa* has twenty-five lbs.); and if the journey is long they do not travel beyond three or four leagues per day. The drivers have their known resting-places, where they find pasture and water, and on arriving there, unload, pitch their tents, light a fire and dress their own food, while the bearers of their burdens are turned out loose."

He further remarks that the flesh of these animals was jerked and made into *cusharqui*, or, as the Spaniards call it, *cecina*, which kept good for a considerable time, and was in very general request. "Both species," he says, "are accustomed to a cold climate, and thrive best in the highlands. Often does it happen that they are covered with snow and sparkling with icicles, and yet healthy and contented." Speaking of the vicuñas, the same author observes that they are wild and timid, inhabiting the *pumas*, or snowy cliffs, and are affected by neither rain or snow. To this he adds that they are gregarious, extremely fleet, and that on meeting a traveller, or beast of the forest, they fly away, collecting and driving their young before them. He further affirms that the vicuña wool is as soft as silk, made into fine stuffs, and requires no dyeing; adding, that many persons also considered it medicinally useful in cases of pains in the loins and other parts of the body, in consequence of which they had mattresses made of it.

Inca Garcilasso de la Vega, a native of Peru, was the next Spaniard of note who described the *Carneros de la tierra*, and subjoined are his leading remarks:—"The domestic animals which God was pleased to bestow on the Indians, congenial to their character and like them in disposition, are so tractable that a child may guide them, more particularly those accustomed to bear burdens. Generally they are called llamas, and the keeper *llama-michec*. As a distinction, the larger kind is called *huanacu-llama*, owing to its resembling the wild one of that name, from which it only differs in colour, the tame breeds being seen of all hues, whereas the wild ones have only one, and that is a light brown. The height of the domestic breeds is that of a deer, and to no animal can they be likened so justly as the camel, excepting that they are smaller and have no hunch on the back. The skin was anciently steeped in tallow, in order to prepare it, after which the Indians used it for shoes, but the leather not being tanned, they were obliged to go bare-footed in rainy weather. Of it the Spaniards now make bridles, girths, and cruppers for saddles. The llama formerly served to bear loads from Cusco to the mines of Potosi, in droves of 800 or 1000, each animal carrying three or four *arobas*. The paco was chiefly valued for its flesh, but more especially for its wool, long, but excellent, of which the natives made cloths, and gave to them beautiful and never-fading colours."

The Peruvian sheep are peculiar to that part of South America, bordering on the Pacific, which extends from the equator beyond the tropic of Capricorn, that long and enormous range of mountains known as the Andes Cordilleras. Along this massive pile every imaginable degree of temperature may be found in successive gradation. Below stretches a narrow strip of land, washed by the sea, where the heat is intense and it never rains, but where, owing to heavy dews and filtration from the mountains, vegetation is luxuriant and an eternal spring reigns. As one ascends, the aspect of the country changes, and new plants appear; but no sooner are the middle

summits gained, and the sun has lost his power, than those cold and icy regions rise up, one above the other, called by the natives *punas*, which are again crowned with rocky crests, broken by deep ravines and rugged chasms, and presenting a wilderness of crags and cliffs never trodden by the human footstep, and never darkened, except by a passing cloud, or the eagle's wing. In this land of mist and snow, or rather in the hollows which surround it, feed the guanaco and vicuña, at an elevation of 12,000 or 14,000 feet above the level of the sea; while in the lower regions, stretching immediately under the snowy belt, and where the Indian fixes his abode at a height from 8,000 to 12,000 feet, may be seen pasturing those flocks of llamas and alpacas which constitute his delight, and at the same time the principal part of his property.

Here, amidst broken and precipitous peaks, on the parapets and projecting ledges, slightly covered with earth, or in the valleys formed by the mountain ridges, like the Pyrenean chamois, the llama and alpaca pick up a precarious subsistence from the mosses, lichens, tender shrubs, and grassy plants which make their appearance as the snow recedes; or, descending lower down, revel in the *pajonales*, or, as they are called in some parts of the country, *ichuales*—natural meadows of the *ichu* plant, the favourite haunts of the tame and wild kinds. Thus the hand of man never prepares food for either species—both readily find it on their native mountains. Besides the extremes of cold, these animals have equally to endure the severities of a damp atmosphere, for while below it seldom rains, in the summer months, when evaporation from the sea is abundant, clouds collect, and being driven over the lower valleys by strong winds from the south and west, and condensed by the cold, burst on the highlands, where the rain falls in torrents, amidst the most awful thunder and lightning.

However bleak and damp the situation, little does it matter for an animal requiring neither fold nor manger, and living in wild and desolate places, where the tender is often obliged to collect the dung of his flock to serve as fuel for himself. Although delicate in appearance, the alpaca is, perhaps, one of the hardiest animals of the creation. His abstinence has already been noticed. Nature has provided him with a thick skin and a warm fleece, and as he never perspires, like the ordinary sheep, he is not so susceptible of cold. There is, therefore, no necessity to smear his coat with tar and butter, as the farmers are obliged to do with their flocks in Scotland, a process which, besides being troublesome and expensive, injures the wool, as it is no longer fit to make into white goods, nor will it take light and bright colours. In the severest winter the alpaca asks no extra care, and his teeth being well adapted to crop the rushes and coarse grass with which our moors abound, he will be satisfied with the refuse left upon them. In a word, he would live where sheep must be in danger of starving.

The importations of sheep's wool from Peru into Liverpool, principally alpaca, have stead

ily advanced since the article became known to the manufacturer,—the best proof of its worth. In 1835 they amounted to 8,000 bales; in 1836, to 12,800; in 1837, to 17,500; in 1838, to 25,765; in 1839, to 34,543; and in 1840, to 34,224—more than quadrupled in six years.

In the Custom House returns, it is to be regretted that alpaca wool is not distinguished

from the ordinary kinds arriving from Peru. The total imports for the last five years of all sheep's wool, distinguishing from Peru (including alpaca) and other parts, and also of red, or vicuña wool, together with raw and thrown silks, and goat's hair or wool, and mohair yarn, are here subjoined:—

	1836.	1837.	1838.	1839.	1840.
	lbs.	lbs.	lbs.	lbs.	lbs.
Sheep's wool:					
From Peru -	953,974	1,914,137	2,303,794	2,145,106	2,762,439
Other parts -	63,284,677	46,464,957	50,289,846	55,228,349	46,630,638
Total -	64,238,651	46,379,094	52,593,640	57,373,455	49,393,077
Red Wool:					
From Peru -	1,248	614	294	4,465	7,940
Other parts -	78	-	421	2,003	34,377
Total -	1,326	614	715	6,468	42,317
Raw silk -	4,453,081	4,146,481	3,458,959	3,746,248	3,758,841
Thrown silk -	396,660	231,203	265,130	225,268	288,994
Goat's hair or wool -	1,117,629	602,373	942,770	992,188	989,257
Mohair yarn -	89,298	29,199	20,546	13,645	2,664

With regard to the number of these sheep now in England, and their capability of being naturalized, Mr. Walton adds, "Mr. Bennett, of Farindon, had a pair of llamas sent to him from Peru twenty years ago, and fed them as sheep are usually fed, with hay and turnips in the winter. From his own experience he found that they are particularly hardy and very long-lived. He increased his stock, and has actually had six females at a time which have had young ones. Of these very few have died. The number of Peruvian sheep in the kingdom at present (July 1841) [is short of 100, chiefly distributed in parks]. The existence of this number among us, supported by their healthy appearance, as reported to me from every quarter where I have been able to institute inquiries, is a better proof of the capacity of Andes sheep to adapt themselves to our climate, than any further arguments or elucidations which I could adduce."

[The demand for alpaca wool in England, which the table indicates is rapidly increasing, certainly shows that it is well worthy the attention of North American farmers to make the experiment of raising Peruvian sheep. At a late meeting of the British Association for the Advancement of the Arts and Sciences, Mr. Dawson made a communication on the subject of the introduction into England, of a species of *Auchenia*, or Llama of South America, and presented specimens of alpaca wool, in its natural and manufactured states, resembling silk, and without being dyed, as black as jet. Naturalists distinguish five species of the llama, all of which afford wool. But the alpaca alone has fine wool, from six to twelve inches long, and the vicuña wool, like the fur of the beaver, at the base of its coarser hair. It is capable of the finest manufacture, and is especially adapted to such fabrics as the finest shawls. The yarns spun in England are mostly sold in France for the shawl trade, at from \$1.50 to \$3.50 per pound, according to quality, the price of the wool in a natural state being about fifty cents per pound. This wool is naturally free from grease, in which respect it differs materi-

ally from that of common sheep, and the animal requires no washing before shearing. Mr. Dawson remarked, that it was not certain whether the alpaca could be made to thrive in Great Britain. The last remark might raise a doubt whether it could be raised to advantage in the United States. Should it be proved that the alpaca was not adapted to any part of Great Britain, it would furnish no solid argument against their adaptation to the climate of the United States, especially the Northern States, and the mountainous districts everywhere. An interesting account of this animal will be found in the third volume of the *American Farmer*.]

ALTERATIVE MEDICINES. In farriery, are such medicines as possess a power of changing the constitution, without any sensible increase or diminution of the natural evacuations.

ALTERNATE HUSBANDRY. That sort of management of farms, which has one part in the state of grass or sward, while the other is under the plough, so as to be capable of being changed as there may be occasion, or as the nature of the land may require. This system of management is supposed to lessen the expense of manure, and keep the land more clean. (See **HUSBANDRY**.)

ALTITUDE (Lat. *albedo*, from *altus*, high). In vegetable physiology, altitude or elevation of surface above the level of the sea is equivalent to a receding, whether north or south, from the line of the equator, 600 feet of altitude being thought to be equal to a degree [of latitude.] Hence it follows that all varieties of climate, and consequently all varieties of vegetable habitat, may exist even in the same latitude, merely by means of variety in the altitude of the spot. This was found by Tournefort to be literally the fact, during his travels in Asia. At the foot of Mount Ararat he met with plants peculiar to Armenia; above these he met with plants which are found also in France; at a still greater height he found himself surrounded with such as grow in Sweden, and at the summit, with such as vegetate in

the polar regions. Baron Humboldt, in his *Personal Narrative*, gives us a similar account of the several zones of vegetation existing in a height of 3730 yards on the ascent of Mount Teneriffe. The first zone is the region of vines, extending from the shores of the ocean to a height of from 400 to 600 yards, well cultivated, and producing date trees, plantains, olives, vines, and wheat. The second zone is the region of laurels, extending from about 600 to 1800 yards, producing many plants with showy flowers, and moss and grass beneath. The third zone is the region of pines, commencing at 1920 yards, and having a breadth of 850 yards. The fourth zone is the region *Retama*, or broom, growing to a height of nine or ten feet, and fed on by wild goats. The last zone is the region of grasses, scantily covering the heaps of lava, with cryptogamic plants intermixed, and the summit of the mountain bare.

This accounts for the great variety of plants which is often found in no great extent of country; and it may be laid down as a botanical axiom, that the more diversified the surface of the country, the richer it will be in species, at least in the same latitudes. It accounts, also, for the want of correspondence between plants of different countries, though placed in the same latitudes; because the mountains, or ridges of mountains, which may be found in the one and not in the other, will produce the greatest possible difference in the character of the genera and species. To this cause we may ascribe the diversity that often actually exists between plants growing in the same country and in the same latitudes; as between those of the north-west and north-east coasts of North America, as also of the south-west and south-east coasts; the former being more mountainous, the latter more flat. Sometimes the same sort of difference takes place between the plants of an island and those of the neighbouring continent; that is, if the one is flat and the other mountainous; but if they are alike in their geographical delineation, they are generally alike in their vegetable productions.

[Meteorologists generally compute, that as land rises above the level of the sea or tide-water, the temperature of its climate grows colder at the rate of 1° Fahrenheit, for every 300 feet or 100 yards of elevation. It has however been found that the decline of temperature on rising above the common level of the sea, is less where large tracts of country rise gradually than when the estimate is made either by balloon ascension, or scaling the sides of isolated and precipitous mountains. A striking illustration of this is offered by the ridges and valleys of the great Himmaleh mountains of Southern Asia, where immense tracts, which theory would consign to the dreariness of perpetual congelation, are found richly clothed in vegetation and abounding in vegetable and animal life. At the village of Zonching, 14,700 feet above the level of the sea, in lat. 31° 36' N. Mr. Colebrook found flocks of sheep browsing on verdant hills; and at the village of Pui, at about the same elevation, there are produced, according to Captain Gerard, the most luxuriant crops of barley,

wheat, and turnips, whilst a little lower the ground is covered with vineyards, groves of apricots, and many aromatic plants.

The effects of gradual elevation in lessening the falling off of temperature, is manifested upon a moderate scale in our own country. The [annual] mean temperature of Eastport, Me., for example, is 42°.95, whilst that of Fort Snelling in the same latitude, but far in the interior, with an elevation of some 600 or 800 feet above the sea, is 2°.88 higher, namely, 45°.83, instead of being two or three degrees colder, to correspond with the law of elevation. (*Amer. Med. Jour.* July, 1842.)

ALUM (Lat. *Alumen*). The sulphate of alumina and potash of the chemist, [or common alum], is composed, according to the analysis of Berzelius (*Ann. de Chim.* 82—258), of

Sulphuric acid	-	-	-	-	-	34.23
Alumina	-	-	-	-	-	10.86
Potash	-	-	-	-	-	9.81
Water	-	-	-	-	-	45.00
						99.90

In veterinary practice, alum in powder is sometimes used externally for destroying trifling excrescences, arresting bleeding, &c. A little, very finely powdered, is occasionally blown through a quill into the eye for the purpose of removing specks of long standing.

Alum lotion is prepared by dissolving from six to eight drachms of alum powder in two pints of water. This forms an inexpensive and tolerably efficacious application for mild forms of grease, cracks in the heels of horses, and for superficial sores of all kinds. It should not be used till the surrounding inflammation has been subdued by time or proper remedies. In its weakest state, the alum lotion is serviceable in the cankered ear of dogs, and wounds or ulcers of the mouth in any animal.

Alum ointment is composed of one drachm of the powder to one ounce each of turpentine and hog's lard, incorporated by heating. This supplies the place of the lotion when the sores are apt to become dry and hard. It is, however, very little used.

Burnt alum is made by boiling a solid piece of the salt on an iron plate over a fire till it becomes quite dry and white, taking care not to make the heat so strong as to decompose it. This, in powder, is sometimes used for specks in the eye. (*Miller's Dictionary*.)

ALUMINA. The pure earth of clay, was so named from having been obtained in a state of the greatest purity from alum, in which salt it exists combined with sulphuric acid, and potash. This earth when pure has but little taste, and no smell. The *earthy* smell which clay emits when breathed upon, is owing to the presence of oxide of iron. Its specific gravity is 2.00. When heated it parts with a portion of water, and its bulk is considerably diminished. Hence most *clay* lands are apt to crack, by their contraction in dry weather. There is little doubt, from the experiments of Davy, but that alumina is the oxide of a metal, which has been denominated aluminum, although he did not succeed in procuring it in a separate state.

Of all the earths alumina is found in plants in the smallest proportions, 32 ounces of the

seeds of wheat only contain 0.6 of a grain, and those of the barley and the oat only about 4 grains.

If some clay be dissolved in water, and some aqua ammonia (*hartshorn*) be added to it, the mixture will assume a milky whiteness, and if left to stand awhile, a white substance will be precipitated, called in chemical language *alumina*. Prof. J. F. W. Johnston does not regard this as a nourishing element to plants. Its use in soils he considers entirely mechanical, binding the other materials together by its tenacity, so as to furnish that degree of stiffness necessary for the support of plants. Liebig takes a different view of the subject. "It is known," he says, "that the aluminous minerals are the most widely diffused on the surface of the earth, and, as we have already mentioned, all fertile soils, or soils capable of culture, contain alumina as an invariable constituent. There must, therefore, be something in aluminous earth which enables it to exercise an influence on the life of plants, and to assist in their development. The property on which this depends is that of its invariably containing potash and soda.

"Alumina exercises only an indirect influence on vegetation, by its power of attracting and retaining water and ammonia; it is itself very rarely found in the ashes of plants, but silica is always present, having, in most places, entered the plants by means of alkalies." (*Liebig*.) (See **EARTHS**; their use to vegetation.) (*Davy, El. Chem. Phil.*; *Thomson's System*; *Professor Schübler, Jour. Roy. Ag. Soc.* vol. i. p. 177; [*Liebig's Organic Chem.*])

ALVEARIUM. A term sometimes employed to signify a bee-hive.

AMAUROSIS. In farriery, is a total blindness, without any altered appearance in the eye. [This irremediable affection proceeds from a paralysis of the nerve of sight, or optic nerve.]

AMBLE. In horsemanship, is a peculiar kind of pace, in which both the horse's legs of the same side move at the same time. In this pace the horse's legs move nearer to the ground than in the walk, and at the same time are more extended: but what is most extraordinary in it is, that the two legs of the same side, for instance, the off hind and fore leg, move at the same time; and then the two near legs, in making another step, move at once; the motion being performed in this alternate manner, so that the sides of the animal are alternately without support, or any equilibrium between the one and the other, which must necessarily prove very fatiguing to him, being obliged to support himself in a forced oscillation, by the rapidity of a motion, in which his feet are scarcely off the ground. For if in the amble he lifted his feet as in the trot, or even in a walk, the oscillation would be such, that he could not avoid falling on his side.

Those who are skilled in horsemanship observe, that horses which naturally amble, never trot, and that they are considerably weaker than others. Colts often move in this manner, especially when they exert themselves, and are not strong enough to trot or gallop. Most good horses, which have been over-worked, and on the decline, are also observed voluntarily to amble, when forced to a

motion swifter than a walk. The amble may, therefore, be considered as a defective pace, not being common, and natural only to a very few horses, which, in general, are weaker than others. Add to this, that such amblers as seem the strongest are spoiled sooner than those which trot or gallop.

AMEL-CORN. A diseased sort of grain, [resembling spelt.]

AMELIORATING CROPS. In husbandry, are such as are supposed to improve the lands on which they are cultivated. Carrots, turnips, artificial grasses, such as contain a large proportion of nutritious materials, and many other green vegetable products, especially if fed off, [or ploughed in,] are considered as ameliorating; but all kinds of crops, carried off the land, are in some degree or other exhausters of the ground; and green crops, such as have been just mentioned, are only less so than crops of grain or other ripe vegetables. The improvement of lands, therefore, by what are commonly termed ameliorating crops, depends, in a great measure, upon the culture which the ground receives while they are growing, and the returns which they make to it in the way of manure, after being consumed by animals.

AMELIORATING SUBSTANCES. In agriculture, are such substances, as, when applied to land, render it more fertile and productive.

AMERICAN BLIGHT. [A popular, but very inappropriate name used in England to designate the injurious effects upon apple trees caused by a species of plant-louse or Aphis, (the *Eriosoma mali*, of Leach, and the *Aphis lanigera*, of Illiger.) Its American origin is rendered doubtful from the fact that nurserymen in the Middle States have never witnessed the mischievous effects described as common in Europe from this kind of blight.] A detailed account of the insect is given in the *Journal of a Naturalist*, which, with the correction of a few errors and oversights of the author, we shall now follow.

Early in summer, and even in spring, about March, a slight hoariness is observed upon the branches of certain species of our orchard fruit. As the season advances this hoariness increases, and becomes cottony; and toward the middle or the end of summer, the upper sides of some of the branches are invested with a thick, downy substance, so long as at times to be sensibly agitated by the air. Upon examining this substance, we find that it conceals a multitude of small, wingless creatures, which are busily employed in preying upon the limb of the tree beneath. This they are well enabled to do, by means of a beak terminating in a fine bristle; this being insinuated through the bark, and the sappy part of the wood, enables the creature to extract, as with a syringe, the sweet, vital liquor that circulates in the plant.

This terminating bristle is not observable in every individual, from being usually, when not in use, so closely concealed under the breast of the animal, as to be invisible. In the younger insects it is often manifested by protruding, like a fine termination, to the vent (*anus*); but as their bodies become lengthened, the bristle is not in this way observable. The pulp wood (*alburnum*) being thus wound-

ed, rises up in excrescences and nodes all over the branch, and deforms it; the limb, deprived of its nutriment, grows sickly; the leaves turn yellow, and the part perishes. Branch after branch is thus assailed, until they become leafless, and the tree dies.

Plant lice (*Aphides*), in general, attack the younger and softer parts of plants; but this insect seems easily to wound the harder bark of the apple, and does not always make choice of the most tender branch. They give a preference to certain sorts, but not always the most rich fruits, as cider apples, and wildings, are greatly infested by them; and from some unknown cause, other varieties seem to be exempted from their depredations. The Wheeler's russet, and Crofton pippin, have never been observed to be injured by them; and the insect is so fastidious in its selections, that it will frequently attack the stock or the graft, leaving the one or the other untouched, should it consist of a kind not to its liking. This insect is viviparous, or produces its young alive, forming a cradle for them by discharging from the extremities of its body a quantity of long, cottony matter; which, becoming interwoven and entangled, prevents the young from falling to the earth, and completely envelopes the parent and the offspring. In this cottony substance, we observe, as soon as the creature becomes animated in the spring, and as long as it remains in vigour, many round pellucid bodies, which at the first sight look like eggs, only that they are larger than we might suppose to be ejected by the animal. They consist of a sweet glutinous fluid, and are not the eggs but the discharges of the insects. In the autumn, the winds and rains of the season partly disperse these insects; and we observe them endeavouring to secrete themselves in the crannies of any neighbouring substance. Should the savory cabbage be near the trees whence they have been dislodged, the cavities of the under sides of its leaves are commonly favourite asylums for them. Multitudes perish by these rough removals, but numbers yet remain; and we may find them in the nodes and crevices, on the under sides of the branches, at any period of the year, the long, cottony vesture being nearly all removed; but still they are enveloped in a fine short downy clothing, to be seen by a magnifier, proceeding apparently from every suture or pore of their bodies, and protecting them in their dormant state from the moisture and frosts of our climate. This insect in a natural state, usually awakens and commences its labours very early in the month of March; and the hoariness on its body may be observed increasing daily; but if an affected branch be cut in the winter, and kept in water in a warm room, these creatures will awaken speedily, spin their cottony nests, and feed and discharge as accustomed to do in a genial season. [For further particulars relating to the habits of these and other similar insects, see *Aphis* and *Aphidians*.]

Remedies.—A considerable number of methods have been proposed for getting rid of the insect in question. White-washing, or washing with lime-water, has been tried, but is not

so efficacious as the application of any glutinous substance, which may cover the insects and dry over them. Double size or glue, liquefied by heat, and applied by means of a brush, particularly in March, when the insects begin to show more cottony than in winter, is a very effectual remedy, if no crevice of a tree is left unsized. This, however, may be dissolved by the rain, and therefore a varnish is recommended by Mr. Knapp, as follows: "Melt about three ounces of resin in an earthen pipkin, take it from the fire, and pour it into three ounces of fish oil; the ingredients perfectly unite, and when cold, acquire the consistence of honey. A slight degree of heat will liquefy it, and in this state paint over every node or infected part in your tree, using a common painter's brush. This I prefer doing in spring, or as soon as the hoariness appears. The substance soon sufficiently hardens, and forms a varnish, which prevents any escape, and stifles the individuals. After this first dressing, should any cottony matter appear round the margin of the varnish, a second application to these parts will, I think, be found to effect a perfect cure. The prevalence of this insect," adds this author, "gives some of our orchards here the appearance of numerous white posts in an extensive drying ground, being washed with lime from root to branch; a practice, I apprehend, attended with little benefit. A few of the creatures may be destroyed by accident; but as the animal does not retire to the earth, but winters in the clefts of the boughs, far beyond the influence of this wash, it remains uninjured, to commence its ravages again when spring returns."

All oily or resinous substances, however, being prejudicial to trees, Mr. George Lindley recommends vinegar as a wash for young trees; and, as less expensive for old trees, a sort of paint, composed of one gallon of quicklime, half a pound of flowers of sulphur, and a quarter of a pound of lamp-black, mixed with boiling water to the consistence of whitening for white-washing, and laying it on rather more than blood warm with a brush. This should be done in March, and again in August when the winged insects spread from tree to tree.

Mr. Couch, as a cheap and certain remedy, recommends three quarters of an ounce of sulphuric acid [oil of vitriol], by measure, to be mixed with seven ounces and a half of water. It should be applied all over the bark by means of rags, the only parts excepted being the present year's shoots, which it would destroy. This destroys moss and lichens, as well as insects; and if applied in showery weather, will be washed into every crevice in which they can harbour.

AMERICAN CRESS (*Lepidium virginicum*). From λεπις, a scale, on account of the form of the seed-vessel. For the winter standing crops, a light dry soil, in an open but warm situation, should be allotted to it, and for the summer, a rather moister and shady border is to be preferred. In neither instance is it required to be rich. It is propagated by seed, which must be sown every six weeks from March to August, for summer and autumn, but

only one sowing is necessary, either at the end of August, or beginning of September, for a supply during winter and spring. It may be sown broadcast, but the most preferable mode is in drills nine inches apart. Water may be given occasionally during dry weather, both before and after the appearance of the plants. If raised from broadcast sowings, the plants are thinned to six inches apart; if in drills, only to three. In winter they require the shelter of a little litter or other light covering; and to prevent them being injured by its pressure, some twigs may be bent over the bed, or some light bushy branches laid amongst them, which will support it. The only cultivation they require is to be kept clear of weeds.

In gathering, the outside leaves only should be stripped off, which enables successional crops to become rapidly fit for use. When the plants begin to run, their centres must be cut away, which causes them to shoot afresh. For the production of seed, a few of the strongest plants raised from the first spring sowing are left ungathered from. They flower in June or July, and perfect their seed before the commencement of autumn. (*G. W. Johnson's Kitchen Garden.*)

[This plant in America is commonly called *wild pepper-grass*. It is frequent in fields and on roadsides in the Middle States.]

AMERICAN GRASS. A term sometimes applied [in England] to a species of agrostis.

AMMONIA. The name given by chemists to the volatile alkali, from its being first prepared in the East from camels' dung near to a temple dedicated to Jupiter Ammon. It is known in commerce under the name of *harts-horn, sal volatile, &c.*, and is prepared by the dry or destructive distillation of animal substances. It is formed also most commonly wherever animal substances undergo putrefaction. It is composed of

Hydrogen	-	-	-	-	-	-	0.125
Azote or nitrogen	-	-	-	-	-	-	1.75

Ammonia is usually produced in the state of carbonate of ammonia, or united with carbonic acid gas, and in this state, or in fact in combination with most other acids, it forms salts, which possess peculiarly fertilizing properties. This alkali fulfils, there is little doubt, a very important part in many organic manures. It is a very universally diffused substance, has been detected in rain-water and even in snow, and there is little doubt but that it exists, and prejudicially too, to the health of the inhabitants, in the atmosphere of many places crowded with animal life. (*Liebig's Organic Chem.* 76, 77.) Wherever this alkali is detected in a substance, such as it commonly is, for instance, in urine, gas-water, &c., the most excellent effects may be anticipated to vegetation by its use. Fresh urine contains phosphate of ammonia, muriate of ammonia, and lactate of ammonia, and there is perhaps no fertilizer more powerful in its effects than this.

[One of the most important discoveries bearing upon agriculture perhaps ever made, is that just promulgated by Liebig, of the existence in the atmosphere of ammonia. Davy and other chemists of the highest celebrity had

analyzed the air collected from the most sickly locations where impurities might certainly be expected to exist, but with their nicest tests and best conducted experiments they failed to detect any essential difference in the composition of the insalubrious air taken from the deadly coast of Africa, and that collected from the most elevated and healthy parts of Europe. The analyses of the air of the different places all gave the same proportions of the gaseous constituents, namely, oxygen, nitrogen, and carbonic acid. It was evident, therefore, that if other matters, in addition to the gases named and watery vapour, existed in the air, some other means must be found to demonstrate their presence; and happily, the genius of Liebig devised a plan by which this has been effected so far as the presence of ammonia is concerned. He knew that ammonia had a strong affinity for water, by which it is promptly absorbed, and that although it could be diffused through such a great bulk of air as to be placed beyond the reach of chemical tests, it might nevertheless be taken up by rain-water, and washed down in sufficient quantity to become apparent. Experiments made, in his laboratory at Geissen, with the greatest care and exactness, fully confirmed his views, and placed the presence of ammonia in rain-water, and consequently in the atmosphere, beyond a doubt. It had hitherto escaped detection because no one thought of searching for it in the same way. A single pound of rain-water contains as much of the gas of ammonia, as is diffused through 28,800 cubic feet of air, namely, only one-fourth of a grain.

"All the rain-water employed in this inquiry," says Liebig, "was collected 600 paces southwest of Geissen, whilst the wind was blowing in the direction of the town. When several hundred pounds of it were distilled in a copper still, and the first two or three pounds evaporated with the addition of a little muriatic acid, a very distinct crystallization of sal-ammoniac was obtained; the crystals had always a brown or yellow colour.

"Ammonia may likewise be always detected in snow-water. Crystals of sal-ammoniac were obtained by evaporating in a vessel with muriatic acid several pounds of snow, which were gathered from the surface of the ground in March, when the snow had a depth of ten inches. Ammonia was set free from these crystals by the addition of hydrate of lime. The inferior layers of snow, which rested upon the ground, contained a quantity decidedly greater than those which formed the surface.

"It is worthy of observation, that the ammonia contained in rain and snow-water possessed an offensive smell of perspiration and animal excrements,—a fact which leaves no doubt respecting its origin.

"Any one may satisfy himself of the presence of ammonia in rain, by simply adding a little sulphuric or muriatic acid to a quantity of rain water, and evaporating this nearly to dryness in a clean porcelain basin. The ammonia remains in the residue, in combination with the acid employed; and may be detected either by the addition of a little chloride of platinum, or more simply by a little powdered lime, which

separates the ammonia, and thus renders its peculiar pungent smell sensible. The sensation which is perceived upon moistening the hand with rain-water, so different from that produced by pure distilled water, and to which the term *softness* is vulgarly applied, is also due to the carbonate of ammonia contained in the former. A small quantity of ammonia water, added to what is commonly called *hard* water, will give it the softness of rain or snow-water.

"The ammonia which is removed from the atmosphere by rain and other causes, is as constantly replaced by the putrefaction of animal and vegetable matters. A certain portion of that which falls with the rain evaporates again with the water, but another portion is, we suppose, taken up by the roots of plants, and, entering into new combinations in the different organs of assimilation, produces albumen, gluten, quinine, morphia, cyanogen, and a number of other compounds containing nitrogen. The chemical characters of ammonia render it capable of entering into such combinations, and of undergoing numerous transformations. We have now only to consider whether it really is taken up in the form of ammonia by the roots of plants, and in that form applied by their organs to the production of the azotized matters contained in them. This question is susceptible of easy solution by well-known facts.

"In the year 1834, I was engaged with Dr. Wilbrand, professor of botany in the university of Giessen, in an investigation respecting the quantity of sugar contained in the different varieties of maple trees, which grew upon soils which were not manured. We obtained crystallized sugars from all, by simply evaporating their juices, without the addition of any foreign substance; and we unexpectedly made the observation, that a great quantity of ammonia was emitted from this juice, when mixed with lime, and also from the sugar itself during its refinement. The vessels, which hung upon the trees in order to collect the juice, were watched with greater attention, on account of the suspicion that some evil-disposed persons had introduced urine into them, but still a large quantity of ammonia was again found in the form of neutral salts. The juice had no colour, and had no reaction on that of vegetables. Similar observations were made upon the juice of the birch-tree; the specimens subjected to experiment were taken from a wood several miles distant from any house, and yet the clarified juice, evaporated with lime, emitted a strong odour of ammonia.

"The products of the distillation of flowers, herbs, and roots, with water, and all extracts of plants made for medicinal purposes, contain ammonia. The unripe, transparent, and gelatinous pulp of the almond and peach emit much ammonia when treated with alkalis. (*Robiquet*.) The juice of the fresh tobacco-leaf contains ammoniacal salts. The water, which exudes from a cut vine, when evaporated with a few drops of muriatic acid, also yields a gummy deliquescent mass, which evolves much ammonia on the addition of lime. Ammonia exists in every part of plants,

in the roots (as in beet-root), in the stem (of the maple-tree), and in all blossoms and fruit in an unripe condition.

"The juice of the maple and birch contain both sugar and ammonia, and therefore afford all the conditions necessary for the formation of the azotized components of the branches, blossoms, and leaves, as well as of those which contain no azote or nitrogen. In proportion as the development of those parts advances, the ammonia diminishes in quantity, and when they are fully formed, the tree yields no more juice.

"The employment of animal manure in the cultivation of grain, and the vegetables which serve for fodder to cattle, is the most convincing proof that the nitrogen of vegetables is derived from ammonia. The quantity of gluten in wheat, rye, and barley, is very different; these kinds of grain also, even when ripe, contain this compound of nitrogen in very different proportions. Proust found French wheat to contain 12.5 per cent. of gluten; Vogel found that the Bavarian contained 24 per cent.; Davy obtained 19 per cent. from winter, and 24 from summer wheat; from Sicilian 21, and from Barbary wheat 19 per cent. The meal of Alsace wheat contains, according to Bous-singault, 17.3 per cent. of gluten; that of wheat grown in the "*Jardin des Plantes*" 26.7, and that of winter wheat 3.33 per cent. Such great differences must be owing to some cause, and this we find in the different methods of cultivation. An increase of animal manure gives rise not only to an increase in the number of seeds, but also to a most remarkable difference in the proportion of the gluten which they contain.

"Animal manure, as we shall afterwards show, acts only by the formation of ammonia. One hundred parts of wheat grown on a soil manured with cowdung (a manure containing the smallest quantity of nitrogen), afforded only 11.95 parts of gluten, and 64.34 parts of amylin, or starch; whilst the same quantity, grown on a soil manured with human urine, yielded the maximum of gluten, namely 35.1 per cent. Putrefied urine contains nitrogen in the forms of carbonate, phosphate, and lactate of ammonia, and in no other form than that of ammoniacal salts.

"Putrid urine is employed in Flanders as a manure with the best results. During the putrefaction of urine, ammoniacal salts are formed in large quantity, it may be said exclusively; for, under the influence of heat and moisture, urea, the most prominent ingredient of the urine, is converted into carbonate of ammonia. The barren soil on the coast of Peru is rendered fertile by means of a manure called *Guano*, which is collected from several islands on the South Sea. It is sufficient to add a small quantity of guano to a soil, which consists only of sand and clay, in order to procure the richest crops of maize. The soil itself does not contain the smallest particle of organic matter, and the manure employed is formed only of *urate, phosphate, oxalate, and carbonate of ammonia*, together with a few earthy salts. (*Boussingault, Ann. de Chim. et de Phys.* t. lxxv. p. 319.)

“Ammonia, therefore, must have yielded the nitrogen to these plants. Gluten is obtained not only from corn, but also from grapes and other plants; but that extracted from the grapes is called vegetable albumen, although it is identical in composition and properties with the ordinary gluten.

“It is ammonia which yields nitrogen to the vegetable albumen, the principal constituent of plants; and it must be ammonia which forms the red and blue colouring matters of flowers. Nitrogen is not presented to wild plants in any other form capable of assimilation. Ammonia by its transformation, furnishes nitric acid to the tobacco plant, sunflower, *Chenopodium*, and *Borago officinalis*, when they grow in a soil completely free from nitre. Nitrates are necessary constituents of these plants, which thrive only when ammonia is present in large quantity, and when they are also subject to the influence of the direct rays of the sun, an influence necessary to effect the disengagement within their stem and leaves of the oxygen, which shall unite with the ammonia to form nitric acid.

“The urine of men and of carnivorous animals contains a large quantity of nitrogen, partly in the form of phosphates, partly as urea. Urea is converted during putrefaction into carbonate of ammonia, that is to say, it takes the form of the very salt which occurs in rain-water. Human urine is the most powerful manure for all vegetables containing nitrogen; that of horses and horned cattle contains less of this element, but infinitely more than the solid excrements of these animals. In addition to urea, the urine of herbivorous animals contains hippuric acid, which is decomposed during putrefaction into benzoic acid and ammonia. The latter enters into the composition of the gluten, but the benzoic acid often remains unchanged; for example, in the *Anthoxanthum odoratum*. The late Professor Gorham obtained from Indian corn a substance to which he gave the name *Zeine*, according to whose analysis it contains no nitrogen; but ammonia has since been obtained from it.”

It has always been a popular opinion among husbandmen, that snow contained some fertilizing salts, as winter crops were generally observed to thrive best after being long covered with snow. Common observation is here fully sustained by science, since ammonia, one of the greatest of fertilizers, may always be detected in snow-water, the inferior layers next the ground containing the largest proportion.

The following interesting calculation is given by Liebig. “If,” says he, “a pound of rain-water contain one-fourth of a grain of ammonia, then a field of 40,000 square feet must receive annually upwards of 80 pounds of ammonia, or 65 pounds of nitrogen; for, by the observations of *Schübler*, which were formerly alluded to, about 700,000 pounds of rain fall over this surface in four months, and consequently the annual fall must be 2,500,000 pounds. This is much more nitrogen than is contained in the form of vegetable albumen and gluten, in 2,650 pounds of wood, 2,800 pounds of hay, or 200 cwt. of beet-root, which

are the yearly produce of such a field, but it is less than the straw, roots, and grain of corn which might grow on the same surface would contain.”

As to the source from which the ammonia diffused in the atmosphere is derived, it is sufficient to refer to the fact that ammonia is the last product of the putrefaction of animal bodies, all of which, whether large or infinitely small, yield their nitrogen to the atmosphere in the form of ammonia. This cannot remain long in the air, as every shower of rain must absorb and convey it to the earth. “Hence also, rain-water must, at all times, contain ammonia, though not always in equal quantity. It must be greater in summer than in spring or in winter, because the intervals of time between the showers are in summer greater; and when several wet days occur, the rain of the first must contain more of it than that of the second. The rain of a thunder-storm, after a long protracted drought, ought for this reason to contain the greatest quantity which is conveyed to the earth at one time.”

Is it asked what direct proof exists that ammonia acts so favourably in promoting vegetation? The answer is furnished in the results of experiments made by Sir Humphry Davy, in which the beaks of retorts containing fermenting manures were introduced into the soil among the roots of grass, which was thus made to grow more luxuriantly than that in other places. The gases emanating from retorts containing similar manure were examined and found to consist chiefly of ammonia. Sir Humphry considered such results as proving conclusively the advantage of applying manures to soils in a recent and fermenting state. (See AZOTE or NITROGEN.)

Dr. Liebig's discovery of the great fertilizer ammonia in rain-water has led to a most simple and beautiful explanation of the manner in which gypsum or plaster of Paris acts in promoting the growth of plants, a matter which has been a subject of great speculation and controversy, but which would seem to be fully settled at last.

“The evident influence of gypsum upon the growth of grasses,—the striking fertility and luxuriance of a meadow upon which it is strewed,—depends only upon its fixing in the soil the ammonia of the atmosphere, which would otherwise be volatilized with the water which evaporates. The carbonate of ammonia contained in rain-water is decomposed by gypsum, in precisely the same manner as in the manufacture of sal-ammoniac. Soluble sulphate of ammonia and carbonate of lime are formed; and this salt of ammonia possessing no volatility is consequently retained in the soil. All the gypsum gradually disappears, but its action upon the carbonate of ammonia continues as long as a trace of it exists. The action of gypsum as well as that of chloride of lime (bleaching salts) really consists in their giving a fixed condition to the nitrogen, or ammonia which is brought into the soil, and which is indispensable to the nutrition of plants.

“Water is absolutely necessary to effect the decomposition of the gypsum, on account of its

difficult solubility (1 part of gypsum requires 400 parts of water for solution), and also to assist in the absorption of the sulphate of ammonia by the plants; hence it happens, that the influence of gypsum is not observable on dry fields and meadows.

“The decomposition of gypsum by carbonate of ammonia does not take place instantaneously; on the contrary, it proceeds very gradually, and this explains why the action of the gypsum lasts for several years.” (*Org. Chem.*)

AMYLACEOUS. A term applied to such farinaceous seeds, grains, and roots, as contain much of the fine flour from which starch is made, and in which chiefly consists their nutritive principle.

ANALYSIS (Gr. ἀνάλυσις). In a general sense, signifies the resolution of compound bodies into their original or constituent principles.

Analysis of Soils.—The means of ascertaining the nature, properties, and proportions of the different materials of which they are composed. The chemical examination of the soil affords perhaps more certain and more valuable information to the farmer, for the improvement of its fertility, than any other mode of investigation. The apparatus and the experiments, necessary for even the most accurate experiments, are by no means so difficult as it is often believed is the case. It is, in fact, a very erroneous conclusion, that an extensive or an expensive apparatus is necessary to carry on even the most valuable chemical researches. The laboratory of one of the most celebrated chemical philosophers of his day, that of Dalton of Manchester, contained apparently but a poor collection of glass bottles, retorts, crucibles, fragments of wine-glasses, &c.

The following descriptions of the philosophically-accurate mode adopted by Sir Humphry Davy for the analysis of soils, [and of the more easily repeated plans of the Rev. W. Rham, of England, and Dr. Dana, of Massachusetts, are given nearly in their own words. The first is taken from his *Elements of Agricultural Chemistry*, the second from the first volume of the *Journal of the Royal Agricultural Society of England*, p. 46, and the last from *Professor Hitchcock's Report of the Geological Survey of Massachusetts*.] It may be well to premise that four earths are almost always the chief constituents of all cultivated soils, viz., silica (flint), alumina (clay), carbonate of lime (chalk), and carbonate of magnesia. These are mixed together in an endless variety of proportions, and are interspersed with animal and vegetable remains, salts, &c., to an equally varying extent. It is to ascertain the presence and the extent of these substances that the analysis of soils is so necessary and so valuable to the farmer.

“The instruments required for the analysis of soils,” said the illustrious Davy, “are few and but little expensive. They are a balance capable of containing a quarter of a pound of common soil, and capable of turning when loaded with a grain; a set of weights from a quarter of a pound troy to a grain; a wire sieve sufficiently coarse to admit a mustard-seed through its apertures; an Argand lamp and stand; some glass bottles; Hessian cruci-

bles; porcelain or queen's ware evaporating basins; a Wedgewood pestle and mortar; some filters made of half a sheet of blotting-paper, folded so as to contain a pint of liquid, and greased at the edges; a bone knife, and an apparatus for collecting and measuring æriform fluids.

“The chemical substances or re-agents required for separating the constituent parts of the soil are muriatic acid (spirit of salt), sulphuric acid (oil of vitriol), pure volatile (ammonia), dissolved in water, solution of prussiate of potash and iron, succinate of ammonia, soap-lye, or solution of potassa, solutions of carbonate of ammonia, of muriate of ammonia, of neutral carbonate of potash, and nitrate of ammonia.

“In cases when the general nature of the soil of a field is to be ascertained, specimens of it should be taken from different places, two or three inches below the surface, and examined as to the similarity of their properties. It sometimes happens that upon plains the whole of the upper stratum of the land is of the same kind, and in this case one analysis will be sufficient; but in valleys, and near the beds of rivers, there are very great differences; and it now and then occurs that one part of a field is calcareous, and another part silicious, and in this case, and in analogous cases, the portions different from each other should be separately submitted to experiment.”

Soils, when collected, if they cannot be immediately examined, should be preserved in phials quite filled with them, and closed with ground glass stoppers. The quantity of soil most convenient for a perfect analysis is from two to four hundred grains. It should be collected in dry weather, and exposed to the atmosphere till it becomes dry to the touch.

The specific gravity of a soil, or the relation of its weight to that of water, may be ascertained by introducing into a phial, which will contain a known quantity of water, equal quantities of water and of soil, and this may be easily done by pouring in water till it is half full, and then adding the soil till the fluid rises to the mouth; the difference between the weight of the soil and that of the water will give the result. Thus if the bottle contains 400 grains of water, and gains 200 grains when half filled with water and half with soil, the specific gravity of the soil will be 2; that is, will be twice as heavy as water; and if it gained 165 grains, its specific gravity would be 1.825, water being 1000. It is of importance that the specific gravity of a soil should be known, as it affords an indication of the quantity of animal and vegetable matter it contains; these substances being always most abundant in the lighter soils.

The other physical properties of soils should likewise be examined before the analysis is made, as they denote to a certain extent their composition, and serve as guides in directing the experiments. Thus silicious soils are generally rough to the touch, and scratch glass when rubbed upon it; ferruginous soils are of a red or yellow colour, and calcareous soils are soft.

1. Soils, though as dry as they can be made

by continued exposure to air, in all cases contain a considerable quantity of water, which adheres with great obstinacy to the earths, and animal and vegetable matter, and can only be driven off from them by a considerable degree of heat. The first process of analysis is to free the given weight of soil from as much of this water as possible, without, in other respects, affecting its composition, and this may be done by heating it for ten or twelve minutes over an Argand lamp in a basin of porcelain to a temperature equal to 300° Fahrenheit; and if a thermometer is not used, the proper degree may be easily ascertained by keeping a piece of wood in contact with the bottom of the dish; as long as the colour of the wood remains unaltered the heat is not too high, but when the wood begins to be charred the process must be stopped. A small quantity of water will perhaps remain in the soil, even after this operation, but it always affords useful comparative results; and if a higher temperature were employed, the vegetable or animal matter would undergo decomposition, and, in consequence, the experiment be wholly unsatisfactory. The loss of weight in the process should be carefully noted, and when in 400 grains of soil it reaches as high as 50°, the soil may be considered as in the greatest degree absorbent and retentive of water, and will generally be found to contain much vegetable or animal matter, or a large proportion of aluminous earth. When the loss is only from 20° to 10°, the land may be considered as only slightly absorbent and retentive, and silicious earth probably forms the greatest part of it.

2. None of the loose stones, gravel, or large vegetable fibres should be divided from the pure soil till after the water is drawn off; for these bodies are often themselves highly absorbent and retentive, and in consequence influence the fertility of the land. The next process, however, after that of heating, should be their separation, which may be easily accomplished by the sieve, after the soil has been gently bruised in a mortar. The weights of the vegetable fibres or wood, and of the gravel or stones, should be separately noted down, and the nature of the last ascertained; if calcareous, they will effervesce with acids; if silicious, they will be sufficiently hard to scratch glass; and if of the common aluminous class of stones, they will be soft, easily cut with a knife, and incapable of effervescing with acids.

3. The greater number of soils, besides gravel and stones, contain larger or smaller proportions of sand, of various degrees of fineness; and it is a necessary operation (the next in the process of analysis) to detach them from the parts in a state of more minute division, such as clay, loam, marl, vegetable and animal matter, and the matter soluble in water. This may be effected in a way sufficiently accurate, by boiling the soil in three or four times its weight of water, and when the texture of the soil is broken down, and the water cool, by agitating the parts together, and then suffering them to rest. In this case, the coarse sand will generally separate in a minute, and the finer in

two or three minutes, whilst the highly divided earthy, animal, or vegetable matter will remain in a state of mechanical suspension for a much longer time; so that by pouring the water from the bottom of the vessel, after one, two, or three minutes, the sand will be principally separated from the other substances, which, with the water containing them, must be poured into a filter, and after the water has passed through, collected, dried, and weighed. The sand must likewise be weighed, and the respective quantities noted down. The water of lixiviation must be preserved, as it will be found to contain the saline, and soluble animal or vegetable, if any exist in the soil.

4. By the process of washing and filtration, the soil is separated into two portions, the most important of which is generally the finely divided matter. A minute analysis of the sand is seldom if ever necessary, and its nature may be detected in the same manner as that of the stones or gravel. It is always either silicious sand, or calcareous sand, or a mixture of both. If it consist wholly of carbonate of lime, it will be rapidly soluble in muriatic acid, with effervescence; but if it consist partly of this substance, and partly of silicious matter, the respective quantities may be ascertained by weighing the residuum after the action of the acid, which must be applied till the mixture has acquired a sour taste, and has ceased to effervesce. This residuum is the silicious part; it must be washed, dried, and heated strongly in a crucible: the difference between the weight of it, and the weight of the whole indicates the proportion of calcareous sand.

5. The finely divided matter of the soil is usually very compound in its nature; it sometimes contains all the four primitive earths or soils, as well as animal and vegetable matter, and to ascertain the proportions of these with tolerable accuracy is the most difficult part of the subject.

The first process to be performed in this part of the analysis, is the exposure of the fine matter of the soil to the action of muriatic acid. This substance should be poured upon the earthy matter in an evaporating basin, in a quantity equal to twice the weight of the earthy matter, but diluted with double its volume of water. The mixture should be often stirred and suffered to remain for an hour or an hour and a half before it is examined. If any carbonate of lime, or of magnesia, exist in the soil, they will have been dissolved in this time by the acid, which sometimes takes up likewise a little oxide of iron, but very seldom any alumina.

The fluid should be passed through a filter, the solid matter collected, washed with rain-water, dried at a moderate heat, and weighed. Its loss will denote the quantity of solid matter taken up. The washings must be added to the solution, which, if not sour to the taste, must be made so, by the addition of fresh acid, when a little solution of prussiate of potassa and iron must be mixed with the whole. If a blue precipitate occurs, it denotes the presence of oxide of iron, and the solution of the prussiate must be dropped in, till no farther effect

is produced. To ascertain its quantity, it must be collected in the same manner as other solid precipitates, and heated red; the result is oxide of iron, which may be mixed with a little oxide of manganese.

Into the fluid freed from oxide of iron a solution of neutralized carbonate of potash must be poured till all effervescence ceases in it, and till its taste and smell indicate a considerable excess of alkaline salt. The precipitate that falls down is carbonate of lime: it must be collected on the filter, and dried at a heat below that of redness. The remaining fluid must be boiled for a quarter of an hour, when the magnesia, if any exist, will be precipitated from it, combined with carbonic acid, and its quantity is to be ascertained in the same manner as that of the carbonate of lime. If any minute proportion of alumina should, from peculiar circumstances, be dissolved by the acid, it will be found in the precipitate with the carbonate of lime; and it may be separated from it by boiling it for a few minutes with soap-lye, sufficient to cover the solid matter: this substance dissolves alumina, without acting upon carbonate of lime.

Should the finely divided matter be sufficiently calcareous to effervesce very strongly with acids, a very simple method may be adopted for ascertaining the quantity of carbonate of lime, and one sufficiently accurate in all common cases.

Carbonate of lime (chalk) in all its states contains a determinate proportion of carbonic acid, *i. e.* nearly 43 per cent.; so that when the quantity of this elastic fluid given out by any soil during the solution of its calcareous matter in an acid is known, either in weight or measure, the quantity of carbonate of lime may be easily discovered.

When the process by diminution of weight is employed, two parts of the acid and one part of the matter of the soil must be weighed in two separate bottles, and very slowly mixed together till the effervescence ceases. The difference between the weight before and after the experiment denotes the quantity of carbonic acid lost: for every $4\frac{1}{2}$ grains of which 10 grains of carbonate of lime must be estimated.

6. After the calcareous parts of the soil have been acted upon by muriatic acid, the next process is to ascertain the quantity of finely divided insoluble animal and vegetable matter that it contains. This may be done with sufficient precision, by strongly igniting it in a crucible over a common fire till no blackness remains in the mass. It should be often stirred with a metallic rod, so as to expose new surfaces continually to the air: the loss of weight that it undergoes denotes the quantity of the substance that it contains destructible by fire and air.

It is not possible without very refined and difficult experiments, to ascertain whether this substance is wholly animal or vegetable matter, or a mixture of both. When the smell emitted during the incineration is similar to that of burnt feathers, it is a certain indication of some substance, either animal, or analogous to animal matter, and a copious blue flame at the time of ignition almost always de-

notes a considerable proportion of vegetable matter. In cases when it is necessary that the experiment should be very quickly performed, the destruction of the decomposable substances may be assisted by the agency of nitrate of ammonia, which at the time of ignition may be thrown gradually upon the heated mass, in the quantity of 20 grains for every 100 of residual soil. It accelerates the dissipation of the animal and vegetable matter, which it causes to be converted into elastic fluids, and it is itself, at the same time, decomposed and lost.

7. The substances remaining after the destruction of the vegetable and animal matter are generally minute particles of earthy matter containing usually alumina and silica, with combined oxide of iron or of manganese. To separate these from each other, the solid matter should be boiled for two or three hours with sulphuric acid, diluted with four times its weight of water; the quantity of the acid should be regulated by the quantity of solid residuum to be acted on, allowing for every 100 grains two drachms, or 120 grains of acid.

The substance remaining after the action of the acid may be considered as silicious, and it must be separated and its weight ascertained, after washing and drying in the usual manner. The alumina, and the oxide of iron and manganese, if any exist, are all dissolved by the sulphuric acid: they may be separated by succinate of ammonia added to excess, which throws down the oxide of iron, and by soap-lye, which will dissolve the alumina, but not the oxide of manganese: the weights of the oxides ascertained after they have been heated to redness will denote their quantities.

Should any magnesia and lime have escaped solution in the muriatic acid, they will be found in the sulphuric acid: this, however, is rarely the case; but the process for detecting them and ascertaining their quantities is the same in both instances. The method of analysis by sulphuric acid is sufficiently precise for all usual experiments; but if very great accuracy be an object, dry carbonate of potash must be applied as the agent, and the residuum of the incineration (6.) must be heated red for half an hour, with four times its weight of this substance in a crucible of silver, or of well baked porcelain. The mass obtained must be dissolved in muriatic acid, and the solution evaporated till it is nearly solid; distilled water must then be added, by which the oxide of iron and all the earths except silica will be dissolved in combination as muriates. The silica after the usual process of lixiviation must be heated red: the other substances may be separated in the same manner as from the muriatic and sulphuric solutions. This process is the one usually employed by chemical philosophers for the analysis of stones.

8. If any saline matter, or soluble vegetable or animal matter, is suspected in the soil, it will be found in the water of lixiviation used for separating the sand. This water must be evaporated to dryness in a proper dish, at a heat below its boiling point. If the solid matter obtained is of a brown colour and inflamma-

ble, it may be considered as partly vegetable extract. If its smell when exposed to heat be like that of burnt feathers, it contains animal or albuminous matter; if it be white, crystalline, and not destructible by heat, it may be considered principally as saline matter. The saline compounds contained in soils are very various. The sulphuric acid combined with potash or sulphate of potash is one of the most usual. Common salt is also very often found in them; likewise phosphate of lime, which is insoluble in water, but soluble in muriatic acid. Compounds of the nitric, muriatic, sulphuric, and phosphoric acids, with alkalis and earths, exist in some soils. The salts of potash are distinguished from those of soda by their producing a precipitate in solutions of platina; those of lime are characterized by the cloudiness they occasion in solutions containing oxalic acid; those of magnesia by being rendered cloudy by solutions of ammonia. Sulphuric acid is detected in salts by the dense white precipitate it forms in solutions of baryta; muriatic acid, by the cloudiness it communicates to solution of nitrate of silver; and when salts contain nitric acid, they produce scintillations by being thrown upon burning coals.

9. Should sulphate or phosphate of lime be suspected in the entire soil, the detection of them requires a particular process upon it. A given weight of it, for instance, 400 grains, must be heated red for half an hour in a crucible, mixed with one third of powdered charcoal. The mixture must be boiled for a quarter of an hour in a half pint of water, and the fluid collected through the filtre and exposed for some days to the atmosphere in an open vessel. If any notable quantity of sulphate of lime (gypsum) existed in the soil, a white precipitate will gradually form in the fluid, and the weight of it will indicate the proportion.

Phosphate of lime, if any exist, may be separated from the soil after the process for gypsum. Muriatic acid must be digested upon the soil in quantity more than sufficient to saturate the soluble earths: the solution must be evaporated, and water poured upon the solid matter. This fluid will dissolve the compounds of earths with the muriatic acid, and leave the phosphate of lime untouched. It will not fall within the limits assigned to this article to detail any processes for the detection of substances which may be accidentally mixed with the matters of soils. Other earths and metallic oxides are now and then found in them, but in quantities too minute to bear any relation to fertility or barrenness, and the search for them would make the analysis much more complicated, without rendering it more useful.

10. Where the examination of a soil is completed, the products should be numerically arranged and their quantities added together, and if they nearly equal the original quantity of soil, the analysis may be considered as accurate. It must, however, be noticed that when phosphate or sulphate of lime are discovered by the independent process just described (9), a correction must be made for the general process, by subtracting a sum equal to their weight from the quantity of carbonate of lime

obtained by precipitation from the muriatic acid. In arranging the products the form should be in the order of the experiments by which they were procured. Thus I obtained from 400 grains of a good silicious sandy soil from a hop garden near Tonbridge Kent,—

	Grains.
Of water of absorption - - - - -	19
Of loose stones and gravel, principally silicious - - - - -	53
Of undecomposed vegetable fibres - - - - -	14
Of fine silicious sand - - - - -	212
Of minutely divided matter, separated by agitation and filtration, and consisting of	Grains.

Loss - - - - -	21
	400

The loss in this analysis is not more than usually occurs, and it depends upon the impossibility of collecting the whole quantities of the different precipitates, and upon the presence of more moisture than is accounted for in the water of absorption, and which is lost in the different processes.

When the experimenter is become acquainted with the use of the different instruments, the properties of the re-agents, and the relations between the external and chemical qualities of soils, he will seldom find it necessary to perform, in any one case, all the processes that have been described. When his soil, for instance, contains no notable proportions of calcareous matter, the action of the muriatic acid (7.) may be omitted. In examining peat soils, he will principally have to attend to the operation by fire and air, and in the analysis of chalks and loams, he will often be able to omit the experiment by sulphuric acid (9.).

In the first trials that are made (adds Davy) by persons unacquainted with chemistry, they must not expect much precision of result; many difficulties will be met with; but, in overcoming them, the most useful kind of practical knowledge will be obtained; and nothing is so instructive in experimental science as the detection of mistakes. The correct analyst ought to be well grounded in general chemical information; but perhaps there is no better mode of gaining it than that of attempting original investigations. In pursuing his experiments, he will be continually obliged to learn the properties of the substances he is employing or acting upon; and his theoretical ideas will be more valuable in being connected with practical operations, and acquired for the purpose of discovery.

Such were the excellent rules for analysis prescribed by Sir Humphry Davy. With the still more simple directions of the Rev. W. Rham, I shall conclude this paper.

A portion of the earth to be analysed may be dried in the sun or near a fire until it feels quite dry in the hand. It is then reduced to powder by the fingers, or by rolling it on a deal board with a wooden roller, so as to sepa-

rate the particles, but not to grind them: any small stones above the size of a pea must be taken out. If these form a considerable part of the soil, their proportion must be ascertained by weight; their nature and quality may be afterwards examined: this being a very simple operation, and obvious to the sight, need not be described. Where the stones and pebbles are evidently accidental, they may be overlooked, as having little influence on the fertility: the dry earth, cleared from stones, should be accurately weighed; and it is convenient to take some determined quantity of grains, as 1000, 500, or 250, according to the accuracy of the instruments at hand. This portion should be put into a shallow earthen or metal vessel, and heated over the fire, or a lamp, for about ten minutes, stirring it with a chip of dry wood; the heat should not be so great as to discolour the wood. It may then be allowed to cool, and be weighed again; the loss of weight indicates the water which remained uncombined after the soil appeared quite dry. This is the first thing to be noted. The power of retaining water without any external appearance of moisture is greatest in humus (a modern term for very finely divided organic matter), next in clay, both of which readily absorb it from the atmosphere; carbonate of lime does so in a less degree, and silicious sand least of all. This moisture occupies the pores of the soil, and is very different from the water, which is combined with clay as a part of its substance, and to which it owes its ductility; for when this last is expelled by a great heat, the clay loses its quality, and approaches to the nature of sand. Pounded brick will not bind with water, and porcelain reduced to fine powder has all the properties of silicious sand in the soil. The finer the division of the particles of the soil, the greater will be its power of absorbing and retaining water; but in a soil where clay greatly predominates, the lumps sometimes become so hard and baked by the sun that the moisture cannot penetrate; and in this case the power of absorption is much diminished. Hence loams in which there is a good proportion of humus have a greater power of absorption than the pure earths. Taking all circumstances into consideration, it will be found that the soils which most readily absorb moisture are also the most fertile, and therefore it is important to ascertain their power of absorption. This can be found by comparison. Equal portions of different soils, dried as before, are placed in the opposite scales of a good balance, and left exposed for some time to a moist atmosphere; that which preponderates has the greatest power of absorption; the degree is measured by the difference of the acquired weights. Another important circumstance is the specific gravity of a soil. The different earths have very different specific gravities; and humus being lighter than any mineral earth, the lightness of the soil is a sure indication of its richness, excepting where this lightness is occasioned by an excess of undecomposed vegetable matter, or peat. Humus, when nearly pure, has specific gravity varying from 1.2 to 1.5; fine porcelain clay, 2; chalk, about

2.3; silicious sand from 2.5 to 2.7; mixed soils have specific gravities varying according to the proportions of their component parts. Those in which clay, chalk, and humus abound, and which are generally the most fertile, are the lightest. The sandy soils are heavier, and the more so if they contain oxides of iron, or of other metals; and it is well known that the ferruginous sands are the most barren. The common expression of *light*, when applied to a sandy soil, has no reference to its specific gravity, but merely to the force required to plough it. No carrier would say that a loose sandy road was a light one. The easiest and readiest method of determining the specific gravity of earth, or any substance which is of a loose texture, is that described by Dr. Ure in his *Philosophy of Manufactures* (p. 97), as employed by him to ascertain the specific gravities of cotton, wool, silk and flax. It is as follows:— Take a narrow-necked phial, capable of holding four or five ounces of water; mark a line round the middle of the neck with the point of a diamond, or a file; fill the phial up to the mark with river or rain water, and poise it with sand, or any other substance, in a scale; then put 1000 grains' weight in the same scale with the phial, and pour out water till the equilibrium is restored. In the vacant space, which is evidently equal to the bulk of 1000 grains of water, introduce the soil till the water rises to the mark in the neck; then put into the opposite scale grain weights sufficient to restore the equilibrium. The number of grains required for this purpose will denote the specific gravity of the soil compared to water as 1000. Suppose, for example, that silicious sand, which is 2.7 times denser than water, is poured into the vacant space, it will require 2.700 grains to fill the space occupied by the 1000 grains of water; and thus we have the specific gravity without any calculation. If, instead of 1000 grains, we use only 500, or 250, the result will be the same, if we multiply the grains in the other scale by 2 or 4.

We will give a few examples of soils, of which the specific gravity has been carefully determined.

A rich garden soil, which contained, per cent.,—

Clay	-	-	-	-	52.4
Silicious sand	-	-	-	-	36.5
Calcareous sand	-	-	-	-	1.8
Carbonate of lime	-	-	-	-	2.0
Humus	-	-	-	-	7.3

had a specific gravity of 2.332.

A good loam, consisting of—

Clay	-	-	-	-	51.2
Silicious sand	-	-	-	-	42.7
Calcareous sand	-	-	-	-	0.4
Carbonate of lime	-	-	-	-	2.3
Humus	-	-	-	-	3.4

had a specific gravity of 2.401.

A poorer soil, of which the component parts were,—

Silicious sand	-	-	-	-	64.0
Clay	-	-	-	-	32.3
Calcareous sand	-	-	-	-	1.2
Carbonate of lime	-	-	-	-	1.2
Humus	-	-	-	-	1.5

had a specific gravity of 2.526.

These examples suffice to show that the specific gravity of a soil is some tolerable indication

tion of its fertility. It cannot, however, be entirely relied upon in the absence of other proofs; for there may be many different mixtures of earths which will have the same specific gravity, although they may differ greatly in their fertility; but it will facilitate the analysis, and often detect mistakes in the process, if the result does not accord with the specific gravity found. We proceed now to the analysis. The portion of soil which has been deprived of all its water, as described above, must be sifted through metallic sieves of different fineness; the first is made of a perforated tin plate, the holes of which are about one-twentieth of an inch in diameter: whatever does not go through this is put by. The remainder is successively passed through two or three more sieves, increasing in fineness to the last; which is of the finest wire-cloth, having from 150 to 170 threads in an inch: whatever passes through this is an impalpable powder. Thus we have already a division of the soil, according to the size of its particles:—1, the coarse grit left in the first sieve; 2, the finer grit in No. 2; 3, fine sand in No. 3; and 4, impalpable powder, which has passed through the last sieve. To facilitate this part of the operation, the sieves may be made so as to fit into one another, like the filterers in a coffee-beggin, the last fitting into a tin pot which will hold about a pint of water; a cover being made to fit on the top sieve, the instrument is complete. (See fig.) Thus, all the sifting may be done at once without any loss. Any lumps which are not thoroughly pulverized must be broken. The coarser sand left in the sieve, No. 1, must now be washed with pure water, to detach any fine dust adhering to it; what runs through may be used to wash No. 2, in the same manner; and then may pass through No. 3 to the impalpable matter which passed through all the sieves. A sufficient quantity of water must be used to

render the whole of this last nearly fluid. There will then be three different portions of the washed soil left in the sieves, and a portion of impalpable matter diffused through the water in the lower division of the instrument. This last is the principal object of analysis, and that to which Sir Humphry Davy usually confined his attention, merely noticing the proportion of coarser sand in the soil. It contains, no doubt, the great principle of fertility and nutrition; and the effect of the coarser parts may be considered as chiefly mechanical; but they may much affect the fertility of the finer parts, and are of the greatest importance to the soil in which they are blended: they consequently deserve a more minute examination, to which we will return.

In the mean time, our attention shall be directed to the composition of the finer earth in No. 4, which is mixed with water in a semi-fluid state. This is well shaken, and suddenly

poured into a deep glass vessel, and allowed to settle for a few minutes, when the heavier earth, which is sand, will be deposited, and the lighter may be poured off suspended in the water. It requires some little practice to effect this at once, but a few trials will soon enable any one to do it. This operation may be repeated until all sand, of which the particles are visible to the naked eye, is separated. The earth and water decanted out of this last vessel are now poured into a glass tube, eighteen inches long, No. 1, the bore of which is less than an inch; one end is stopped with a cork fitted into it, and the other has a small lip for the convenience of pouring out the contents. In a short time, there will be a further deposition of earth, which will be principally alumina. What remains suspended in the water over it is gently poured off into another similar tube (No. 2); this will contain nearly the whole of the humus, which will take some hours to be deposited in the form of a fine brown mud. The contents of the tube No. 1 may now have a little more water added to them: after being well shaken, the tube may be set upright, and left for half an hour to settle: what remains suspended in the water after this, must be added to the humus in the tube No. 2. After some time, this will also be deposited, and the clear water may be decanted off. The mud which remains is put on filtering paper in a glass funnel; and when all the water has drained from it, it is dried over the fire, and weighed.

This is the most important portion of the soil. The fine earths deposited in the tube No. 1 will consist of very fine particles of sand, clay, and perhaps carbonate of lime. The sand will appear deposited in the bottom of the tube. The clay may be easily diffused in the water above it, by stirring it carefully with a small rod, without reaching the sand. It may then be decanted with the water into another tube (No. 3), and allowed to settle. This part of the operation may be carried to much perfection by great care, and by examining the results occasionally with a small microscope; but for all common practical purposes it is sufficient to separate the vegetable earth from the mineral, and the particles of sand from the finer. The contents of No. 1 having been collected, as well as those of No. 3, are dried over the fire, and accurately weighed. The same is done with the earth which remains on the sieves. All the water in which the earths have been diffused and washed is collected and passed through filtering paper, and then set over the fire in a common saucepan. It is boiled away gently, until it is reduced to a small portion, which begins to look turbid. The complete evaporation is finished in an evaporating dish as slowly as possible; and the residue is the soluble matter contained in the soil. It will be sufficient to dry and weigh this, as its further analysis would require more skill and chemical knowledge than we suppose in the operation. Salts may be detected by the taste, or by the crystals formed in the evaporation; but unless there is a decided saline taste, the whole may be consi-

dered as soluble humus, and the immediate fertility of the soil depends greatly on the quantity of it.

To recapitulate what has been obtained, we shall have the coarse grit in sieve No. 1; the sand in Nos. 2 and 3; the fine earth separated in the tubes, Nos. 1 and 3; the humus in tube No. 2, and on the filtering paper, and on the soluble parts in the evaporating dish. All these substances must be well dried over the fire, as was done with the soil at first, and each separated part accurately weighed: the sum of them ought to be equal to the original portion of soil subjected to analysis after the water was drawn off; but there always is a loss, even with the most experienced analyser; this loss will be principally in the finer parts which are dissipated in the operation. But the analysis is not yet completed: we have separated the sand, clay, and humus, but there may be a portion of carbonate of lime in the form of sand, or of finely divided earth mixed with the other earths. To ascertain this, each portion, excepting the humus, is put into a separate cup, and a little muriatic acid, diluted with four times its own weight of water, is poured on it: if there is any effervescence, it shows the presence of carbonate of lime; diluted acid is then added gradually, as long as the effervescence is renewed by the addition. When this ceases, and the water continues to have an acid taste, more pure water is added, and each portion separately filtered, dried, and weighed. The loss of weight in each of these gives the quantities of carbonate of lime dissolved by the muriatic acid, and which has passed with the water in the form of muriate of lime. The different weights being now collected, the result of the operations may be set down. There may be many mineral substances in the soil, which this mode of analysing will not detect; and some of these may materially affect the fertility. In most cases there will be something to indicate the presence of metals. Iron abounds in most soils: when the quantity is considerable, it will be detected by pouring a decoction of gall-nuts into the water which has washed the earth; it will immediately become of a bluish dark colour. The other metals are not of frequent occurrence. Sulphate of lime or gypsum, and also magnesia, are found in some soils; but the separation of them can only be effected by those who are well acquainted with chemistry: they fortunately occur very seldom, and the places where they are found are generally well known. For all practical purposes it is sufficient to ascertain the proportion of sand, clays, carbonate of lime, and humus, which any soil contains. Many soils which have been highly manured, contain portions of undecomposed vegetable substances, and fibres of roots: these will be found mixed with the coarser earths separated by the sifting: not being a part of the natural soil, they need not be taken into the account; but they may be separated by washing the earths, as they are much lighter, and will come over in the first decantations. They may be dried and weighed,

and the quantity set down in the result, if it is desirable. Some very barren sands, containing very little argillaceous earth or humus, may readily be known by the copious sandy deposit which they rapidly make when diffused through water. Good natural loams are not so easily judged of; but the preceding mode of analysis will in general detect their intrinsic value. When a soil contains peaty matter, it is easily discovered by the irregular black particles which are visible in it. Peat differs from humus only in being in a different state of decomposition, and containing a considerable portion of tannin: when acted upon by lime or alkalies, and brought into a state of greater decomposition, it is not to be distinguished from humus in its qualities. The only instruments absolutely required for the foregoing analysis are, in the first place, two good balances, one capable of weighing a pound and turning with a grain, and one weighing two ounces and turning with the tenth part of a grain. Next, the combination of sieves which we have described, and which may easily be made by any tinsmith. But any sieves of the required fineness, whether of metal, horse-hair, or silk, provided they be of the proper texture, will answer the purpose for a trial. Some earthen or glass jugs, and two or three glass tubes, 18 inches long, open at both ends, which may be obtained at any glass-blower's or chemist's, a glass funnel, and some filtering paper, will complete the apparatus. The only chemical substance indispensable to the analysis is some muriatic acid, commonly called spirit of salt. A little test-paper to detect acids in the water with which the soil has been washed, and an infusion of gall-nuts to ascertain the presence of iron, may be useful. A small glass phial will serve for the specific gravities. The whole of these instruments and materials may be procured for a very small sum. If the foregoing process is carefully followed, any person, however unaccustomed to chemical operations, will soon be enabled to satisfy himself as to the composition of any soil of which he desires to know the comparative value. He must not be disheartened by a few failures at first. However simple every operation may appear, it requires a little practice and much patience, if we would come to a very accurate result. Every portion must be dried to the same degree before it is weighed: minute portions which adhere to the vessels when dried must be carefully collected by scraping and brushing off with a feather: pieces of filtering-paper and linen must be weighed before they are used, that small portions of matter adhering to them may be ascertained by the increase of weight. By attending to these particulars, it is surprising how nearly the whole original weight is accounted for in the summing up of the separate parts. If this mechanical analysis should be thought lightly of by experienced chemists, let them only carefully analyse a portion of soil by this process, and then another by any more perfect mode, and compare the importance of the results as regards practical agriculture. The object is to

ascertain the productive powers of the soils; and for this purpose the separation of the different earths is sufficient, in the present imperfect state of our knowledge of the mysteries of vegetation. The process which we have described, simple as it is, may yet be too tedious for the farmer who is desirous of speedily comparing different soils; and we will indicate a still simpler method of ascertaining, nearly, the composition of a soil, and a simple instrument by which it may be done. Take a glass tube, $\frac{3}{4}$ ths of an inch in diameter, and three feet long; fit a cork into one end and set it upright; fill it half full of pure water; take nearly as much water as has been poured into the tube, and mix with it the portion of soil which is to be examined, in quantity not more than will occupy 6 inches of the tube; pour the mixture rapidly into the tube, and let it stand in a corner of a room, or supported upright in any way; in half an hour it may be examined. The earths will have been deposited according to the size and specific gravity of their particles. The portion still suspended in the water may be allowed to settle; and there will appear in the tube layers of sand, clay, and humus, which may be measured by a scale, and thus the proportion nearly ascertained. When a farmer is about to hire a farm of which the quality is not well known to him, he may be much assisted in his judgment by this simple experiment, if he has no time or opportunity for a more accurate analysis. For the glass tube may be substituted one of tin or zinc two feet in length, with a piece of glass tube a foot long joined to it by means of a brass collar or ferule with a screw cut in it, which is cemented to the glass, and screws on the metal tube; and thus the instrument may be made more portable. When the water has been poured off, and the earths only remain, the cork may be taken out and the contents pushed out on a plate, by means of a rod and a plug which exactly fits the internal diameter of the tube. They may thus be more particularly examined. The result of various accurate analyses of soils shows that the most fertile are composed of nearly equal quantities of silicious and argillaceous earths in various states of division, and a certain proportion of calcareous earth, and of humus in that state in which it attracts oxygen and becomes soluble, giving out at the same time some carbonic acid. No chemist has yet been able to imitate the process of nature in the formation of this substance; and the circumstances which are most favourable to it are not yet fully ascertained. Here is the proper field for the application of science and accurate chemical analysis. As an example of an analysis will be useful to those who may desire to try the proposed method, we will add one actually made under very unfavourable circumstances, and without any apparatus; the only instrument at hand were scales and weights of tolerable accuracy, three glasses a foot long, and $1\frac{1}{4}$ inch in diameter, belonging to French lamps, a tin coffee-strainer, a piece of fine gauze, and a very fine cambric pocket-handkerchief. A little muriatic acid was ob-

tained at the apothecary's. The soil to be analyzed was taken from a piece of good arable land on the south side of the slope of the Jura mountains in Switzerland. Its specific gravity was taken as described before, and found to be 2.358 nearly. 500 grains of the dry soil were stirred in a pint of water, and set by in a basin. To save time, 500 grains more of the same soil were weighed, after having been dried over the fire. It was well pulverized with the fingers, and sifted through the coffee-strainer, then through gauze, and, lastly, through the cambric handkerchief. Some portion was left behind at each sifting. The two first portions were washed in the strainer and the gauze. The residue was sand of two different degrees of fineness, which, when dried, weighed, the coarser, 24 grains, the next, 20 grains. The earth and water which had passed through the strainer and the gauze were now strained through the cambric, and left some very fine sand behind, which, dried, weighed, and added to what had remained on the cambric, when sifted in a dry state, weighed 180 grains. All that which had gone through the cambric was mixed with water in a jug and stirred about. The heavier earth subsided, and the lighter was poured in one of the lamp-glasses, which had a cork fitted into it, and was placed upright. In about two minutes there was a deposit, and the lighter portion was poured into a similar glass, where it was left some time to settle. In this a slower deposition took place, and in about a quarter of an hour the muddy water was poured off into the third glass. The three glasses were placed upright, and left so till the next day. In the first glass was some very fine earth, apparently clay; in the second the same, but more muddy; and in the third nothing but thin mud. The contents of No. 2 were divided between No. 1 and No. 3, by pouring off the muddy part into No. 3 after some of the pure water had been poured off, and the remaining earth into No. 1; they were then left to settle. As much water as appeared quite clear over the sediment was decanted off. The sediment was poured on a plate by taking the cork out of the tube, which was cleaned with a piece of fine linen, which had been carefully dried and accurately weighed. The plates were examined, and some of the lighter part, which floated on the least agitation, was poured from one plate to another, until it was thought that all the humus had been separated. Most of the water could now be poured off the earths, by inclining the plates gently, without any muddiness. It was, however, passed through a piece of filtering-paper, which had been previously dried and weighed. The earth was slowly dried, by placing the plates on the hearth before a good fire, until they were quite dry, and so hot that they could not be easily held in the hand. The deposit left in the jug was poured on a plate, and a little muddy part, which was observed, was poured off with the water on another. This was again transferred, and the finer added to that which was in the second plate. Collecting now all the separate portions, there were found

Leaving 10 grains to be accounted for.

Each portion, except the three last, was now put into a cup, and diluted muriatic acid poured over them: an effervescence appeared in all of them, which continued on the addition of diluted acid, and when the contents of the cups were stirred with a piece of tobacco-pipe they were left till the next day, when all effervescence ceased, and the calcareous part seemed entirely dissolved: pure water was added to dissolve all the muriate of lime which had been formed. After some time, the clear liquor was poured off, and the remainder was strained through filtering-paper, and dried on plates before the fire. The earths were now found to weigh, respectively, 20, 17, 162, and 182.5 grains, having lost 4, 3, 18, and 57.5 grains of calcareous earth dissolved by the acid. The soil and water which had been put by in a basin were now repeatedly stirred, and poured into a filter, and more water was passed through the earth to wash out all the soluble matter: all the water was boiled down and evaporated, and left two grains of a substance which had the appearance of a gum with a little lime in it. Thus the loss was reduced to eight grains, a very small quantity, considering the means used in analyzing the soil. The corrected account, therefore, is as follows:—

ANALYSIS.

	Specific gravity, 2.258	Grains.
Silicious sand.	Coarse - - - - -	20
	Finer - - - - -	17
	Very fine - - - - -	162

Or, in round numbers,—

40 per cent. Sand.	500
36 — Clay.	
17 — Calcareous earth.	
5.5 — Vegetable earth, or humus.	
0.5 — Soluble matter.	

From the composition of this soil, it is evident that it is a most excellent loam, capable of producing with good tillage and regular manuring every kind of grain, artificial grasses, and roots commonly cultivated. The field from which the soil was taken was always considered to be of superior quality. This simple rule will suffice to enable any one to analyze any soil of which he desires to know the component parts, so far as they affect the general fertility. To ascertain minute portions of salts or metals, or any peculiar impregnation of the waters, must be left to practical chemists. To those who may be inclined to try the analysis of soils, it may be interesting to compare the results of their own experiments with some which have been obtained with great care. Thaër in his very excellent work on *Rational Husbandry*, written in German and translated into French, has given a table in which different soils analyzed by him are classed according to their comparative fertility, which is expressed in numbers, 100 being the most fertile.

No.	Clay.	Sand.	Carb. of Lime.	Finely divided Organic Matter, or Humus.	Comparative Value.	
1	74	10	4	11½	100	Rich alluvial soils.
2	81	6	4	8½	98	
3	79	10	4	6½	96	
4	40	22	36	4	90	
5	14	49	10	27	-	The value of this could not be fixed, as it was grass land; perhaps bog-earth
6	20	67	3	10	78	
7	58	36	2	4	77	Good wheat and barley lands.
8	56	30	12	2	75	
9	60	38	Very little carbonate of lime.	2	70	
10	48	50		2	65	
11	68	30		2	60	
12	38	60		2	60	
13	33	65	Barley land not fit for wheat.	2	50	
14	28	70		2	40	
15	23½	75		1½	30	
16	18½	80		1½	20	

The above table is the result of very patient investigation, the natural fertility of each soil being ascertained by its average produce with common tillage and manuring.

[In describing his new method of analyzing soils, Dr. Dana, the distinguished American chemist, sets out by stating that *geine* constitutes the basis of all the nourishing part of vegetable manures. By the term *geine*, he means all the decomposed organic matter of the soil, chiefly derived from decayed vegetable matter. Animal substances, he says, produce a similar compound containing *azote* or *nitro-*

gen. There may be undecomposed vegetable fibres so minutely divided as to pass through the sieve, but as one object of this operation is to free the soil from vegetable fibre, the portion will be quite inconsiderable, and can only affect the amount of insoluble *geine*. When so minutely divided, it will probably pass into soluble *geine* in a season's cultivation. *Geine*, or the vegetable nourishing matter of soils, exists in two states, in one of which it is soluble in water, &c., whilst in the insoluble state it resists the solvent power of water. Soluble *geine* he considers the immediate food of grow-

ing plants, whilst insoluble geine becomes food after sufficient exposure to air and moisture. Hence the reason and result of tillage.

Rules of Analysis.—"1. Sift the soil through a fine sieve. Take the fine part; bake it just up to browning paper.

"2. Boil 100 grains of the baked soil, with 50 grains of pearl ashes, saleratus or carbonate of soda, in four ounces of water, for half an hour; let it settle; decant the clear; wash the grounds with four ounces boiling water; throw all on a weighed filter, previously dried at the same temperature as was the soil, (1); wash till colourless water returns. Mix all these liquors. It is a brown-coloured solution of all the soluble geine. All sulphates have been converted into carbonates, and with any phosphates, are on the filter. Dry therefore that, with its contents, at the same heat as before. Weigh—the loss is soluble geine.

"3. If you wish to examine the geine; precipitate the alkaline solution with excess of lime-water. The geate of lime will rapidly subside, and if lime-water enough has been added, the nitrous liquor will be colourless. Collect the geate of lime on a filter; wash with a little acetic or very dilute muriatic acid, and you have geine quite pure. Dry and weigh.

"4. Replace on a funnel the filter (2) and its earthy contents; wash with two drachms muriatic acid, diluted with three times its bulk of cold water. Wash till tasteless. The carbonate and phosphate of lime will be dissolved with a little iron, which has resulted from the decomposition of any salts of iron, beside a little oxide of iron. The alumina will be scarcely touched. We may estimate all as salts of lime. Evaporate the muriatic solution to dryness, weigh and dissolve in boiling water. The insoluble will be phosphate of lime. Weigh—the loss is the sulphate of lime; (I make no allowance here for the difference in atomic weights of the acids, as the result is of no consequence in this analysis.)

"5. The earthy residuum, if of a grayish white colour, contains no insoluble geine—test it by burning a weighed small quantity on a hot shovel—if the odour of burning peat is given off, the presence of insoluble geine is indicated. If so, calcine the earthy residuum and its filter—the loss of weight will give the insoluble geine; that part which air and moisture, time and lime, will convert into soluble vegetable food. Any error here will be due to the loss of water in a hydrate, if one be present, but these exist in too small quantities in 'granitic sand' to affect the result. The actual weight of the residuary mass is 'granitic sand.'

"The clay, mica, quartz, &c., are easily distinguished. If your soil is calcareous, which may be easily tested by acids; then before proceeding to this analysis, boil 100 grains in a pint of water, filter and dry as before, the loss of weight is due to the sulphate of lime, even the sulphate of iron may be so considered; for the ultimate result in cultivation is to convert this into sulphate of lime.

"Test the soil with muriatic acid, and having thus removed the lime, proceed as before, to

determine the geine and insoluble vegetable matter.

"In applying Dr. Dana's rules given in the text, to the soils of Massachusetts, I found it necessary to adopt some method of carrying forward several processes together. I accordingly made ten compartments upon a table, each provided with apparatus for filtering and precipitations, also ten numbered flasks, ten evaporating dishes, and a piece of sheet-iron pierced with ten holes, for receiving the same number of crucibles. I provided, also, a sheet-iron oven, with a tin bottom large enough to admit ten filters, arranged in proper order, and a hole in the top to admit a thermometer. The sand bath was also made large enough for receiving the ten flasks. In this manner I was able to conduct ten processes with almost as great facility as one could have been carried forward in the usual way."

As before stated, Dr. Dana regards *geine* as the basis of all the nourishing part of vegetable manures. The relations of soils to heat and moisture, he says, "depend chiefly on geine. It is in fact, under its three states of 'vegetable extract, geine, and carbonaceous mould,' the principle which gives fertility to soils long after the action of common manures has ceased. In these three states it is essentially the same. The experiments of Saussure have long ago proved that air and moisture convert insoluble into soluble geine. Of all the problems to be solved by agricultural chemistry, none is of so great practical importance as the determination of the quantity of soluble and insoluble geine in soils. This is a question of much higher importance than the nature and proportions of the earthy constituents and soluble salts of soils. It lies at the foundation of all successful cultivation. Its importance has been not so much overlooked as undervalued. Hence, on this point the least light has been reflected from the labours of Davy and Chaptal. It needs but a glance at any analysis of soils, published in the books, to see that fertility depends not on the proportion of the earthy ingredients. Among the few facts, best established in chemical agriculture, are these: that a soil, whose earthy part is composed wholly, or chiefly, of one earth; or any soil, with excess of salts, is always barren; and that plants grow equally well in all soils, destitute of geine, up to the period of fructification,—failing of geine, the fruit fails, the plants die. Earths, and salts, and geine, constitute, then, all that is essential; and soils will be fertile, in proportion as the last is mixed with the first. The earths are the plates, the salts the seasoning, the geine the food of plants. The salts can be varied but very little in their proportions, without injury. The earths admit of wide variety in their nature and proportions. I would resolve all into 'granitic sand;' by which I mean the finely divided, almost impalpable mixture of the detritus of granite, gneiss, mica-slate, sienite, and argillite; the last, giving by analysis, a compound very similar to the former. When we look at the analysis of vegetables, we find these inorganic principles constant constituents—silica, lime, magnesia, oxide of iron, potash, soda, and sulphuric

and phosphoric acids. Hence, these will be found constituents of all soils. The phosphates have been overlooked from the known difficulty of detecting phosphoric acid. Phosphate of lime is so easily soluble when combined with mucilage or gelatine, that it is among the first principles of soils exhausted. Doubtless the good effects, the lasting effects, of bone manure, depend more on the phosphate of lime, than on its animal portion. Though the same plants growing in different soils are found to yield variable quantities of the salts and earthy compounds; yet I believe, that accurate analysis will show, that similar parts of the same species, at the same age, always contain the inorganic principles above named, when grown in soils arising from the natural decomposition of granite rocks. These inorganic substances will be found not only in constant quantity, but always in definite proportion to the vegetable portion of each plant. The effect of cultivation may depend, therefore, much more on the introduction of salts than has been generally supposed. The salts introduce new breeds. So long as the salts and earths exist in the soil, so long will they form voltaic batteries with the roots of growing plants; by which, the 'granitic sand' is decomposed and the nascent earths, in this state readily soluble, are taken up by the absorbents of the roots, always a living, never a mechanical operation. Hence, so long as the soil is granitic, using the term as above defined, so long is it as good as on the day of its deposition; salts and geine may vary, and must be modified by cultivation. The universal diffusion of granitic diluvium will always afford enough of the earthy ingredients. The fertile character of soils, I presume, will not be found dependent on any particular rock formation on which it reposes. Modified they may be, to a certain extent, by peculiar formations; but all our granitic rocks afford, when decomposed, all those inorganic principles which plants demand. This is so true, that on this point the farmer already knows all that chemistry can teach him. Clay and sand, every one knows: a soil too sandy, too clayey, may be modified by mixture, but the best possible mixture does not give fertility. That depends on salts and geine. If these views are correct, the few properties of geine which I have mentioned, will lead us at once to a simple and accurate mode of analyzing soils,—a mode, which determines at once the value of a soil, from its quantity of soluble and insoluble vegetable nutriment,—a mode, requiring no array of apparatus, nor delicate experimental tact,—one, which the country gentleman may apply with very great accuracy; and, with a little modification, perfectly within the reach of any man who can drive a team or hold a plough.”]

ANALYSIS OF VEGETABLES. The process or means by which such bodies are resolved into their constituent or elementary principles. (See **CHEMISTRY, OR VEGETABLE CHEMISTRY.**)

ANBURY. In farriery, a kind of wen, or spongy soft tumour or wart, commonly full of blood, growing on any part of an animal's

body. Substances of this kind may be removed either by means of ligatures being passed round their bases, or by the knife, and the subsequent application of some caustic material, in order to effectually destroy the parts from which they arise.

ANBURY, THE, AMBURY, HANBURY, or CLUB-ROOT. The anbury, the correct name, is evidently derived from the Saxon word *ambre*, a wart, suffused with blood, to which horses are subject. In Holderness, a district of Yorkshire, this disease is known as “fingers and toes,” from its causing the top root of the turnip to be divided into swollen fibres, resembling those members of the human body. On this, Mr. Spence, the entomologist, wrote a very sensible pamphlet, entitled “Observations on the Diseases in Turnips, termed in Holderness Fingers and Toes, Hull, 1812.” The deficiency of knowledge relative to the diseases of plants is well illustrated by the imperfect and inaccurate observations that have been adventured upon this disease. Where there is much difference of opinion there is little real knowledge, and both these are certainly the case in the instance before us. Some cultivators assert that the disease arises from a variableness and unfavourable state of the seasons; a second party of theorists advance, that it is caused by insects; and a third, that it is owing to a too frequent growth of the same crop upon the same site. Every man having formed an opinion, usually clings to it pertinaciously, and sets its estimate far above its real value or correctness. “It is with our opinions as our watches, none go just alike, yet each believes his own.” The chief error appears to be in considering any of the above enumerated causes as the exclusive one; for beyond doubt they each contribute, either immediately or remotely, to induce or exasperate the attacks of the anbury. [The disease attacks the hollyhock, and other plants, especially those belonging to the brassica or cabbage family.] Cabbage-plants are frequently infected with anbury in the seed-bed, and this incipient infection appears in the form of a gall or wart upon the stem, immediately in the vicinity of the roots; if this wart is opened it will be found to contain a small white maggot, the larva of a small insect called the weevil. If the gall and its tenant being removed, the plant is placed again in the earth where it is to remain unless it is again attacked, the wound usually heals, and the growth is little retarded. On the other hand, if the gall is left undisturbed, the maggot continues to feed upon the alburnum, or young woody part of the stem, until the period arrives for its passing into the other insect form, previously to which it gnaws its way out through the exterior bark. The disease is now almost beyond the power of remedies, the gall, increased in size, encircles the whole stem; the alburnum being so extensively destroyed, prevents the sap ascending, consequently, in dry weather, sufficient moisture is not supplied from the roots, to counterbalance the transpiration of the leaves, and the diseased plant is very discernible among its healthy companions, by its pallid hue and flagging foliage.

The disease now makes rapid progress; the swelling continues to increase; for the vessels of the alburnum and the bark continue to afford their juices faster than they can be conveyed away. Moisture and air are admitted to the interior of the excrescence through the perforation made by the maggot; the wounded vessels ulcerate, putrefaction supervenes, and death concludes the stunted existence of the miserable plant. The tumour usually attains the size of a large hen's egg, has a rugged, ichorous, and even mouldy surface, smelling strong and offensively. The fibrous roots, besides being generally thickened, are distorted and monstrous, from swellings which appear throughout their length, which apparently arise from an effort of nature to form receptacles for the sap, deprived as it is of its natural spissation in the leaves. These swellings do not seem to arise immediately from the attacks of the weevil, for I have never observed them containing its larva. Mr. Marshall very correctly describes the form which this disease assumes when it attacks the turnip. It is a large excrescence appearing below the bulb; growing to the size of both hands, and as soon as the hard weather sets in, or it is, by its own nature, brought to maturity, becoming putrid, and smelling very offensively. On the last day of August, when the bulbs of the turnips were about the size of walnuts in the husk, the anburies were as big as a goose's egg. These were irregular and uncouth in their form, with excrescences resembling the races of ginger hanging to them. On cutting them, their general appearance is that of a hard turnip; but on examining them through a magnifier there are veins, or string-like vessels, dispersed among the pulp. The smell and taste somewhat resemble those of turnips, but without their mildness, having an austere and somewhat disagreeable flavour resembling that of an old stringy turnip. The tops of those much affected turn yellow, and flag with the heat of the sun, so that in the daytime they are obviously distinguishable from those which are healthy. These distortions manifest themselves very early in the turnip's growth, even before the rough leaf is much developed. Observation seems to have ascertained, that if the bulbs have attained the size of a walnut unaffected, they do not subsequently become diseased. Mr. Spence has clearly shown, from established facts, that the anbury does not arise from any imperfection of the seed sown: for experience demonstrates that, in the same field and crop, the attacks are very partial; and crops in two adjoining fields, sown with seed from the same growth, will one be diseased, and the other healthy. Secondly, it does not arise from an unfavourable time of sowing, or from dry, unpropitious seasons, during their after-growth; for on this supposition we might expect that in all turnip districts the disease would occasionally make its appearance, in consequence of variations in the period and mode of sowing, or from following droughts; yet we know that, in many parts of the country, it has never been heard of. Thirdly, it does not arise from the quality of the soil, for Sir Joseph Banks suffered from its infecting thin stapled, sandy fields;

whilst all Holderness, which is generally a strong loamy soil, was found equally liable to the disease. It is occasioned by the poisonous wound inflicted by an insect in an early stage of vegetation, or rather by its insinuating its egg into the tender plant. The maggot found in the turnip anbury, is the larva of a weevil called *Curculio pleurostigma* by Marsham, and *Rhynchænus sulcicollis* by Gyllenhal. "I have bred this species of weevil," says Mr. Kirby, from the knob-like galls on turnips, called the anbury, and I have little doubt that the same insects, or a species allied to them, cause the clubbing of the roots of cabbages." (*Kirby and Spence's Introduction to Entomology.*) Marsham describes the parent as a coleopterous insect, of a dusky, black colour, with the breast spotted with white, and the length of the body one line and two-thirds.

A very full description of this insect is in the *Insecta Svecica descripta*, of Gyllenhal, vol. iii. p. 229, under the name of *Rhynchænus sulcicollis*.

The general experience of farmers and gardeners upon the subject, testifies that the anbury of the turnip and cabbage usually attacks these crops when grown for successive years on the same soil. This is precisely what might be expected; for the parent insect always deposits her eggs in those situations where her progeny will find their appropriate food; and in the fragments of the roots, &c., of preceding crops, some of these embryo ravagers are to be expected. That they never attack the plants upon a fresh site is not asserted; Mr. Marshall's statement is evidence to the contrary; but it is advanced that the obnoxious weevil is most frequently to be observed in soils where the turnip or cabbage has recently and repeatedly been cultivated. Another general result of experience is, that the anbury is most frequently observed in dry seasons. This is also what might be anticipated, for insects that inhabit the earth just beneath its surface are always restricted and checked in their movements by its abounding in moisture. Moreover, the plants actually affected by the anbury are more able to contend against the injury inflicted by the larva of the weevil by the same copious supply. The development of their parts, their growth is more rapid; consequently the maggot has not to extend his ravages so extensively in search of food as in drier seasons, when the stem is less juicy and of a smaller growth. In wet periods, also, the affected plants show less the extent of the injury they have sustained, for their foliage does not flag; because their transpirations of watery particles is less, and their supply of nutriment from the soil is more free.

In considering the best modes of preventing the occurrence of the disease, and of palliating its attacks, it is apparent that any addition to the soil that renders it disagreeable to the weevil will prevent the visits of this insect. The gardener has this in his power with but little difficulty; for he can keep the vicinity of his cabbage, cauliflower, and brocoli plants soaked with water. Mr. Smith, gardener to Mr. Bell, of Woolsington in Northumberland, expresses his conviction, after several years'

experience, that charcoal dust spread about half an inch deep upon the surface, and just mixed with it by the point of a spade, effectually prevents the occurrence of this disease. (*Trans. of Lon. Hort. Soc.* vol. i. art. 2.) That this would be the case we might have surmised from analogy; for charcoal dust is offensive to many insects, and is one of the most powerful preventives of putrefaction known. Soot, I have reason to believe, from a slight experience, is as effectual as charcoal dust. Judging from theoretical reasons, we might conclude that it would be more specific; for in addition to its being like charcoal, finely divided carbon, it contains ammonia, to which insects have an antipathy. Mr. Drurey, a practical farmer at Erpingham, in Norfolk, considered marl a certain preventive of this disease. He, and several other judicious farmers also, thought that *teathing*, that is, giving sheep and cattle their green food, turnips, &c., upon the barley stubbles, intended for turnips as the succeeding crop, will cause the anbury. (*Marshall's Rural Economy of Norfolk*, ii. 33, 35.) It is very evident that it would mix fragments with the soil that would be liable to contain the eggs of the weevil. The marl, approved by Mr. Drurey, is probably the calcareous marl which occurs at Thorp Market, in the hundred of North Erpingham; but as there is a slight doubt, owing to the deficiency of accuracy in the statement, it affords me an opportunity to impress upon agriculturists in general, the great importance of employing more certain terms than they usually do. What can be more indefinite than the statement, that marl is a certain preventive of the anbury? For the very first question suggested to the reader's mind is, What marl is intended? Is it a chalky marl, or a clay marl? is it a mixture of chalk and clay, or of chalk and silicious sand? for all these varieties of marl are known to agriculture. The want of a correct nomenclature is one of the drawbacks and deficiencies checking the improving progress of agriculture. Few farmers ever thought upon this point, and still smaller is the number who duly appreciated its importance; yet it is an incontrovertible fact, that no art or science can advance rapidly until its technical terms are fixed, terse, expressive, and generally understood. Chemistry attained a greater aid to its advancement by the introduction of its new nomenclature by Lavoisier, than by any series of discoveries that have since been made on its rapid and brilliant progress. If a sulphate, an acid, or a metal is mentioned, a chemist immediately has a definite idea of the nature and properties of the substance alluded to; but if a loam or marl is spoken of, would any two farmers agree in their idea of what description of earthy compound was intended! To make it well understood, a long detail must be added; and nothing checks the imparting of knowledge more, than the person capable of imparting it being conscious that he must define every term as he goes on, and that even then it is doubtful, if he shall succeed in making himself intelligible. The very name, anbury, usually applied to the disease, which is the subject of this paper, is another proof of the necessity of a reformed

agricultural nomenclature; for in Suffolk, the same title is given to another disease which merely affects the leaves of the turnip. Sir Joseph Banks, Mr. Baker of Norfolk, and others, agree that marl is the best preventive of anbury. And another evidence of the efficacy of applications to the soil is afforded by a gentleman in Holderness, a Mr. Brigham, who had a highly manured clayey ridge, which he had levelled the year before, and this grew turnips entirely free of the disease, whilst in the natural rich loam of the field they were much infected. Francis Constable, Esq., of Burton Constable, had a field that had been in grass twenty years: this he pared, burned and sowed with turnips, obtaining a crop perfectly free from the disease. Two white crops were then taken, after which turnips were again sown; a considerable portion of the crop was then infected with the disease. (*Spence's Observations on the Disease of Turnips, termed in Holderness Fingers and Toes.*) I have myself tried the efficacy of common salt in preventing the occurrence of this disease: its tendency to keep the soil moist, and to irritate the animal frame, certainly checks the inroads of the weevil; and its generally beneficial effects as a manure enables the plants better to sustain themselves under the weakening influence of the disease; but it is not a decisive preventive.

With regard to the use of salt as a cure for the disease, I am inclined to think, from the results of experiments which I have instituted, that unless the salt be applied very early, it would be useless; for the root soon becomes so diseased as to be entirely past recovery. (*C. W. Johnson's Essay on Salt*, p. 136.)

I have a strong opinion that a slight dressing of the surface soil with a little of the dry hydro-sulphate of lime, that may now be obtained so readily from the gas-works introduced throughout England, would prevent the occurrence of the disease, by driving the weevils from the soil. It would probably as effectually banish the turnip-fly or flea, if sprinkled over the surface immediately after the seed is sown. I entertain this opinion of its efficacy in preventing the occurrence of the anbury, from an instance when it was applied to some broccoli, ignorantly grown upon a bed where cabbages had as ignorantly been endeavoured to be produced in successive crops; these had invariably failed from the occurrence of the anbury, but the broccoli was uninfected. The only cause for this escape that I could trace was, that just previously to planting, a little of the hydro-sulphuret of lime had been dug in. This is a very ietid, powerful compound, and must be used with great caution.

Where dry lime purifiers are employed at gas-works, it may be obtained in the state of a dry powder; but where a liquid mixture of lime and water is employed, the hydro-sulphuret can only be had in the form of a thick cream. Of the dry hydro-sulphuret I would recommend eight bushels per acre to be spread regularly by hand upon the surface, after the turnip seed is sown, and before harrowing. If the liquid is employed, I wo

recommend thirty gallons of it to be mixed with a sufficient quantity of earth or ashes, to enable it to be spread over an acre in a similar manner. For cabbages twelve bushels, or forty-five gallons per acre, would not, probably, be too much, spread upon the surface, and turned in with the spade or last ploughing. Although I specify the quantities as those I calculate most correct, yet in all experiments it is best to try various proportions: three or four bushels may be found sufficient; perhaps twelve, or even twenty, may not be too much. Frequent hoeing has been recommended as a preventive of this disease; but I believe this to be unsustained either by reason or practice. (*G. W. Johnson, Quar. Journ. Agric.*, vol. vii. p. 308, et seq.)

[ANDES GRASS. The *Holcus avenaceus* of some writers, and *Avena elatior* of others. Oat Grass, and sometimes Tall Meadow Grass. (Plate 5, *cc.*) A perennial cultivated grass, flowering in the Middle States in May, and ripening its seeds in July. (*Flor. Cestriac.*) Its name would imply that it came originally from the mountains of South America, whereas the English botanists treat of the *Holcus avenaceus*, or *Avena elatior*, as a native of Britain. The Andes Grass was introduced to the notice of American farmers several years ago, when its merits were perhaps too highly extolled, which has contributed to its being now estimated much below its real worth. Perhaps, too, that those who have reported unfavourably of the value of Andes Grass, have mistaken some other plant for it, a very common occurrence, leading to great discrepancy of opinion. This grass is certainly highly prized by many persons in the Middle States, where, especially in the state of Delaware, it is frequently, though not very extensively, cultivated. It grows luxuriantly in soils of clay loam, even of a very light description, affording very early as well as late pasture. Even an open spell in winter, with a few warm days, will start this grass to vegetating so rapidly as to furnish a good bite to cattle. The grass grows very tall, and the hay, if left too late before cutting, is coarse. It grows in tufts, is very durable, and extremely difficult to eradicate from the soil when once well set. This last circumstance perhaps constitutes the most common objection to its introduction into fields and meadows. It stands drought well, and would probably be found a highly valuable grass for southern pastures. It certainly deserves more attention than it now receives, and is, we think, destined to be much more extensively cultivated as a permanent pasture grass. Its durability renders it unfit for alternate husbandry.

From Colman's Fourth Report of the Agriculture of Massachusetts the following passage is extracted.

"The tall meadow oat (*Avena elatior*) has been cultivated in the county. This grass is not familiar to our farmers, but the success which has attended its cultivation encourages its extension. A Virginia farmer of the highest authority speaks of it, after fifteen years' experience, as a hardy plant, bearing drought and frost, heat and cold, better than any other

grass known to him. A Pennsylvania farmer pronounces it of all other grasses the earliest, latest, and best for green fodder or hay. It blossoms about the middle of June, and is preferred to all others by horned cattle. It must be cut seasonably or it becomes hard like straw. A Middlesex farmer, who has cultivated it several years, and whose authority is of the highest character, confirms the above statements of its excellence both for grazing and hay. He says, from its early flowering it is adapted to be sown with red clover, and is fit to be cut about the first of June. His own account is as follows:

"In the spring he sowed with barley a field of four acres, and put on $2\frac{1}{2}$ bushels of oat-grass seed, 5 lbs. of red clover, and 2 lbs. of white clover seed, to the acre. The soil was thin, and had been exhausted by long cropping. On the 3d of June in the following year it was cut, and gave two tons to the acre of the finest and best hay, either for cattle or horses, he ever had in his barn."

"He thinks three bushels of seed should be sown to the acre. It is well adapted for grazing on poor and exhausted lands, as well as on those of a richer quality. It is a fortnight earlier than the common grasses, and throughout the driest weather exhibits a green appearance. From three-fourths of an acre, in good condition, he obtained over 20 bushels of well-cleaned seed.

"The late John Lowell, a man behind no other in his intelligent, successful, and disinterested efforts to advance the cause of an improved agriculture in Massachusetts and New England generally, says that, 'under his cultivation, it has proved a most valuable grass, and fully sustained its high character. It is a very early and tall grass, yielding a good burden. It will start rapidly after cutting. It is a perennial and enduring grass, and on his first experiment it lasted seven years without the necessity of renewal.'

"A farmer in Waltham objects to sowing the tall meadow oats and the herdsgrass (Timothy) together, as they do not ripen at the same time. The tall meadow oats, when I visited him, would be ready for the scythe in ten days, or about the middle of June, while the herdsgrass, at the same time, had not begun to show its head.

"This grass—*Avena elatior*, tall oat grass—sends forth flower-straws during the whole season; the latter math contains nearly an equal number with the flowering crop. It is subject to the rust, but the disease does not make its appearance till after the period of flowering. It affects the whole plant, and at the time the seed is ripe the leaves and straws are withered and dry. This accounts for the superior value of the latter math over the seed crop, and points out the propriety of taking the crop when the grass is in flower. The nutritive matter afforded by this grass, when made into hay, according to the table is very small." (*Geo. Sinclair.*)

"J. Buel speaks of his 'field experiments with this grass not being so successful as he expected—owing partly to the seed not vegetating well; and partly, he supposed, to the

soil (a light sandy loam) not being sufficiently strong and tenacious.'

'Taylor, of Virginia, says that, 'according to his experience, it will not succeed in lands originally wet, however well they are drained.'

'The opinion of the farmers generally in this county is in favour of cutting herdsgrass (Timothy) early rather than late; perhaps for the reason that the hay is then of a bright green, and on this account commands in the city market a higher price. If we can rely upon chemical examination in determining the nutritive properties of grasses, it will be found that the grain in this respect, in cutting herdsgrass when its seed is ripe over cutting it when in flower, is as 86.1 to 37.2.']

ANETHUM. See DILL and FENNEL.

ANEURISM. In farriery, a throbbing tumour, produced by the dilatation of the coats of an artery in some part of the body of an animal. Aneurisms in the limbs may be cured by making an incision, exposing the artery, and tying it above and below the tumour with a proper ligature.

ANGELICA (*Angelica Archangelica*). This plant was formerly blanched and eaten like celery; but at present its tender stalks are the only part made use of, which are cut in May for candying.

It grows in gardens, and also wild. It flowers in July and August in England, and the roots perish after the seed has ripened. This plant grows as high as eight feet; the stalks robust, and divided into branches. The flowers are small, and stand in large clusters of a globular form. Two seeds follow each flower.

It may be grown in any soil and exposure, but flourishes best in moist situations; consequently the banks of ponds, ditches, &c., are usually allotted to it. It is propagated by seed, which is to be sown soon after it is ripe, about September, being almost useless if preserved until the spring, as at that season not one in forty will be found to have preserved its vegetative powers; if, however, it be neglected until that season, the earlier it is inserted the better. It may be sown either broadcast moderately thin, or in drills a foot asunder, and half an inch deep. When arrived at a height of five or six inches, they must be thinned, and those removed transplanted to a distance of at least two feet and a half from each other, either in a bed, or on the sides of ditches, &c., as the leaves extend very wide. Water in abundance must be given at the time of removal, as well as until they are established; but it is better to discontinue it during their further growth, unless the application is regular and frequent. In the May or early June of the second year they flower, when they must be cut down, which causes them to sprout again; and if this is carefully attended to, they will continue for three or four years, but if permitted to run to seed, they perish soon after. A little seed should be saved annually as a resource in case of any accidental destruction of the crop. (*G. W. Johnson's Kitchen Garden*.)

Angelica is fragrant when bruised, and every part of it is medicinal. The bruised seeds are the most powerful. They are cordial and su-

dorific. Three table-spoonfuls of the distilled water is a remedy for flatulence and pains in the stomach. A paste of the fresh root of angelica, beaten up in vinegar used to be carried by physicians in times of great contagion, to apply to the nose. Some preferred holding a dry piece in their mouths, to resist infection. It has always been celebrated against pestilential and contagious diseases. The stalks of the angelica candied are much esteemed in winter desserts as a sweetmeat in England. The Laplanders boil or bake the stalks till extremely tender, and eat them as a delicacy. The seeds bruised are cordial, stomachic, and sudorific. (*L. Johnson*.)

ANGINA. In farriery, a name sometimes applied to the quinsy, or what in animals is termed anticor.

ANGLE-BERRY. In farriery, a sort of fleshy excrescence, to which cattle and some other animals are subject under different circumstances; and are supposed to proceed from a rupture of the cutaneous vessels, which give vent to a matter capable of forming a *sarcoma*, or fleshy excrescence. They frequently appear upon the belly and adjacent parts, hanging down in a pendulous manner.

ANGORA GOAT. A particular species of goat.

ANIMAL. A creature that is endowed with life, and commonly with spontaneous motion, though in some cases without it. They are distinguished in general from vegetables by having motion, though this gives us no perfect definition, as there are entire classes of animals which are fixed to a place, as the *lithophytes* and *zoophytes*, which are produced and die upon the same spot; and on the other hand, certain vegetables have as much motion in their leaves and flowers as certain animals. However, by attending to the most general characters, they may be defined to be bodies endowed with sensation and motion necessary to preserve their life. They are all capable of reproducing their like: some by the union of the sexes, produce small living creatures; others lay eggs, which require a due temperature to produce young; some multiply without conjunction of the sexes; and others are reproduced when cut in pieces like the roots of plants. See BOTANY. FOR PERIODS OF BREEDING and HATCHING, with other interesting facts connected with the subject, see GESTATION and INCUBATION.

ANIMALS, DANGEROUS. See NUISANCE.

ANIMALS, WILD, STEALING OF. In England no larceny at common law (says Mr. Archbold in his *Crim. Law*, p. 165) can be committed of such animals, in which there is no property either absolute or qualified; as of beasts that are *feræ naturæ*, and unreclaimed, such as deer, hares, and conies, in a forest, chase, or warren; fish, in an open river or pond; or wild fowls, rooks for instance (*Hunman v. Hockett*, 2 B. & C. 934; 4 D. & R. 518) at their natural liberty. (1 *Hale*, 511; *Fost* 366.) But if they are reclaimed or confined and may serve for food, it is otherwise; for if deer so enclosed in a park that they may be taken at pleasure, fish in a trunk or net, and pheasants or partridges in a mew, larceny ma

be committed. (1 *Hale*, 511; 1 *Hawk*. c. 33, s. 39.) Swans, it is said, if lawfully marked, are the subject of larceny at common law, although at large in a public river (*Dalt. Just.* c. 156); or whether marked or not if they be in a private river or pond. (*Ib.*) So, all valuable domestic animals, as horses, and all animals *domitæ naturæ*, which serve for food, as swine, sheep, poultry, and the like, and the product of any of them, as eggs, milk from the cow while at pasture (*Foster*, 99), wool pulled from the sheep's back feloniously (*R. v. Martin*, 1 *Leach*, 171), and the flesh of such as are *feræ naturæ*, may be the subject of larceny. (1 *Hale*, 511.) But as to all other animals which do not serve for food, such as dogs, ferrets though tame and saleable (*R. v. Spearing*, R. & R. 250), and other creatures kept for whim and pleasure, stealing these does not amount to larceny at common law. (1 *Hale*, 512.) But now, to course, hunt, snare, or carry away, or kill or wound, or attempt to kill or wound, any deer kept or being in the enclosed part of any forest, chase, or purlieu, or in any enclosed land wherein deer are usually kept, is felony, punishable as simple larceny; and if committed in the unenclosed part of any forest, chase, or purlieu, the first offence is punishable upon summary conviction by fine not exceeding 50*l.*, and the second after a previous conviction is felony, and punishable as simple larceny. (7 & 8 G. 4, c. 29, s. 27.) Summary punishment may also be imposed by fine, not exceeding 20*l.*, upon any person who shall have in his possession, or upon his premises, with his knowledge, any deer, or the head, skin, or other part thereof, or any snare or engine for the taking of deer, without satisfactorily accounting for such possession (7 & 8 G. 4, c. 29, s. 27); or who shall set or use any snare or engine whatsoever for the purpose of taking or killing deer in any part of any forest, chase, or purlieu, whether enclosed or not, or in any fence or bank dividing the same from any land adjoining, or in any enclosed land where deer are usually kept, or shall destroy any part of the fence of any land where deer are then kept. (7 & 8 G. 4, c. 29, s. 28.) To take or kill hares or coney in the night-time, in any warren or ground lawfully used for the breeding or keeping of the same is a misdemeanor; and to take and kill them in any warren or ground in the day-time, or at any time to set any snare or engine for the taking of them, is punishable upon summary conviction by fine. (7 & 3 G. 4, c. 29, s. 30.) Stealing dogs, or any beast or bird ordinarily kept in a state of confinement, not being the subject of larceny at common law (7 & 8 G. 4, c. 29, s. 31); knowingly being in possession thereof, or of the skin or plumage thereof (7 & 8 G. 4, c. 29, s. 32); killing, wounding, or taking any dove-house pigeon, under such circumstances as shall not amount to larceny at common law (*see R. v. Brooke*, 4 C. & P. 131; 7 & 8 G. 4, c. 29, s. 33), is punishable upon summary conviction by fine, imprisonment, and whipping, according to the nature of the offence. So, to take or destroy any fish in any water which shall run through, or be in any land adjoining or belonging to the dwelling-house of any per-

son, being the owner of such water, and having a right of fishery therein, is a misdemeanor; and to take and destroy fish in any other water, being private property, or in which there shall be any private right of fishery; and to destroy fish by angling, in the day-time, in either description of water is punishable upon summary conviction by fine, varying according to the nature of the offence. (7 & 8 G. 4, c. 29, s. 34.) And, lastly, to steal any oyster or oyster brood from any oyster bed, laying, or fishery, being the property of another, and sufficiently marked out or known as such, is larceny; and to use any dredge or any net, instrument or engine whatsoever within the limits of such oyster fishery for the purpose of taking oysters or oyster brood, although none be taken, or to drag upon the soil of any such fishery with any net, instrument, or engine, is a misdemeanor. (7 & 8 G. 4, c. 29, s. 36.)

ANIMAL CHEMISTRY. See CHEMISTRY.

ANIMAL MANURES. For the information I have to furnish with regard to animal manures, I must refer the farmer to other heads of this work, such as FARM-YARD MANURE, NIGHT-SOIL, BONES, LIQUID MANURE, FISH, &c. A very elaborate paper by Dr. C. Sprengel, translated by Mr. Hudson, will be found in the *Journal of the Roy. Ag. Soc. of Eng.*, vol. i. p. 455, and to that I am indebted for most of the general observations on animal manures in this article. The excrements of animals vary with the age of the animal, its food, &c. That of young animals is poorer than that of the aged, for the young and growing animal requires, for its nourishment and increase in size, a greater proportion of the phosphate of lime, and other solid ingredients of its food, than the more aged animal, because the excrements or refuse matters of the vegetables consumed are proportionately diminished in quantity and in richness. The richer the food, too, the better is the quality of the manure. That from animals fed upon oil-cake is the richest; then that from corn-fed animals; then that from green crops, hay; and, lastly, that from straw-yard cattle is decidedly the poorest. Then again the water consumed by animals to some extent influences the quantity of their manure. In the water usually drank by an ox, amounting daily to about 80 lbs., is often found from half an ounce to an ounce of saline matter. These consist of gypsum, common salt, carbonate of lime, and carbonate of magnesia. "It may be always regarded," as is observed by M. Sprengel, "as an indication that the excrements of animals contain many powerfully manuring substances when they pass quickly into the putrefactive state, and develop a large quantity of the offensive gases, ammonia; for in such cases they contain not only much sulphur, phosphorus, and nitrogen, but an abundance also of chlorine, soda, potash, lime, and magnesia, the whole of which are so much the more important in vegetation, as the soil manured with the excrements is deficient in these particular substances."

The mode in which animal fertilizers operate, varies, however, according to their chemical composition. Some are enriching from possessing peculiar saline substances, which

are direct food for plants. Thus bones abound with phosphate of lime. Night-soil and urine do the same. Farm-yard compost contains all the essential ingredients of the farmer's crops, and they all copiously yield, by their decomposition, the gases of putrefaction, such as the carburetted hydrogen, and carbonic acid gas, as well as various easily decomposable salts of ammonia; all of which are found to be highly nourishing when applied to the roots of the plants, or even to their leaves. And, in fact, some of the most powerful of the animal fertilizers, such as train-oil, whale-blubber, &c., can yield the plant nothing else: they do not contain either saline or earthy matters. It is their gaseous elements only, therefore, which, when applied to the roots of vegetables, produces such a rankness of growth, such a dark green, as the farmer invariably finds to follow in moist seasons from their use.

The quantity of animal manures employed in England besides that produced by the farmer's live stock, is annually increasing, and it is a happy circumstance that it is so. Not only are sprats and other cheap fish bought up in every direction, but all northern Europe, and even the South Sea, is searched for bones; refuse train oil, and greaves are, to a considerable extent, also used, and there are several manufactories in the metropolis for the preparation of manure powders of an animal description, such as the urate of the London Manure Company, and the disinfected night-soil of M. Poittevin. These are both, especially the first, powerful enrichers, and are admirably adapted for application by the drill.

ANIMAL POISONS. Several animals are furnished with liquid juices of a poisonous nature, which, when injected into fresh wounds, occasion the disease or death of the wounded animal. Well known examples are furnished by the sting of serpents, bees, scorpions, spiders, &c. The poison of the viper is a yellow liquid, which lodges in two small vesicles in the animal's mouth. These communicate by a tube with the crooked fangs which are hollow, and terminate in a small cavity. When the animal bites, the vesicles are squeezed, and the poison forced through the fangs into the wound. This poisonous juice occasions the fatal effects of the viper's bite. If the vesicles be extracted, or the liquid prevented from flowing into the wound, the bite is harmless. It has a yellow colour, resembling gum, but no taste; and when applied to the tongue occasions numbness. The poison of the viper, and of serpents in general, is most hurtful when mixed with the blood. Taken into the stomach, it kills if the quantity be considerable. Fontana has ascertained that its fatal effects are proportional to its quantity compared with the quantity of the blood. Hence the danger diminishes as the size of the animal increases. Small birds and quadrupeds die immediately when they are bitten by a viper; but to an adult the bite seldom proves fatal. "Sweet oil," says Mr. Beckford, "has long been esteemed as a certain antidote to the bite of a viper; some should be applied to the part, and some taken inwardly; but the common

cheese-rennet, externally applied, is asserted to be a more efficacious remedy than oil. Ammonia, or spirits of hartshorn, has also been proposed as an antidote. It was introduced in consequence of the theory of Dr. Mead, that the poison was of an acid nature. The numerous trials of that medicine by Fontana robbed it of all its celebrity; but it has been lately revived and recommended by Dr. Ramsay as a certain cure for the bite of the rattlesnake." (*Phil. Mag.* vol. xvii. p. 125.)

The venom of the bee and the wasp is also a liquid contained in a small vesicle, forced through the hollow tube of the sting into the wound inflicted by that instrument. From the experiments of Fontana we learn that it bears a striking resemblance to the poison of the viper. That of the bee is much longer in drying when exposed to the air than the venom of the wasp. The sting of the bee should be immediately extracted; and the best application is opium, and olive oil; one drachm of the former finely powdered, rubbed down with an ounce of the latter, and applied to the part affected by means of lint, which should be frequently renewed. (See BEE.) The poison of the scorpion resembles that of the viper. But its taste is hot and acid, which is the case also with the venom of the bee and the wasp. No experiments upon which we can rely have been made upon the poison of the spider tribe. From the rapidity with which these animals destroy their prey, and even one another, we cannot doubt that their poison is sufficiently virulent. (*Mead and Fontana on Poisons; Thomson's Chem.* vol. iv. pp. 531—533.)

[Soft poultices of fresh flesh, bread and milk, or in the absence of these, even mud, are excellent applications to stings of insects and even the bites of the most venomous snakes. The vaunted specifics recommended in such cases for internal use, are not to be compared in efficacy with the timely application of a poultice of the flesh of a chicken or other animal recently killed. The flesh of the rattle-snake itself is in some parts of America reckoned to possess specific virtues, and doubtless will answer nearly, if not quite as well, as any other good soft and moist poultice, which will seldom fail to effect a cure when promptly applied and frequently renewed. In this way the irritation and inflammation induced by the poison in the part bitten is often arrested at once, and prevented from extending to vital parts. These conclusions are the results of experiments made with the poison of the rattle-snake, in which the most celebrated Indian and other specifics were used with little if any advantage.]

ANJOU CABBAGE. An excellent vegetable both for the kitchen and the food of cattle.

The great Anjou cabbage, said the Marquis de Turbilly, is one of the most useful leguminous plants for country use. It will grow in almost any soil, not excepting even the most indifferent, provided it be sufficiently dunged. The seeds of this cabbage are commonly sown in June, in a quarter of good mould, in the kitchen-garden, and watered from time to time in case of drought. The plants will rise pretty speedily, and should be thinned soon after

wherever they stand too thick. The next care is to keep them free from weeds whilst they continue, by hoeing the ground between them. About the first of November (probably September or October would be better in this climate), they should be transplanted into the field where they are to remain. They should be planted there in trenches dug with a spade, pretty deep; that is, they should be buried almost up to the leaves. The distance between them should be two feet or two feet and a half every way, according to the soil. Particular care should be taken never to plant them with a dibble, as gardeners plant other sorts of cabbages. A layer of dung should be spread along the bottom of the trench, and the roots of the transplanted cabbages covered therewith. The mould taken out should then be returned back upon the dung; and, as the trench will then no longer hold it all, there will remain a ridge between each row of cabbages. Towards the middle of the ensuing May, the ground should be well stirred between the plants with a spade, or some other proper instrument, and its whole surface laid quite level. After this, nothing more remains to be done, except pulling up the weeds, from time to time, as they appear.

In the month of June, such of these cabbages as are already large, and do not turn in their leaves for cabbaging, but still continue green, begin to be fit for use, and soon arrive at their full perfection, which they retain till the next spring, when they begin to run up, and afterwards blossom. Their seeds ripen towards the end of July, and what is intended for sowing should then be gathered. In Anjou, when these cabbages are entirely run up, they generally grow to the height of seven or eight feet; sometimes they reach to eight feet and a half, or nine feet; nay, some have even been seen of a greater height. From the month of June, when these cabbages begin to be fit for use, their leaves are gathered from time to time, and they shoot out again. They are large, excellent food, and so tender that they are dressed with a moment's boiling. They never occasion any flatulencies or uneasiness in the stomach; and are also very good for cattle, which eat them greedily. They likewise greatly increase the milk of cows. Such are the properties of this kind of cabbage, which is greatly esteemed in the districts formerly denominated Anjou, Poitou, Brittany, Le Maine, and some other neighbouring provinces. In the first, farmers were formerly bound by their leases to plant early a certain number of these cabbages, and to leave a certain number of them standing when they quitted their farms.

ANNONA (*Triloba*). The *North American Papaw*. This is the only sort which will grow in the open air in England. [See *PAPAW*.]

ANNOTTA, or ARNOTTA (Fr. *rocou*; Ger. *orlean*; It. *oriana*). In rural economy, anatto or arnatto, for it is written in various ways, is a colouring substance, or dye, obtained from the skin or pulp of the kernel of the *Bixa orellana* of South America and the West Indies.

Of the preparation of this matter from the red pulp which covers the seeds, Mr. Miller gives the following account:—The contents of

the fruit are taken out and thrown into a wooden vessel, where as much hot water is poured upon them as is necessary to suspend the red powder or pulp, and this is gradually washed off with the assistance of the hand, or of a spatula, or spoon. When the seeds appear quite naked, they are taken out, and the wash is left to settle; after which the water is gently poured away, and the sediment put into shallow vessels to be dried by degrees in the shade. After acquiring a due consistence, it is made into balls or cakes, (which are known in commerce as the *flag*, or *cake*, and *roll* arnotta, and comes chiefly from Cayenne,) and set to dry in an airy place until it be perfectly firm. Some persons first pound the contents of the fruit with wooden pestles; then, covering them with water, leave them to steep six days. This liquor being passed through a coarse sieve, and afterwards through three finer ones, it is again put into the vat or wooden vessel, and left to ferment a week; it is then boiled until it be pretty thick, and when cool spread out to dry, and afterwards made up into balls, which are usually wrapped up in banana leaves.

Arnotta, when of good quality, is of the colour of fire, bright within, soft to the touch, and capable of being dissolved in water. But the substance commonly met with under this name is a preparation made by the druggists, in which madder is probably a principal ingredient; it is of a brick colour, and a hard compact texture. Arnotta is much used in Gloucestershire, and other cheese counties, and in the butter dairies. The method of using the soft, or genuine sort, is simply by dissolving such a quantity as is necessary in a small portion of milk; allowing such particles as will not dissolve to settle to the bottom. The milk thus coloured is then poured off, and mixed with that which is to be made into cheese. But when the hard preparation is used, pieces of it are frequently under the necessity of being rubbed against a hard, smooth, even-faced pebble, or other stone, being previously wetted with milk to forward the levigation, and to collect the particles as they are loosened. For this purpose, a dish of milk is generally placed upon the cheese-ladder; and, as the stone becomes loaded with levigated matter, the pieces are dipped in the milk from time to time, until the milk in the dish appear to be sufficiently coloured. The stone and the "colouring" being washed clean in the milk, it is stirred briskly about in the dish; and, having stood a few minutes for the suspended particles of colouring-matter to settle, is returned into the cheese-cowl; pouring it off gently, so as to leave any sediment which may have fallen down in the bottom of the dish. The grounds are then rubbed with the finger on the bottom of the dish, and fresh milk added, until all the finer particles be *suspended*: and in this the skill in colouring principally consists. If any fragments have been broken off in the operation, they remain at the bottom of the dish: hence the superiority of a hard closely-textured material, which will not break off or crumble in rubbing. The decoction of arnotta has a peculiar smell and a disagreeable flavour. An

ounce of arnotta will colour about twenty cheeses of 10 or 12 lbs. each. The rolls usually weigh 2 or 3 oz. each. In Gloucestershire, it is usual to allow 1 oz. to a cwt. of cheese; in Cheshire, 8 pennyweights to a cheese of 60 lbs. By the Spanish Americans, it is mixed with their chocolate. The average annual import of arnotta [into England] in the three years ending in 1831, was 128,528 lbs. (*Comp. Farm., M'Culloch's Com. Dict.; Gray's Supplement; Loudon's Encyc.; Thomson's Chem.*)

ANNUAL MEADOW-GRASS. See POA ANNUA.

ANNUAL PLANTS. Such as are only of one year's duration, or which come up in the spring and die in the autumn. They are frequently denominated simply *annuals*. Wheat, oats, barley, beans, peas, &c., are of this kind.

ANNULAR. Having the form or resemblance of a ring. This appearance is observed in the wood of some kinds of trees after they have been cut down; and in the horns of cattle and sheep, by which their ages may in some measure be ascertained.

ANODYNE. In farriery, a term applied to such medicines as ease pain and procure sleep.

ANOREXY. In farriery, a term applied to a want of appetite.

ANT. A sort of insect, extremely injurious to pasture lands and gardens; in the former by throwing up hills, and in the latter by feeding on the fruit, &c. The best methods of keeping them from trees, are those of having the earth round them constantly dug up, and the application of saw-dust, coal-ashes, or other matters of the same kind, about their roots. The same purpose may be effected by covering the bottom part of the trees with tar; but, as it is prejudicial to the trees, night-soil may, perhaps, answer better; as it is found to destroy them when spread upon or put into their hills. A liquor, prepared by boiling rain-water with black-soap and sulphur, has been made use of for destroying those animals, it is said, with considerable success. Where this liquor is employed, care should be taken that the ground where they inhabit be perfectly saturated with it.

ANT-HILLS. The habitations of ants, consisting of little eminences, composed of small particles of sand or earth, lightly and artfully laid together. These hills are very detrimental to the farmer, depriving him of as much land as the hills cover, which may often be computed at a tenth part, or more, of his grasslands. And in some places, where negligence has suffered them to multiply, almost half of it has been rendered useless, the hills standing as thick together as grass-cocks in a hay-field: and what is very surprising is, that, by some, this indolence is defended, by affirming, that the area or superficies of their land is thereby increased; whereas it is well known that very little or no grass ever grows thereon; and, therefore, if the surface be increased, the produce is proportionably decreased.

In order to remove the hills, and destroy the insects, it has been a custom in some places, at the beginning of winter, and often when the

weather was not very cold, to dig up the ant-hills three or four inches below the surface of the ground, and then to cut them in pieces, and scatter the fragments about. But this practice only disseminates the ants, instead of destroying them, as they hide themselves among the roots of the grass for a little time, and then collect themselves together again upon any little eminence, of which there are great numbers ready for their purpose, such as the circular ridges round the hollows where the hills stood before. It is, therefore, a much better method to cut the hills entirely off, rather lower than the surface of the land, and to let them lie whole at a little distance, with their bottom upwards: by this means the ants, who continue in their habitations until the rains, running into their holes of communication, and stagnating in the hollows formed by the removal of the hills and the frosts, which now readily penetrate, will be destroyed. If a little soot is sown on the places, it will contribute to the intended effect. The hills, when rendered mellow by the frosts, may be broken and dispersed about the land. By this method of cutting off the hills, one other advantage is gained: the land soon becomes even and fit for mowing, and the little eminences being removed, the insects are exposed to the rain, which is destructive to them. In wet weather these insects are apt to accumulate heaps of sandy particles among the grass, called by labourers sprout-hills, which quickly take off the edge of the scythe. These hills which are very light and compressible, may be removed by frequent heavy rolling.

ANTHELMINTIC. In farriery, a term applied to such remedies as are supposed to destroy or carry off the worms which lodge in the intestines of an animal.

ANTHOXANTHUM ODORATUM. The sweet-scented vernal grass. [See Plate 6, a.] This grass constitutes a part of the herbage of English pastures on almost every kind of soil, attaining its greatest perfection on the deep and moist, loving shady places, such as the skirts of woods. Its very early growth and hardness, with the superior nutritive properties of its latter-math, give it high claims in the composition of all permanent pastures. In England it comes into flower about the middle of April, and in Pennsylvania about the middle of May, the seed ripening in both countries about the second week in June. In the moist climate of England it continues throwing up flower stalks till the end of autumn, but in Pennsylvania the efflorescence is confined to spring. When properly combined with other grasses, and mown at maturity, it gives to the hay a peculiarly delightful fragrance.

The cause of the high flavour for which Philadelphia "May butter" is so highly celebrated, has hitherto been a matter of vague speculation. This superior flavour, like that distinguishing the Epping and Cambridge butter of the London market, has very naturally been ascribed to something eaten by the cows; but this *something* has never yet been defined or specified so as to enable persons in other localities to avail themselves of it for the improvement of their own pastures and dairy products.

The American editor of the Farmer's Encyclopædia claims to have traced the source of the peculiar flavour of Philadelphia "May butter" to the sweet-scented vernal grass naturalized and abounding in the pastures within marketing distance of the city. He assigns the following reasons for this conclusion. 1. In the dairy region around Philadelphia the vernal grass, with its vanilla fragrance, constitutes the predominant spring herbage on all pasture-fields and meadows left several years unploughed. The older the pasture the greater the proportion of the vernal grass, and the higher flavoured the butter. 2. The flavour continues during the development of this grass, and invariably declines with its seeding, after which the cattle push its dry stems aside in search of fresher herbage. 3. The sweet-scented vernal grass is shown by chemical analysis to contain an aromatic essential oil, the basis of which is benzoic acid or flowers of benzoïn. This is abundant, and can be distilled so as to furnish a delightful perfume. As the milk of animals is so very susceptible of acquiring disagreeable tastes from substances fed upon, it is natural to infer that it may be im-

bued with agreeable flavours could the proper agents for this purpose be presented in their food. That the benzoic acid is the proximate cause of the peculiar fine flavour of butter made from pastures where the sweet-scented vernal grass abounds, he has shown by several experiments made in different places where the flowers of benzoïn given to cows produced the characteristic flavour. From 20 to 30 grains of the benzoïn was administered twice a day, previously mixed with a little rye or wheat flour, then stirred up with some hot water and mingled with the customary mess.

Hitherto, but little, if any, exact knowledge has been acquired in regard to the effects of particular grasses in improving the flavour of dairy products, or the meat of animals. The abundant presence of the sweet-scented vernal grass in pastures will, it is believed, not only contribute a rich flavour to dairy products, but to the mutton and beef of cattle and sheep pastured upon it.

[See Dr. Emerson's communication to J. S. Skinner, on the subject of Philadelphia butter, originally published in the Farmer's Library for April, 1846.]

ANTICOR. In farriery, a disease among horses, arising from an inflammation in the gullet and throat, or a kind of quinsy. The swelling sometimes extends as far as the sheath; and is attended with fever, great depression, weakness, and a total loss of appetite.

ANTIDOTE. See POISON, and ANIMAL and VEGETABLE POISONS.

ANTIMONY, SULPHURET OF. In farriery, a mineral substance, of a shining, striated appearance, hard, brittle, and very heavy. It is employed as a remedy in many diseases of horses and other animals, and is said to have been given to fattening cattle and hogs with advantage. An ounce is the common quantity for a full-grown animal, which may be repeated according to circumstances. It is composed according to Dr. J. Davy (*Phil. Trans.* 1812, p. 231), of

Antimony	- - - -	100
Sulphur	- - - -	34.960

ANTISEPTIC SUBSTANCES. In agriculture, are such substances as have a tendency to resist the putrefaction and decay of animal and vegetable matters.

ANTISPASMODICS. In farriery, are such medicines as are suited to cure spasmodic affections. Opium, assafœtida, and the essential oils of many vegetables, are the most powerful remedies of this kind.

ANTLER (Fr. *andouiller*). Properly the first branches of a stag's horns; but, popularly and generally, any of his branches, and so used, by poetic license, in all our modern authors.

AORTAL ARTERIES, of vegetables. The large vessels destined to convey the elaborated juice or blood of plants to the leaves and extremities, are so denominated by Dr. Darwin.

APERIENTS. In farriery, are such remedies as are calculated to keep the bowels of animals in a gentle open state.

APHERNOUSLI, or ARKENOUSLI. A species of fir, pine, or pinaster, which grows wild on the Alps.

The timber of this tree is frequently large, and has many uses for internal work. The branches resemble those of the spruce-fir: but the cones are more round in the middle, being of a purplish colour, shaded with black. The bark of the trunk, or bole of the tree, is not reddish like the bark of the pine, but of a whitish cast like that of the fir. The husk, or sort of shell, which encloses the kernels, is easily cracked, and the kernels are covered with a brown skin, which peels off; they are about as large as a common pea, triangular like buckwheat, and white and soft as a blanched almond; of an oily agreeable taste, but leaving in the mouth that small degree of asperity which is peculiar to wild fruits, and is not unpleasant. These kernels sometimes make a part in a Swiss dessert; they supply the place of mushroom-buttons in ragouts, and are also recommended in consumptive cases.

Wainscoting, flooring, and other joiner's work, may be made with the planks of apherousli, which is a wood of a finer grain, and more beautifully variegated than deal, and the smell is more agreeable. The apherousli is a tree of a healthy, vigorous growth, and will bear removing when it is young, even in dry

warm weather. From this tree is extracted a white odoriferous resin. The wood also makes excellent firing in stoves, ovens, and kilns.

[APHIDIANS. A group of minute insects, which includes those commonly called *plant-lice*. Some of these insects have the power of leaping, like the leaf-hoppers, from which, however, they differ. These hoppers are by no means so prolific as other kinds of plant-lice, since they produce only one brood during the year. They live in groups, composed of about a dozen individuals each, upon the stems and leaves of plants, the juices of which they imbibe through their tubular beaks. The young are often covered with a substance resembling fine cotton arranged in flakes. This is the case with some which are found on the alder and birch in the spring of the year.

Another tribe of aphidians called *Thrips*, are very small and slender insects, exceedingly active in their motions. They live on leaves, flowers, buds, &c. Their punctures appear to poison plants, and often occasion deformities in the leaves and blossoms. The peach tree sometimes suffers severely from their attacks, as from those of the true plant-lice; and they are found beneath the leaves, in little hollows caused by their irritating punctures. The same applications that are employed for the destruction of plant-lice may be used with advantage upon plants infested with *Thrips*. (*Dr. Harris's Report on Destructive Insects.*)

[APHIDES, or *plant-lice*, as they are commonly called, are found upon almost all parts of plants, and there is scarcely a plant which does not harbour one or two kinds peculiar to itself. They are exceedingly prolific, and Reaumur has proved that one individual, in five generations, may become the progenitor of nearly six thousand millions of descendants. It often happens that the succulent extremities and stems of plants will, in an incredibly short space of time, become completely coated with a living mass of little lice. These are usually wingless, consisting of the young and of the females only; for winged individuals appear only at particular seasons, usually in the autumn, but sometimes in the spring, and there are small males and larger females. After pairing, the latter lay their eggs upon or near the leaf-buds of the plant upon which they live, and, together with their males, soon afterwards perish. The genus to which plant-lice belong is called *Aphis*, from a Greek word signifying to exhaust. They hatch out in the spring and immediately begin to pump up sap from the tender buds, stems, and leaves, increase rapidly in size and quickly come to maturity.

"Plant-lice seem to love society, and often herd together in dense masses, each one remaining fixed to the plant by means of its long tubular beak; and they rarely change their places till they have exhausted the part first attacked. The attitudes and manners of these little creatures are exceedingly amusing. When disturbed, like restive horses, they begin to kick and sprawl in the most ludicrous manner. They may be seen, at times, sus-

pending by their beaks alone, and throwing up their legs as if in a high frolic, but too much engaged in sucking to withdraw their beaks. As they take in great quantities of sap, they would soon become gorged if they did not get rid of the superabundant fluid through the two little tubes or pores at the extremity of their bodies. When one of them gets running-over full, it seems to communicate its uneasy sensations, by a kind of animal magnetism, to the whole flock, upon which they all, with one accord, jerk upwards their bodies, and eject a shower of the honeyed fluid. The leaves and bark of plants much infested by these insects, are often completely sprinkled over with drops of this sticky fluid, which, on drying, becomes dark coloured, and greatly disfigures the foliage. This appearance has been denominated honey-dew; but there is another somewhat similar production observable on plants, after very dry weather, which has received the same name, and consists of an extravasation or oozing of the sap from the leaves. We are often apprized of the presence of plant-lice on plants growing in the open air by the ants ascending and descending the stems. By observing the motions of the latter we soon ascertain that the sweet fluid discharged by the lice is the occasion of these visits. The stems swarm with slim and hungry ants running upwards, and others lazily descending with their bellies swelled almost to bursting. When arrived in the immediate vicinity of the plant-lice, they greedily wipe up the sweet fluid which has distilled from them, and, when this fails, they station themselves among the lice, and catch the drops as they fall. The lice do not seem in the least annoyed by the ants, but live on the best possible terms with them; and, on the other hand, the ants, though unsparing of other insects weaker than themselves, upon which they frequently prey, treat the plant-lice with the utmost gentleness, caressing them with their antennæ, and apparently inviting them to give out the fluid by patting their sides. Nor are the lice inattentive to these solicitations, when in a state to gratify the ants, for whose sake they not only seem to shorten the periods of the discharge, but actually yield the fluid when thus pressed. A single louse has been known to give it drop by drop successively to a number of ants, that were waiting anxiously to receive it. When the plant-lice cast their skins, the ants instantly remove the latter, nor will they allow any dirt or rubbish to remain upon or about them. They even protect them from their enemies, and run about them in the hot sunshine to drive away the little ichneumon flies that are forever hovering near to deposit their eggs in the bodies of the lice."

Plant-lice differ much in form, colour, length of tubes, &c. The *Rose-louse* (*Aphis Rosæ*) has a long tube. The cabbage-louse (*Aphis Brassicæ*) has also long honey-tubes, its body being covered with a whitish mealy substance. This species is very abundant on the lower side of cabbage-leaves in the month of August. The largest species of plant-lice observed by Dr. Harris, he found in clusters beneath the limbs of the pig-nut hickory. He

also found another large species living on the under side of the branches of various kinds of willows, and clustered together in great numbers. This species, the Doctor thinks, cannot be identical with the willow-louse described by Linnæus. When crushed, it communicates a stain of a reddish or deep orange colour.

Some plant-lice live in the ground, and derive their nourishment from the roots of plants, which they often exhaust and destroy. Indian corn crops frequently suffer severely from their depredations, especially when the soil is light and reduced. They are generally of a white colour, and are closely clustered together on the roots. Dr. Harris, from whose Report all the information upon this subject is obtained, says that he never has been able to ascertain whether these are of the same species as the root-lice described by European writers. It is stated by those great entomologists, Kirby and Spence, that ants bestow the same care upon the root-lice as upon their own offspring, defending them from the attacks of other insects, bringing them in their mouths to the surface of the ground to give them the advantage of the sun, &c. The sweet fluid which exudes from them whilst pumping in the sap of the roots, forms the chief nourishment of the ants and their young.

"The injuries occasioned by plant-lice are much greater than would at first be expected from the small size and extreme weakness of the insects; but these make up by their numbers what they want in strength individually, and thus become formidable enemies to vegetation. By their punctures, and the quantity of sap which they draw from the leaves, the functions of these important organs are deranged or interrupted, the food of the plant, which is there elaborated to nourish the stem and mature the fruit, is withdrawn, before it can reach its proper destination, or is contaminated and left in a state unfitted to supply the wants of vegetation. Plants are differently affected by these insects. Some wither and cease to grow, their leaves and stems put on a sickly appearance, and soon die from exhaustion. Others, though not killed, are greatly impeded in their growth, and their tender parts, which are attacked, become stunted, curled, or warped. The punctures of these lice seem to poison some plants, and affect others in a most singular manner, producing warts or swellings, which are sometimes solid and sometimes hollow, and contain in their interior a swarm of lice, the descendants of a single individual, whose punctures were the original cause of the tumour. I have seen reddish tumours of this kind as big as a pigeon's egg, growing upon leaves, to which they were attached by a slender neck, and containing thousands of small lice in their interior. Naturalists call these tumours galls, because they seem to be formed in the same way as the oak-galls which are used in the making of ink. The lice which inhabit or produce them generally differ from the others, in having shorter antennæ, being without honey-tubes, and in frequently being clothed with a

kind of white down, which, however, disappears when the insect becomes winged.

"These downy plant-lice are now placed in the genus *Eriosoma*, which means woolly body, and the most destructive species belonging to it was first described, under the name of *Aphis lanigera*, by Mr. Hausmann, in the year 1801, as infesting the apple-trees in Germany. It seems that it had been noticed in England as early as the year 1787, and has since acquired there the name of American blight, from the erroneous supposition that it had been imported from this country. It was known, however, to the French gardeners for a long time previous to both of the above dates, and, according to Mr. Rennie, is found in the orchards about Harfleur, in Normandy, and is very destructive to the apple-trees in the department of Calvados. There is now good reason to believe that the miscalled American blight is not indigenous to this country, and that it has been introduced here with fruit-trees from Europe. Some persons, indeed, have supposed that it was not to be found here at all; but the late Mr. Buel has stated that it existed on his apple-trees, and I have once or twice seen it on apple-trees in Massachusetts, where, however, it still appears to be rare, and consequently I have not been able to examine the insects sufficiently myself. The best account that I have seen of them is contained in Knapp's 'Journal of a Naturalist,' from which, and from Hausmann's description, the following observations are chiefly extracted.

"The eggs of the woolly apple-tree louse are so small as not to be distinguished without a microscope, and are enveloped in a cotton-like substance furnished by the body of the insect. They are deposited in the crotches of the branches and in the chinks of the bark at or near the surface of the ground, especially if there are suckers springing from the same place. The young, when first hatched, are covered with a very short and fine down, and appear in the spring of the year like little specks of mould on the trees. As the season advances, and the insect increases in size, its downy coat becomes more distinct, and grows in length daily. This down is very easily removed, adheres to the fingers when it is touched, and seems to issue from all the pores of the skin of the abdomen. When fully grown, the insects of the first brood are one tenth of an inch in length, and when the down is rubbed off, the head, antennæ, sucker, and shins are found to be of a blackish colour, and the abdomen honey-yellow. The young are produced alive during the summer, are buried in masses of the down, and derive their nourishment from the sap of the bark and of the alburnum or young wood immediately under the bark. The adult insects never acquire wings, at least such is the testimony both of Hausmann and Knapp, and are destitute of honey-tubes, but from time to time emit drops of a sticky fluid from the extremity of the body. These insects, though destitute of wings, are conveyed from tree to tree by means of their long down, which is so plentiful and so light, as easily to be wafted by the winds of

autumn, and thus the evil will gradually spread throughout an extensive orchard. The numerous punctures of these lice produce on the tender shoots a cellular appearance, and whenever a colony of them is established, warts or excrescences arise on the bark; the limbs thus attacked become sickly, the leaves turn yellow and drop off; and, as the infection spreads from limb to limb, the whole tree becomes diseased, and eventually perishes. In Gloucestershire, England, so many apple-trees were destroyed by these lice in the year 1810, that it was feared the making of cider must be abandoned. In the north of England the apple-trees are greatly injured, and some annually destroyed by them; and in the year 1826 they abounded there in such incredible luxuriance, that many trees seemed, at a short distance, as if they had been whitewashed.

“Mr. Knapp thinks that remedies can prove efficacious in removing this evil only upon a small scale, and that when the injury has existed for some time, and extended its influence over the parts of a large tree, it will take its course, and the tree will die. He says that he has removed this blight from young trees, and from recently attacked places in those more advanced, by painting over every node or infected part of the tree with a composition consisting of three ounces of melted resin, mixed with the same quantity of fish oil, which is to be put on while warm with a painter’s brush. Sir Joseph Banks succeeded in extirpating the insects from his own trees by removing all the old and rugged bark, and scrubbing the trunk and branches with a hard brush. The application of the spirits of tar, of spirits of turpentine, of oil, urine, and of soft soap, has been recommended. Mr. Buel found that oil sufficed to drive the insects from the trunks and branches, but that it could not be applied to the roots, where, he stated, numbers of the insects harboured. The following treatment, I am inclined to think, will prove as successful as any which has heretofore been recommended. Scrape off all the rough bark of the infected trees, and make them perfectly clean and smooth early in the spring; then rub the trunk and limbs with a stiff brush wet with a solution of potash, as hereafter recommended for the destruction of bark-lice; after which remove the sods and earth around the bottom of the trunk, and with the scraper, brush, and alkaline liquor cleanse that part as far as the roots can conveniently be uncovered. The earth and sods should immediately be carried away, fresh loam should be placed around the roots, and all cracks and wounds should be filled with grafting cement of clay or mortar. Small limbs and extremities of branches, if infected, and beyond reach of the applications, should be cut off and burned.”

Dr. Harris found in Massachusetts several other species of *Eriosoma* or downy lice, inhabiting various forest and ornamental trees, some of which he thinks may have been introduced from abroad.

Remedies. With regard to the best means of destroying plant-lice, Dr. Harris recommends as follows: “Solutions of soap, or a

mixture of soap-suds and tobacco water, used warm, and applied with a watering pot or with a garden engine, may be employed for the destruction of these insects. It is said that hot water may also be employed for the same purpose with safety and success. The water, tobacco-tea, or suds, should be thrown upon the plants with considerable force, and if they are of the cabbage or lettuce kind, or other plants whose leaves are to be used as food, they should subsequently be drenched thoroughly with pure water. Lice on the extremities of branches may be killed by bending over the branches and holding them for several minutes in warm and strong soap-suds. Lice multiply much faster, and are more injurious to plants, in a dry than in a wet atmosphere; hence in green houses, attention should be paid to keep the air sufficiently moist; and the lice are readily killed by fumigations with tobacco or with sulphur. To destroy subterranean lice on the roots of plants, I have found that watering with salt water was useful, if the plants were hardy; but tender herbaceous plants cannot be treated in this way, but may sometimes be revived, when suffering from these hidden foes, by free and frequent watering with soap-suds.”

A solution of *whale oil soap*, in the proportion of two pounds of soap to fifteen gallons of water, is recommended as the best known means of destroying plant-lice, and other insects injurious to plants, flowers, and fruits. It was first made known by Mr. Haggerston, of Boston, who designed it originally for the destruction of the rose slug, and received a premium of \$125 from the Massachusetts Horticultural Society for his discovery. In preparing the solution of soap, the weight required for use is to be taken and dissolved in boiling water in the proportion of a pound to a quart. Strain this strong solution through a fine wire or hair sieve, which takes out the dirt, and prevents its stopping the valves of the engine, or rose of the syringe. Then add cold water to bring it to the proper strength, namely, about two pounds of the soap to fifteen gallons of water, and apply to the rose bush, or other plant, with a hand engine or a syringe, using as much force as practicable, saturating every part of the foliage. What falls on the ground will not be lost, but do much good in destroying worms and enriching the soil. From its trifling cost, it can be used with profusion, a hogshead of 136 gallons costing only about 45 cents. The soap sells for about 6 or 7 cents per pound. Early in the morning, or in the evening, is the proper time for making the application. Among other insects mentioned by Mr. Haggerston as destroyed by the solution of *whale oil soap*, are the *Aphis*, or plant-louse, which goes by the name of the brown fly; an insect not quick in motion, very abundant on, and destructive to, the young shoots of the rose, peach trees, and many other plants; and the black fly, a very troublesome and destructive insect, that infests the young shoots of the cherry and the snowball tree. “I have never,” he says, “known any positive cure for this insect until this time.”

“Two varieties of insects that are destructive to and very much disfigure evergreens, the Balsam or Balm of Gilead fir in particular; one an aphid, the other very much like the rose-slug.

“The above insects are all destroyed by one application, if properly applied to all parts of the leaves; the eggs of most insects continue to hatch in rotation during their season; to keep the plants perfectly clean, it will be necessary to dress them two or three times.”

As every plant has its insect destroyers, so have these their created enemies to keep them in check. If this was not so, the astonishing fecundity of plant-lice would make them far more formidable than at present. Indeed it is difficult to say where the plague might end. The destroyers of plant-lice described by Dr. Harris are of three kinds.—The first are the young or larvæ of the hemispherical beetles familiarly known by the name of lady-birds, and scientifically by that of *Coccinella*. These little beetles are generally yellow or red, with black spots, or black, with white, red, or yellow spots; there are many kinds of them, and they are very common and plentiful insects, generally diffused among plants, living upon plant-lice, and thus performing a great service to the husbandman and gardener.

The second kind of plant-lice destroyers are the young of the golden-eyed lace-winged fly (*Chrisopa perla*), a fly of a pale green colour, with four wings resembling lace, and eyes of the brilliancy of polished gold, as its generic name implies. But, notwithstanding its brilliancy, it is extremely disgusting, from the offensive odour it exhales. It makes great havoc among the plant-lice.

The third and last enemy are the maggots or young of various two-winged flies belonging to the genus *Syrphus*, many of which flies are black, with yellow bands on their bodies. The eggs are laid and the destructive maggot hatched immediately among the sluggish lice which become its victims.

The more minute account given by Dr. Harris, of the nature and habits of all these insects, is extremely interesting. (See his *Report upon Destructive Insects* submitted to the legislature of Massachusetts in 1841.)

APIUM. See CELERY and PARSLEY.

APOPLEXY. In farriery, is a disease which is often called the *staggers*, to which horses and other animals are subject, and by which they drop down suddenly, without sense or motion, except a working of the flanks. (See SHEEP, DISEASES OF.)

APPETITE. Horses, more than most other creatures, are subject to diseases of the stomach, particularly to a want of appetite, and a vitiated or voracious appetite.

Want of appetite is when a horse feeds poorly, and is apt to mangle his hay, or leave it in the rack, and at the same time gathers little flesh, his dung being habitually soft, and of a pale colour. This state of the stomach evidently arises either from some error in respect of diet and management, want of grass, or from a relaxed constitution, in which the stomach

and bowels are more particularly affected with debility. This weakness of the digestive organs may be either accidental or constitutional; and it may proceed from the use of food administered in an improper state, such as too much scalded bran, or hot meat of any kind, which relaxes the tone of the stomach and bowels, and ultimately produces a weak digestion, and consequently a loss of appetite. The best method to strengthen and recover horses in this state, is to give them gentle exercise in the open air, especially in dry weather; never to load their stomachs with large feeds; and to keep them as much as possible to a dry diet, indulging them now and then with a handful of beans among their oats. But where the disorder has been caused by over-feeding with dry food, and the neglect of proper evacuation and exercise, mashes, with gentle saline purges, would seem to be the most suitable remedies; and where horses do not gain strength under the above management, a run at grass will most probably be the readiest method of removing their complaints.

APPLE. See MALUS.

APPLES OF LOVE (*Poma amoris; tomato*). These apples are juicy, and large fruit, growing upon a low plant in gardens. The flowers are yellow and small; when the fruit ripens, it becomes red, containing soft juicy pulp and seeds. Its juice is cooling to the system, and is applied externally to remove eruptions upon the skin. (*L. Johnson.*) See TOMATO.

[APPLE-TREE BLIGHT, and Apple-tree lice. See APHIDES and BLIGHT.]

[APPLE-TREE BORER. The larva of a kind of beetle. See BORERS.]

APPRAISEMENT. It is not only customary, but essential to the maintenance of the good condition of a farm, that the outgoing tenant should be induced to carry on the proper course of husbandry up to the period of his quitting the farm; notwithstanding that much of the labour and manure he bestows is for the benefit of crops which a succeeding tenant will reap. Hence the good practice has arisen, that the outgoing tenant shall be allowed for these matters, according to agreement, or, in its absence, by the custom of the district, which varies considerably. (See CUSTOM OF THE COUNTIES.)

The following real appraisement of a farm in Surrey, by Mr. Hewitt Davis, an eminent appraiser of the Haymarket, London, will afford the young farmer a complete view of the matters usually included in such appraisements. It is usual for these valuations to be made by appraisers, one being appointed by the outgoing, and the other by the incoming tenants, who choose an umpire to decide in case of difference.

[The document cannot fail to be acceptable to the American farmer, since it communicates so many interesting facts relating to the estimates of putting in crops, the value of manures, various workings, rent, rates, taxes, &c., in England.]

APPRAISEMENT.

*Appraisement of the Tenant's Property on the
of Surrey, made this 29th September, 1841.*

Farm, County

From , outgoing tenant.
To , incoming tenant.
By , outgoing tenant's appraiser.
And , incoming tenant's appraiser.

Made according to the terms of the Lease, which says, "at leaving the Landlord or Incoming Tenant shall pay for the Turnips, Leys, Seeds sown, and Crops in or on the Ground, Ploughings, Dressings, Half Dressings, Fallows, Half Fallows, and preparations of the Land for the Manure and Underwoods, according to their growth, and all other Matters and Things according to the Custom of the County."

The farm is principally a light turnip soil, and consists of—

Arable	-	-	-	-	-	227½	acres.
Grass	-	-	-	-	-	48	—
Wood	-	-	-	-	-	24	—
Hedges	-	-	-	-	-	10	—
						309½	

And has been very highly cultivated on the Scotch Drill system.

APRICOT (*Armeniaca vulgaris*). The name of the apricot has been thought to be derived from *apricus*, open and exposed to the sun, or from *præcox*, early ripe; but there can be no doubt that the word is a corruption of the Arabic name of the fruit. In England, it is one of the earliest wall-fruits, and held in the highest estimation. The fruit, when gathered young to thin the crop, makes an excellent tart; and when ripe, it is second to no fruit for preserves or jam: it gives an excellent flavour to ice, and makes a delicious *liqueur*: of all the fruits used in pastry, none is more beautiful or agreeable than the ripe apricot. To prolong the enjoyment of this fruit in its natural state, we should be careful to plant the earliest variety in the warmest situation, as the frost often injures the blossoms unless it is protected by a glass shutter. The apricot, as well as the plum, may be kept for our dessert two or three weeks later, by gathering it when half ripe, and placing it in an ice-house, a dairy, or any cool place, where it slowly ripens.

Apricots, if not too ripe, agreeably astringe and strengthen the stomach; but like all other perfumed watery fruit, it loses its aromatic and tempting flavour, becomes clammy, and is less easy of digestion, when over-ripe: they should therefore be gathered at least twenty-four hours before they acquire the last degree of maturity.

Of this excellent fruit, thirty-nine varieties have been described in the *Horticultural Society's catalogue*. For a small garden, Mr. Lindley recommends the following selection.

Breda	Peach apricot.
Brussels.	Red masculine.
Hemskirke.	Roman.
Large early.	Royal.
Moorpark	Turkey.

The Moorpark and Turkey have been recommended where variety is not wanted, the former being fine, and a good bearer; the latter not a good bearer, but very fine. The apricot requires a rich soil, rather lighter than the apple and pear.

Budding is generally performed from the middle of June to the end of July, on mussel plum stocks two or three years old. The Breda, peach apricot, royal, and a few others are those generally budded upon the mussel, "and although," says Mr. Lindley, "the Moorpark is, for the most part, budded upon the common plum, on which it takes freely, yet I am persuaded that if it were budded on the mussel, the trees would be better, last longer in a state of vigour, and produce their fruit superior both in size and quality."

In planting out trees for training, young plants, or those called maiden plants, should be made choice of, being far preferable to those which have been headed down, and stood two years in the quarters of the nursery; observing, in all cases, without exception, that the bud should stand outwards, and the wounded part where the stock has been headed down, inwards, or next the wall. The apricot in general bears chiefly upon the young shoots of the preceding year, and also upon small spurs

rising on the two or three year old fruit branches. The pruning of wall-apricots comprehends both a summer and a winter course of regulation. In May, the summer pruning commences by the disbudding and removal of the superfluous shoots, and shortening the smaller shoots to half an inch, which will occasion many of them to form natural spurs for blossoms at the base. This should be carefully done with a sharp thin-bladed knife. Care must also be taken to select and train as many of the best placed young shoots as may be wanted to form the figure of the tree, proceeding thus from year to year, till it is completely furnished, both in its sides and middle, for there ought not then to be a blank space in any part within its extent.

For the winter pruning of apricots, every shoot should be shortened according to its strength, none being permitted to exceed 18 inches, while a few will require to be even less than 6. By pruning thus short, and training the branches thus, the trees will be kept in vigour, the fruit will always attain its full size under favourable circumstances, and its quality will be good.

When the fruit is found to be too numerous and growing in clusters, thinning must be resorted to in May and June, leaving the most promising fruit singly, at three or four inches distance; or from about two to six on the respective shoots, according to their strength. The retained fruit should in all instances be situated at the *sides* of their respective shoots, and no *fore-right* fruit be suffered to remain; for these being exposed to the full power of the sun, will perish before they can arrive at maturity. The apricot is very liable to be attacked by wasps and large flies, which should be kept off by a net. The other insects and diseases of this tree are the same as in the peach tree; but it is not nearly so obnoxious to their attacks, probably owing to the comparatively hard nature of its bark and wood, and coriaceous leaves. [The apricot is the earliest and tenderest of American fruits, the blossoms coming so early as to be commonly nipped by frost. The position of the trees should be such as tends to retard flowering.] (*Phillip's Pom. Brit.*; *Lindley's Guide to the Orchard and Kitchen Garden*.)

ARBOR VITÆ (*Thuja*). The generic name of this tree is a corruption from *Θύα* of Theophrastus, or *thya* of Pliny, which were derived from the verb *thyô*, I perfume; as the *thya* of the ancients gave out an aromatic smoke when it was burnt. It is called *arbor vitæ*, or tree of life, because it keeps in full leaf winter and summer; and not in allusion to the tree of life mentioned in the book of Genesis. The first mention we have of it in England is by Gerard, in his *History of Plants*, which was published in 1597. He tells us that it was then growing plentifully in his garden at Holborn, where it flowered about May, but it had not then ripened seed.

"The Thuja from China's fruitful lands,"

being of a brighter green and thicker verdure, has nearly superseded the arbor vitæ of Canada in our plantations. It is well adapted to

screen private walks or low buildings, as it gives out flat spreading branches near the ground; but it has a sombre appearance, unless associated with more cheerful foliage, or ornamented by some gay climbing plant, as the everlasting pea, the flaming nasturtium, or our native bindweed.

The arbor vitæ, which we have borrowed from the extremity of the east and of the west, as a mere ornament to our pleasure-grounds, forms an article of utility and profit to the inhabitants of its native soil. It is reckoned the most durable wood in Canada, where it is known by the name of the white cedar. All the posts which are driven into the ground, and the palisades round the forts, are made of this wood. The planks in the houses are made of it; and the thin narrow pieces of wood which form both the ribs and the bottom of the bark boats commonly made use of there, are taken from this wood, because it is pliant enough for the purpose, when fresh, and also because it is very light. The thuja wood is reckoned one of the best for the use of limekilns. Its branches are used all over Canada for brooms, which leave their peculiar scent in all the houses where they are used. The arbor vitæ affords [a popular remedy for rheumatic and some other complaints among the Indians and settlers of North America.]

The finest trees are always raised by seed, but they are more easily propagated by layers or cuttings. (*Phil. Syl. Flor.*)

ARBUTUS. A genus of evergreen shrubs which is characterized by its fruit being a berry, containing many seeds. The only variety necessary to be enumerated in these pages is the *Arbutus unedo*, or strawberry tree.

In Pliny's time, when Rome abounded in wine and oil, they called the tree *unedo*, which was an abridgment of *unum edo*, meaning, "You will eat but one." It has the name of strawberry-tree with us, because its berries so nearly resemble in appearance that delicious fruit. It is found growing spontaneously on rocky limestone situations in the west of Ireland, particularly in the county of Kerry, near the lake of Killarney, where the peasants eat the fruit. The arbutus is a native of the south of Europe, Greece, Palestine, and many other parts of Asia.

Horace celebrates the shade of this tree:—

"Nunc viridi membra sub arbuto
Stratus."

But Virgil describes its foliage as rather thin (*Ecl.* vii.), and recommends the twig as a winter food for goats.

The arbutus tree succeeds best in a moist soil, for when planted in dry ground it seldom produces much fruit. It is therefore recommended to place it in warm situations; and if the earth is not naturally moist, there should be plenty of loam and rotten neat's dung laid about its roots, and in dry springs it should be plentifully watered.

The arbutus trees may be propagated by layers, but they are principally raised from seed; and they require to be kept in pots for several years before they are ready for the plantation. We meet with a variety of this

tree in our shrubberies with double blossoms, and another with red flowers. Aiton enumerates five different species of the arbutus, and there are several varieties of them in the Parisian gardens not to be seen in our shrubberies. The leaves of the arbutus are said to be usefully employed by tanners in preparing their leather. (*Phillips's Sylva Florifera.*)

This beautiful evergreen grows to the height of ten and fifteen feet. Its flowers, which are of a yellowish white or red colour bloom in September, October, and November, and are succeeded by the fruit, which remain till the flowers of the following year are full blown, thus giving the tree a beautiful appearance.

ARCHED. A term employed among horsemen. A horse is said to have arched legs when his knees are bent archwise. This only relates to the fore-quarters, and the infirmity sometimes happens to such horses as have their legs spoiled in travelling.

ARGILLACEOUS. [Clayey.] Containing clay.

ARM OF A HORSE. A term applied to the upper part of the fore-leg.

ARNOTTO. See **ANNOTTA.**

AROMATIC. An epithet applied to such plants, and other bodies, as yield a fragrant odour, and have a warm spicy taste.

AROMATIC REED (*Acorus calamus*). The common sweet-flag. A marshy perennial plant of the easiest culture, flowering from June till August, which grows among rushes in moist ditches and watery places, about the banks of rivers, but not very general. Root, thick, rather spongy; leaves, erect, two or three feet high, bright green, near an inch broad. It rarely flowers unless it grows in water, but when it does bloom, it puts forth a mass of very numerous, thick-set, brownish green flowers, which have no scent except when bruised. Every part of the herbage is stimulant, and very aromatic, but the roots are especially so. The dried root powdered is used by the country people of Norfolk, [England,] for curing the ague. It is affirmed to possess carminative and stomachic virtues, having a warm, pungent, bitterish taste, and is frequently used in preparing bitters, though it is said to impart a nauseous flavour. It is the *Calamus aromaticus* of the shops, and Linnæus says, the roots powdered might supply the place of foreign spices. (*Eng. Flor.* vol. ii. p. 157; *Paxton's Bot. Dict.*; *Willich's Dom. Encyc.*)

ARPENT. The French name for an acre. [The French arpent contains 51,691 square English feet, or very nearly one acre and three-quarters of a rood English measure.]

ARROW-GRASS (*Triglochin*). Perennial marsh herbs, of which there are two kinds, the marsh arrow-grass and the sea arrow-grass, both perennials, flowering from May till August. They grow in wet boggy meadows and salt marshes, &c., abundantly, and are very grateful to domestic cattle, the herbage containing a large proportion of salt. (*Eng. Flor.* vol. ii. p. 200.)

ARROW-HEAD (*Sagittaria sagittifolia*, from *sagitta*, an arrow; because of the resemblance of the leaves to the head of that weapon)

[In England,] an indigenous, aquatic, perennial herb, flowering in July or August. Root, tuberous, nearly globular, with many long fibres. It is industriously cultivated in China for its esculent properties: its mealy nature rendering it easily convertible into starch or flour. It is much relished by most cattle. Nothing is more variable than the breadth and size of the floating leaves, which are diminished almost to nothing when deeply immersed in the water, or exposed to a rapid current. Hence has arisen the several varieties mentioned by authors, but which the slightest observation will discover to be evanescent. This plant, especially the seed, was formerly supposed to possess medicinal properties, which time and improved knowledge have demonstrated to be imaginary. The leaves, however, feel cooling when applied to the skin; hence they have been used and may be serviceable as a dressing to inflamed sores. (*Eng. Flor.* vol. iv. p. 144; *Willich's Dom. Encyc.*)

[ARROW-ROOT. This nutritious flour, which constitutes a very mild, light, agreeable and easily digested article of diet, so much resorted to for the sick and convalescent, and also for children, is the fecula or starch most commonly obtained from the root of a plant called *Morantia arundinacea*. It is a native of South America, where, as well as in the West Indies, it is extensively cultivated. It grows also in Florida, in the southern parts of which it is manufactured at the very low price of 6 to 8 cents per lb. The low price at which arrow-root is sold at Key West and other parts of Florida, allows of its being used for the common purposes of starch, and also for the preparation of niceties for the table, being in fact often substituted for the ordinary bread-stuffs. Though thus cultivated in the south, still most of that used is imported from the West Indies and Brazil, the best coming from Bermuda. The mode generally pursued in the West Indies for obtaining the fecula from the root and subsequently preparing it, is as follows:—The roots are dug up when a year old, washed, and then beat into a pulp, which is thrown into water, and agitated so as to separate the starchy from the fibrous or stringy portion. The fibres are removed by the hand, and the starch remains suspended in the water, to which it gives a milky colour. This milky fluid is strained through coarse linen, and allowed to stand that the fecula may subside, which is afterwards washed with a fresh portion of water and then dried in the sun. The powder is a light white colour, sometimes having small masses easily crushed. It is a pure starch like that obtained from wheat, potatoes, and several other vegetable substances, especially the plant called in the West Indies *Jatropha Manihot*, which yields the substance called *Yapioca*, used for similar purposes with arrow-root.]

[ARROW-WOOD. A name given in the United States to a shrub (*Viburnum*) the young and straight branches of which were, according to Marshall, formerly used by the aborigines for making arrows. The slender stems, when the pith is removed, afford good

fuse-sticks for blasting rocks. Ten or twelve species of *Viburnum* are enumerated in the United States. (*See Darlington's Flor. Cestrica.*)

ARSENIC. See POISON.

ARTEMISIA. See WORMWOODS.

ARTESIAN WELLS have been so named from the opinion that they were first used in Artois, in France. These wells have been found extremely beneficial in the low lands of Essex and Lincolnshire, and in some other districts where good water is scarce, and that of the surface of indifferent quality. Some practical knowledge of geology is necessary in order to fix with judgment upon the most eligible spot for sinking these wells, or else much labour and expense may be uselessly applied. They are formed by boring with a long auger and rod to such a depth into the earth, that a spring is found of sufficient power to rise to and run over the surface.

ARTICHOKE (*Cynara*). From *cinere*, according to Columella, because the land for artichokes should be manured with ashes. ["A plant little cultivated in America, but very well worthy of cultivation. In its look it very much resembles a thistle of the big-blossomed kind. It sends up a seed stalk, and it blows, exactly like the thistle that we see in the Arms of Scotland. It is, indeed, a thistle upon a gigantic scale. The parts that are eaten are, the lower end of the thick leaves that envelope the seed, and the bottom out of which those leaves immediately grow. The whole of the head, before the bloom begins to appear, is boiled, the pod leaves are pulled off by the eater, one or two at a time, and dipped in butter, with a little pepper and salt, the mealy part is stripped off by the teeth, and the rest of the leaf put aside, as we do the stem of asparagus. The bottom, when all the leaves are thus disposed of, is eaten with knife and fork. The French, who make salads of almost every garden vegetable, and of not a few of the plants of the field, eat the artichoke in salad. They gather the heads, when not much bigger round than a dollar, and eat the lower ends of the leaves above mentioned raw, dipping them first in oil, vinegar, salt and pepper; and, in this way, they are very good. Artichokes are propagated from seed, or from offsets. If by the former, sow the seed in rows a foot apart, as soon as the frost is out of the ground. Thin the plants to a foot apart in the row; and, in the fall of the year, put out the plants in clumps of four in rows, three feet apart, and the rows six feet asunder. They will produce their fruit the next year. When winter approaches, earth the roots well up; and, before the frost sets in, cover all well over with litter from the yard or stable. Open at the breaking up of the frost; dig all the ground well between the rows; level the earth down from the plants. You will find many young ones, or offsets, growing out from the sides. Pull these off, and, if you want a new plantation, put them out, as you did the original plants. They will bear, though later than the old ones, that same year. As to sorts of this plant, there are two, but they contain no difference of any consequence: one has its head, or fruit pod, round, and the other rather conical. As to the

quantity for a family, one row across one of the plats will be sufficient." (*Cobbett's American Gardener.*)]

Those plants produce the finest heads which are planted in a soil abounding in moisture, but in such they will not survive the winter. Manure must be applied every spring, and the best compost for them is a mixture of three parts of well-putrefied dung, and one part of fine coal-ashes. They should always have an open exposure, and, above all, be free from the influence of trees; for, if beneath their shade or drip, the plants spindle, and produce worthless heads. For planting, these must be slipped off in March or early in April, when eight or ten inches in height, with as much of their fibrous roots pertaining as possible. Such of them should be selected as are sound and not woody. The brown, hard part, by which they are attached to the parent stem, must be removed; and if that cuts crisp and tender, it is evidence of the goodness of the plant; if it is tough and stringy, the plant is worthless. Further, to prepare them for planting, the large outside leaves are taken off so low, that the heart appears above them. If they have been some time separated from the stock, or if the weather is dry, they are greatly invigorated by being set in water for three or four hours before they are planted.

They produce heads the same year, from July to October, and will continue to do so annually, if preserved in succeeding years, from May until June or July; consequently, it is the practice, in order to obtain a supply during the remainder of the summer and autumn, to make an annual plantation in some moist soil, as the plants are not required to continue.

As often as a head is cut from the permanent bed, the stem must be broken down close to the root, to encourage the production of suckers before the arrival of winter. In November or December they should receive their winter's dressing. The old leaves being cut away without injuring the centre or side shoots, the ground must be dug over, and part of the mould thrown into a moderate ridge over each row, close about the plants, but leaving the hearts clear. If this dressing is neglected until severe frosts arrive, or even if it is performed, each plant must be closed round with long litter or pea haulm: it is, however, a very erroneous practice to apply stable-dung immediately over the plants, previous to earthing them up, as it in general induces decay. Early in February all covering of this description must be removed. In March, or as soon as the shoots appear four or five inches above the surface, the ridges thrown up in the winter must be levelled, and all the earth removed from about the stock to below the part from whence the young shoots spring. All of these but two, or at most three of the straightest and most vigorous, must be removed, care being taken to select from those which proceed from the under part of the stock; the strong thick ones proceeding from its crown, having hard woody stems, are productive of indifferent heads. Those allowed to remain should be carefully preserved from injury. Every other

sucker must be removed and every bud rubbed off, otherwise more will be produced, to the detriment of those purposely left. These must be separated as far apart as possible without injury, the tops of the pendulous leaves removed, and the mould then returned, so as to cover the crowns of the stocks about two inches. Some gardeners recommend, as soon as the ground is levelled, a crop of spinach to be sown, which will be cleared off the ground before the artichokes cover it; but this mode of raising or stealing a crop is always in some degree injurious.

Although the artichoke, in a suitable soil, is a perennial, yet after the fourth or fifth year the heads become smaller and drier. The beds, in consequence, are usually broken up after the lapse of this period, and fresh ones formed on another side.

If any of the spring-planted suckers should not produce heads the same year, the leaves may be tied together and covered with earth, so as just to leave their tops visible, and, on the arrival of frost, being covered with litter, so as to preserve them, they will afford heads either during the winter or very early in spring.

As a vegetable, the artichoke is wholesome, but not very nourishing; and as a medicine, it is of little use. Sir John Hill, M. D., states having known patients cured of jaundice, by perseverance in this medicine alone, without combining its virtues with any other plant; but the statement of Sir J. Hill is of no value in the present day. The flowers of the artichoke have the property of rennet in curdling milk. The heads of the second crop of artichokes, when dried, are excellent baked in meat pies, with mushrooms, as they dress them in France. (*G. W. Johnson's Kitchen Garden.*)

ARTICHOKE, JERUSALEM (*Helianthus tuberosus*, from *ἥλιος*, the sun, and *ἄνθος*, a flower). It flourishes most in a rich light soil, with an open enclosure. Trees are particularly inimical to its growth. As it never ripens its seeds in England, the only mode of propagation is by planting the middle-sized tubers or cuttings of the large ones, one or two eyes being preserved in each. These are best planted towards the end of March, though it may be performed as early as February, or even in October, and continued as late as the beginning of April.

They are planted by the dibble, in rows, three feet by two feet apart, and four inches deep. They make their appearance above ground about the middle of May. The only attention necessary is to keep them free from weeds, and an occasional hoeing to loosen the surface, a little of the earth being drawn up about the stems. Some gardeners, at the close of July or early in August, cut the stems off about their middle, to admit more freely the air and light; in other respects it may be beneficial to the tubers.

The tubers may be taken up as wanted during September; and in October, or as soon as the stems have withered, entire for preservation in sand, for winter's use. They should be raised as unbroken as possible, for the smallest piece of a tuber will vegetate, and appear

in the spring; for which reason they are often allotted some remote corner of the garden; but their culinary merits certainly demand a more favourable treatment. (*C. W. Johnson's Kitchen Garden*).

The *Jerusalem Artichoke* thrives well in the United States on soft, moist, and it is said even on peaty soils. This root is abundant in the English and French markets, where it sells for a little more than the price of Irish potatoes. The fibres of the stems may be separated by maceration similar to hemp, so as to be capable of being manufactured into cordage or cloth, as is practised in some parts of Europe, where the plant is an object of field culture, especially on the poor and sandy soils. The artichoke will yield, with similar culture, 30 per cent. more than the potato, and if the land be poor, they will yield at least double the quantity per acre that can be raised with the potato, and the expense of culture is no more. They are particularly adapted to the climate and soil of the Middle and Southern States, and being hardy, can be left during the fall and winter in the ground to be rooted up by hogs, great numbers of which may be thus fattened at little expense. Or they may be taken up and given to all kind of stock, for which purpose it is more requisite to steam them than potatoes. One of the chief objections urged against their culture is, that not being killed in winter by the frost, they grow among the crops which succeed them. But this is a comparatively trifling objection. The Jerusalem artichoke certainly deserves more attention from farmers than it now gets in the United States.

ARTIFICIAL GRASSES. See GRASSES.

ARUM. Common Cuckow-pint, or Wake-Robin (*Arum maculatum*). See WAKE-ROBIN and INDIAN TURNIP.

ARUNDO. A genus of grasses in which a number of useful species was once comprehended; but in consequence of the altered views of botanists regarding the limits of genera, it is now confined to the *Arundo donax*, and the species most nearly agreeing with it. These are grasses of considerable size, sometimes acquiring a woody stem, and found only in the warm parts of the world. The *Arundo* is closely allied to the genus *Saccharum*, the last of which includes the sugar-cane. (*Penny Cyclop.*)

Arundo arenaria. Sea-reed, marram, starr, or bent. (See Plate 7, o.) The nutritive matter of this grass affords a large portion of saccharine matter when compared with the produce in this respect of other grasses. The *Elymus arenarius*, however, affords about one-third more sugar than the present plant. The quantity of nutritive matter afforded by the *Elymus arenarius* is superior to that afforded by the *Arundo arenaria*, in the proportion of 4 to 5. From experiments as to the produce, it would appear that the *A. arenaria* is unworthy of cultivation as food for cattle, out of the influence of the salt spray. But from the habit of the plant in its natural place of growth, it is of great utility, particularly when combined with the *Elymus arenarius*, in binding the loose sands of the sea-shore, and thereby raising a

natural barrier, the most lasting against the encroachments of the ocean upon the land. So far back as the reign of William III., the important value of the *Elymus arenarius* and *Arundo arenaria* was so well appreciated as to induce the Scottish parliament of that period to pass an act for their preservation on the sea-coasts of Scotland. And these provisions were, by the British parliament in the reign of George I., followed up by other enactments, extending the operation of the Scottish law to the coasts of England, and in passing further penalties for its inviolability, so that it was rendered penal, not only for any individual, not even excepting the lord of the manor, to cut the bent, but for any one to be in possession of any within eight miles of the coast. This plant is likewise applied to many economical purposes; hats, ropes, mats, &c., being manufactured from it. (*Sinclair's Hort. Gram. Wob.*)

ASCARIDES. See WORMS, INTESTINAL.

ASH (*Fraxinus excelsior*). This tree was called by the Greeks *μαλίς*, and by some *μαλίς*. The Latins, it is thought, named it *Fraxinus*, *quia faciliè frangitur*, to express the fragile nature of the wood, as the boughs of it are easily broken. We are thought to have given the name of ash to this tree, because the bark of the trunk and branches is of the colour of wood-ashes, whilst some learned etymologists affirm that the word is derived from the Saxon *ære*. Virgil tells us that the spears of the Amazons were of this wood, and Homer celebrates the mighty ashen spear of Achilles. Many of the ancient writers highly extolled the ash. It has been asserted that serpents have such an antipathy to the ash, that they will not approach even within its morning or evening shadows; and Pliny tells us (he says upon experience), that if a fire and serpent be surrounded by ash boughs, the serpent will sooner run into the fire than into the boughs. There are many other superstitious notions attached to the ash, which it would be foreign to our purpose to notice.

There are several varieties of the ash, among which are, 1. The weeping, which forms a beautiful arbour when grafted upon a lofty stem: it is said to have originated incidentally in a field at Garthingay, Cambridgeshire: 2. The entire leaved: 3. The curl-leaved, which has a dark aspect: and, 4. The wasted.

Ash plantations have lately been formed in many parts of the kingdom to a very considerable extent. The Romans used the ash-leaves for fodder, which were esteemed better for cattle than those of any other tree, the elm excepted: and they were also used for the same purpose, before agriculture was so well understood, and our fields clothed with artificial grasses. In Queen Elizabeth's time, the inhabitants of Colton and Hawkshead Fells remonstrated against the number of forges in the country, because they consumed all the loppings and croppings which were the sole winter food for their cattle. In the north of Lancashire the farmers still lop the tops of the ash to feed their cattle in autumn, when the grass is on the decline; the cattle peeling off the bark as food. The Rev. Mr. Gilpin tells us, that in forests the keepers make the deer

browse on summer evenings on the sprays of ash, that they may not stray too far from the walk. The branches are frequently given to deer in time of frost. The ash-tree, in early days, served both the soldier and the scholar. It was also a principal material for forming the peaceable implements of husbandry, as it continues to be with us to this day, in the snape of carts, wagons, teeth and spokes of wheels, harrows, rollers, &c. The gardener recognises it in his rake-stem, spade-tree, and other tool handles. The hop-planter knows its value for poles, the thatcher for spars, the oullder for ladders, the cooper for hoops, the turner for his lathe, the shipwright for pulleys, the mariuer for oars and ship-blocks, the fisherman for tanning his nets and drying his herrings; the wheelwright employs it usefully, and the coach-maker profitably, whilst the cabinet-maker palms it off upon us as green ebony. The ashes of this wood afford very good potash, and the bark is used in tanning calf-skins, and dyeing green, black, and blue. The ash-keys were formerly gathered in the green state, and pickled with salt and vinegar, and served to table for sauce.

Were we to transcribe all we have seen written on the medicinal virtues of this plant, it might naturally be asked how it happens that we do not meet our ancestors upon earth, who had in this tree a cure for every malady? The Arabian as well as the Greek and Roman physicians, highly extol the medicinal properties of the seed which the Latins named *lingua avis*, bird's tongue, which it resembles. Drs. Taner, Robinson, and Bowles, are amongst the later physicians who commend the good qualities of this little seed. The common ash propagates itself plentifully by the seed, so that abundance of young plants may be found in the neighbourhood of ash-trees, provided cattle are not suffered to graze on the land. It produces its leaves and *keys* in spring, and the seeds ripen in September. The foliage changes its colour in October. (*Baxter's Lib. Ag. Kn.*; *Phillips's Syl. Flor.*) [Michaux states that eight species of ash are mentioned by botanists as indigenous to Europe, whilst a much greater number exist in the United States. Probably more than thirty species can be found east of the Mississippi. A striking resemblance runs through the whole genus; but it is the *white ash* of America, the wood of which, by its strength and elasticity, is adapted to so many useful purposes, that bears the nearest resemblance to the common ash of Europe.]

ASHES (Goth. *atzgo*, *azgo*, dust; Sax. *arca*; Dutch and Germ. *asche*; Su. Goth. *aska*). "Ashes contain a very fertile salt, and are the best manure for cold lands, if kept dry, that the rains doth not wash away their salt." (*Mort. Husb.*; *Todd's Johnson*.)

The use of ashes may be traced to a very early age. The Romans were well acquainted with paring and burning. Cato recommends the burning of the twigs and branches of trees, and spreading them on the land. Palladius says, that soils so treated would require no other manure for five years. They also burnt their stubbles, a practice common among the Jews. The ancient Britons, according to Pliny,

used to burn their wheat-straw and stubble, and spread the ashes over the soil. And Conradus Heresbachius, a German counsellor, in his *Treatise on Husbandry*, published in 1570, which was translated by Googe, tells us, p. 20, that "in Lombardy, they like so well the use of ashes, as they esteem it farre above any dung, thinking dung not meete to be used for the unholsonnesse thereof."

It is the earthy and saline matters of the burnt soils, and combustibles employed, which constitute the substance of the ashes employed in agriculture. Their use as a manure is very general in most parts of England, although many errors are usually committed in their application, and much erroneous reasoning wasted in accounting for their unsuccessful application in some districts, or their general success in others. Those usually employed for agricultural and horticultural purposes in this country are, 1. The ashes of coal; 2. Ashes of wood; 3. Peat ashes; 4. The ashes from turf, as in paring and burning; 5. The ashes of burnt clay; 6. The ashes from soap-boilers. I will remark upon these, in the order in which I have enumerated them.

1. *Coal Ashes*.—The only analysis of coal that I am acquainted with is that of earth-coal, by M. Klapproth: he found it to be composed of—

Volatile matter	-	-	-	62.25	} = 82.5
Charcoal	-	-	-	20.25	
Lime	-	-	-	02.00	} = 17.5
Sulphate of lime	-	-	-	02.05	
Oxide of iron	-	-	-	01.00	
Alumina	-	-	-	00.05	
Sand	-	-	-	11.05	
				100	

The combustion of the coals dissipates almost all the gaseous matters, and much of the charcoal; and the ashes, therefore, will consist almost entirely of the various earths, a small portion of charcoal, and the saline matters of which the sulphate of lime (gypsum) and lime constitute about a fourth.

The presence of these last-named substances gives to the coal-ash almost all its value as a fertilizer, for these ashes are always most beneficially applied to those crops which contain sulphate of lime in sensible quantities, such as to lucern, sainfoin, red-clover, &c. In the garden, they are more often employed for the purpose of forming walks, and to prevent the ravages of garden-mice, than as a manure; or, when they are employed as an addition to the soil, it is generally in considerable quantities, on stiff clay soils, with the intention, by the mechanical operation of the cinders, of rendering the soil more friable and permeable by the gases of the atmosphere. As a top dressing for lucern, red clover, sainfoin, and other grasses, there is no application superior to coal ashes. This fact was clearly proved in some comparative experiments made by Lord Albemarle, with a variety of manures, as a top dressing for sainfoin. He found coal ashes far superior in value to any other fertilizer. As a manure for gardens, it is generally employed in quantities much too large; and thence an idea has been entertained by many gardeners, that coal ashes are inimical to plants and trees. Mr. Loudon has given several experiments of this description. In these,

one gardener imbedded his potted chrysanthemums, by placing a "large handful" at the bottom of each of his pots, and then was surprised that other pots, not thus partly filled, produced better plants. Another "horticultural friend" states the case of a Scotch gardener, who "coated over," for two successive years, his garden with coal ashes; and then our experimentalist, who was, doubtless, a persevering character, finding that, with this over-dose of cinders, the "fruit trees did not thrive so well as he expected," actually took them up, and placed them under a "substratum of ashes, in order to lay them," as he said, "dry and comfortable." The trees of course grew worse, and were taken up. (*Gard. Mag.* vol. vi. p. 224.) It is to be lamented that such trials as these are ever brought forward; they are merely sources of erroneous conclusions, and strong proofs of the ignorance of those who have thus been wasting their master's time and property.

Mr. Loudon has, in another place (*Gard. Mag.* vol. ii. p. 406), given some experiments of a very different character, which I shall give in his correspondent's own words:—"I sowed, on the 15th of May, 1826, three rows of Swedish turnips. No. 1, was manured with well-rotted dung from an old melon bed. No. 2, with the tops of cabbages just come into bloom. No. 3, with coal ashes. They vegetated about the same time, but the row manured with the cabbage-tops seemed to suffer most from the drought; the season being hot and dry, they made little progress until the end of August, and in November they were a middling, or rather a bad crop. The row manured with coal ashes had, all along, a more luxuriant appearance than the other two. The rows were 20 yards in length, 3 feet apart, and 15 inches from plant to plant in the row. I took them up in February, and they weighed as follows:—No. 1, 78 lbs.; No. 2, 88 lbs.; No. 3, 121 lbs.; which is very much in favour of the coal ashes." It may be remarked, that sulphate of lime, which abounds in coal ashes, is found in very sensible quantities in turnips. In the garden, coal ashes are very useful when spread over the surface, to prevent the depredations of garden-mice; they cannot burrow through them; and, in the case of early sown peas, it will be found that the peas covered on the surface of the ground, with coal ashes, say a quarter, or half an inch in thickness, will be three or four days earlier than those to which the ashes have not been applied. This may be attributed to the greater heat absorbed from the sun by the black coal ashes.

Wood Ashes.—The wood of various trees, &c., has been analyzed by M. Saussure, Jun.; the following was the result (*Chem. Rec. Veg.*):—

	Parts of Ashes.
1000 parts of the dry wood of a young oak, yielded	2
1000 ditto of the bark of oak	60
1000 ditto of perfect oak wood	2
1000 ditto of poplar wood	8
1000 ditto of poplar bark	72
1000 ditto of wood of hazel	5
1000 ditto bark of ditto	62
1000 ditto wood of mulberry	7
1000 ditto bark of ditto	89
1000 ditto wood of hornbeam	6

1000 ditto bark of ditto	-	-	-	134
1000 ditto wood of horse-chestnut	-	-	-	35
1000 ditto straw of wheat	-	-	-	43
1000 ditto branches of the pine	-	-	-	15

100 parts of these ashes were found to consist of the following substances, in varying proportions. I have arranged the results in a tabular form, by which my readers will readily ascertain the composition of the ashes procured by the combustion of various woods, barks, &c.:—

	Soluble Salts.	Earthy Phosphates.	Earthy Carbonates.	Silica.	Metallic Oxides.	Loss.
100 parts of ashes of young oak dry wood, contain	26.0	28.5	12.25	0.12	1.	59
Bark of ditto, ditto	7.0	4.5	63.25	0.25	1.75	22.75
Perfect oak wood, do.	28.6	4.5	32.	2.	2.25	20.65
Poplar wood, ditto	—	16.75	27.	3.3	1.5	24.5
Poplar bark, ditto	6.	5.8	60.	4.	1.5	23.2
Wood of the hazel, do.	24.5	35.	8.	0.25	0.12	32.2
Bark, ditto, ditto	12.5	5.5	54.	0.25	1.75	26.
Mulberry wood, ditto	21.	2.25	56.	0.12	0.25	20.38
(Cut in November.)						
Bark of ditto, ditto	7.	8.5	45.	15.25	1.12	22.13
Wood of hornbeam	22.	23.	26.	0.12	2.25	26.63
Bark, ditto	4.5	4.5	59.	1.5	0.12	30.38
Wood of chestnut	9.5	—	—	—	—	—
Straw of wheat	22.5	6.2	1.	61.5	1.	7.8
Branches of the pine	15.	—	—	—	—	—

The soluble salts of these ashes are chiefly carbonate and muriate of potash. The earthy phosphates are the phosphates of lime and magnesia (or the principal salt of bones); the earthy carbonates are those of lime (chalk), and magnesia; silica is the pure earth of *flint*; and the oxides were those of iron and manganese.

The cultivator will readily see, by the results of these valuable investigations, the reason why wood ashes are so much superior to those from coal as a manure. The ashes from wood, he will notice, contain a very considerable proportion of the phosphates of lime and magnesia; those from the hazel, containing 35 per cent., and those from the wood of young oak 25 per cent., essential vegetable ingredients, of which the ashes from coal are entirely destitute. The phosphate of lime, it will be remembered, is the chief fertilizing constituent of bones, in which valuable manure it is invariably present, in proportion varying from 37½ per cent. in the bones of the ox, to 35 per cent. in those of the hare. Wood ashes also contain a considerable proportion of carbonate of potash, a salt which is more or less present in all vegetable substances, and for which, therefore, it must be highly serviceable as a food. The carbonate of potash, too, promotes the dissolution of dead vegetable substances, and it also, from its attraction of moisture from the atmosphere, must promote an increased supply to the soil. Wood ashes are often very judiciously added to common manure, the quality of which is much improved by the mixture. The leaves of trees, when burnt, generally produce more ashes, or potashes as they are called, (from being formerly produced by burning vegetable substances in large open pots), than the branches, and the stem of the tree the least of all; herbs produce four or five times, and shrubs three or four times as much as either. All vegetables produce more

ashes if burnt when green than when they are previously dried. Davy (*Lectures*, p. 113) has given a table of the quantity of potashes furnished by the combustion of various common vegetable substances, which I shall here insert, as the cultivator will see by it that there is a very remarkable difference in the quantity produced by equal weights of different trees and plants.

10,000 parts of the	poplar produced	Parts of Potashes.

Peat Ashes.—Peat ashes are made in many parts of England for the use of the farmer by burning peat in large heaps, after it has been sufficiently dried by the heat of the sun; and for grass lands and turnips they have been found a very valuable manure. They are usually applied as a top dressing. The composition of peat ashes more nearly resembles that of coal ashes than those from wood or vegetables—which is a result hardly to be expected, when we consider that the immense beds of peat, or turf, as it is sometimes called, which are dispersed over Britain, are evidently composed of the remains of vegetable substances; trunks of trees, leaves, fruits, stringy fibres, the remains of water mosses, &c., and this in some places to a depth of 15 yards. Peat ashes were analyzed by Davy, with much care: he came to the conclusion that they owe most of their fertilizing properties to the presence of gypsum (or sulphate of lime). In the Berkshire and Wiltshire peat ashes, he discovered a considerable portion of it. The Newbury peat ashes he found to be composed of from one-fourth to one-third gypsum, and in the peat ashes of Stockbridge and Hampshire, a still larger proportion of the same substance. The other constituents of peat ashes are calcareous, aluminous, and silicious earths, with varying quantities of sulphate of potash, a little common salt, and occasionally oxide of iron, especially in the red varieties of peat ashes.

“These peat ashes,” said Davy, “are used as a top dressing for cultivated grasses, particularly sainfoin, clover, and rye-grass. I found that they afforded considerable quantities of gypsum, and probably this substance is intimately combined as a necessary part of their woody fibre; if this be allowed, it is easy to explain the reason why it operates in such small quantities; for the whole of a clover or sainfoin crop on an acre, according to my estimation, would afford, by incineration, only three or four bushels of gypsum. In examining the soil in a field near Newbury, which was taken from below a footpath, near the gate, where gypsum could not have been artificially furnished, I could not detect any of this sub-

* Hence potash was formerly called “salt of wormwood.”

stance in it, and at the very time I collected the soil, the peat ashes were applied to the clover in the field. I have mentioned certain peats, the ashes of which afford gypsum: but it must not be inferred from this, that all peats agree with them. I have examined various peat ashes from Scotland, Ireland, Wales, and the northern and western parts of England, which contained no quantity that could be useful; and these ashes abound in silicious, aluminous earths, and in oxide of iron. Lord Charleville found in some Irish peat ashes, sulphate of potash. Vitriolic matter is usually found in peats; and if the soil or substratum is calcareous, the ultimate result is the production of gypsum. In general, when a recent potash emits a strong smell resembling that of rotten eggs (sulphuretted hydrogen), when acted upon by vinegar, it will furnish gypsum.” (*Agric. Chem.* p. 336.)

In the valley of the Kennet, in Berkshire, where the peat ashes are made in very considerable quantities, and are used by the farmers as a manure for both grass and turnips, they are sold at three-pence per bushel, and are applied at the rate of 40 or 50 bushels an acre broadcast. On most grass lands there is no dressing equal to them; and on some soils, near to Hungerford, they produce the most luxuriant crops of grass, in cases where the effects of common farm-yard manure are hardly perceptible. As a manure for turnips, they answer best in wet seasons. In very dry weather, the crops growing on the ashed land are described by the farmers as putting on a “burned” appearance.

Peat ashes are extensively employed in Flanders as a manure; they are carefully preserved by the householders, who burn turf or peat, and are sold to the farmers by the bushel, in the same way that those of Newbury are in England. Their use is chiefly confined to clover, for which purpose they are an excellent top dressing. Mr. Radcliffe, in his *Agriculture of Flanders*, has given an analysis of these ashes, from which the farmer will see they owe nearly all their fertilizing properties to the presence of 12 per cent. of gypsum. 100 parts are composed of—

Silicious earth	-	-	-	-	-	32
Sulphate of lime	-	-	-	-	-	12
Sulphate and muriate of soda	-	-	-	-	-	6
Carbonate of lime	-	-	-	-	-	40
Oxide of iron	-	-	-	-	-	3
Loss	-	-	-	-	-	7

Paring and burning Ashes.—This is hardly the place to enter into the often argued and yet undecided question, as to the advantages of paring and burning. It is pretty universally agreed, that the practice is highly injurious to sandy soils, beneficial to clay lands, and still more advantageous to those of a peaty description; that is, to soils where there is an excess of inert vegetable remains. The cultivator of the soil will see, by the results of the analysis by Davy of the ashes produced by the paring and burning of three different descriptions of soil, the usual products of paring and burning. 200

grains of the ashes from paring and burning a chalk soil in Kent, yielded that great chemist

80	grains of chalk,
11	— gypsum,
9	— charcoal,
15	— oxide of iron,
3	— saline matter, consisting of sulphate of potash, muriate of magnesia, and vegetable alkali,
82	— alumina (clay), and silica (flint).
<hr/>	
200	
<hr/>	

According to the estimate of Mr. Boys, who has published a treatise upon paring and burning, it appears that on the chalk soils of Kent, about 2660 bushels of ashes are usually produced by paring and burning an acre of ground, and that this quantity of ashes, which he calculates will weigh 172,900 lbs., will contain

Chalk	-	-	-	-	-	69,160 lbs.
Gypsum	-	-	-	-	-	9,509
Oxide of iron	-	-	-	-	-	12,967
Saline matter	-	-	-	-	-	2,594
Charcoal	-	-	-	-	-	7,781

The second specimen of ashes was from a soil at Colerton, in Leicestershire, composed of three-fourths sand, one-fourth clay, and about 4 per cent. of chalk.

100 grains of the ashes yielded

6	grains charcoal,
3	— common salt, sulphate of potash, and a trace of vegetable alkali,
9	— oxide of iron,
82	— sand, clay, and chalk.
<hr/>	
100	
<hr/>	

The third variety of ashes was produced by paring and burning a stiff clay soil at Mount's Bay, in Cornwall.

100 grains of these were found to contain

8	grains of charcoal,
2	— common salt, and other saline matters,
7	— oxide of iron,
2	— chalk,
81	— clay and sand.
<hr/>	
100	
<hr/>	

Such are the ashes from paring and burning. The cultivator of the soil will judge whether any of these products are required by his land, and whether all the good results of paring and burning might not be generally obtained by other means, without destroying that large portion of the vegetable matters of the turf, destroyed during combustion. In those cases, however, where it is practicable to transfer the ashes produced by paring and burning a chalk soil to a clay, or, *vice versa*, the ashes of a clay soil to a chalk, the result must, in general, be highly and permanently beneficial to both.

The Ashes of burnt Clay.—The composition of the ashes of burnt clay, although varying according to the earthy proportions of the soil, will be found pretty generally to accord with the analysis of the ashes from the clay soil, from Mount's Bay, given above under the head, *Paring and burning Ashes*. Clay burning is practised with decided success in many districts of England, and, in every point of view, is by far the most eligible mode of producing ashes for manure; for the soil of the field is not thereby impoverished of its vegetable remains, the clay which is burnt being generally

procured from ditches, banks, hedgerows, &c. The account of clay burning, given several years since by General Vavasour, of Melbourne Hall, in Yorkshire, is so practical and satisfactory, that I cannot do better than quote his own words:—"I would recommend to a beginner, that the kiln should be made small, about three yards wide, and six yards long in the inside; as he becomes more skilful, they may be made larger. The walls of the kiln are to be made of sods, two feet thick at the bottom, and one foot thick at the top, leaving two flues on each side, and one at each end, about one foot square; these walls may be built at first four feet high. We then put in the wood, beginning with the larger pieces at the bottom, particularly near the flues, supported by sods to keep them open, adding tops of firs, or any brushwood, until the kiln is nearly filled. It might be burnt with coal or peat, if more convenient. Cover the wood with a layer of clay taken from some bank or ditch in the field, and which has been digged sometime before to dry; it is not necessary that it should be very dry. The fire is then to be lighted at the flue by means of straw previously placed there. The greatest care is required that the fire shall not escape at the top; but fresh clay constantly thrown on, wherever it seems likely to burn out, at the same time not overloading the kiln, so as to put out the fire. As the quantity of clay is increased, the walls should be raised, keeping them a foot higher than the clay. About six feet will be as high as can be conveniently burned. The chief art seems to be, to procure a great mass of fire at first, and to let the fire rise through the clay as you go, to let it smoke in every part at the top, but not to burn out. My men, who burnt by contract, watch the kilns by night and day. I have applied the ashes almost exclusively for wheat, upon a clay soil, spreading them on a fallow after the last ploughing, and harrowing them in with the seed, at the rate of 30 tons per acre, on 80 acres. The longer the ashes remain upon the land, before harrowing, the better, that the lumps may fall, and mix with the soil. If the walls are well made, one end may be taken down, and, after the kiln is emptied, rebuilt for a second burning; if not likely to stand, they may be entirely burned in a succeeding kiln. If the weather should not be moist, the kilns will burn for some weeks, as the clay will continue hot long after the wood is consumed."

Clay ashes have been used to a very considerable extent by Mr. Hewitt Davis, of Spring Park, near Croydon, on several of his farms, and with the most decided success. This excellent farmer and land-agent has the clay dug out in pits, that it may be more readily dried. He burns in heaps; and employs as fuel collections of hedge-clippings, furze, &c.; and these he thinks it best not to use in too dry a state, since one great object in clay-burning, he is of opinion, is to produce a steady mouldering heat, not too fast. A fire, therefore, should not be suffered to flame. The fire in the heaps usually works against the wind, when those heaps are properly made. He applies about 150 bushels of the ashes per acre; pays 1*d.* to 1½*d.* per bushel for burning; dress-

ing with them with great advantage all kinds of soil, for turnips, &c.

Mr. Poppy, of Winesham, in a pamphlet published in 1830, after giving various directions for burning clay, adds:—"Salt (the only inexhaustible universal manure, besides burnt earth) does not increase the bulk of straw; and although it may be, and is, beneficial to corn, it will not be very extensively used, because its benefit is not apparent to the eye: burnt earth produces an abundance of straw. I have seen the corn so luxuriant on the sites of the heaps, where due caution was not used in laying a floor of earth under the fire, that it was rotted on the ground, and destroyed the clover plant. I have seen the beans on the site of a burnt-earth heap even too luxuriant; and potatoes and mangel wurzel a double produce to the rest of the crop. There is no limit to burning earth on stiff clay soils, because the most sterile subsoil, brought up purposely by the plough will, by the action of fire, be converted into useful manure. If it is converted into *staple*, it increases the depth of titheable soil, and acts both physically and mechanically." The Suffolk plan of clay-burning is similar to that adopted in Yorkshire. "The common mode of burning earth is to dig old borders, surfaces of banks, &c.; turn it over, and, when dry, cart it to a heap, and burn; formerly much wood was used, but haulm, straw, dry weeds, and a few bushes, whins, or any thing of that kind, may be employed; then build a circular wall of turfs around it, cover the heap slightly with turfs and earth, and set fire to it in several places; feeding with the most inflammable materials at first, afterwards clay or any earth will burn; when all the earth is on the heap, the walls may be pulled down and thrown on, raising it by degrees as the fire ascends, in the shape of a cone, till all is consumed."

The expense of this kind of clay-burning is thus estimated by Mr. Poppy:—

	£ s. d.
Labour, digging, and burning 100 loads, at 9d. per load	3 15 0
Filling, 1s. 6d. per score—7s. 6d.; carting three horses and two carts, 16s.	1 3 6
Filling and spreading after burning, 3d. per acre	0 15 0
Carting, and laying out over two acres	0 16 0
Total per 100 loads	£6 9 6

Or 3*l.* 4*s.* 9*d.* per acre for 50 loads, or 1*s.* 4*d.* per load.

Clay-burning, according to Mr. Poppy, is certainly not a modern Suffolk improvement. "I have constantly seen it practised for half a century; and the oldest man I ever conversed with on the subject, spoke of it as common as long as he could remember. I have a workman on the farm who is, I think, upwards of eighty years of age, and has always followed the vocation of burning earth."

The Ashes from Soap Boilers.—Soap boilers' ashes are a mixture of a peculiar description; they are principally the insoluble portion of the barilla, potashes, or kelp, employed in soap-making, mixed with cinders, lime, salt, and other occasional additions; and also with muriate of potash, common salt, and other saline matters.

The quantity of pearl and potashes imported into the United Kingdom is very considerable; in 1837, it amounted to 147,329 cwts.; in 1838, to 127,101 cwts.: of barilla and alkali in the same year were imported 102,135 cwts. and 72,587 cwts. (*McCulloch's Dictionary of Commerce.*)

The insoluble portion of barilla consists principally of lime, charcoal, sand, and oxide of iron. The insoluble portion of potash, or *ashes*, as they are denominated by the trade, will consist of a considerable portion of the same ingredients, added to a varying portion of phosphate of lime. Much difference of opinion has subsisted among farmers with regard to the advantages of soap-makers' ashes. It has been recommended as very useful upon strong, cold soils, on peat moss, and on cold, wet pastures. The quantity recommended to be applied per acre by Arthur Young, was 60 bushels for turnips; to be harrowed in with the seed. For wet grass lands, six loads per acre. For wet arable soils, seven loads per acre. He describes the immediate effects as very great. For poor loamy land, ten loads per acre: the effect very satisfactory. Dr. Cogan, who has written a paper on the use of soap ashes, has given this letter of one of his correspondents, whom he describes as a plain, sensible farmer:—"My experience of soap-makers' ashes is confined to the application of it as a top dressing on pasture land. About twelve years ago, I agreed with a soap boiler for 1500 tons of soap-makers' ashes. I used to apply about twenty wagon loads per acre, and a single bushing would let the whole in. I was laughed at, and abused by every body for my folly: these wiseacres alleging that my land would be burned up for years, and totally ruined; all which I disregarded, and applied my soap-makers' ashes every day in the year, reeking from the vat, without any mixture whatever.

"I tried a small quantity (say six acres), mixed up with earth; but I found it was only doing things by halves. My land never burned, but, from the time of the application, became of a dark green colour, bordering upon black, and has given me more, but never less than two tons per acre, ever since, upon being *hayned*, forty-two days, viz. from May 31 to July 11. The ground I so dressed was twenty-four acres; and I have had 120 sheep (hogs of the new Leicester breed), upon the ground from last August to this day (March 2); but I allowed them plenty of hay: and although they were culled in August last, as the *worst* I had out of 700 lambs, and selected for this ground on purpose to push them, they are now as good as the best I have."

As by far the most considerable portion of soap ashes is lime and chalk, wherever lime or calcareous matter is a fertilizer to the soil, soap-makers' ashes will generally, if not invariably, succeed; but they must be applied in quantities nearly as large as if lime was employed.

Such are the chief agricultural properties of the various ashes hitherto employed in agriculture. The research is, however, by no means nearly exhausted, for these fertilizers have showed the fate generally attendant upon

all agricultural or horticultural investigations: they have been lauded as equally beneficial to every description of soil, and in all situations; or they have been condemned, with equal folly, by the results of blundering trials—begun in ignorance, continued without care, and perhaps nearly forgotten in the hurry of a conclusion.

They furnish ingredients, such as the carbonate of lime, carbonate of potash, charcoal, phosphate of lime, sulphate of lime, &c., which, in limited quantities, enter into the composition of all plants, as an absolute constituent part; and for these they must, according to the natural deficiency of the soil in these ingredients, be extremely useful. They absorb moisture from the atmosphere, too, in quantities much superior to what is generally believed, and in this property the ashes of burnt clay and coal ashes considerably exceed both chalk, lime, gypsum, and even crushed rock salt, as will be seen by the result of the experiments given under the head MANURES.

Some very valuable comparative experiments on the influence of ashes upon the growth of potatoes were made by the Rev. Edmund Cartwright, of Hollenden House, in Kent. (*Com. Board of Agric.*, vol. iv. p. 370.) "The soil on which these experiments were made was previously analyzed: 400 grains gave—

"Silicious sand, of different degrees of fineness	- - - - -	250	grs.
Finely divided matter	- - - - -	104	
Loss in water	- - - - -	16	
		<hr/>	
		400	

"The finely divided matter contained—

"Carbonate of lime	- - - - -	18	grs.
Oxide of iron	- - - - -	7	
Loss by incineration (probably vegetable decomposing matter)	- - - - -	17	
Silex, alumina, &c.	- - - - -	62	
		<hr/>	
		104	

"It will appear," says Mr. Cartwright, "from the above analysis, that these experiments could not have been tried upon a soil better adapted to give impartial results; for of its component parts there is no ingredient (the oxide of iron possibly excepted) of sufficient activity to restrain or augment the peculiar energies of the substances employed." The beds were laid out and planted on the same day, the 14th of April; they were manured as in the following table. These beds were each forty yards in length, and one yard wide. Every bed was planted with a single row of potatoes, "and, that the general experiment might be conducted with all possible accuracy, each bed received the same number of sets." The potatoes were taken up on the 21st of September when the produce of the beds were as follows:—

Land without any manure produced, per acre	Potatoes in Bushels.
— with 60 bushels of wood-ashes	157
— — 60 bushels of wood-ashes, salt 8 bushels	187
— — peat 363 bushels	217
— — peat ashes 368 bushels, salt 8 bushels	159
— — peat 363 bushels, salt, 8 bushels	185
— — peat 363 bushels, salt, 8 bushels	171

Another series of experiments was made by Dr. Cartwright, upon a cold, wet, tenacious clay, with burnt clay, wood-ashes, and soot; in all of which the clay ashes had a decided superiority of effect. The following table shows the quantity of manure applied per acre, and the produce of the land thus fertilized. (*Trans. Soc. Arts*, vol. xxxvi.)

Per Acre.	Produce per Acre.					
	Swedes.		Potatoes.		Barley.	
	tons.	cwts.	bush.	qrs.	lbs.	
Burnt clay, 400 bushels -	25	2	460	4	4	
Wood ashes, 100 bushels	23	12	456	4	2	
Soot — 50 —	16	12½	432	4	2	
Soil simple - - - -	10	4	340	3	0	

The operation of burning clay produces but a slight chemical alteration in the composition of the clay; its tenacity is merely destroyed, and a portion of soot and of carbonized animal and vegetable remains are diffused through the ashes; added to which, the ashes of the wood employed for the burning, which usually contain a quantity of phosphate of lime and potash, are mixed up with the mass. (*Johnson on Fertilizers*, 296; *Brit. Farm. Mag.*, vol. i. p. 58.)

ASPARAGUS (from the Greek *ασπαραγος*, a young shoot before it expands). There are only two varieties, the red-topped and the green-topped; the first is principally cultivated. There are a few sub-varieties which derive their names from the places of their growth, and are only to be distinguished for superior size or flavour, which they usually lose on removal from their native place. The soil best suited to this vegetable is a black, fresh, sandy loam, made rich by the abundant addition of manure; it should be neither tenacious from the too great preponderance of clay, nor too dry from a superabundance of silica, but should be retentive of moisture chiefly by reason of its richness. To raise fine roots for hot-beds, they may be raised in a much moister soil (*Miller's Dictionary*); but for natural productions this will not answer, as such plants are much shorter lived. The site of the beds should be such as to enjoy the influence of the sun during the whole of the day, as free as possible from the influence of trees and shrubs, and, if choice is allowed, ranging north and south. The subsoil should be dry, or the bed kept so, by being founded on rubbish or other material to serve as a drain. The space of ground required to be planted with this vegetable for the supply of a small family is at least eight rods, if less, it will be incapable of affording one hundred heads at a time (Marshall says six rods will afford this quantity), so that part must be kept two or three days after it is cut, especially in ungenial seasons, to allow time for the growth of more to make a sufficient number for a dish. Sixteen rods will, in general, afford two or three hundred every day in the height of the season. To raise plants the seed may be sown from the middle of February to the beginning of April; the most usual time is about the middle of March. The best mode is to insert them by the dibble, five or six inches apart and an inch below the surface, two seeds to be put in each

hole; or they may be sown in drills made the same distance asunder, or broadcast. If dry weather, the bed should be refreshed with moderate, but frequent waterings, and if sown as late as April, shade is required by means of a little haulm during the meridian of hot days, until the seeds germinate. Care must be taken to keep them free from weeds, though this operation should never commence until the plants are well above ground, which will be in the course of three or four weeks from the time of sowing. If two plants have arisen from the same hole, the weakest must be removed as soon as that point can be well determined. Towards the end of October, as soon as the stems are completely withered, they must be cut down, and well-putrefied dung spread over the bed to the depth of about two inches: this serves not only to increase the vigour of the plants in the following year, but to preserve them during the winter from injury by the frost. About March in the next year, every other plant must be taken up, and transplanted into a bed, twelve inches apart, if it is intended that they should attain another, or two years' further growth, before being finally planted out; or they may be planted immediately into the beds for production. It may be here remarked, that the plants may remain one or two years in the seed-bed; they will even succeed after remaining three, but if they continue four they generally fail: it is, however, nearly certain that they are best removed when one year old, for the earlier a plant can possibly be removed, the more easily does it accommodate itself to the change, and less injury is it apt to receive in the removal. Some gardeners sow the seed in the beds where they are to remain for production. This mode, too, has the sanction of Miller. The time for the final removal is from the middle of February until the end of March, if the soil is dry and the season warm and forward; otherwise it is better to wait until the commencement of April. The plan which some persons have recommended, to plant in autumn, is so erroneous, that, as Miller emphatically says, the plants had better be thrown away. Mr. D. Judd has mentioned (*Trans. Hort. Soc. Lond.*, vol. ii. p. 236) a very determinate signal of the appropriate time for planting, which is, when the plants are beginning to grow: if moved earlier, and they have to lie torpid for two or three months, many of them die, or in general shoot up very weak.

Immediately that the buds begin to swell they should be removed, and this may easily be ascertained by occasionally opening the ground down to the stool. A successful experiment, tried by Mr. J. Smith, gardener to the Earl of Kintore, would evince that one year old asparagus plants may be removed even as late as June. The stems of his plants, at the time of removal in that month, were twelve or fifteen inches high: they were removed and treated with the greatest care, the earth being gently pressed round the root, and water given plentifully; but although the experiment perfectly succeeded, for none of them died, and although they surpassed in growth those left in the seed-bed—so much so, that they might have been cut from—yet still, for many reasons, we

are justified in considering that this must have been tried under accidental or very favourable circumstances of soil and season, and it requires repeated experiments from different counties before the practice is confirmed. (*Caled. Hort. Mem.*, vol. i. p. 71.) In forming the beds for regular production, it is customary to have them four or five feet wide. In the first instance, they have three rows of plants, in the latter four. The site of the bed being marked out, the usual practice is to trench the ground two spades deep, and then to cover it with well-rotted manure from six to ten inches deep; the large stones being sorted out and care taken that the dung lies at least six inches below the surface. To mix the manure with the soil effectually, Mr. D. Judd, before mentioned, trenches his ground two feet deep, three times successively during the autumn or winter, at intervals of a fortnight, and then lays it in ridges until wanted, performing the work in the absence of rain or snow: he justly observes, that the preparation of the soil is of more consequence to be attended to than all the after management. (*Trans. Hort. Soc. Lond.*, vol. ii. p. 234.)

In France, however, where the beds are celebrated for the number of years they continue in production, a pit is dug five feet in depth, and the mould that is raised from it sifted, care being taken to reject all stones, even as small as a filbert; the best part of the mould is laid aside for making up the bed. The bed is then formed as follows, beginning at the bottom; six inches deep of common manure—eight of turf, very free from stones—six of manure—six of sifted earth—eight of turf—six of very rotten dung—eight of best earth; finally, this last layer of mould is well incorporated with the adjoining one of dung. The bed is then ready for the reception of the plants. (*Dr. McCulloch, in the Caled. Hort. Mem.*) The plants being taken from the seed-bed carefully with a narrow, prolonged dung-fork, with as little injury to the roots as possible, they must be laid separate and even together, for the sake of convenience whilst planting, the roots being apt to entangle, and cause much trouble and injury in parting them. They should be exposed as short a time as possible to the air; and to this end it is advisable to keep them until planted in a basket, with a little sand, and covered with a piece of mat. The mode of planting is to form drills or narrow trenches, five or six inches deep and a foot apart, cut out with the spade, the line side of each drill being made perpendicular, and against this the plants are to be placed, with their crowns one and a half or two inches below the surface, and twelve inches asunder: in France eighteen are allowed. The roots must be spread out wide in the form of a fan, a little earth being drawn over each to retain it in its position whilst the row is proceeded with. If the plants have begun to shoot, it is the practice in France to remove the sprouts, and with this precaution the planting is successfully performed as late as July, and if any of those die which were first planted, they are replaced at that season. This is a practice to be avoided as much as

possible, for it obviously must weaken the plants, and be particularly detrimental to such young plants. For the sake of convenience, one drill should be made at a time, and the plants inserted and covered completely before another is commenced; the two outside drills must be each six inches from the side of the bed. When the planting is completed the bed is to be lightly raked over, and its outline distinctly marked out. Care must be had never to tread on the beds—they are formed narrow to render that unnecessary—for every thing tending to consolidate them is injurious, as, from the length of time they have to continue without a possibility of stirring them to any considerable depth, they have a natural tendency to have a closer texture than is beneficial to vegetation. Water must be given occasionally in dry weather until the plants are established. The paths between the beds are to be two and a half feet wide. Throughout the year care must be taken to keep the beds clear of weeds. In the latter end of October or commencement of November the beds are to have their winter dressing: the stalks must be cut down and cleared away, and the weeds hoed off into the paths, care being taken not to commence whilst the stems are at all green, for if they are cut down whilst in a vegetating state, the roots are very prone to shoot again, and consequently are proportionably weakened. This habit might perhaps be taken advantage of in assisting our forcing this esculent; cutting down the summer-produced stems of such stools as are intended for the hotbed, a considerable time before they lose their verdant colour, would give them a natural tendency to shoot again, and consequently assist the effect of the artificial heat employed. It is generally recommended not to add any manure until the bed has been two or three years in production, and then only to apply it every other year; but I consider it much more rational to manure regularly every year from the time of forming the bed, though in less quantity than if done every other year. I put on about two inches of well decayed hotbed. By this means a continued and regular supply of decomposing matter is kept up, which is not so perfectly effected by the usual mode; and from the experiments purposely instituted by Miller, we learn, that on the richness of the ground and warmth of the season the sweetness of asparagus depends; in proportion to the poverty of the soil it acquires a strong flavour. The dung needs merely to be laid regularly over the bed, and the weeds, as well as some manure, to be slightly pointed into the paths, some of the mould from which must be spread to the depth of two inches over the dung just laid upon the beds. In France the asparagus beds at this season are covered with six inches depth of manure and four of sea sand if procurable, otherwise, of river sand or fine earth. No forking is required; but the boundaries of the bed must be marked out distinctly, as they should be kept, indeed, at all times. In the end of March or early in April, before the plants begin to sprout, the rows are to be stirred between to a moderate depth with the asparagus fork, running it slantingly two or

three inches beneath the surface, as the object is merely to stir the surface and slightly mix it with the dung. Great care must be taken not in the least to disturb the plants. Some gardeners recommend that the beds should only be hoed again, so fearful are they of the injury which may be done to the stools; but if it be done carefully as above directed, the fork is the best implement to be employed, as by more effectually loosening the soil, it is by far the most beneficial in its effects upon the plants. This course of cultivation is to be continued annually, but with this judicious modification, that earth be never taken from the paths after the first year, but these merely be covered with dung, and which is only to be slightly dug in; for every gardener must have observed that the roots of the outer row extend into the alleys, and are consequently destroyed if they are dug over; and rather than that should take place, the beds should have no winter covering, unless mould can be obtained from some other source, as asparagus does not generally suffer from frost, as is commonly supposed. In May the beds are in full production of young shoots, which, when from two to five inches high, are fit for cutting, and as long as the head continues compact and firm. Care must be taken, in cutting, not to injure those buds which are generally rising from the same root, in various grades of successional growth within the ground. The knife ought to be narrow-pointed, the blade about nine inches in length, and saw-edged: the earth being carefully opened round the shoot, to observe whether any others are arising, the blade is to be gently slipped along the stalk until it reaches its extremity, where the cut is to be made in a slanting direction. It almost always occurs that the same stool produces a greater number of small heads than large ones, but the latter only should be cut; for the oftener the former are removed, the more numerously will they be reproduced, and the stools will sooner become exhausted. Great attention must be paid to the seed. For the obtaining it, some shoots should be marked and left in early spring, for those which are allowed to run up after the season of cutting is over, are seldom forward enough to ripen their seeds perfectly. In choosing the shoots for this purpose, those only must be marked which are the finest, roundest, and have the closest heads; those having quick opening heads, or are small or flat, are never to be left. More are to be selected than would be necessary if each stem would assuredly be fruitful; but as some of them only bear male or unproductive blossoms, that contingency must be allowed for. Each chosen shoot must be fastened to a stake, which, by keeping it in its natural position, enables the seed to ripen more perfectly. The seed is usually ripe in September, when it must be collected, and left in a tub for four or six weeks, for the pulp and husk of the berry to decay, when it may be well cleansed in water. The seeds sink to the bottom, and the refuse floats and will pass away with the water as it is gently poured off. By two or three washings the seeds will be completely cleansed; and when perfectly dried

exposure to the sun and air, may be stored for use. Some gardeners keep them in the soil until the time of sowing, unless required to be sent to a distance.

To force Asparagus.—Such plants must be inserted in hotbeds as are five or six years' old, and appear of sufficient strength to produce vigorous shoots: when, however, any old natural ground plantations are intended to be taken up at the proper season, some of the best plants may be selected to be plunged into a hotbed or any spare corner of the stove or kitchen-beds. When more than ten years old, they are scarcely worth employing. To plant new stools for the *main* forcing crop, is, however, decidedly erroneous; for, as Mr. Sabine remarks, if plants are past production, and unfit to remain in the garden, little can be expected from them when forced. The first plantation for forcing should be made about the latter end of September: the bed, if it works favourably, will begin to produce in the course of four or five weeks, and will continue to do so for about three; each light producing at that time 300 or 400 shoots, and affording a gathering every two or three days. To have a regular succession, therefore, a fresh bed must be formed every three or four weeks, the first crop to be planted in March or the early part of April: this will continue in production until the arrival of the natural ground crops. The last-made beds will be in production a fortnight sooner than those made about Christmas.

The bed must be substantial, and proportioned to the size and number of the lights, and to the time of year—being constructed of stable dung, or other material. The common mode of making a hotbed is usually followed; but, as Mr. Sabine remarks, the general appearance of forced asparagus in December and the two following months, gives a sufficient indication of defective management. The usual mode he considers erroneous, inasmuch as that the roots of the plants come in contact with, or are over, a mass of fermenting matter; and the mode of raising potatoes practised by Mr. Hogg, which will be hereafter stated, first suggested the plan for obviating this defect, and has been confirmed as correct by the successful practice of Mr. Ross, gardener to E. Wallace, Esq., of Brentford, who, by planting his asparagus in the tan of his exhausted pine pits, which consist of eighteen inches of leaves, and over that the same depth of tan, and applying hot dung, successively renewed, round the sides, and thus keeping up a good heat, produced in five weeks asparagus so fine, and by admitting as much air as possible during the day, of such good colour and so strong, as nearly to equal the natural ground crops. It is the best practice to plant the asparagus in mould laid upon the tan, which, or some other porous matter, is indispensable for the easy admission of the heat from the linings. The bed must be topped with six or eight inches of light rich earth. If a small family is to be supplied, three or four lights will be sufficient at a time; for a larger, six or eight will not be too many. Several hundred plants may be inserted under each, as they may be

crowded as close as possible together; from 500 to 900 are capable of being inserted under a three-light frame, according to their size. In planting, a furrow being drawn the whole length of the frame, against one side of it the first row or course is to be placed, the crowns upright, and a little earth drawn on to the lower ends of the roots; then more plants again in the same manner, and so continued throughout, it being carefully observed to keep them all regularly about an inch below the surface; all round on the edge of the bed some moist earth must be banked close to the outside roots.

If the bed is extensive, it will probably acquire a violent heat; the frames must therefore be continued off until it has become regular, otherwise the roots are liable to be destroyed by being, as it is technically termed, *scorched* or *steam-scalded*. When the heat has become regular the frames may be set on, and more earth be applied by degrees over the crowns of the plants, until it acquires a total depth of five or six inches. The glasses must be kept open an inch or two, as long and as often as possible, without too great a reduction of temperature occurring, so as to admit air freely and give vent to the vapours, for on this depends the superiority in flavour and appearance of the shoots. The heat must be kept up by linings of hot dung, and by covering the glasses every night with mats, &c. The temperature at night should never be below 50°, and in the day its maximum at 62°. In gathering, for which the shoots are fit when from two to five inches in height, the finger and thumb must be thrust down into the earth, and the stem broken off at the bottom. This excellent vegetable possesses some diuretic properties. Its juice contains a peculiar crystallizable substance, which was discovered by Vauquelin and Robiquet, and named by them *Asparagine*. It is hard, brittle, colourless, and in the form of rhomboidal prisms: its taste is nauseous. The decoction of the plant is sometimes used on the Continent as a diuretic; but it is rarely or never prescribed in England. M. Dubois, of Paris, has submitted asparagus berries to fermentation, and procured a spirit from them by distillation, with which he makes an excellent liqueur. (*Dict. des Drogues*; *G. W. Johnson's Kitchen Garden*, 81; *Miller's Dictionary*; *Trans. Hort. Soc. Lond.* vol. ii. pp. 234, 263, 361; *Dr. Macculloch, Caled. Hort. Mem.* vol. i.)

ASPEN TREE (*Populus Tremula*). This is a branch of the poplar family, which derives its Latin name from the incessant trembling of its leaves. The English name is from the German *espe*, which is the general name for all poplars. The heart-shaped leaves adhere to the twigs by a long and slender stalk, the plane of which is at right angles to that of the leaf, and consequently allows them a much freer motion than other leaves that have their planes parallel with their stalks. This, with their cottony lining below, and their hairy surface above, causes that perpetual motion and quivering, even when we cannot perceive by other means the least breath of air stirring in the atmosphere. This trepidation is attended of course with a rustling noise, on which ac-

count country people often call it *ratiler*. The aspen tree may be planted so as to ornament large grounds, but its effect is lost when crowded. When it meets the eye as a foreground to plantations of firs, it has both a pleasing and singular appearance, as its foliage changes with the wind from a silver gray to a bright green, for when the sight goes with the wind, it catches only the under side of the leaves which are covered with a pale floss; but when it meets the current of air, the tree presents the upper surface of its foliage to the view; thus its tints are as changeable as its nature is tremulous. Like its relative, the poplar, this tree is of speedy growth, and will thrive in any situation or soil, but worst in clay. It is cultivated to the greatest advantage on such as are inclined to be moist, without having much stagnant surface water. In such situations they sometimes grow to a considerable size. It is accused of impoverishing the land, and its leaves are charged with destroying the grass, whilst its numerous roots, which spread near the surface, will not, it is said, permit any thing else to grow. The wood is extremely light, white, soft, and smooth, but it is of little value as timber, being chiefly used for making milk-pails, wooden shoes, clogs, and pattens, &c. From its lightness it might, however, probably be used to advantage for the construction of common field-gates. The bark is the favourite food of beavers, whilst the leaves and the stalks form the nourishment and birthplace of the *tipula juniperina*, a species of long-legged fly. The aspen tree will not bear lopping, like other species of the poplar. (*Phillip's Sylva Florifera*.)

[ASPEN, AMERICAN (*Populus Tremuloides*). This species of poplar is common in the northern and middle sections of the United States, and Michaux thinks, still more common in Lower Canada. The same author remarks, that in the vicinity of New York and Philadelphia, where he observed it, it appeared to prefer open lands of a middling quality. Its ordinary height is about 30 feet, and its diameter 5 or 6 inches. It blooms about the 20th of April, 10 days or a fortnight before the birth of the leaves. Of all the American poplars, this species has the most tremulous leaves, the gentlest air being sufficient to throw them into great agitation.

The wood of the American aspen is light, soft, and without either strength or durability. The most useful purpose which the wood subserves, is perhaps the furnishing of thin laminæ, for the manufacture of women's hats, light baskets, &c. The tree is considered very inferior to several species of the same genus, the Virginia poplar, for example, which is three times as large, more rapid in its growth, and of a more pleasing appearance.

The large American aspen (*Populus grandidentata*), belongs rather to the Northern and Middle, than to the Southern States. In the most northerly districts it is rather a rare tree, so that a person may perhaps travel several days without seeing one. For this reason, Michaux thinks it has been confounded with the preceding species, which is more multiplied. It surpasses the trembling aspen in height, on which

account it has received from Michaux its name. It grows as favourably on uplands as on the border of swamps, and attains a height of about 40 feet, with 10 or 12 inches in diameter. In the spring, the leaves are covered with a thick white down. The wood is light, soft, and unequal to that of the Virginia and Lombardy poplars. It possesses few, if any valuable qualities for the arts, and is only valuable for its agreeable foliage, which entitles it to a place in yards and ornamental gardens. (*Michaux's Am. Sylva*.)]

ASS (Fr. *Ane*; Ger. *Esel*; It. *Asino*; Lat. *Asinus*). A well-known and useful domestic animal, whose services might be rendered even still more useful for various purposes of husbandry, if it were properly trained and taken care of. Buffon has well observed, that the ass is despised and neglected, only because we possess a more noble and powerful animal in the horse; and that if the horse were unknown, the care and attention which are lavished upon him being transferred to his now neglected and despised rival, would have increased the size, and developed the mental qualities of the ass, to an extent which it would be difficult to anticipate, but which Eastern travellers, who have observed both animals in their native climates, and among nations by whom they are equally valued, and the good qualities of each justly appreciated, assure us to be the fact.

Indeed the character and habits of these two quadrupeds are directly opposed in almost every respect. The horse is proud, fiery, and impetuous, nice in his tastes, and delicate in constitution; like a pampered menial, he is subject to many diseases, and acquires artificial wants and habits which are unknown in a state of nature.

The ass, on the contrary, is humble, patient, and quiet, and bears correction with firmness. He is extremely hardy, both with regard to the quantity and quality of his food, contenting himself with the most harsh and disagreeable herbs, which other animals will scarcely touch. In the choice of water he is, however, very nice; drinking only of that which is perfectly clear, and at brooks with which he is acquainted.

This animal is very serviceable to poor cottagers, and those who are not able to buy or keep horses; especially where they live near heaths or commons, the barrenest of which will keep the ass, who is contented with any kind of coarse herbage, such as dry leaves, stalks, thistles, briers, chaff, and any sort of straw. Animals of this sort require very little looking after, and sustain labour, hunger, and thirst, beyond most others. They are seldom or never sick; and endure longer than most other kinds of animals. They may be made useful in husbandry to plough light lands, to carry burdens, to draw in mills, to fetch water, cut chaff, or any other similar purposes. They are also very serviceable in many cases for their milk, which is excellent for those who have suffered from acute diseases, and are much weakened; and they might be of much more advantage to the farmer, were they used, as they are in foreign countries, for the purpose of breeding mules.

The subjugation of the ass appears, from the records of the Bible, to have preceded that of the horse; and we infer from the same authority, that this subjugation took place prior to that of the dog.

The structural difference between the horse and the ass are trifling; perhaps that on which the very different tones emitted by the voice depends is one of the most striking. In all other essential points the organization of the horse and ass is the same; and, with the exception of the lengthened ears of the ass, their form, size, and proportions in a wild state, they differ but little; consequently, they possess conditions more favourable to the multiplication of species than those afforded by any other nearly allied animals. The ass is, properly speaking, a mountain animal; his hoofs are long, and furnished with extremely sharp rims, leaving a hollow in the centre, by which means he is enabled to tread with more security on the slippery and precipitous sides of hills and precipices. The hoof of the horse, on the contrary, is round and nearly flat underneath, and we accordingly find that he is most serviceable in level countries; and indeed experience has taught us that he is altogether unfitted for crossing rocky and steep mountains. As, however, the more diminutive size of the ass rendered him comparatively less important as a beast of burden, the ingenuity of mankind early devised a means of remedying this defect, by crossing the horse and ass, and thus procuring an intermediate animal, uniting the size and strength of the one with the patience, intelligence, and sure-footedness of the other.

The varieties of the ass in countries favourable to their development are great. In Guinea the asses are large, and in shape even excel the native horses. The asses of Arabia (says Chardin) are perhaps the handsomest animals in the world. Their coat is smooth and clean; they carry the head elevated, and have fine and well formed legs, which they throw out gracefully in walking or galloping. In Persia, also, they are finely formed, some being even stately, and much used in draught and carrying burdens, while others are more lightly propor-

tioned, and used for the saddle by persons of quality, frequently fetching the large sum of 400 livres; and being taught a kind of easy ambling pace are richly caparisoned, and used only by the rich and luxurious nobles. With us, on the contrary, the ass unfortunately exhibits a stunted growth, and appears rather to vegetate as a sickly exotic, than to riot in the luxuriant enjoyment of life like the horse.

The diseases of the ass, as far as they are known, bear a general resemblance to those of the horse. As he is more exposed, however, and left to live in a state more approaching to that which nature intended, he has few diseases. Those few, however, are less attended to than they ought to be; and it is for the veterinary practitioner to extend to this useful and patient animal the benefit of his art, in common with those of other animals. The ass is seldom or never troubled with vermin, probably from the hardness of its skin. (*Blaine's Encyc. Rural Sports.*)

ASTRINGENT (*Astringo*, Lat.). In farriery, a term applied to such remedies as have the property of constringing or binding the parts.

ATMOSPHERE. The name given to the elastic invisible fluid, which, to a considerable height, surrounds our globe. It is composed chiefly of two simple or undecomposed gases, viz.:—

Azote, or nitrogen	-	-	-	-	-	79.16
Oxygen	-	-	-	-	-	20.84
						100.

It contains, also, about $\frac{1}{1000}$ th of its weight of carbonic acid gas, or fixed air, a considerable portion of aqueous vapour (which is always the most considerable in amount in dry weather), and occasionally foreign substances, called Aerolites. The average proportion in which these exist in the atmosphere, are—

Air	-	-	-	-	-	98.9
Watery vapour	-	-	-	-	-	1.
Carbonic acid gas	-	-	-	-	-	.1
						100.

(*Thomson's Chem.* vol. iii. 181.) It fulfils a very essential office with regard to the growth of plants. (See GASES, THEIR USE TO VEGE-

ration.) The composition of the atmosphere is always the same, although it has been analyzed when obtained from the most elevated mountains, the lowest marshes, from crowded cities, and the surface of the ocean, in all winds, and in all states of the barometer.

The following table exhibits the atmospheric mean temperatures in various parts of the United States and Territories, not only for the whole year, but for each month. It is abridged from Dr. Forry's Treatise upon the Climatology of the United States. The mean temperatures of some other celebrated places in the old world, are subjoined for the purpose of comparison.

The mean temperatures of the various military posts, are the results of 90 observations for each month, and 1095 for each year. The rule followed for computing the mean, was that adopted by the regents of the University of New York, viz.:—Take the lowest morning temperature, the highest afternoon temperature, and the temperature an hour after sunset. The mean of these observations for the day is

found, by adding together the first, twice the second and third, and the first of the next day, and dividing the same by six. To most common observers this will appear rather an intricate mode of attaining an object which is so conveniently, and, in general, so satisfactorily accomplished by the very simple process of dividing the sum of the highest and lowest observations during the day. Strictly speaking, the mean temperature of a day is equal to the sum of the temperature observed by the thermometer every hour or every minute, divided by the number of hours or minutes in the day. The hourly changes of atmospheric temperature have actually been observed for a continued year in some instances, among which we may mention that at the Arsenal at Frankford, near Philadelphia, in the year 1835—6, conducted under the superintendence of Capt. Mordecai, of the United States army. The results of these hourly observations are published in the 19th volume of the Journal of the Franklin Institute, New Series.

Table with columns: PLACES OF OBSERVATION, Latitude, Longitude, No. of years of Observation, Mean Annual Temp., and MEAN TEMPERATURE OF EACH MONTH (Jan-Dec). Includes entries for various US locations and foreign climates like Edinburgh, London, Paris, etc.

For further information relative to weather, and atmospheric conditions in general, see BAROMETER, CLIMATE, TEMPERATURE, &c.

ATROPHY. In farriery, a morbid wasting and emaciation, attended with a great loss of strength in animals.

AUGER, BORING. An implement for boring into the soil. An auger of the above kind, when made of a large size, and with different pieces to fix on to each other, may be very usefully applied to try the nature of the under soil, the discovering springs, and drawing off

water from lands, &c. In order to accomplish the first purpose, three augers will be necessary; the first of them about three feet long, the second six, and the third ten. Their diameters should be near an inch, and their bits large, and capable of bringing up part of the soil they pierce. An iron handle should be fixed crossways to wring it into the earth, from whence the instrument must be drawn up as often as it has pierced a new depth of about six inches, in order to cleanse the bit, and examine the soil.

AUGER, DRAINING. An instrument employed for the purpose of boring into the bottoms of drains or other places, in order to discover and let off water. It is nearly similar to that made use of in searching for coal or other subterraneous minerals. The auger, shell, or wimble, as it is variously called, for excavating the earth or strata through which it passes, is generally from two and a half to three and a half inches in diameter; the hollow part of it one foot four inches in length, and constructed nearly in the shape of the wimble used by carpenters, only the sides of the shell come closer to one another. The rods are made in separate pieces of four feet long each, that screw into one another to any assignable length, one after another as the depth of the hole requires. The size above the auger is about an inch square, unless at the joints, where, for the sake of strength, they are a quarter of an inch more.

There is also a chisel and punch, adapted for screwing on, in going through hard gravel, or other metallic substances, to accelerate the passage of the auger, which could not otherwise perforate such hard bodies. The punch is often used, when the auger is not applied, to prick or open the sand or gravel, and give a more easy issue to the water. The chisel is an inch and a half or two inches broad at the point, and made very sharp for cutting stone; and the punch an inch square, like the other part of the rods, with the point sharpened also.

As it is remarked by Johnstone, in his account of Elkington's mode of draining, to judge when to make use of the borer is a difficult part of the business of draining. Many who have not seen it made use of in draining, have been led into a mistaken notion, both as to the manner of using it and the purpose for which it is applied. They think, that if by boring indiscriminately through the ground to be drained, water is found near enough the surface to be reached by the depth of the drain, the proper direction for it is along these holes where water has been found; and thus make it the first implement that is used. The contrary, however, in practice, is the case, and the auger is never used till after the drain is cut; and then for the purpose of perforating any retentive or impervious stratum, lying between the bottom of the drain and the reservoir or strata containing the spring. Thus it greatly lessens the trouble and expense that would otherwise be requisite in cutting the trench to that depth to which, in many instances, the level of the outlet will not admit. The manner of using it is simply thus:—in working it, two, or rather three men, are ne-

cessary. Two stand above, on each side of the drain, who turn it round by means of the wooden handles, and when the auger is full they draw it out; and the man in the bottom of the trench clears out the earth, assists in pulling it out, and directing it into the hole, and who can also assist in turning with the iron handle or key when the depth and length of rods require additional force to perform the operation. The workmen should be cautious in boring not to go deeper at a time, without drawing, than the exact length of the shell, otherwise the earth, clay, or sand, through which it is boring, after the shell is full, makes it very difficult to pull out. For this purpose the exact length of the shell should be regularly marked on the rods, from the bottom upwards. Two flat boards, with a hole cut into the side of one of them, and laid alongside of one another over the drain, in the time of boring, are very useful for directing the rods in going down perpendicularly, for keeping them steady in boring, and for the men standing on when performing the operation.

AVENA. A genus of grasses; the oat-grass. Some of the species may be cultivated to advantage in suitable situations, intermixed with a due proportion of other grasses.

Avena flavescens. Golden oat, or yellow oat-grass. This is one of those grasses which never thrives when cultivated simply by itself: it requires to be combined with other grasses to secure its continuance in the soil, and to obtain its produce in perfection. It thrives best in England when combined with the *Hordeum pratense* (meadow barley), *Cynosurus cristatus* (crested dog's-tail), and *Anthoxantum odoratum* (sweet-scented vernal-grass). It affects most a calcareous soil, and that which is dry. It grows naturally, however, in almost every kind of meadow: it is always present in the richest natural pastures in England where its produce is not, however, very great, nor its nutritive qualities considerable. The nutritive matter it affords from its leaves, (the properties of which are of more importance to be known than those of the culms, for a permanent pasture grass,) contains proportionally more bitter extractive than what is contained in the nutritive matters of the grasses with which it is more generally combined in natural pastures, and which have just now been mentioned. This latter circumstance is the chief claim it has to a place in the composition of the produce of rich pasture land; but more particularly, if the land be elevated, and without good shelter, this grass becomes more valuable, as it thrives better under such circumstances than most other grasses, and sheep

Description of Grass.	Soil.	Green Produce	Dry Produce	Produce per Acre

eat it as readily as they do most others. The seed is very small and light; but it vegetates freely if sown in the autumn, or not too early in the spring. I have sown the seeds of this grass in almost every month of the year, and after making due allowance for the state of the weather, the third week in May, and the first week of August to September, were evidently the best. It flowers in England in the first, and often in the second week of July, and ripens the seed in the beginning of August. The value of the grass, at the time of flowering, is to that at the time the seed is ripe, as 5 to 3.

The value of the grass, at the time of flowering, exceeds that of the latter-math, as 3 to 1; and the value of the grass at the time the seed is ripe is to that of the latter-math, as 9 to 5.

Avena pratensis. Meadow oat-grass. This species of oat-grass is much less common than the *Avena pubescens*, or *Avena flavescens*. It is found more frequent on chalky than on any other kind of soils: I have also found it in moist meadows as well as on dry heaths. This property of thriving on soils of such opposite natures is not common to the different species of grass. When this grass was planted in an irrigated meadow, the produce did not appear to exceed that which it afforded on a dry elevated soil, though it appeared more healthy, by the superior green colour of the foliage; and it thus appears to thrive under irrigation. The produce and nutritive powers, however, seem to be inferior to many other species of the secondary grasses. The produce or value of the yellow oat is superior to that of the meadow oat in the proportion nearly of 7 to 3. The downy oat-grass is also superior to the meadow oat-grass in the quantity of nutritive matter it affords from the crops of one season, in the proportion nearly of 3 to 2. From these facts and observations it cannot justly be recommended for cultivation in preference to either of the two species with which it has now been compared. Its nutritive matter contains a less proportion of bitter extractive and saline matters than any other of the oat-grasses that have been submitted to experiment. It flowers in July, and the seed is ripe in August.

Avena pubescens. Downy oat-grass. [See Plate 6, b.] This grass has properties which recommend it to the notice of the agriculturist, being hardy, and a small impoverisher of the soil; the reproductive power is also considerable, though the foliage does not attain to a great length if left growing. Like the *Poa pratensis*, it seldom or never sends forth any flowering culms, after the first are cropped, which is a property of some value for the purpose of permanent pasture, or dry soils, which are sooner impoverished by the growth of plants than those that are moist. Among the secondary grasses, therefore, I hardly know one whose habits promise better for the purpose now spoken of. The nutritive matter it affords contains a greater proportion of the bitter extractive principle than the nutritive matter of those grasses that affect a similar soil, which lessens its merits in those respects and must prevent its being employed in any considerable quantity as a constituent of a

mixture of grasses for laying down such soils to grass. In one part of Woburn Park, where the soil is light and silicious, the downy oat grows in considerable abundance. The downy hairs which cover the surface of the leaves of this grass when growing on poor, dry, or chalky soils, almost disappear when cultivated on richer soils. The crop at the time of flowering is superior to that at the time the seed is ripe, in the proportion nearly of 5 to 3. The grass of the latter-math, and that at the time the seed is ripe, are of equal proportional value. It flowers in the second or third week of June, and the seed is ripe about the beginning or in the middle of July.

[*Avena elatior*. See ANDES GRASS.

Avena sativa. Cultivated oats.

Avena sterilis. Animated oats, grown in gardens as a curiosity.]

AVENS, COMMON, or HERB BENNET (*Geum urbanum*). An indigenous perennial plant, which grows plentifully in woods and about shady dry hedges, producing small bright yellow flowers from May till August. The stalks of this useful plant attain two feet high, they are erect, round, finely, hairy branched at the upper part, bearing several flowers. The root consists of a root-stock and many stout brown fibres, which are astringent, and in some degree aromatic in spring. They are said to impart an agreeable clove-like flavour when infused in beer or wine. In medicine, the powdered root of the common avens has been employed with good effect in conjunction with Peruvian bark, or quinine, in cases of ague and intermittent fever, and it is also valuable in long-standing cases of diarrhœa, and in the last stage of dysentery. The dose is from thirty to sixty grains. Sheep are extremely fond of its herbage, which may likewise, when young, be used for culinary purposes, and especially in the form of salad. It is stated (*Trans. of Swed. Acad.*) that if a portion of the dried root be placed in a bag and hung in a cask of beer, it will prevent the beer from turning sour. There is a variety of this plant called the great-flowered avens. (*Eng. Flora*, vol. ii. p. 429; *Willich's Dom. Ency.*)

AVENS, WATER. A variety of the before-named plant, which is common in moist meadows and woods, especially in mountainous countries, and is not rare in the north of England, Scotland, Wales, nor even in Norfolk. It has drooping flowers, which distinguish it from the common avens. It is readily produced by transplanting the wild roots into a dry gravelly soil, by which the flowers become red, as well as double and proliferous, with many strange changes of leaves into petals, and the contrary. (*Smith's Eng. Flora.*)

AVENUE (Fr.). An alley or walk planted on each side with trees. These kinds of walks were formerly much more the fashion than they are at present. When they are to be made, the common elm answers very well for the purpose in most grounds, except such as are very wet and shallow, and is preferred to most other trees, because it bears cutting, heading, or lopping in any manner. The rough Dutch elm is approved by some, because of its quick growth; and it is a tree that will ne-

only bear removing very well, but that is green in the spring almost as soon as any plant whatever, and continues so equally long. It makes an incomparable hedge, and is preferable to all other trees for lofty espaliers. The lime is very useful on account of its regular growth and fine shade; and the horse-chestnut is proper for such places as are not too much exposed to rough winds. The common chestnut does very well in a good soil, or on warm gravels, as it rises to a considerable height when planted somewhat close; but, when it stands single, it is rather inclined to spread than grow tall. The beech naturally grows well with us in its wild state, but it is less to be chosen for avenues than others, because it does not bear transplanting well. The abele may also be employed for this use, as it is adapted to almost any soil, and is the quickest grower of any forest tree. It seldom fails in transplanting, and succeeds very well in wet soils, in which the others are apt to suffer. The oak is but seldom used for avenues, because of its slow growth.

The old method of planting avenues was by regular rows of trees, a practice which has been adhered to till lately; but now, when they are used, a much more ornamental way of planting them is adopted, which is by setting the trees in clumps or platoons, making the opening much wider than before, and placing the clumps of trees from one to three hundred feet distant from each other. In these clumps there should always be planted either seven or nine trees; but it must be observed that this method is only proper to be practiced where the avenue is of considerable length, as in short walks such clumps will not appear so sightly as single rows of trees. The avenues made by clumps are the most suitable for large parks. The trees in the clumps in such should be planted thirty feet asunder; and a trench thrown up round each clump to prevent the deer from coming to the trees and barking them.

AVERAGES (Fr. *aver*; Lat. *averagium*). In the corn trade, is the average amount of the prices at which the several kinds of corn are sold in the chief corn markets of England, as ascertained by the returns of certain inspectors, according to the act of the 9 G. 4, c. 60. (See CORN LAWS.)

AVERDUPOIS, or **AVOIRDUPOIS WEIGHT** (*Avoir du poids*, Fr., Dr. Johnson says, but he should have added, *averia ponderis*, Lat., literally goods of weight, goods sold by weight; *aver* in old French, and *avoir* in modern, signifying goods, like the low Lat. *averium*, *averum*, *avere*). That kind of weight commonly made use of for weighing most kinds of large and coarse goods, as cheese, butter, salt, hops, flesh, wool, &c. According to it, sixteen drachms make an ounce, sixteen ounces one pound, one hundred and twelve pounds one hundred weight, and twenty hundred weight one ton. It is most commonly written *avoirdupois*.

AVIARY (Lat. *avis*, a bird). A place set apart for the feeding and propagating birds.

AWNS (Goth. *ahana*; Sw. *agri*). The needle-like bristles which form the beards of

wheat, barley, and other grasses. The word is in some parts of England pronounced *ails* and *iles*.

AXIS (Lat., *axel*, Sw.), or axle-tree. The strong piece of wood or iron which supports the weight of wagons, carts, carriages, &c., and round the extremities of which the wheels turn.

AZALEA. American honey-suckle; the white-flowered (Lat. *Azalea viscosa*). A hardy shrub growing three feet high, and blowing its white flowers in June and July. *Azalea nudiflora*, also a native of North America, grows three feet high, with red flowers, blooming in May and June; and *Azalea pontica*, a native of the neighbourhood of the Black Sea, blooming yellow flowers in May: it grows three feet high. These hardy shrubs love shade and a moist soil. Propagate by layers and suckers: the seed does not ripen well in this climate. Do not prune, only cut out the dead wood. Remove the young well-rooted plants with a good ball of earth in the autumn or early in spring.

AZOREAN FENNEL (*Anethum azoricum*, or *Finocchio*; from *ανθηον*, on account of its running up straight). A plant kept in kitchen gardens; it is not in much esteem here, its peculiar flavour being agreeable to few palates. In Italy, and some other countries, it is served with a dressing like salads.

AZOTE is as commonly known by the name of nitrogen. The name of azote (derived from the Greek α , from, and $\zeta\epsilon$, life), was given to it by the French chemists, from animals being unable to breathe it [in a state of purity.] This gas, which constitutes 79.16 parts per cent. of the air we breathe, was discovered in 1772 by Dr. Rutherford. Before his time there had been much confusion with regard to the composition of the atmospheric and other gases; they were chiefly regarded by the old chemists as being all of the same kind, but mixed with various unknown substances. When all the oxygen is absorbed from a confined portion of atmospheric air, the remainder is nearly pure azote; it is known only in the state of gas. Azotic gas is invisible and elastic, and has no smell; its specific gravity is 0.969. Animals cannot breathe it [in a pure state:] when they are placed in a jar of it, they die as rapidly as if immersed in water; neither will it support combustion. It unites with oxygen in various proportions: thus,—

Parts.	Parts.	
1.75	azote and 2	oxygen forms nitrous gas.
1.75	— 5	— nitric acid, or aquafortis.
1.75	— 4.178	— nitrous acid.

Azote, or nitrogen, abounds in animal substances, for it forms 16.998 per cent. of gelatine; 15.705 per cent. of albumen (white of egg), &c., and these are commonly present in all animal substances. Azote unites also with hydrogen gas, and forms the volatile alkali ammonia, which is composed of—

Azote	-	-	-	-	-	26 parts
Hydrogen	-	-	-	-	-	74

Now, as both these substances exist in animal matters, when such substances putrefy, or are subjected to the destructive distillation,

they readily unite and form the volatile alkali ammonia.

Azote exists also in gluten; and wherever this substance is present in vegetable matter, there, in consequence, azote is to be found, but otherwise it does not often enter into the composition of vegetable substances. And yet it is worthy of remark, that although azote cannot be regarded as a direct food of plants, yet most of those substances which contain it are exceedingly grateful to them, such as ammonia, saltpetre, animal matter, &c.; and again, vegetables certainly emit, and probably inhale, this gas. Thus some plants of *Vinca minor* being made to vegetate in a confined portion of air for six days, and the composition of the air being ascertained by M. Saussure (*Rech. Chim.* p. 40), the following were the results in cubic inches:—

	Composition of atmosphere,			
	when put in.		when taken out.	
Azote	-	211.92	-	218.95
Oxygen	-	56.33	-	71.05
Carbonic acid	-	21.75	-	0.00
		290.		290.

The plants, therefore, had evidently increased the proportion of azote and oxygen, but had entirely exhausted the air of its carbonic acid gas.

Similar experiments made with the *Mentha aquatica*, *Cactus opuntia*, *Lythrum salicaria*, and the *Pinus genevensis*, afforded similar results.

Azote, therefore, evidently fulfils a more considerable office in vegetable economy than we are yet exactly aware of, and it is more than probable that considerable discoveries are yet to be made in the investigation of its uses to vegetable life. See GASES, their use to vegetation. (*Davy's Chem. Phil.* p. 255; *Thomson's Chem.*)

[The chief element contained in vegetable substances resorted to for the support of animals, is azote or nitrogen. On the other hand we see, in the vegetable kingdom, plants appropriating carbon as the prime element of their structure. The quantity of food which animals take for their nourishment diminishes or increases in the same proportion as it contains more or less of the substances yielding nitrogen. A horse may be kept alive by feeding it with potatoes, which contain a very small quantity of nitrogen; but life thus supported is a gradual starvation; the animal increases neither in size nor strength, and sinks under every exertion. The quantity of rice which an East Indian eats astonishes the European or American; but the fact that rice contains less nitrogen than any other grain, at once explains the circumstance.

"We cannot suppose," says Liebig, "that a plant would attain maturity, even in the richest vegetable mould, without the presence of matter containing nitrogen; since we know that nitrogen exists in every part of the vegetable structure. The first and most important question to be solved, therefore, is: How and in what form does nature furnish nitrogen to vegetable albumen, and gluten, to fruits and seeds?"

"This question is susceptible of a very simple solution.

"Plants, as we know, grow perfectly well in pure charcoal, if supplied at the same time with rain-water. Rain-water can contain nitrogen only in two forms, either as dissolved atmospheric air, or as ammonia. Now, the nitrogen of the air cannot be made to enter into combination with any element except oxygen, even by employment of the most powerful chemical means. We have not the slightest reason for believing that the nitrogen of the atmosphere takes part in the processes of assimilation of plants and animals; on the contrary, we know that many plants emit the nitrogen, which is absorbed by their roots, either in the gaseous form, or in solution in water. But there are, on the other hand, numerous facts, showing that the formation in plants of substances containing nitrogen, such as gluten, takes place in proportion to the quantity of this element which is conveyed to their roots in the state of ammonia, derived from the putrefaction of animal matter.

"Ammonia is a compound gas, consisting of one volume of nitrogen and three volumes of hydrogen. It is produced during the decomposition of many animal substances. It is given off when sal-ammoniac and lime are rubbed together. It was formerly called volatile alkali.

"Ammonia, too, is capable of undergoing such a multitude of transformations, when in contact with other bodies, that in this respect it is not inferior to water, which possesses the same property in an eminent degree. It possesses properties which we do not find in any other compound of nitrogen; when pure, it is extremely soluble in water; it forms soluble compounds with all the acids; and when in contact with certain other substances, it completely resigns its character as an alkali, and is capable of assuming the most various and opposite forms."

With regard to the sources from which vegetables draw those supplies of nitrogen, so essential to their growth and development, Liebig makes the following observations:—

"Let us picture to ourselves the condition of a well-cultured farm, so large as to be independent of assistance from other quarters. On this extent of land there is a certain quantity of nitrogen contained both in the corn and fruit which it produces, and in the men and animals which feed upon them, and also in their excrements. We shall suppose this quantity to be known. The land is cultivated without the importation of any foreign substance containing nitrogen. Now, the products of this farm must be exchanged every year for money, and other necessaries of life, for bodies therefore which contain no nitrogen. A certain proportion of nitrogen is exported with corn and cattle; and this exportation takes place every year, without the smallest compensation; yet after a given number of years, the quantity of nitrogen will be found to have increased. Whence, we may ask, comes this increase of nitrogen? The nitrogen in the excrements cannot reproduce itself, and the

earth cannot yield it. Plants, and consequently animals, must therefore derive their nitrogen from the atmosphere." (*Org. Chem.*)

B.

BACCIFEROUS (from *bacca*, a berry, and *fero*, to bear). A term applied to trees bearing berries.

BACK, the spine. The back of a horse should be straight, in order that it may be strong: when it is hollow, or what is termed *saddle-backed*, the animal is generally weak.

Back sore. A complaint which is very common to young horses when they first travel. To prevent it, their backs should be cooled every time they are baited, and now and then washed with warm water, and wiped dry with a linen cloth. The best cure for a sore back is a lotion of 1 oz. of Goulard's extract (sugar of lead and vinegar), 1 oz. of turpentine, 1 oz. of spirit of wine, and 1 pint of vinegar.

Back sinews, sprain of the. This is often occasioned by the horse being overweighted, and then ridden far and fast, especially if his pasterns are long; but it may occur from a false step, or from the heels of the shoes being too much lowered. Sprain of the back sinews is detected by swelling and heat at the back of the lower part of the leg; puffiness along the course of the sinews; extreme tenderness, so far as the swelling and heat extend; and very great lameness.

The first object is to abate the inflammation, and this should be attempted by bleeding from the plate vein; by means of which blood is drained from the inflamed part. Next, local applications should be made to the back of the leg, in the form of fomentations of water sufficiently hot and frequently repeated. At the same time, as much strain as possible should be taken from the sinew, by putting a high calkin on the heel of the shoe.

BACON. Probably from *baken*, that is, dried flesh. Dr. Johnson says, and Mr. Horne Tooke contends, that it is evidently the past participle of the Saxon *bacan*, to bake or dry by heat. (*Div. of Pur.* vol. ii. p. 71.) I may, however, refer perhaps as strongly to the old French *bacon*, which means dried flesh and pork. The Welsh also have *bacwn*. The flesh of the hog after it has been salted and dried, and it is either smoked or kept without smoking, when it is termed green bacon. (*Todd.*)

Such hogs as have been kept till they are full grown, and have then attained to a large size, are for the most part converted to the purpose of bacon. The seasons for killing hogs for bacon are between October and March, but it of course varies according to custom and circumstances in peculiar districts. The process of curing bacon is so well known throughout the country, that it is scarcely necessary to add any thing on the subject; but the following practical hints may not be without their utility. In order to have good bacon, the hair should be *swealed* off, not scalded, the flesh will be more solid and firm. The best method of doing this is to cover the hog thinly with straw, and to set light to it in the direction of the wind. As the straw is burnt off, it

should be renewed, taking care, however, not to burn or parch the skin. After both sides have been treated in this way, the hog is to be scraped quite clean, but water must not be used. After the hog has been properly cut up, the inside, or flesh-side of each flitch is to be well rubbed with salt, and placed above each other in a tray, which should have a gutter round its edge to drain off the brine. Once in four or five days the salt should be changed, and the flitches frequently moved, putting the bottom one at top, and then again at the bottom. Some persons, in curing bacon, add for each hog half a pound of bay salt, and a quarter of a pound of saltpetre, and one pound of very coarse sugar or treacle. Very excellent bacon may, however, be made with common salt alone, provided it be well rubbed in, and changed sufficiently often. Six weeks, in moderate weather, will be time sufficient for the curing of a hog of twelve score. Smoking the bacon is much better than merely drying it. The flitches should, in the first place, be rubbed over with bran or fine saw-dust (not deal), and then hung up in a chimney out of the rain, and not near enough to the fire to melt. The smoke must be from wood, stubble, or litter. If the fire is tolerably constant and good, a month's smoking will be sufficient. The flitches are afterward frequently preserved in clear, dry wood ashes, or very dry sand.

The counties of England most celebrated for bacon, are York, Hants, Berks, and Wilts. Ireland produces great quantities, but it is neither so clean fed, nor so well cured as the English, and is much lower priced. Of the Scotch counties, Dumfries, Wigtown, and Kirkcudbright, are celebrated for the excellence of their bacon and hams, of which they now export large quantities, principally to the Liverpool and London markets. The imports of bacon and hams from Ireland have increased rapidly of late years. The average quantity imported during the three years ending the 25th of March, 1800, only amounted to 41,948 cwt.; whereas during the three years ending with 1820, the average imports amounted to 204,380 cwt.; and during the three years ending with 1825, they had increased to 338,218 cwt.

In 1825 the trade between Ireland and Great Britain was placed on the footing of a coasting trade; and bacon and hams are imported and exported without any specific entry at the Custom-house. We believe the imports of bacon into Great Britain from Ireland amounts, at present, to little less than 500,000 cwt. a year. The quantity of bacon and hams exported from Ireland to foreign countries is inconsiderable, not exceeding 1500 or 2000 cwt. a year. The duty on bacon and hams being 8s. the cwt. is in effect prohibitory. See PROVISIONS TRADE.

BAIT (Sax. *baetan*, German, *baitzen*). A feed of oats, or any other material given to an animal employed in travelling or labour. These should always be proportioned to the condition of the animal, and the nature of his labour. It also signifies any thing applied with the view of catching an animal.

BAKING. The application of heat in the preparation of bread. See BREAD.

BAKING OF LAND. A term applied to such kinds of land as are liable, from the large proportions of clayey or other matter which they contain, to become hard and crusty on the surface. In order to prevent this, the best practice is to lessen the tenacity of such soils by the application of substances capable of rendering them more open and friable, as lime, and other calcareous materials, rich earthy composts, sand, &c.

BALL. Whatever was round was called by the ancients either *bal*, or *bel*, and likewise *bol* and *bül*. In farriery, a well-known form of medicine, for horses or other animals, which may be passed at once into the stomach. They should be made of a long oval shape, and about the size of a small egg, being best conveyed over the root of the tongue by the hand. This method of administering medicines is preferable in most cases to that of drenches. I subjoin the recipes for a few of those balls most commonly used by the farmer.

Mild Physic Ball.

Barbadoes aloes	-	-	-	6 drachms.
Powdered ginger	-	-	-	2
Castile soap	-	-	-	2
Oil of cloves	-	-	-	20 drops.
Syrup of buckthorn sufficient to form a ball.				

Strong Physic Ball.

Barbadoes aloes	-	-	-	8 drachms.
Ginger, powdered	-	-	-	2
Castile soap	-	-	-	2
Oil of cloves	-	-	-	20 drops.
Syrup of buckthorn sufficient to form a ball.				

Calomel Ball for a Riding Horse.

Calomel	-	-	-	1 drachm.
Aloes, powdered	-	-	-	6
Ginger, powdered	-	-	-	2
Castile soap	-	-	-	2
Oil of cloves	-	-	-	20 drops.
Syrup of buckthorn sufficient to make into a ball.				

Calomel Ball for a Cart Horse.

Aloes, powdered	-	-	-	8 drachms.
Otherwise same as the last.				

Diuretic Ball.

Castile soap	-	-	-	4 ounces.
Nitre, powdered	-	-	-	2
Rosin, powdered	-	-	-	2
Oil of juniper	-	-	-	1/2
Aniseed powder and treacle sufficient to make into eight balls.				

Cordial Ball.

Cummin seed, powdered	-	-	-	4 ounces.
Aniseed, powdered	-	-	-	4
Caraway seed, powdered	-	-	-	4
Liquorice powder	-	-	-	4
Ginger, powdered	-	-	-	2
Honey sufficient to make into balls the size of a hen's egg.				

BALM, or BAUM (*Melissa officinalis*. From Gr. *μυσα*, honey, on account of the bee being supposed to collect it abundantly from their flowers). Balm is used both as a medicinal and culinary herb. The leaves are employed green, or dried.

The soil best suited to its growth is any poor friable one, but rather inclining to clayey than silicious. Manure is never required. An eastern aspect is best for it. It is propagated by offsets of the roots, and by slips of the young shoots. The first mode may be prac-

tised any time during the spring and autumn, but the latter only during May or June. If offsets are employed, they may be planted at once where they are to remain, at ten or twelve inches; but if by slips, they must be inserted in a shady border, to be thence removed, in September or October, to where they are to remain. At every removal, water must be given, if dry weather, and until they are established. During the summer they require only to be kept clear of weeds. In October the old beds require to be dressed, their decayed leaves and stalks cleared away, and the soil loosened by the hoe or slight digging.

Old beds may be gathered from in July, for drying, but their green leaves, from March to September; and those planted in the spring will even afford a gathering in the autumn of the same year. For drying, the stalks are cut with their full clothing of leaves to the very bottom, and the process completed gradually in the shade. (*G. W. Johnson's Kitchen Garden.*)

This very common and well-known plant in our kitchen gardens is fragrant in smell, and its root creeps and spreads rapidly and abundantly. It flowers in July, and is best taken as an infusion when fresh, as it loses considerable power when dried. Its medicinal qualities are derived principally from the proportion of volatile oil, resin, and bitter extractive, which it contains. It is occasionally used in consequence of its moderately stimulant powers, in conjunction with more potent drugs, to produce profuse perspiration. Mixed with honey and vinegar, it forms a good gargle for an inflamed sore throat.

BALSAM (*Impatiens Balsamina*). This favourite flower is a native of the East Indies and Japan, where the natives, according to Thunberg, use the juice prepared with alum for dyeing their nails red. It is a tender annual, rising from one to two feet high, with a succulent branchy stem, serrated leaves, and various coloured flowers. It blows from July to October, and its flowers are single and double, red, pink, white, or variegated. It loves a good soil, and shelter from a hot sun. It blooms very handsomely in a window. Sow the seed early in March in a hot bed. Put the plants singly, and accustom them by degrees to the open air. Place them in larger pots, or put them out in the garden in May. They will require no watering, after being well rooted. Stir the earth round each plant frequently, and do it gently, with a small trowel.

The varieties are infinite, but not so marked or permanent as to have acquired names. The seed from one plant will hardly produce two alike.

This plant, which has been introduced into almost every flower-garden in the country, is commonly called *Lady's Slipper*. Several species of the genus are found in the United States, and have been described by Pursh, Nuttall, Darlington, and other botanists. One of these, the *Pale Impatiens*, known by the popular names of Yellow Balsam, Snap-weed, and Touch-me-not, is frequent in Pennsylvania, and other states, in moist, shaded grounds and along streams, where its gamboge yellow

flowers appear from July to September. The most common species, however, is the *Fulvous* or *Towny* Impatiens, or Touch-me-not, the flowers of which are of a deep orange colour, with numerous reddish brown spots. The tender and succulent stems of this plant afford a domestic application to inflamed tumours, being bruised in the form of a poultice. It has sometimes been used for dying salmon-red. (*Nuttall's Genera, Darlington's Flora Cestrica.*) The popular name of this plant must not lead to its being confounded with another, also called Lady's Slipper, the *Stemless Cypripedium*, a very different plant.

BALSAM TREE (*Tacamahacca*). This tree possesses considerable medicinal virtues. It is known among us as the Tacamahac tree, from its similitude to the real tree of that name, which is a native of the East and of America. The leaves of our balsam tree are long, of a dusky green on the outside, and brown underneath. The buds of the tree in spring are very fragrant, and a sticky substance surrounds each bud, which adheres to the fingers on touching them. (See *TACAMAHACCA*.)

BAN-DOG. A corruption of band-dog, a large kind of fierce dog, which was formerly kept chained up as a watch-dog.

BANDS. The cords by means of which sheaves and trusses are tied. They are formed of twisted straw or hay.

Bands, where the straw is tender, should be made in the morning, that they may not crack; for the straw will not twist so well after the sun is up. The turning of three or four of the stubble or bottom ends of the straw to the ears of the band sometimes tend greatly to add to their strength and toughness.

The bands for the sheaves should not be spread out, except in fair weather, because they will grow sooner than any other part of the corn if rain should come; for they cannot dry, on account of their lying undermost. But though the bands may be made while the morning dew is upon them, the sheaves ought never to be bound up wet; for, if they are, they will grow mouldy.

BANE. The disease in sheep generally termed the rot.

BANE BERRIES (*Actæa*), and **BLACK BANE BERRIES** (*Herb Christopher*). Perennial herbs, natives of cold countries, with compound or lobed cut leaves and clustered white flowers. The berries of the former are black, red, or white, of the latter, purplish, black, juicy, the size of currants, and have fetid, nauseous, and dangerous qualities. In England these herbs are found sometimes in bushy, mountainous, limestone situations.—(*Smith's Engl. Flora.*)

Several species of *Actæa*, or Bane-berry are found in the United States. Among those mentioned by Dr. Darlington, as met with in Chester county, Pennsylvania, are the *Racemose Actæa*, commonly called *Black Snakeroot*, a perennial, common in rich woodlands, in which the white flowers rising above most other surrounding plants, are very conspicuous in the month of June. The plant has an oppressive, disagreeable odour when bruised. The root is somewhat mucilaginous and as-

tringent; and is a very popular medicine for man and beast. For the former, it is used in infusion or decoction, chiefly as a remedy in diseases of the breast. Many persons consider it almost a panacea for a sick cow. Its virtues, however, are probably overrated. Another species is the *White Actæa*, or *White Cohosh*, found in rocky woodlands, flowering in May, and not so common as the former. Its berries also differ from those of the *Black Snakeroot*, being oval, about a fourth of an inch in diameter, milk white, or often tinged with purple when fully ripe. (*Flor. Cestrica.*)

BANE-WORT. See **DEADLY NIGHTSHADE.**

BANGLE-EARS. An imperfection in the ears of horses.

BANKS, of rivers and marshes, &c., (*banc*, Sax.). In agriculture, are heaps or mounds of earth piled up to keep the water of rivers, lakes, or the sea, from overflowing the grounds which are situated contiguous to them on the inside. (See **EMBANKMENTS**.)

The common law of England is very severe against those who wantonly or maliciously injure or destroy embankments.

The 7 & 8 G. 4, c. 30, s. 12, enacts that if any person shall unlawfully and maliciously break down or cut down any sea-bank, or seawall; or the bank or wall of any river, canal, or marsh, whereby any lands shall be overflowed or damaged, or shall be in danger of being so, or shall unlawfully and maliciously throw down, level, or otherwise destroy any lock, sluice, or flood-gate, or other work on any navigable river or canal, every such offender shall be guilty of felony; and, being convicted thereof, shall be liable, at the discretion of the court, to be transported beyond the seas for life, or for any term not less than seven years, or to be imprisoned for any term not exceeding four years; and if a male, to be once, twice, or thrice publicly or privately whipped (if the court shall so think fit), in addition to such imprisonment.

For protecting embankments exposed to water washing against them, a thick coat of the joint grass, or, as it is likewise called, the Bermuda grass, (*Cynodon dactylon*, Pl. 7, k,) is one of the best means that can be adopted. It is of a remarkably creeping nature, and grows very luxuriantly where no other grass will live, as on the sea-coast, and on poor loose soils. It is taken advantage of by the rice planters of the Southern States, whose extensive embankments are much exposed to the washing of water against them, and which are greatly protected from injury by the dense mat of joint grass made to grow upon them. Its extirpation is extremely difficult where it has once got possession. Mr. Nuttall says there is only one species (the *C. dactylon*) common to Europe, North America, and the West India Islands. (*Nuttall's Genera.*)

BANNOCK. The Scotch name for a small loaf or cake.

BARB. A general name for horses imported from Barbary. The barb, one of the most celebrated of the African racers, is to be met with throughout Barbary, Morocco, Fez, Tripoli, and Bornou. It seldom exceeds fourteen hands and a half in height. The countenance

of the barb is usually indicative of its spirit, and the facial line, in direct contradiction to that of the Arabian, is often slightly rounded; the eyes are prominent; the ears, though frequently small and pointed, are occasionally rather long and drooping: the neck is of sufficient length; the crest is generally fine and not overlaid with mane; the shoulders are flat and oblique; the withers prominent, and the chest almost invariably deep; the back is usually straight; the carcass moderately rounded only; the croup long, and the tail placed rather high; the arms and thighs being commonly muscular and strongly marked; the knee and hock are broad and low placed; the back sinews singularly distinct and well-marked from the knee downwards; the pasterns rather long, and the feet firm, and but moderately open.

The barb requires more excitement to call out his powers than the Arabian; but when sufficiently stimulated, his qualities of speed and endurance render him a powerful antagonist, while the superior strength of his forehead enables him to carry the greater weight of the two. The Godolphin barb, which was imported from France into England, at the conclusion of the last century, about 25 years after the Darley Arabian, was one of those most worthy of note. The former appears to have rivalled the latter in the importance of his get. He was the sire of Lath, Cade, Abraham, Regulus, Bajazet, Tarquin, Dormouse, Sultan, Blank, Dismal, and many other horses of racing note; and without doubt, the English blood-breeds were more indebted to the Darley Arabian and the Godolphin barb than to all the other eastern horses which had previously entered the country. Among other barbs of some notoriety introduced in the 18th century, we may mention the Thoulouse, the Curwen Bay, Old Greyhound, St. Victor's, Tarran's Black, Hutton's Bay, Cole's Bay, and Compton's Barb. (*Blaine's Encyc. Rural Sports*, p. 243.)

BARBERRY, COMMON, or PIPPERIDGE BUSH (*Berberis vulgaris*). In England an indigenous thorny shrub, bearing bunches of pale yellow drooping flowers in May, which are succeeded by oblong scarlet berries, ripening in September. The branches are flexible, covered with alternate tufts of deciduous, egg-shaped, pinnated leaves, finely fringed on the edge. Sharp, three-cleft thorns rise at the base of each leaf-bud. The barberry likes any kind of soil, and makes good hedges. It may be propagated by seed, or by layers, which should remain two years before they are removed. The gross shoots, if the shrub stands singly, should be pruned away, and it will fruit better. The berries are gratefully acid, and the juice, when diluted with water, may be used as lemonade in fevers. The leaves, eaten in salad, are like sorrel. The fruit, made into conserve, is good. It is also excellent as a pickle and a preserve.

The common barberry bush is a native of England; and notwithstanding the high state of cultivation that kingdom has now arrived at, it is still to be found growing wild in many parts of the northern counties. Gerarde says in his time (1597), most of the hedges near

Colnbrook were nothing else but barberry-bushes. It is now very properly introduced into our gardens and shrubberies, being both ornamental and useful; but it should not be planted near the house or principal walks, on account of its offensive smell when in blossom. The flowers are small, but beautiful; and, on their first appearance, have a perfume similar to that of the cowslip, which changes to a putrid and most disagreeable scent, particularly towards the evening, and at the decay of the flowers. Barberries are of an agreeable, cooling, astringent taste, which creates appetite. The fruit and leaves give an agreeable acid to soup. The Egyptians were used to employ a diluted juice of the berries in ardent and pestilential fevers; but it is merely an agreeable acidulous diluent. The inner bark, with alum, dyes a bright yellow, and in some countries is used for colouring leather, dyeing silk and cotton, and staining wood for cabinet and other purposes. Cows, sheep, and goats are said to feed on the leaves: but horses and swine refuse them. A very singular circumstance has been stated respecting the barberry shrub: that grain sown near it becomes mildewed, and proves abortive, the ears being in general destitute of grain; and that this influence is sometimes extended to a distance of 300 or 400 yards across a field. This, if correct, is a just cause for banishing it from the hedge-rows of our arable fields, for which otherwise its thorny branches would have made a desirable fence.

I will cite a few instances which have been brought forward in proof of the injurious effects of this plant upon standing corn. Mr. Macro, a very respectable farmer at Barrow, in Suffolk, planted a barberry bush in his garden, on purpose to ascertain the disputed fact. He set wheat round it three succeeding years, and it was all so completely mildewed, that the best of the little grain it produced was only about the size of thin rice, and that without any flour. He adds, that some which he set on the opposite side of his garden on one of the years before mentioned, produced very good grain, although the straw was a little mildewed. From this observation, Mr. Phillips was induced to try the experiment by sowing clumps of canary seed in his shrubbery. Those which were planted immediately under the barberry-bush certainly produced no seed; but other plants of this grass yielded seed, although not at many yards' distance. The celebrated Duhamel and M. Boussonet, who have paid such particular attention to agriculture, assure us that there is no just reason for ascribing this baneful effect to the barberry-bush; and Mr. G. W. Johnson is of the same opinion. (See *MILDew.*) On the other hand, we have it affirmed to be most destructive and injurious to all kinds of crops of grain and pulse, as proved by various observations, experiments, and testimonies, made in Brandenburg, Hanover, Prussia, and Germany. (See *Com. Board of Agr.*, vol. vii. pp. 18—126; and the writer there says, towards the conclusion of his article, "To those still inclined to regard the barberry as innocent, notwithstanding all the above proofs to the contrary, I would

only make the request that they no longer urge their opinion on abstract and general grounds, until they have collected the result of impartial observation and careful experiment."

The Rev. Dr. Singer, in the *Trans. High. Soc.*, vol. vi. p. 310, in considering the barberry as the cause of rust or mildew on corn crops, says, when quoting the survey of Dumfriesshire, "On one farm alone, that of Kirkbank, the tenant lost about 100*l.* in his oat-crops yearly; and altogether the annual damage in the county was considerably above 1000*l.* The views of Sir Joseph Banks, and of some intelligent practical farmers, relative to the evil influence of the *Berberis vulgaris*, induced the late Admiral Sir William Johnstone Hope to give orders for the total extirpation of the barberry bushes which grew intermixed with thorns in his hedgerows; and since that was done, and for above twenty years, no such distemper has appeared in these fields. The same thing has been done in some parts of Ayrshire, and the like result has followed. These facts," adds Dr. Singer, "appear to indicate some connection between the occurrence of rust or mildew on growing corn and the neighbourhood of barberry bushes." Phillips inquires (*Pom. Brit.*), whether the blighting effects of this shrub may not in some degree be accounted for by its May-flowers alluring insects, which breed on the branches, and then feed their progeny on the nutritious juices of the surrounding blades of young corn?

BARILLA. See *SODA*.

BARING *Roots of Trees.* A practice formerly much adopted, but which later experience has shown to be highly injurious and hurtful to their growth.

BARK (Dan. *barck*; Dutch, *berck*; from the Teutonic *bergen*, to cover). The rind or covering of the woody parts of a tree. The bark of trees is composed of three distinct layers, of which the outermost is called the *epidermis*, the next the *parenchyma*, and the innermost, or that in contact with the wood, the *cortical layers*. The epidermis is a thin, transparent, tough membrane; when rubbed off, it is gradually reproduced, and in some trees it cracks and decays, and a fresh epidermis is formed, pushing outwards the old: hence the reason why so many aged trees have a rough surface. The parenchyma is tender, succulent, and of a dark green. The cortical layer, or *liber*, consists of thin membranes encircling each other, and these seem to increase with the age of the plant. The liber, or inner bark, is known by its whiteness, great flexibility, toughness, and durability: the fibres in its structure are ligneous tubes. It is the part of the stem through which the juices descend, and the organ in which the generative sap from whence all the other parts originate is received from the leaves. The bark in its interstices contains cells which are filled with juices of very varying qualities; some, like that of the oak, remarkable for their astringency; others, like the cinnamon, abounding with an essential oil: others, as the jesuits' bark, containing an alkali; some mucilaginous; many resinous. Several of these barks have been analysed by various chemists: they have found them to

consist chiefly of carbon, oxygen, and hydrogen, with various saline and earthy substances. (*Thom. Chem.* vol. iv. p. 231.)

M. Saussure (*Chem. Rec. Veg.*) found in 100 parts of the ashes of the barks of various trees the following substances:—

	Oak.	Hazel.	Poplar.	Mulberry.	Horn-bean.
Soluble salts - -	7.	12.5	6.	7.	4.5
Earthy phosphates	3.	5.5	5.3	8.5	4.5
Earthy carbonates	66.	54.	60.	45.	59
Silica - - -	1.5	0.25	4.	15.12	1.5
Metallic oxides -	2.	1.75	1.5	1.12	0.12

From this analysis the farmer will see that the earthy and saline ingredients of the bark of forest trees must be considerable fertilizers: it is only to the slowness with which refuse tanner's bark undergoes putrefaction that its neglect by the cultivator must be attributed. It might certainly, however, be mixed with farm-yard compost with very considerable advantage, as has been often done with saw-dust and peat, in the manner so well described by Mr. Dixon of Hathershaw (*Journ. of Roy. Eng. Agr. Soc.* vol. i. p. 135), see *FARM-YARD MANURE*; and in its half putrefied or even fresh state it produces on some grass lands very excellent effects as a top dressing; and in instances where carriage is an object, even its ashes would be found, from the quantity of earthy carbonates and phosphates which they contain, a very useful manure.

The different uses of barks in tanning and dyeing are numerous and important. The strength or fineness of their fibres is also of consequence: thus, woody fibres are often so tough as to form cordage, as exemplified in the bark of the lime, the willow, and the cocconut; the liber of some trees, as for example the lime and the paper mulberry, is manufactured into mats; and it is scarcely requisite to refer to hemp and flax for spinning and weaving. The bark of the papyrus, or flag of the Nile, was first used for paper; that of the mulberry is still employed in the cloth of Otahete; that of the powdered Swedish pines, as bread for the poor peasants of Scandinavia. In England, the bark of the oak is used for affording tannic acid in the manufacture of leather; but other barks, such as that of the Spanish chestnut and the larch, are also employed. The following table of Davy will show the relative value of different kinds of bark to the tanner: it gives the quantity of tannic acid afforded by 480 lbs. of different barks in that great chemist's own experiments (*Lect.* p. 83.)

Average from the entire bark of—	lbs.
Middle-sized oak, cut in spring - - -	29
cut in autumn - - -	21
Spanish chestnut - - -	21
Leicester willow (large size) - - -	33
Elm - - -	13
Common willow (large) - - -	11
Ash - - -	16
Beech - - -	10
Horse chestnut - - -	9
Sycamore - - -	11
Lombardy poplar - - -	15
Birch - - -	8
Hazel - - -	14
Blackthorn - - -	16
Coppice oak - - -	32
Larch, cut in autumn - - -	8
White interior cortical layers of oak bark -	79

The difference of seasons makes a considerable variation in the produce of tannic acid; it is the least in cold springs. The tannic acid most abounds when the buds are opening, and least in the winter; 4 or 5 lbs. of good oak bark of average quality are required to form 1 lb. of leather. The consumption of oak bark in Great Britain is about 40,000 tons, more than one half of which is imported from the Netherlands.

Cork is the outer bark of a species of oak, which grows abundantly in the south of Europe. The average quantity imported annually is about 44,551 cwts.

The quantity of *Quercitron* bark, which is the production of black oak (*Quercus nigra*), is 22,625 cwts.

The quantity of *Cinchona*, or *Peruvian* bark, is on an average about 300,000 lbs., but the consumption does not exceed 45,000 lbs.: the remainder is re-exported.

The bark of trees is best cleansed from the parasitical mosses with which it is wont to be infected, by being washed with lime-water or a solution of common salt in water (4 oz. to a gallon), applied by a plasterer's brush.

BARK-BEETLES, see **PINE-TREE BEETLE**, or **WEEVIL**.

BARK-BOUND. A disease common to some fruit and other trees, which is capable of being cured by making a slit through the bark, from the top of the tree to the bottom, in February or March; where the gaping is pretty considerable, fill it up with cow-dung, or other similar composition.

BARKING IRONS, are instruments for removing the bark of oak and other trees. They consist of a blade or knife for cutting the bark, while yet on the trunk, across at regular distances, and of chisels or spatulæ, of different lengths and breadths for separating the bark from the wood.

BARKING OF TREES. the operation of stripping off the bark or rind. It is common to perform the operation of oak-barking in the spring months, when the bark, by the rising of the sap, is easily separated from the wood. This renders it necessary to fell the trees in these months. The tool commonly made use of in most countries is made of bone or iron. If of the former, the thigh or shinbone of an ass is preferred, which is formed into a two-handed instrument for the stem and larger boughs, with a handle of wood fixed at the end. The edge being once given by the grinding-stone, or a rasp, it keeps itself sharp by wear.

In Europe, two descriptions of persons are usually employed in this business, the hagmen or *cutters*, and the *barkers*. The latter chiefly consists of women and children. The cutters should be provided with ripping-saws, widely set, with sharp, light hatchets, and with short-handled pruning-hooks. The barkers are provided with light, short-handled, ashén mallets, the head being about eight inches long, three inches diameter in the face, and the other end blunt, somewhat wedge-shaped; with sharp ashér wedges, somewhat spatula-shaped, and which may either be driven by the mallet, or, being formed with a kind of handle, may be pushed with the hand; and with a smooth-

skinned whin, or other land-stone. The cutters are divided into two parties; hatchet-men, who sever the stem, and hook-men, who prune it of small twigs, and cut it into convenient lengths. Small branches and twigs are held by one hand on the stone; the bark is then stripped off, and laid regularly aside, as in reaping of corn, till a bundle of convenient size be formed. The trunk and branches, as large as the leg, &c. are laid along the ground; the bark is started, at the thick end, by thrusting or driving in the wedge, which, being run along the whole length, rips it open in an instant; the wedge is applied on both sides of the incision, in the manner of the knife in skinning a sheep. A skilful barker will skin a tree or branch as completely as a butcher a beast. But the point most particularly to be observed in this art is, to take off the bark in as long shreds or strands as possible, for the convenience of carriage to, and drying it on, the horses. These are formed of long branches; and pieces of a yard in length, sharpened at one end, and having a knag at the other to receive and support the end of the former.

The horses or supports may stand within four or five feet of each other, and are always to be placed on a dry, elevated spot, that the bark may have free air in drying. At the end of each day's work, the bark is carried to, and laid across, the horses, to the thickness of about six or eight inches. The large pieces are set up on end, leaning against the horses, or they are formed into small pyramidal stacks. Due attention must be paid to turning the bark once, or perhaps twice a day, according to the state of the weather. Good hay weather is good barking weather. Gentle showers are beneficial; but long continued rains are productive of much evil; nor is the bark the better for being dried too fast. A careful hagman will take pains to lay the strong pieces of the trunk in such a manner as to shoot off the wet, in continued rains, from the smaller bark of the extremities; at the same time, preserving as much as possible the colour of the inner bark, and consequently the value of the whole, by turning the natural surface outwards. For it is chiefly by the high brown colour of the inner rind, and by its astringent effect upon the palate when tasted, that the tanner or merchant judges of its value. These properties are lost, if through neglect, or by the vicissitudes of the weather, the inner bark be blanched or rendered white.

After it becomes in a proper state, that is, completely past fermentation; if it cannot conveniently be carried off the ground and housed, it must be stacked. An experienced husbandman who can stack hay can also stalk bark. But it may be proper to warn him against building his stalk too large, and to caution him to thatch it well.

The method of drying bark in Yorkshire is generally the common one of setting it in a leaning posture against poles lying horizontally on forked stakes. But in a wet season, or when the ground is naturally moist, it is laid across a line of top-wood, formed into a kind of banklet, raising the bark about a foot from the ground. By this practice no part of the

Plate 3.

VARIETIES OF BARLEY, OATS, BUCKWHEAT AND MILLET.

rk is suffered to touch the ground: and it is, perhaps, upon the whole, the best practice in all seasons and situations.

BARK-LICE. The mischiefs effected through these minute insects, to fruit and other valuable trees, are far greater than is generally supposed, and hence every farmer and gardener must be interested in becoming intimately acquainted with the nature and habits of so formidable an enemy. For the following exceedingly interesting account of bark-lice commonly met with in the eastern states, we are indebted to our eminent countryman, Dr. Thaddeus William Harris of Massachusetts, who was employed by that extremely liberal and enlightened state to write an account of the "*Insects Injurious to Vegetation*," and made his report to the legislature in 1841. His treatise upon the subject forms a large octavo volume of 460 pages.

"The celebrated scarlet in grain, which has been employed in Asia and the South of Europe, from the earliest ages, as a colouring material, was known to the Romans by the name of *Coccus*, derived from a similar Greek word, and was, for a long time, supposed to be a vegetable production, or grain, as indeed its name implies. At length it was ascertained that this valuable dye was an insect, and others agreeing with it in habits, and some also in properties, having been discovered, Linnæus retained them all under the same name. Hence all the genus *Coccus* are included not only the *Thola* of the Phœnicians and Jews, the *Kermes* of the Arabians, or the *Coccus* of the Greeks and Romans, but the scarlet grain of Poland, and the still more valuable Cochenille of Mexico, together with various kinds of bark-lice, agreeing with the former in habits and structure. These insects vary very much in form; some of them are oval and slightly convex scales, and others have the shape of a muscle; some are quite convex, and either formed like a boat turned bottom upwards, or are kidney-shaped, or globular. They live mostly on the bark of the stems of plants: some, however, are habitually found upon leaves, and some on roots. In the early state, the head is completely withdrawn beneath the shell of the body and concealed, the beak or sucker seems to issue from the breast, and the legs are very short and not visible from above. The females undergo only a partial transformation, or rather scarcely any other change than that of an increase in size, which, in some species indeed, is enormous, compared with the previous condition of the insect; but the males pass through a complete transformation before arriving at the perfect or winged state. In both sexes we find threadlike or tapering antennæ, longer than the head, but much shorter than those of plant-lice, and feet consisting of only one joint, terminated by a single claw. The mature female retains the beak or sucker, but does not acquire wings; the male on the contrary has two wings, but the beak disappears. In both there are two slender threads at the extremity of the body, very short in some females, usually quite long in the males, which moreover are provided with a

stylet at the tip of the abdomen, which is re-curved beneath the body.

"The following account drawn up by me in the year 1828, and published in the seventh volume of the '*New England Farmer*,' p. 186, 187, contains a summary of nearly all that is known respecting the history and habits of these insects. Early in the spring the bark-lice are found apparently torpid, situated longitudinally in regard to the branch, the head upwards, and sticking by their flattened inferior surface closely to the bark. On attempting to remove them they are generally crushed, and there issues from the body a dark coloured fluid. By pricking them with a pin, they can be made to quit their hold, as I have often seen in the common species, *Coccus hesperidum*, infesting the myrtle. A little later the body is more swelled, and, on carefully raising it with a knife, numerous oblong eggs will be discovered beneath it, and the insect appears dried up and dead, and only its outer skin remains, which forms a convex cover to its future progeny. Under this protecting shield the young are hatched, and, on the approach of warm weather, make their escape at the lower end of the shield, which is either slightly elevated or notched at this part. They then move with considerable activity, and disperse themselves over the young shoots or leaves. The shape of the young *Coccus* is much like that of its parent, but the body is of a paler colour and more thin and flattened. Its six short legs, and its slender beak are visible under a magnifier. Some are covered with a mealy powder, as the *Coccus cacti*, or cochenille of commerce, and the *Coccus adonidum*, or mealy bug of our green-houses. Others are hairy or woolly; but most of them are naked and dark-coloured. These young lice insert their beaks into the bark or leaves, and draw from the cellular substance the sap that nourishes them. Réaumur observed the ground quite moist under peach-trees infested with bark-lice, which was caused by the dripping of the sap from the numerous punctures made by these insects. While they continue their exhausting suction of sap, they increase in size, and during this time are in what is called the larva state. When this is completed, the insects will be found to be of different magnitudes, some much larger than the others, and they then prepare for a change that is about to ensue in their mode of life, by emitting from the under-side of their bodies numerous little white downy threads, which are fastened, in a radiated manner, around their bodies to the bark, and serve to confine them securely in their places. After becoming thus fixed they remain apparently inanimate; but under these lifeless scales the transformation of the insect is conducted; with this remarkable difference, that, in a few days the large ones contrive to break up and throw off, in four or five flakes, their outer scaly coats, and reappear in a very similar form to that which they before had; the smaller ones, on the contrary, continue under their outer skins, which serve instead of cocoons, and from which they seem to shrink and detach themselves, and then be-

come perfect pupæ, the rudiments of wings, antennæ, feet, &c., being discoverable on raising the shells. If we follow the progress of these small lice, which are to produce the males, we shall see, in process of time, a pair of threads and the tips of the wings protruding beneath the shell at its lower elevated part, and through this little fissure the perfect insect at length backs out. After the larger lice have become fixed and have thrown off their outer coats, they enter upon the pupa or chrysalis state, which continues for a longer or shorter period according to the species. But when they have become mature, they do not leave the skins or shells covering their bodies, which continue flexible for a time. These larger insects are the females, and are destined to remain immovable, and never change their place after they have once become stationary. The male is exceedingly small in comparison to the female, and is provided with only two wings, which are usually very large, and lie flatly on the top of the body. After the insects have paired, the body of the female increases in size, or becomes quite convex, for a time, and ever afterwards remains without alteration; but serves to shelter the eggs which are to give birth to her future offspring. These eggs, when matured, pass under the body of the mother, and the latter by degrees shrink more and more till nothing is left but the dry outer convex skin, and the insect perishes on the spot. Sometimes the insect's body is not large enough to cover all her eggs, in which case she beds them in a considerable quantity of the down that issues from the under or hinder part of her body. There are several broods of some species in the year; of the bark-lice of the apple-tree at least two are produced in one season. It is probable that the insects of the second or last brood pair in the autumn, after which the males die, but the females survive the winter, and lay their eggs in the following spring.

“Young apple-trees, and the extremities of the limbs of older trees are very much subject to the attacks of a small species of bark-lice. The limbs and smooth parts of the trunks are sometimes completely covered with these insects, and present a very singularly wrinkled and rough appearance from the bodies which are crowded closely together. In the winter these insects are torpid, and apparently dead. They measure about one-tenth of an inch in length, are of an oblong oval shape, gradually decreasing to a point at one end, and are of a brownish colour very near to that of the bark of the tree. These insects resemble in shape one which was described by Réaumur in 1738, who found it on the elm in France, and Geoffroy named the insect *Coccus arborum linearis*, while Gmelin called it *conchiformis*. This, or one much like it, is very abundant upon apple-trees in England, as we learn from Dr. Shaw and Mr. Kirby; and Mr. Rennie states that he found it in great plenty on currant-bushes. It is highly probable that we have received this insect from Europe, but it is somewhat doubtful whether our apple-tree bark-lice be identical with the species found

by Réaumur on the elm; and the doubt seems to be justified by the difference in the trees and in the habits of the insects, our species being gregarious, and that of the elm nearly solitary. It is true, that on some of our indigenous forest-trees bark-lice of nearly the same form and appearance have been observed; but it is by no means clear that they are of the same species as those on the apple-tree. The first account that we have of the occurrence of bark-lice on apple-trees, in this country, is a communication by Mr. Enoch Perley, of Bridgetown, Maine, written in 1794, and published among the early papers of the Massachusetts Agricultural Society. These insects have now become extremely common, and infest our nurseries and young trees to a very great extent. In the spring the eggs are readily to be seen on raising the little muscle-shaped scales beneath which they are concealed. These eggs are of a white colour, and in shape nearly like those of snakes. Every shell contains from thirty to forty of them, imbedded in a small quantity of whitish friable down. They begin to hatch about the 25th of May, and finish about the 10th of June, according to Mr. Perley. The young, on their first appearance, are nearly white, very minute, and nearly oval in form. In about ten days they become stationary, and early in June throw out a quantity of bluish white down, soon after which their transformations are completed, and the females become fertile, and deposit their eggs. These, it seems, are hatched in the course of the summer, and the young come to their growth and provide for a new brood before the ensuing winter.

“Among the natural means which are provided to check the increase of these bark-lice, are birds, many of which, especially those of the genera *Parus* and *Regulus*, containing the chickadee and our wrens, devour great quantities of these lice. I have also found that these insects are preyed upon by internal parasites, minute ichneumon flies, and the holes (which are as small as if made with a fine needle), through which these little insects come forth, may be seen on the backs of a great many of the lice which have been destroyed by their intestine foes. The best application for the destruction of the lice is a wash made of two parts of soft soap and eight of water, with which is to be mixed lime enough to bring it to the consistence of thick white-wash. This is to be put upon the trunks and limbs of the trees with a brush, and as high as practicable, so as to cover the whole surface, and fill all the cracks in the bark. The proper time for washing over the trees is in the early part of June, when the insects are young and tender. These insects may also be killed by using in the same way a solution of two pounds of potash in seven quarts of water, or a pickle consisting of a quart of common salt in two gallons of water.

“There has been found on the apple and pear tree another kind of bark-lice, which differs from the foregoing in many important particulars, and approaches nearest to a species inhabiting the aspen in Sweden, of which a description has been given by Dalman in the ‘Transactions of the Royal Academy of Sci-

es of Stockholm.' for the year 1825, under name of *Coccus cryptogamus*. This species of the kind in which the body of the female is not large enough to cover her eggs, for the protection whereof another provision is made, consisting, in this species, of a kind of membranous shell, of the colour and consistence most of paper. In the autumn and throughout the winter, these insects are seen in a dormant state, and of two different forms and sizes on the bark of the trees. The larger measure less than a tenth of an inch in length, and have the form of a common oyster-shell, being broad at the hinder extremity, but tapering towards the other, which is surmounted by a little oval brownish scale. The small ones, which are not much more than half the length of the others, are of a very long oval shape, or almost four-sided with the ends rounded; and one extremity is covered by a minute oval dark-coloured scale. These little shell-like bodies are clustered together in great numbers, are of a white colour and membranous texture, and serve as cocoons to shelter the insects while they are undergoing their transformations. The large ones are the pupas or cocoons of the female, beneath which eggs are laid; and the small ones are the shells of the males, and differ from those of the females not only in size and shape, but also in colour, of a purer white colour, and in having a elevated ridge passing down the middle. The minute oval dark-coloured scales on one end of these white cases are the skins of the lice while they were in the young or larval state, and the white shells are probably shed in the same way as the down which comes from the bodies of other bark-lice, but each in these assumes a regular shape, varying according to the sex, and becoming membranous after it is formed. Not having seen these insects in a living state, I have not been able to trace their progress, and must therefore refer to Dalman's memoir above mentioned, for such particulars as tend to illustrate the natural history of this species. The body of the female insect, which is covered and concealed by the outer case above described, is minute, of an oval form, wrinkled at the sides, flattened above, and of a reddish colour. By means of her beak, which is constantly thrust into the bark, she imbibes the sap, by which she is nourished; she undergoes no change, and never emerges from her habitation. The male becomes a chrysalis or pupa, and about the middle of July completes its transformations, makes its escape from its case, which it leaves at the hinder extremity, and the wings with which it is provided are exercised over its head during the operation, and are the last to be extricated. The perfect female is nearly as minute as a point, but a powerful magnifier shows its body to be divided into segments, and endued with all the important parts and functions of a living animal. The unassisted eye, says Dalman, it appears as a red atom, but it is furnished with a pair of long whitish wings, long antennæ or feelers, six legs with their respective joints, and two bristles terminating the tail. This minute insect perforates the middle of the case cover-

ing the female, and thus celebrates its nuptials with its invisible partner. The latter subsequently deposits her eggs and dies. In due time the young are hatched and leave the case, under which they were fostered, by a little crevice at its hinder part. These young lice, which I have seen, are very small, of a pale yellowish brown colour, and of an oval shape, very flat, and appearing like minute scales. They move about for a while, at length become stationary, increase in size, and in due time the whitish shells are produced, and the included insects pass from the larva to the pupa state. The means for destroying these insects are the same as those recommended for the extermination of the previous species. (See APHIS, THURIPS, &c.)

"Many years ago, when on a visit from home, I observed on a fine native grape-vine, that was trained against the side of a house, great numbers of reddish brown bark-lice, of a globular form, and about half as large as a small pea, arranged in lines on the stems. An opportunity for further examination of this species did not occur till the last summer, when I was led to the discovery of a few of these lice on my Isabella grape-vines, by seeing the ants ascending and descending the stems. Upon careful search I discovered the lice, which were nearly the colour of the bark of the vine, partly imbedded in a little crevice of the bark, and arranged one behind another in a line. They drew great quantities of sap, as was apparent by their exudations, by which the ants were attracted. Further observations were arrested by a fire which consumed the house and the vines that were trained to it." (*Harris's Treatise on Insects.*)

BARLEY (*Lat. hordeum*). A species of bread corn, which in Europe ranks next to wheat in importance, and of which there are several varieties. The generic name seems either *hordeum*, from *horreo*, on account of its long awns, or, as it was anciently written, *fordeum*, rather from $\varphi\sigma\lambda\omega$, to feed or nourish, whence $\varphi\sigma\lambda\eta$ and *forbea*, and, changing the *b* into *d*, *fordeum*. (*Vossius.*) The name is, however, derived by Junius from the Hebrew בָּר . The plant belongs to the natural order *Gramineæ*, or grasses. It readily accommodates itself to any climate, bearing the heat of the torrid zone, and the cold of the frigid, and ripening in both equally well. Of the genus *Hordeum*, says Professor Low, the following species may be enumerated as cultivated for their seeds:—

1. Two-rowed barley (*Hordeum distichum*). Pl. 3, a.
2. Two-rowed naked barley (*H. Gymnodistichum*).
3. Two-rowed sprat, or battledore barley (*H. disticho-zeocriton*). Pl. 3, d.
4. Six-rowed winter barley (*H. hexastichum*). Pl. 3, b.
5. Six-rowed naked barley (*H. Gymnohexastichum*).
6. Six-rowed sprat, or battlebore barley (*H. hexasticho-zeocriton*).

The two leading species of this grain in cultivation are (No. 1.) the two-rowed, or common barley, and (No. 4.) the six-rowed barley. The

minor varieties of two-rowed barley are numerous, and are distinguished chiefly by the quality of the grain, and by their habit of early or later ripening; and some varieties are more productive than others: effects apparently dependent upon differences of climate and situation.

Barley is an annual plant, but like wheat it may be sown in autumn, and then it acquires the habit of later ripening, and is termed winter barley.

Two-rowed naked barley is said to have been introduced into England in the year 1768. It is now little cultivated, and is by some asserted, though without any evidence, to merge into the common species.

The next species, two-rowed sprat, or battledore barley, is scarcely cultivated in England, the shortness of the straw being regarded as an objection; but it is much esteemed in Germany, where it is termed *rice barley*, owing to its smelling like rice in boiling, when it is decorticated.

The fourth enumerated species is six-rowed barley. When sown before winter, this species acquires the habit of late-ripening, and is then termed winter barley.

One of the kinds of six-rowed barley, and the best known in this country, is bere, bear, or bigg. Bigg ripens its seeds in a shorter period than the two-rowed barleys. It is cultivated very generally in the north of Scotland, in Denmark, Sweden, and other parts of Europe, and in the south of England for green food in spring, and for this purpose is sown early in the autumn. The number of its grains is greater than in the two-rowed kinds, but they do not weigh so heavy in proportion to their bulk. It is hence regarded as an inferior crop, and is only cultivated in the more elevated parts of the country. It ripens very early when sown in spring, thence the advantages which it possesses in a late climate. (*Low's Prac. Agr.* p. 240.)

The six-rowed naked barley is cultivated in various parts of Europe, and is greatly esteemed for its fertility. In some parts of Germany it is regarded as the most valuable kind of barley, and by the French, on account of its supposed productiveness, it has been termed *orge céleste*. An excellent variety of this naked barley has been produced by Mr. C. Alderman, of Kintbury, in Berkshire, and M. Mazucco, in a French paper, earnestly recommends the more general cultivation of naked barley, as he states that it weighs as much as the best wheats, and its quality resembles them so much that it may be used for the purpose of making good bread, and also for pearl barley. In mountainous countries, its produce is twenty-four to one. (*Quart. Journ. of Agr.* vol. iii. p. 373.) This and the other superior kinds of barley deserve more attention than they have yet received. Mr. Warren Hastings, (in an article in the *Com. to the Board of Agr.* vol. vi. p. 304), after twelve years' experience in the cultivation of naked barley, very justly observes, "that it is of the greatest importance to promote the culture of this sort of grain." "It is," he adds, "the corn that, next to rice, gives the greatest weight of flour per acre, and

it may be eaten with no other preparation than that of boiling. It requires little or no dressing when it is sent to the mill, having no husk, and consequently produces no bran. It is gathered into the barn, and may even be consumed, when the seasons are favourable, in about eighty or ninety days after being sown; and there is no species of grain better calculated for countries where the summer is short, provided the vegetation be rapid."

The last of the species to be mentioned, says Professor Low, is six-rowed sprat, or battledore barley. This has been sometimes termed six-rowed barley; whereas the character of six-rowed barley does not belong to it alone. An examination of the plant will show that it is the common battledore barley, with all the florets entire. Much confusion has arisen in the arrangement by agriculturists of the cultivated barleys, and in an especial degree, by their speaking of four-rowed and six-rowed kinds. There is, however, no barley to which the term four-rowed can be applied. Barley is termed two-rowed, or six-rowed, according to the number of its fertile florets. In two-rowed barley, one row of florets on each of the two sides of the spike is fertile, and consequently one row of seeds on each side is perfected.

In six-rowed barley, three rows on each side are perfected. In this sense only it is termed six-rowed barley. But there is no species known to us in which only two rows on each side of the spike are fertile. Slightly examined, indeed, six-rowed barleys frequently present the appearance of four rows; but this is in appearance only, for such barleys have always the three rows on each side perfect. In poor soils and unfavourable situations, two of the rows run much into each other, and this has perhaps given rise to the mistake; but the two rows which thus run into each other in appearance are on the opposite sides of the rachis. I have ventured, adds Professor Low (from whose work the above preliminary observations are taken), to propose a new arrangement of the cultivated barleys; under which it will be seen that the *Hordeum vulgare* of some botanists is *Hordeum hexastichum*, and that of the *Hordeum hexastichum*, of some botanists is *Hordeum hexasticho-zeocriton*. Particular varieties have been in great repute at different times, when first introduced, and then seem to have, on many soils, lost their superiority. "Of this kind is the *Moldavian* barley, which was much sought after some years ago; and lately, the *Chevalier* barley, so called from the gentleman who first brought it into notice, has risen into great repute. It is said, that, having observed an ear of barley in his field, greatly superior to the rest, he carefully sowed the seed, and cultivated it in his garden, till he had a sufficient quantity to sow a field. It has since been extremely multiplied and diffused through the country. Some eminent maltsters and brewers have declared, that it forms more saccharine matter than any other sort; and the trials hitherto made have convinced most agriculturists that it is not only heavier in the grain, but more productive. In 1832 Lord Leicester, who was always foremost in all agri-

cultural experiments and improvements, sowed a considerable portion of land with this barley, and the result is said to have been perfectly satisfactory. In 1833 two acres of Chevalier barley were sown in the same field with some of the best of the common barley. The soil was poor, light sand, but in good order and very clean. The produce of the whole was nearly the same, 4 quarters per acre; but the Chevalier barley weighed 57 lbs. per bushel, while the common barley weighed only 52. This gives the farmer an advantage of ten per cent. The sample was very fine, and the whole that the cultivator could spare was eagerly purchased by his neighbours for seed at his own price. It is long in the ear, and very plump, and the plant *tillers* so much, that half a bushel of seed may be saved per acre. This is probably owing to its grains being all perfect, and vegetating rapidly. The straw, like that of the other long-eared barleys, appears weak in proportion to the ear; it is said also to be harder, and not so palatable to cattle. These are circumstances which experience alone can ascertain. That hitherto it has a decided superiority over the common sorts, no one who has tried it fairly in well-prepared lands seems to deny." (*Penny Cyc.*)

A new and seemingly very superior variety has lately been introduced, called the *Annat* barley. (See *Quart. Journ. of Agr.* vol. v. p. 18.) It is the produce of three ears which were picked by Mr. Gorrie in a field in Perthshire, in the harvest of 1830, since which period it has been grown at Annat Gardens, hence its name. In 1834, it was sown on a ridge in the middle of a field, with common barley on the one side and Chevalier barley on the other. In bulk of straw it seemed to have the advantage of both these kinds; it was five days earlier ripe than the former, and about a fortnight before the latter, and it was also 2½ lbs. per bushel heavier than the Chevalier. At a meeting of the Stoke Ferry Farmers' Club, in February of the present year (1841), it was stated by one of the members, that the Chevalier was decidedly the best stock for good barley land; but for very poor soils he preferred the Moldavian; though, probably even this was surpassed by the stock usually known as the old field barley. The Annat barley was alluded to by one gentleman who had tried it last season; but not having thrashed it, he could only say that from its appearance it augured well. He always adopted the drill system, using wide, winged coulters, so as to disperse the grain in the rows as much as possible, giving the field the appearance of having been ploughed in. Very little difference of opinion existed as to the superiority of the Chevalier over any other variety, on the average of soils. One member had grown 15 coombs an acre on it; but he acknowledged it was on very excellent land. A curious fact was elicited in connection with this stock of barley; which was, that however much the crop might be laid and beaten down, either by storms or its own weight, the grain did not receive that injury to which any other sort under similar circumstances would be liable. (*Brit. Farm. Mag.* vol. v. p. 190.)

There can be no doubt of the general superiority of the Chevalier as a malting barley. Its introduction has occasioned a complete revolution in certain districts, where formerly no such thing as malting barley was thought of. It is one of the greatest improvements of modern times, and now commands a higher price in the market than other barleys by two or three shillings a quarter.

Barley is evidently a native of a warmer climate than Britain; for in this moist atmosphere it is observed to degenerate, when either neglected or on a poor soil. We have the best authority for its having been cultivated in Syria so long back as 3153 years; therefore that part of the world may be fairly fixed as its native soil. We find that the Romans obtained barley from Egypt, and other parts of Africa, and Spain. It was also grown in France, as Columella calls one variety of barley *Galaticum*.

Barley, like all grains, is liable to diseases, namely smut, the burnt ear, blight, and mildew: for an account of which I must refer the reader to these words. It is also apt to germinate in the ear even before it is reaped, in wet weather, giving the ear a singular appearance, and rendering the grain, even when kiln-dried, unfit for malting, and only of use to feed fowls or pigs. The diseases of barley are not so numerous or fatal as those of wheat. It is attacked by the larvæ of certain flies. The smut, which attacks it in a partial degree, is generally the fungus *uredo segetum*.

Barley is now extensively cultivated in most European countries, in America, and in the temperate districts of Asia and Africa. It may also be raised between the tropics, but not at a lower elevation than from 3000 to 4000 feet, and then it is not worth cultivating. In Spain and Sicily it produces two crops in the year. Large quantities of barley have been for a lengthened period raised in Great Britain. Recently, however, its cultivation has been supposed, though probably on no good grounds, to be declining. In 1765, Mr. Charles Smith estimated the number of barley consumers in England and Wales at 739,000; and as a large proportion of the population of Wales, Westmoreland, and Cumberland continue to subsist chiefly on barley bread, I am inclined to think that this estimate may not, at present, be very wide of the mark. "Barley" (husked), says Pliny, "was the most ancient food in old times, as will appear by the ordinary custom of the Athenians, according to the testimony of Menander, as also by the surname given to the sword fencers, who, from their allowance or pension of barley, were called *Hordearii*, barley men." (Book xviii. chap. 7.) It was not until after the Romans had learned to cultivate wheat, and to make bread, that they gave barley to their cattle. They made barley-meal into balls, which they put down the throats of their horses and asses, after the manner of fattening fowls, which was said to make them strong and lusty.

There are no means of ascertaining whether barley was cultivated in Britain when the Romans discovered that country; but as *Cæsar*

found corn growing on the coast of Kent, it is probable that this species of grain had been obtained from Gaul.

In the rotation of crops, barley may succeed to summer fallow, to potatoes, turnips, or any other green crop, and to any of the pulse crops. It now generally follows turnips in England, and is a very important crop in the rotation, best adapted to light soils. The principal barley counties of England are Norfolk, Suffolk, Cambridge, Bedford, Herts, Leicester, Nottingham, the upper parts of Hereford, Warwick, and Salop. The produce varies according to soil, preparation, season, &c., from about 25 to 60 or 70 bushels an acre. The usual crop is from 28 to 36 or 38 bushels. The Winchester bushel of good English barley generally weighs about 50 lbs.; but the best Norfolk barley sometimes weighs 53 or 54 lbs. Its produce in flour is about 12 lbs. to 14 lbs. of the grain.

Barley is said to contain 65 per cent. of nutritive matter; wheat contains 78 per cent. A bushel of barley weighing 50 lbs. will therefore contain about 32 lbs. of nutriment; while a bushel of wheat weighing 60 lbs. contains 47 lbs. Good oats weighing 40 lbs. contain about 24 lbs. of nutritive matter; so that the comparative value of wheat, barley, and oats, in feeding cattle, may be represented by 47, 32, and 24, the measure being the same. The experiments on which this calculation is founded were carefully made by Einhof, and confirmed on a large scale by Thäer, at his establishment at Mögelin, the account of the results being accurately kept.

Barley is a tender plant, and easily hurt in any stage of its growth. It is more hazardous than wheat, and is, generally speaking, raised at a greater expense, so that its cultivation should not be attempted except where the soil and climate are favourable for its growth. There is no grain perhaps more affected (says Baxter, in his *Lib. of Agr. Knowledge*, p. 36.) by soil and cultivation than barley, the same species exhibiting opposite qualities, modified by the nature of the soil from which it is produced; these opposite productions of the same individual will, if sown at the same period, on the same land, and under the same course of cultivation, exhibit corresponding differences, which are manifested during the growth of the crop, and subsequently in the quality of the sample when in hand. Thus the finest samples, the growth of suitable and well-cultivated lands, would, if sown on a poor and sterile soil, become alike coarse in appearance, and indifferent in quality. This fact, however important, has hitherto but little engaged the attention of the farmer; and the spring or early barley is therefore indiscriminately sown, as being found more productive for the purpose of malting than any of the afore-mentioned varieties. The sprat, or battledore barley, makes good malt; and being short and erect in the ear, and tapering in the stem, is, on strong lands, less liable to injury from falling, and is consequently preferred by a few individuals. The common, or long-eared barley, being long in the ear and weak in the straw, is very liable to lodge early, whereby the grain

is rendered inferior in quality, and is, therefore, not extensively cultivated. Naked barley, or wheat barley, is so termed in consequence of the grain separating readily from the chaff when thrashed. It is a native of the north, and will bear sowing early in the season; it is not, however, in much estimation in the south of England, and is seldom cultivated, although it makes strong malt, and is excellent for fattening of hogs and cattle. Winter barley, or square-eared barley, is grown to a considerable extent in the north-western part of England, and in Scotland. It is usually sown for the feeding of sheep in the south of England, and mixed with tares for the soiling of cattle. As food for sheep, it is far more productive than rye, as it admits of being fed down every two or three days during summer; and if intended for seed, it may previously be fed off by sheep early in the season, without injury to the crop.

The land that produces the best barley is generally of a silicious, light, dry nature; for a good mellow preparation and free soil are essential to the growth of malting barleys. Cold, wet soils, which are peculiarly retentive of water, are ill adapted to the growth of this grain, both in reference to its weight and its malting qualities. The whole matter of barley and its straw contains more silicious particles than that of any other grain cultivated by the British farmer; and hence one reason why a sandy soil is most congenial to the growth of this plant. Barley is propagated by seed, sown either broadcast or in drills, the quantity varying according to the quality of the soil, cultivation, and time of sowing; less being required on rich mellow lands than on poor soils; early sowing, with good tillage, requiring less seed than the late sowing with indifferent tillage. The quantity of seed generally varies from $2\frac{1}{2}$ to 4 bushels the acre (or sometimes more), when sown broadcast; but when drilled, the quantity of seed need not exceed two bushels to the acre.

Barley is an early ripening grain. It may be sown at a late period, but the sooner the better. The more early that barley can be sown, the produce in grain is the surer, though the bulk of the straw will be less. The common sprat barleys may be sown from the second week in March, if the weather prove dry, until the 10th of May. The bigg, a variety of the winter barley, will stand against the wind, and may be sown either in the autumn or the beginning of March. The bear, or square barley, should be sown as early in the autumn as the clearing of the harvest will admit, and may be sown after wheat, barley, oats, or any pulse crop, being a plant of sturdy growth. In the choice of seed, great care should be taken that it is not of a reddish hue, as in that case it is more than probable that a great part of it will never vegetate; the sample should be of a pale, lively colour, and uniform. Some farmers, not aware of its importance, are in the habit of sowing thin corn; but unless the land is quite adapted, from its nature and cultivation, for the fullest encouragement of the plant, it will in the end be found a "penny-wise and pound-foolish" speculation. In all

cases it will be well for the farmer to select the finest samples and the plumpest grain; for in unfavourable seasons the crop from thin grain is always delicate, and assumes an unkindly hue, whilst, on the contrary, plump seed throws up strong, healthy stems, capable of resisting the effects of inclement seasons, and, in more congenial weather, pushing forth with renewed vigour and redoubled strength. In England, barley, for the most part, succeeds best after turnips, tares, potatoes, carrots, mangel wurzel, or other green ameliorating crops; but does not succeed so well after wheat or other white straw crops, nor after rape so well as other green crops, except on the South Downs of Sussex, and certain lands adjoining the sea-coast, where both the quantity of grain is greater, and the quality better, after wheat (particularly wheat sown upon a clover ley), and also after rape, than from any other course of tillage. The lands require more or less ploughing, according to the quality of the soil, and the state in which it is found after the season for the working of it commences. On recent soils, as compact gravelly clay, if the turnips have been fed off during wet weather, the earth breaks up in large clods, and requires to be reduced by the roller, and at least a second ploughing should be given before the barley can be safely sown. On light soils of the best quality one ploughing may be sufficient; but if the land is twice ploughed in the spring, as soon as it is sufficiently dry for that purpose, it will be found amply to repay both the labour and expense. After the grass-seeds are sown, the barley-land admits of no further tillage. Should any larger weeds appear, they may be pulled up by the hand; but it is the evidence of bad husbandry if a spring-sown barley crop requires weeding during the comparatively short period in which it is on the ground. If weeding be necessary, it should be attended to early, or the crop will be injured by treading, and the roller should be used before the blade becomes spindled.

In the harvesting of barley more care is requisite than in taking any other of the white crops, even in the best of seasons; and in bad years it is often found very difficult to save it. When the period of harvest arrives, barley must be allowed to be sufficiently ripe, but not become what is termed "dead ripe." It may be cut either by the scythe or the sickle. Barley, says Professor Low, on account of the softness of its stem, and the tendency of its ears to vegetate, is more apt to be injured, and even destroyed, by wet weather than any of the other cereal grasses. For this reason the safer course, in a humid climate like ours, is to place it when cut down in sheaves and shocks, and not to allow it, as is frequently practised, to lie loose upon the ground. By some farmers, however, it is suffered to lie in the fields until the straw is quite dry, being turned over early in the morning while the dew is still upon it. This practice, they say, is found to improve the colour of the skin, and thereby render the grain of more value to the maltster. It should never be carried unless perfectly dry, otherwise it is in danger of being heated in the mow, which reduces the value

very materially, for the undue action of the heat destroys the spear, or germination of the grain; the malting process is consequently very unequally performed, and as the duty has to be paid upon the whole bin, maltsters will scarcely purchase such samples, unless for the purpose of grinding, and then always at an inferior price. It will be prudent, therefore, not to carry barley until the heat of the sun has evaporated the dew from it, when it should be carried in a perfectly dry state the remainder of the day, until the dew is again deposited in the evening. It is a very common practice to sow clover and other grass seeds with this crop; but great care must be taken that they are thoroughly harvested, for otherwise considerable fermentation will be created, and the sample injured. It not unfrequently occurs, that when it is supposed to be well harvested, heat is soon found to subsist in the mows, which should be daily examined, by placing a long iron spit, that should be kept for that purpose, deep into the mow; when, if the heat is found to increase, no delay should take place, but the middle should be instantly cut asunder, and taken out in proportion to the size of the mow, when it will generally escape without further injury. This operation, however, must not be deferred, as the injury sustained rapidly increases. By heating in the stalk, it quickly becomes discoloured and injured. When barley is grown in large quantities, it is usual to tread the mows with horses or oxen, to get as much as possible into the barns, in which case more guarded caution is necessary than when thrown loosely over the floor.

This grain should never be thrashed by a machine, as the injury done thereby is frequently of a very serious nature; it bruises the malting spear, which is as injurious to the maltsters as if heated in the mow, and, therefore, should be guarded against. Care must also be taken not to have too large heaps lying together without frequent examination, as, until it has undergone a proper fermentation in the mow, it will be very apt to heat in the heap; in order to prevent which it requires to be moved daily, or every other day, till cleaned up from the chaff, which, from the fineness of its texture, scarcely admits the introduction of air, and consequently promotes fermentation.

The principal demand for barley in Great Britain is for conversion into malt, to be used in the manufacture of ale, porter, and British spirits; and though its consumption in this way has not certainly increased proportionally to the increase of wealth and population, still there does not seem to be any grounds for supposing that it has diminished.

But it is not only the most useful for making into malt, it is the best food for promoting the fattening of hogs, after they have been fed to a certain extent with beans, peas, &c., from which it has been found that the meat is not only more tender, but increases in boiling, whilst the meat of those fed on beans and peas alone has not only been hard, but has not yielded any increase. Barley is employed for various other purposes. It is excellent for fattening poultry. The flour is still used in

some parts for bread; but the bread, though sufficiently nutritious, is dark and strong-tasted. Barley, in its green state, especially the Siberian winter-barley, makes excellent spring food for milch cows, as is well known to the cow-keepers about London; it comes in early, and greatly increases the milk. For sheep it is more nourishing than rye, and is earlier. When fed off quite close in April, it will spring up again, and on good land produce a fair crop of grain in August; but, in general, it is ploughed up as soon as it is fed off, and succeeded by spring tares or turnips. It is also good food for horses, when given in the spring of the year in small proportion with oats, sparingly at first, and after being soaked in water, and allowed to vegetate. It is in general use in the south of Europe (*Com. Board of Agr.* vol. vi. p. 298). Mixed with other grain, in its ground state, it has been found an excellent food for fattening bullocks. The straw is employed partially for fodder, but chiefly for litter. It is lighter than the straws of oats and wheat, and less esteemed than either. The awns are given to stock, either in their natural state or boiled. Malt is the great purpose, however, to which barley is applied in this country. To understand the process of malting, it may be necessary to observe, that, in the germination of grasses and grains before the young plant is produced, the fecula of the seed is changed by the heat and moisture of the earth into sugar and mucilage. Malting grain is only an artificial mode of effecting this object. The grain is steeped in cold water during a certain period; the water is then allowed to drain off, the grain is spread out into a deep heap: it gradually heats, the rootlets begin to shoot out, afterwards the plumula begins to grow; and when this has grown to a certain extent within the grain, the further germination is checked by exposing the grain on a kiln, heated by fire to such a degree as extinguishes the vitality of the seed. At this period it is found that the starch is, in a great measure, converted into saccharine matter, and by subsequent fermentation, or distillation, either beer or spirits is obtained. (See FERMENTATION, MALTING, and BREWING.) It is only necessary to add here that malt requires the best and heaviest barley, with its germinating powers entire.

Barley was formerly in general use in England as bread corn: it is still, for this purpose, much used on the Continent. It is generally used in the warmer climates as the food for horses, for which purpose, in fact, it appears to answer equally as well as oats. In this country, in some seasons, a considerable saving may be made by using for this purpose inferior barley. This was done in the season of 1840 by Mr. Hewitt Davis, of Spring Park, who sold his oats at the same price that he gave for the barley. And to this end the farmer should remember, that two parts of barley are fully equal, in feeding properties, to three parts of oats. In Germany they grind the barley, and form it into cakes, with which they feed their horses; and it is no unusual circumstance, in travelling in that country, to see the

driver take a slice of the loaf with which he baits his horses.

Wine made from malt, when kept to a proper age, has a good body, and a flavour nearly as agreeable as the generality of Madeira wines. The wort of malt is useful in scurvy, but it is apt to increase the diarrhœa which attends that disease. Barley was used by the ancients for many medicinal purposes. Pot barley, pearl barley, and French barley, are only barley freed from the husk by a mill; the distinction between them being, that the pearl barley is reduced to the size of small shot, all but the very heart of the grain being ground away. For a description of the mode of manufacture, I refer the reader to the *Penny Cyclop.* vol. iii. p. 466. Barley-water is a decoction of either of these, and is reputed soft and lubricating; a very useful cooling drink or gruel in many disorders, and is recommended to be taken with nitre in fevers. Its use is of great antiquity, as Hippocrates wrote a whole book on the merits of gruel made of barley. Barley-water is an admirable liquid to administer any medicine in, being pleasant, emollient, and cooling. The French or Scotch barley is principally used to thicken broth and soup.

The German chemist, Einhof, has analysed ripe barley, and found 100 parts to consist of 70.05 parts of meal, 18.75 of husk, and 11.20 of water. The meal he found to contain 67.18 parts of starch, 5.21 of uncrystallizable sugar, 4.62 of gum, 3.52 of gluten, 1.15 of albumen, 0.24 of superphosphate of lime, and 10.79 of water and loss, in 100 parts. The husk contains a bitter principle which is tasted in the decoction of entire barley.

M. Saussure has carefully analysed the ashes produced by burning barley and its straw, and the result of his experiments is given in *Recherches Chem. sur la Veg.*, Paris, 1804.

The grain reduced to ashes, with its skin, gave, out of 100 parts, 18 of ashes, which contained:—

Potash	-	-	-	-	-	-	-	18
Phosphate of potash	-	-	-	-	-	-	-	9.2
Sulphate of potash	-	-	-	-	-	-	-	1.5
Muriate of potash	-	-	-	-	-	-	-	0.25
Earthy phosphates	-	-	-	-	-	-	-	32.5
Silica	-	-	-	-	-	-	-	35.5
Metallic oxides	-	-	-	-	-	-	-	0.25
Loss	-	-	-	-	-	-	-	2.8
								100

1000 parts of the straw produced 42 of ashes, containing:—

Potash	-	-	-	-	-	-	-	16
Sulphate of potash	-	-	-	-	-	-	-	3.5
Muriate of potash	-	-	-	-	-	-	-	0.5
Earthy phosphates	-	-	-	-	-	-	-	7.75
Earthy carbonates	-	-	-	-	-	-	-	12.5
Silica	-	-	-	-	-	-	-	57
Metallic oxides	-	-	-	-	-	-	-	0.5
Loss	-	-	-	-	-	-	-	2.25
								100

These products no doubt vary in different soils; but the proportion of silica in the straw and in the skin of barley is remarkable. This barley grew on a chalky soil. In addition to these the cubic saltpetre, or nitrate of soda, is usually found in minute proportions in barley.

The average price in England, per Winchester quarter of barley, according to McCulloch, was in

The account in imperial quarters of the foreign barley and barley-meal entered for home consumption every five years since 1815, was (McCulloch's Com. Dict.)—

	Qrs.
1815	160
1820	—
1825	270 679
1830	52 107
1835	137 374

The annual average, from 1801 to 1825, of barley imported into England, in Winchester quarters, was from

	Qrs.
Russia	7 112
Sweden and Norway	957
Denmark	18 808
Prussia	18 718
Germany	24 839
Netherlands	9 500
France and Southern Europe	1 097
United States	31
British North America	51
Other countries	2 194
Ireland	33 331

For further particulars as to its consumption and culture, see *Smith's Tracts on the Corn Trade*, 2d edit. p. 182; *Penny Cyclop.*, vol. iii. p. 461; *Brown on Rural Affairs*, vol. ii. p. 42; and *Elements of Prac. Agr.*, by Prof. Low, p. 246, &c.; to which last-named valuable work I have, in this and other articles, been under very considerable obligation.

(Phillip's Cult. Veg.; McCulloch's Com. Dict.; Com. Board of Ag. vol. vi.; Hitchin, in Baxter's Ag. Lib.; Professor Low's El. of Ag.; Brande's Dict. of Science.)

Barley, in the United States, is cultivated almost exclusively for the breweries, the grain being rarely given to cattle, and barley-bread being unknown to native Americans.

BARLEY GRASSES. Some coarse kind of grasses which are known under the several names of meadow barley grass (Plate 7, d), wall barley grass, way-bennet, and mouse barley, and are of little use to the farmer. (See *HORDEUM murinum*, and *H. pratense*.)

BARLEY HUMMELLER. This is an instrument worked by the hand, which is employed when the threshing machine is not in use, or performs its work imperfectly. It consists of a set of parallel iron plates fixed to a frame, and worked by the hand like a paver's instrument. The barley to be hummelled is laid upon the barn-floor, and by repeated strokes of the hummeller, is freed from its awns. Messrs. Grant, wheelwrights of Aberdeenshire, have described this instrument very fully, with some improvements, in *Trans. High. Soc.* vol. iv. p. 334.

BARM. The foam or froth of beer or any other liquor in a state of fermentation, which is used as a leaven in the making of bread, &c. (See YEAST.)

BARN. A covered building, constructed for the purpose of laying up grain, &c. Farms should always be furnished with barns proportioned to the quantity of grain they produce; but since the practices of stacking and thrashing by mills have become more general, there is much less need of large barns. They should have a dry situation, and be placed on the north or north-east side of the farm yard, so that the sun at noonday may shine on the thrashing-floor, and the lean-toos for stock in the yard be thus open only to the south. Every farm should have at least two thrashing-floors, that different kinds of grain may be thrashing at the same time. Barns may either be constructed of timber, or be built of brick or stone, whichever the country affords in the greatest plenty, but wooden barns are the best for the corn; and in either case there should be such vent-holes or openings in their sides or walls as to afford free admittance to the air, in order to prevent the mouldiness that would otherwise occur from the least dampness lodging in the grain. The foundations, and for two feet out of the ground, are best made of brick or stone, on account of greater solidity, and the protection from vermin; the whole may be roofed with either thatch, slate (which is the best of all), or tiles, as can be most conveniently procured. They should have two large double folding doors facing each other, one in each side of the building, for the convenience of carrying in or out wagon-loads; and these doors should be of the same breadth as the thrashing-floor, to afford the more light and air. Formerly, a much larger expenditure in the number and size of these buildings was incurred than is now requisite, since the practice of stacking has become general. It is found that all grain is a better sample from stacks than from barns; vermin have less chance of injuring it, indeed may be set at defiance, and at harvest the corn may admit of being carried two days sooner for stacking than for housing.

BARNACLES. A name given to horse-twitchers or brakes, a sort of instrument used by farriers to put upon horses' noses, when they will not stand quietly to be shod, bled, or dressed.

BARN OWL (*Strix flammea*). The white, or screech owl, unlike some of the species, is resident in England throughout the year, and is so peculiar in the colour of its plumage, and so generally diffused, that it is probably the best known of all the British species of owls. It inhabits churches, barns, old malting kilns, or deserted ruins of any sort, and also holes in decayed trees. If unmolested, the same haunts are frequented either by parent birds or their offspring, for many years in succession. As a constant destroyer of rats and mice, and that to a very considerable extent, the services performed by barn owls for the agriculturists have obtained for these birds toleration at least, while by some they are, as they deserve to be, strictly protected in return for benefits received. Unless disturbed, these birds seldom leave their retreat during the day; and, if the place of concealment be approached with caution, and a view of the bird obtained, it will generally

be observed to have its eyes closed as if asleep. About sunset, the pair of owls, particularly when they have young, issue forth in quest of food, and may be observed flapping gently along, searching lanes, hedgerows, orchards, and small enclosures near outbuildings. "In this irregular country," says White of Selborne, "we can stand on an eminence and see them beat the fields over like a setting dog, and often drop down in the grass or corn." Besides rats and mice, they feed on shrews, small birds, insects, &c., and have sometimes been known to capture and eat fish. It is said of this owl, that when satisfied, it will hide the remainder of its meat like a dog. The barn owl lays from three to five eggs, which are oval and white, measuring one inch six lines in length, and one inch three lines in breadth. Young birds are found from July to September, and occasionally as late as December. The young birds are easily tamed, and live in harmony with other birds. The barn owl is common in most, if not all the counties of England, and, according to Mr. Thompson, it is also the most common owl in Ireland. In Scotland, it is less numerous. Over the temperate part of the European continent, and in North America, it is generally diffused. Its form and colour are too common to need description. The whole length of the bird is about fourteen inches. (*Yarrell's Brit. Birds*, vol. i.)

BAROMETER. The word is derived from two Greek words, which signify the measurer of weight. This, the most valuable instrument for meteorological observations in the farmer's possession, was invented about the middle of the 17th century, by Torricelli, an Italian philosopher. Some observations of Galileo had, perhaps, led the way to the discovery; the attention of this great philosopher, according to a well known story, having been drawn to the fact that water would not rise higher than 32 feet in a tube exhausted of air, by some workmen of the Duke of Florence, who had vainly endeavoured to construct a comon lifting pump to raise water a greater height. Galileo explained the phenomenon, by saying that nature had a horror of a vacuum, but that this horror had its limits. It was found by Torricelli, that a column of water of about 32 feet exactly balanced the weight of the atmosphere which surrounds our earth, and that this was equal to the weight of a column of mercury of about 28 inches. Now this column of mercury, under various outward shapes, forms the barometer, or weather-glass, so useful to the farmer. For as the pressure of the atmosphere commonly varies with approaching changes in the weather, the consequent rise or fall of the mercury merely marks its amount: one end of the mercurial tube is hermetically sealed and is void of air, so that the quicksilver rises or falls in it unresisted; but the other end of the tube is open, and the atmosphere forces the mercury through this, by pressure on the surface of the fluid mercury in the cistern. Thus, the atmosphere operates by its varying pressure. When, therefore, the quicksilver rises, the atmospheric pressure is increasing; when it falls, the pressure is diminishing.

The more dense the state of the atmosphere, the higher the mercury will rise in the instrument. It is a popular notion that the atmospheric pressure must be greatest when the air is thick and cloudy. The term *density*, when applied to the condition of the atmosphere and its relations with the barometer, means specific weight, without reference to its clearness or cloudiness. Vapour or moisture in the air always lessens its weight, and the more vapour, whether this be invisible, or in the condensed states constituting fogs and clouds, the less the weight or density and pressure upon the barometer.

It is more from this rising and falling of the barometer, observes Mr. Forster, than from its height or lowness, that we are to infer fair or foul weather. In very hot weather the falling of the mercury indicates thunder: in winter, the rising indicates frost; and in frosty weather, if the mercury fall three or four divisions, there will follow a thaw; but in a continued frost, if the mercury rises it will snow. When foul weather happens soon after the falling of the mercury, it will not continue; and, on the contrary, you may expect, if the weather becomes fair as soon as the mercury rises, that it will be of short duration. In foul weather, when the mercury rises much and high, and so continues for two or three days before the foul weather is quite over, then expect a continuance of fair weather to follow.

The words usually inscribed on the scale plates of barometers, such as "Very Dry," "Set Fair," "Fair," etc., etc., are extremely fallacious, and have tended to bring the instrument into great discredit as a weather glass. We may perhaps except "Stormy," for when the lowest falls happen, they are always the precursors of very high winds and storms. The words inscribed are, perhaps, better indications of the weather in England than on the American side of the Atlantic. It must be evident that when a barometer, with a scale plate marked as usual, is carried to high and mountainous positions, the mercurial column falls, and has its relations with the words on the scale plate entirely changed. The person who wishes to make the barometer useful in foretelling the changes of weather in the United States must throw aside all dependence upon inscriptions, with the exception mentioned, and study its fluctuations with reference to the prevailing winds, dew-point, and other conditions of the weather at the time. Rain or snow is frequently preceded by a rise, instead of a fall, of the mercurial column, and a fall of the barometer often indicates the cessation of rain.

The rise in the mercurial column generally indicates a northerly wind. The highest conditions of the barometer in the United States, near the Atlantic, commonly precede north-easterly storms of rain and snow. The very highest elevations have been attended with very cold weather and a light wind from the north, followed by snow or rain within forty-eight hours. A subsidence of the mercury generally indicates wind from a southerly point, and should this be so far round as to blow from land, the fall of rain or snow will commonly

BARREL.

BARROWS.

cease, for a while at least. When, during a wet spell of weather, the wind has veered to the south-easterly points, with a cessation of rain, the wind rising to east and north-east is generally preceded or attended by a rise of the barometer and a renewal of the rain. When the wind has been from the south and south-west, with a moist condition of the atmosphere, or high dew-point, a rise of the barometer indicates that the wind is coming from a point north of west, and a clearing up shower about to ensue.

The following tabular view is intended to show the manner in which the mercurial column of the barometer fluctuates at Philadelphia, a position in the United States, which

may be regarded rather central and removed from the extremes of more northerly and southerly situations. The higher north, the greater the fluctuations of the barometer. The observations were carefully made during the year 1842, by Mr. Owen Evans, a member of the Committee on Meteorology, of the Franklin Institute of Pennsylvania. The graduation of his barometer agrees with that of the standard constructed for the Committee on Meteorology, by which the instruments distributed to the various counties of Pennsylvania are regulated. The elevation of the place of observation is about 30 feet above high-water mark of the Delaware. The means are corrected for temperature to 42° Fahr.

	Jan.	Feb.	March	April	May.	June.	July.	Aug.	Sept.	Oct	Nov.	Dec.	Year.
Mean of Barometer for each month of the year 1842, - - - - -	30.04	30.00	30.04	29.95	29.90	29.92	29.96	29.98	29.97	30.00	30.01	29.99	29.98
Greatest height at the hours of observation, - - - - -	30.63	30.47	30.51	30.42	30.31	30.41	30.30	30.37	30.22	30.34	30.43	30.47	30.63
Lowest falls at the hours of observation, - - - - -	29.53	29.12	29.52	29.57	29.60	29.70	29.78	29.75	29.63	29.66	29.37	29.32	29.12

Many are the natural indications of vegetables which portend changes in the weather; thus, the Pimpernel, or Red Chickweed (*Anagallis arvensis*), is styled the poor man's weather-glass. This little plant blooms in June, in stubble fields and gardens, and continues in flower all the summer. When this plant is seen in the morning with its little red flowers widely extended, we may generally expect a fine day; on the contrary, it is a sign of rain when its petals are closed. (*The Farmer's Almanac.*)

The following table has been constructed from a long series of observations made in London; they will apply, however, to a considerable distance around the metropolis:—

	Barometer, mean Height.	Thermometer, mean Temperature.	Mean quantity of Rain in Inches.
January -	29.921	36.1	1.483
February -	30.067	38.	0.746
March -	29.843	43.9	1.440
April -	29.881	49.9	1.786
May -	29.893	54.	1.853
June -	30.020	58.7	1.830
July -	29.874	61.	2.516
August -	29.891	61.6	1.453
September -	29.931	57.8	2.193
October -	29.774	48.9	2.073
November -	29.776	42.9	2.400
December -	29.693	39.3	2.426

BARREL. A cask or vessel for holding liquids, particularly ale and beer. Formerly the barrel of beer in London, contained only 32 ale gallons = 32½ Imperial gallons. By a statute of 1 W. & M., the ale and beer barrels were equalized for every part of England, except London, and ordered to contain 34 gallons; but it was enacted by 43 Geo. 3, c. 69, that 36 gallons of beer should be taken to be a barrel; and by the 6 Geo. 3, c. 58, it is enacted, that whenever any gallon measure is mentioned in any excise law, it shall always be deemed and taken to be a standard Imperial gallon. At present, therefore, the barrel contains 36 Imperial gallons. It may be worth while observing, that the barrel or cask is exclusively the pro-

duce of European ingenuity, and that no such article is known to any nation of Asia, Africa, or America, who have not derived it from Europeans. The term barrel was formerly used to denote, in a rough way, other sorts of goods. Thus, a barrel of salmon was 42 gallons; a barrel of soap, 256 pounds. In common language, any hollow cylinder is called a barrel. Air and water-tight iron barrels coated with waterproof composition are now used in the navy, and might be made useful to the farmer. (*M'Culloch's Com. Dict.; Brande's Dict. of Science.*)

A measure for Indian corn, in Maryland, Virginia, and other Southern States, containing 10 bushels in the ear = to 3 flour barrels.

BARREN FLOWERS are those which either have stamens and no pistil, or which have neither stamens nor pistil. The latter are the production of art.

BARREN SOILS, in general, owe their sterility to the presence of too great a proportion of particular earths—saline, or organic matters. No soil can be productive in which 19 parts out of 20 are composed of any one earth or other substance. The improvement of such soils constitutes the great art of all manuring and tillage. Lands containing an excess of calcareous matter may be improved by the addition of clay or sand. Sands may be dressed with clay or marl, or vegetable matter. Where organic matters are in excess, the earths may be applied. Water must be removed by draining. (*Davy's Lectures*, p. 203.) See **SOILS**.

BARROWS. The common term for tumuli, or huge mounds of earth which were raised in former times over the bodies of heroes and warriors: many of which exist to the present day on the plains of Wilts and the downs of Dorset, Surrey, Sussex, and other counties. Barrow is also the name for a hog, and for any kind of carriage moved or borne by the hand. The most common barrows in use at present are the wheel-barrow, which is employed for the carriage of light loads, as of earth to short distances, lime for building, manure from the

heaps for spreading, and the like. The hand-barrow is, under certain circumstances, substituted for the wheel-barrow. The load-barrow is used for carrying filled sacks to and from the granary, &c.

BARS. In farriery, a term applied to those portions of the crust or hoof of horses that are reflected inwards, and which form the arches that are situated between the heels and the frog.

Bars of a Horse's Mouth.—The fleshy rows that run across the upper part of the mouth, and reach almost quite to the palate, very distinguishable in some young horses. They form that part of the mouth on which the bit should rest, and have its effect.

BAR-SHOE. A particular kind of shoe, which is sometimes of necessity used to protect a tender frog from injury, the hinder part of the shoe being thickened and hollowed over the frog; but unless it is made exceedingly heavy, it will soon be flattened down, and in the mean time it will most injuriously press upon the heels.

BARTER (Span. *baratar*; Fr. *barrater*; Ital. *barrature*, which signify to cheat as well as to barter: hence also our word *barratry*). The exchanging one commodity for another, without the payment of money. The term *barter* seems to have been derived from the languages of southern Europe. This rude mode of trade grows into desuetude as a country or nation advances in commercial knowledge, and progresses in civilization; and even where an actual exchange of commodities does take place between merchants and traders, their comparative value is expressed by certain current moneys, and balanced accordingly, and not by the proportionate value one article bears to another. The exchange of a civilized people amongst themselves, or with other countries, are principally carried on by bills of exchange. The actual money payments in a country, by no means represent the amount of its commercial transactions. (*Penny Cyclop.*)

BARTH. A provincial term, which signifies a warm enclosed place or pasture for calves, lambs, and other young animals.

BARTON, or BARKEN (Sax. *bepe-tun*, an area). A term employed in some districts to signify the yard of a farm-house. Blount describes this word as meaning the demesne lands of a manor; the manor-house itself, and sometimes the out-houses. Most of our old lexicographers explain it as an enclosed place, or inner yard, where poultry is kept, or husbandry used. Blount's is the provincialism of the west of England; the latter is still used in other places.

BASIL, SWEET (*Ocimum*. Probably from *ἄζα* and *μύρα*, on account of its lasting fragrance). A culinary aromatic exotic used in salads and soups; the peculiar flavour of mock-turtle soups is chiefly derived from this valuable pot-herb. There are two species commonly cultivated, both annuals, and originally coming from the East Indies. 1. The sweet-scented or larger basil (*O. basilicum*), and, 2. The dwarf-basil basil (*O. minimum*). They thrive most in a rich light soil, entirely free from any overshadowing body; but they re-

quire, especially for the earliest plants, a sheltered border. In wet earth, the seed always rots.

BASIL, COMMON WILD (*Chenopodium vulgare*). This is also slightly aromatic, and is a perennial succulent herb, growing in bushy places, about hedges, and by road sides, on a gravelly or chalky soil. The herb rises about a foot high on a wavy, light green, hairy stem, with ovate leaves, an inch long, serrated, and the ribs beneath armed with bristly hairs. The whole of the flowers are also bristly, on branched hairy stalks, both arising from the axilla of the leaves and the top of the stem, of a light purple colour. The flowers blow in July and August. This plant flourishes abundantly in gardens. It is well known among kitchen herbs. Its very odour is fragrant and refreshing.

BASIL-Thyme. Field Thyme (*Thymus acina*). A leafy, small annual plant, much branched and spreading, but scarcely nine inches high, with acute, bluntly serrated leaves, rough at the edges, and slightly aromatic. The flowers are in axillary whorls of a bluish colour, variegated at the tip with white and dark purple; six on a whorl on simple stalks. It grows luxuriantly in cultivated fields, especially on a sandy, gravelly, or chalky soil. (*Smith's Eng. Flor.*)

BASIL. The skin of a sheep tanned.

BASILISK. (Lat.) The name for a serpent.

BASIN, or BASON (Fr. *bassin*; It. *bacino*). In agriculture, a natural or artificial hollow or excavation in the ground, for the reception and preservation of water. See **POND**.

BASKETS (*Basged*, Welsh; *bascauda*, Lat. probably from *bass*, of which baskets were often made). They are made principally of the interwoven twigs of willow, osier, and birch, &c., but frequently also of grass, rushes, splinters of wood, straw, &c. They are made to hold all sorts of dry goods, and constructed of every variety of quality and shape, from the small fruit-pottle to the bushel basket. For market baskets the osiers are used whole. Besides the vast quantities made in England, some of the finer kinds are imported under an *ad valorem* duty of 20 per cent. In 1832 this duty produced 1044*l.* 7*s.* 9*d.*, showing that the value of the foreign baskets entered for home consumption in the same year had been 5221*l.* 18*s.* 9*d.* The fishing basket, pannier, or creel for the angler, should be made of wicker-work, with two openings for a leather strap to pass through, which strap should encircle one shoulder and be buckled, so that it may be let down or taken up as occasion may suit. There are great varieties of these panniers; some are made of sufficient width to carry a fish of four or five pounds at full length.

BASS. The material of which packing mats are made. It consists of the bark of the lime tree.

The American Bass wood, or American Lime, or Linden (*Tilia Americana*), abounds in the forests east of the Mississippi. It exists in Canada, but is most common in the more northern portions of the United States. It becomes less frequent towards the south, and in Virginia, the Carolinas, and Georgia, is found

only on the mountains. Michaux says he found this species of lime tree most abundant in the Genesee country, bordering on Lakes Erie and Ontario, where it frequently constitutes two-thirds, and sometimes the whole of the forests. The sugar maple, the white elm, and the white oak are the trees with which it most frequently associates. On newly cleared land its stump and roots frequently sprout, causing no little trouble to the settler.

The presence of the lime tree indicates a loose, deep, and fertile soil. It is sometimes more than eighty feet high and four feet in diameter. Its straight and even trunk, terminating in an ample and tufted summit, forms a beautiful tree.

The wood is white and soft. In the Northern States, where the tulip poplar does not grow, it is used for the pannels of carriage bodies and the seats of Windsor chairs. It is, however, apt to split, and is not considered equal to poplar for such and other useful purposes. (*North Amer. Sylva.*) The American Lime tree or Linden is extensively cultivated in Europe, where its larger leaves easily distinguish it from the European Lime or Linden, which last bears such sweet blossoms, perfuming the air like the mock orange. The European Linden is so much the prey of insect borers and caterpillars as to make its preservation extremely difficult, especially in cities. The American Linden escapes much better.

BASTARD ALKANET (*Corn Gromwell*, *Lithospermum arvense*). An annual weed common in waste grounds and corn-fields, especially among rye, flowering in May and June. It may be easily known by its tapering root, with a bright red bark, which communicates its colour to oily substances, as well as to paper, linen, and pale faces; and it is therefore occasionally used by the young girls in Sweden to colour their cheeks. This colouring matter is also used to tinge some ointments, especially lip-salves, of a red colour. From the root usually rises a single stem, about a foot high, rough, and generally branched and spreading at the top; sometimes decumbent. The flowers are small and white, surrounded with five long, narrow, hairy leaves. Wildenow says, he has seen a variety with blue flowers. (*Smith's Eng. Flor.*)

BASTARD-TOADFLAX (*Thesium linophyllum*). An English perennial wild plant, with terminal clusters of whitish or yellowish blossoms, many-flowered, erect, generally branched or subdivided, flowering in July. Its root is woody and yellowish, stems widely spreading, angular, leafy, a span or more in length; leaves turned to one side, rough-edged, light-green, an inch long at most. Found in high open chalky pastures. The only species of this genus known in the United States is the *Thesium umbellatum*. (See *Darlington's Flora Cestrica.*)

BAT, or **FLITTERMOUSE** (*Cheiroptera*, a hand and wing). A mammiferous animal which has a body like a mouse, with wings not feathered, but consisting of a membranous skin extended. These wings of the bat, osteologically considered, are hands; the bony stretchers of the cutaneous membrane being

the digital phalanges, or fingers; extremely elongated; one digit or finger of each wing is tipped with a small nail. Bats are widely spread over the globe; they are to be found in the Old and New World, and in New Holland. A tolerably temperate climate seems necessary for them, and the greatest developement of the form takes place in warm countries. Generally speaking, they remain in concealment during the day in caverns, ruinous buildings, hollow trees, and such hiding places, and flit forth at twilight or sunset to take their prey. They feed mostly on flies, insects, &c., but do not refuse raw flesh, so that the notion that bats go down chimneys and gnaw men's bacon is no improbable story.

Bats are divided into two classes, the omnivorous or fruit-eating, and the insectivorous. Those who are desirous of further investigating the subject will find ample particulars under the head "*Cheiroptera*" in the *Penny Cyclo.* vol. vii. p. 19.

BATEABLE HERBAGE. Provincially, such herbage as has the tendency of readily fattening stock of different kinds.

BAT FOWLING. A particular manner of bird-catching in the night, while they are at roost under the eaves of barns, or upon trees or hedges. The fowler lights torches or straw, and beats the bushes, upon which the birds, dazzled by the light, fly into the flames, and are then knocked down with sticks, or caught either with nets or by other means.

BATING. An abbreviation of abating. From bate, to lessen any thing, to retrench, to sink the price. Thus Locke says, "When the landholder's rent falls, he must either bate the labourer's wages, or not employ or not pay him." It is also used synonymously with *barring*, to except.

BATTEN (probably from the French *baton*, from its slender width). A name in common use for a slip or scantling of wood from two to four inches broad and one inch thick, the length inconsiderable, but undefined. If above seven inches wide, it is called deal.

It also signifies strong broad fencing rails. It is sometimes written *batton*.

BAY (Lat. *badius*; old Fr. *baye*, *bai*, rouge brun; Ital. *baio*). The term for a colour inclining to a chestnut. In reference to the horse this colour has various shades, from the very light bay, to the dark bay, which approaches nearly to the brown; but it is always more gay and shining. There are also coloured horses that are called dappled bays. All bay horses are commonly called brown. Bay horses have black manes, which distinguish them from the sorrel, that have red or white manes. There are light bays, and gilded bays, which are somewhat of a yellowish colour. The chestnut bay is that which comes nearest to the colour of the chestnut.

The bay is one of the best colours of horses, and horses of all the different shades of bays are commonly good.

BAYARD. A provincial term for a bay horse.

BAY OF A BARN. That part where the mow is placed. Hence such barns as have the thrashing-floor in the middle, and a space

for a mow on each side, are called barns of two bays, &c.

BAY-SALT. The salt made naturally on the sea-shore at St. Ubes and other bays, in the natural hollows of the sea-shore which are only overflowed at spring tides. The salt thus made at a low temperature by the action of the sun and wind is the strongest and best for butter and other agricultural purposes. (*Brownrigg on Salt; Brande's Dict. of Science.*)

Bay-salt is in large, moderately white cubes. St. Ubes' salt contains 960 parts of pure chloride of sodium in 1000 parts; the remainder consists of 28 parts of sulphate of lime and of magnesia; 3 parts of chloride of magnesia, or bittern; and 9 of insoluble matter. It is consequently very pure. Similar salt, but less pure, is made at St. Martin and Oleven. (For its dietical uses and as a manure, see **SALT, SALTING.**)

BAY-TREE (*Laurus nobilis*). This plant, the laurel of antiquity, is a native of classical ground. We cannot ascertain at what exact period the bay-tree was first cultivated in this country; but in all probability it was planted by the Romans, and fell with their villas. Chaucer, who wrote in the time of Edward III., mentions it; and Turner, our oldest writer on plants, says, in 1564, "the bay-tre in England is no great tre, but it thryueth there many parts better, and is lustier than in Germany." We find that during the reign of Elizabeth it was common to strew the floors of distinguished persons in England with bay-leaves. And we may conclude that it was rare in this country, even so late as the beginning of the eighteenth century, for Bradley says, in 1716, "they (bay-trees) should be put in pots or cases, and housed in the winter, that their beauty may be preserved." He states, that "he has seen pyramids and headed plants of bays introduced in parterre work, but he cannot advise the doing it, lest they should be injured by the weather." There need be no such care taken now, for they have become thoroughly hardy and acclimated. Bradley adds, the finest bay-trees he had ever seen, either abroad or in England, were then in the royal gardens of Kensington, and were of very great value.

The bay is a small tree, seldom exceeding fifteen to twenty feet in height. The bark is greenish, smooth, and aromatic: the leaves lanceolate, sharp-pointed, wavy on the edge, and leathery and smooth on both sides. The flowers are four or six in a cluster, of a yellowish white, glandular, and dotted. The fruit is about the size of a large pea, black, and succulent.

Observation instructs us to place this tree in situations where it is sheltered from north and north-east winds, which affect its beauty, and often its growth. It thrives under the very wings of larger trees, where it is difficult to make other shrubs prosper, and this is of importance in our plantations. A warm, dry, sandy, or gravelly soil is recommended for the bay; but it thrives well on a rich loam. We are told by Mortimer, that bay-trees, whose branches are killed by the weather, or other accident, if cut down to the ground, will send up strong shoots, which we know by experi-

ence to be correct; therefore, the roots should not be grubbed up too hastily. This tree should never have a branch taken from it but in the spring. The directions for raising these trees from seed are given in the same manner by all writers on the subject, from Pliny down to Miller. It is, to gather the fruit when quite ripe, which is not before January or February. The berries are then to be preserved in dry sand until the middle of March, when they may be sown in a shady border of rich, loose, undunged earth. The berries, should be dropped in rows as French beans are planted, and covered with fine, rich mould about an inch thick. The young plants will require frequent but moderate watering for the first two years. The French nurserymen raise them under glass, or in an orangery. The bay-tree will grow by cuttings, but these should be planted in a moderate hot-bed, and kept moist and covered from the heat of the sun during summer, and from the frost in winter. April is the proper time to plant cuttings, but layers may be laid down either in March or August, which, by the second spring, will make good plants.

The variegated bay is increased by budding it on the common sort. Neither the broad nor the narrow-leaved varieties are so hardy as the common bay. The leaves and berries of the bay-tree have an aromatic, bitter, astringent taste, and a fragrant smell: and are accounted stomachic, carminative, and narcotic; but they are not much used in medicine at the present day, although old writers are very voluminous in describing their virtues. (*Philips's Syl. Flor.*)

This well-known evergreen is always handsome in shrubberies, and grows well. It prefers a northern aspect: indeed, we may almost consider the bay-tree a native of England, since gardens and shrubberies are now rarely formed without their presence. The leaves and berries are used as medicine; the leaves should be dried in the proper way, pounded, and kept in glass bottles; they are said to be cordial and beneficial in nervous complaints, and in paralysis: in large doses they prove emetic. The green leaves applied to the part allays the pain of the sting of bees. The berries of the bay-tree contain both volatile and fixed oil, wax, resin, uncrystallizable sugar, gums, starch, some salts, and a peculiar substance, which has been named *laurin*, and bears some resemblance to camphor. The dried berries are given in powder or infusion in flatulent colic; but they are of little value.

BEAGLE (Fr. *bigle*). A small well-proportioned hound, slow but sure, having an excellent nose and most enduring diligence; formerly much in fashion for hunting the hare, but now comparatively neglected, its place being occupied, where hare-hunting is patronized, by the harrier. There are still several varieties of beagles, but formerly there appear to have been many more, from the deep-flewed diminutive type of the old southern hound, to the fleet and elegant fox-hound beagle, to which we may add the pigmy breed called lap-dog beagles. Beagles were formerly distinguished into the rough and the smooth. The rough, wire-haired, or terrier beagle, is now seldom

met with, although it was a hardy, and altogether a vermin-loving breed, and very strongly formed. (*Blaine's Encyclopædia of Rural Sports.*)

BEAM. The principal piece of timber which supports a building.

BEAM OF A PLOUGH. The upper principal timber into which the handles and all the other parts of the tail of the plough are fixed. It is most commonly made of ash wood, somewhat bent in its form, and of different lengths according to the nature of the plough. (See **Ploughs.**)

BEAM-TREE. The *Pyrus aria* of botanists. The white beam-tree or wild pear-tree, is a deciduous British tree of small growth inhabiting the mountainous parts of the country, and resembling a small apple-tree with berries like those of the mountain ash. Its leaves are strongly veined, in a plaited manner, and white underneath; the wood is hard, compact, and tough, and is used for axle trees, naves of wheels, and cogs of machinery. (*Brande's Dict. Science.*)

BEANS (*Vicia Faba*). A well-known vegetable of the pulse species, largely cultivated both in gardens and fields. Sax. bean; *vicia* is the Latin name for the tare or vetch; derived, according to Varro, a *viciardo*, because its tendrils entwine or bind round other plants. The bean was called in Greek *κίχμος*; by the Falisci, a people of Etruria (now Tuscany), *Haba*, whence the name *Faba* seems to be taken. Martinius derives the word from *παω*, to feed, as if it were *Paba*; Isidorus from *φαγα*, to eat. Its cultivation is of much importance in rural economy, inasmuch as it has gone far to supersede fallows on strong loams and clays. The bean is a plant of considerable importance to the farmer, as affording him a valuable food for both horses and swine; its varieties are numerous, but as it is cultivated both for agricultural and horticultural purposes, it will be necessary, in treating of its cultivation, to adopt the following arrangement:—1. Field beans; 2. Garden beans. The English growth of beans has of late years diminished, a large portion of the consumption of this country now coming from abroad; yet I am of opinion that beans or peas, according to the soil, should enter into the rotation of the crops of all English farms: for if drilled and well horse-hoed, it is one of the finest preparations for wheat. And it may be well to observe, that the Russian or winter bean may be successfully cultivated on moist soils.

The flowers of the bean emit a most agreeable perfume. Of all the pulse kind, this was held in the first rank in ancient times. We find the Athenians used beans sodden, in their feasts dedicated to Apollo; and the Romans presented beans as an oblation in their solemn sacrifice called *Fabaria*. Pliny informs us that they offered cakes made of bean meal unto certain gods and goddesses in these ancient rites and ceremonies. Lempriere states that bacon was added to the beans in the offerings to Cama, not so much to gratify the palate of the goddess, as to represent the simplicity of their ancestors. One of the most noble and powerful families of Rome derived the

name of *Fabii* from some of their ancestors having cultivated the bean called *Faba*. The meal of beans is the heaviest made from pulse, and was called in Latin *lomentum*. This was mingled with *frumentii* corn, whole, and so eaten by the ancients; but they sometimes bruised it first; it was considered a strong food, and was generally eaten with gruel or pottage. Many superstitious customs and notions were in olden times attached to this pulse. The ancients made use of beans in gathering the votes of the people, and for electing the magistrates. A white bean signified absolution, and a black one condemnation. From this practice, no doubt, was derived the plan of black-balling obnoxious persons. The Roman husbandman had a religious ceremony respecting this pulse, somewhat remarkable: when they sowed corn of any kind, they took care to bring some beans from the field for good luck's sake, superstitiously thinking that by such means their corn would return home again to them; these beans were then called *Refrinæ* or *Referinæ*. The Romans carried their superstition even further, for they thought that beans mixed with goods offered for sale at the ports would infallibly bring good luck to the seller.

In some places bean meal is still mixed with other meal in making coarse bread; or the beans are boiled into a mess with fat meat, in which state they are very nutritious. Bean meal given to oxen soon makes them fat; mixed with water and given as a drink to cows, it greatly increases their milk. A small quantity of beans is generally mixed with new wheat when ground to flour: the millers pretend that soft wheat will not grind well without beans, and they generally contrive that there shall be no deficiency in the necessary proportion. Thus a quantity of beans is converted into what is considered as wheaten flour.

The bean came originally from the east, and was cultivated in Egypt and Barbary in the earliest ages of which we have any records. It spread thence into Spain and Portugal, from whence some of the best varieties have been introduced into this country. The proportion of nutritive matter in beans, compared with other grain, is, according to Einhof, as follows:—

	By weight.	Or in a bushel.
Wheat	- 74 per cent. - - -	- about 47 lbs.
Rye	- 70 - - -	- 39
Barley	- 65 - - -	- 33
Oats	- 58 - - -	- 23
Beans	- 68 - - -	- 45
Peas	- 75 - - -	- 49
French beans	84 - - -	- 54

(*Davy, Ag. Chem., p. 132.*)

Beans are best given broken, especially to aged live stock. An excellent bean mill constructed by the Messrs. Ransome of Ipswich, will break one quarter of beans in an hour. It is also made with an extra roller and plate for malt; and is sometimes constructed so as to render it suitable for horse power.

Field Beans.—In England, the sorts usually cultivated in the fields are, the tick bean, the horse bean, and the small Dutch Heligoland, or prolific bean. In some situations the mazagon, longpod, and winter or Russian bean, have produced good crops in the field: the first three are, however, best suited for general cultivation. The last, a new and useful variety, has been more recently introduced, and has lately come into very general cultivation in various parts of the kingdom. It is planted in autumn in the usual manner, and is superior to the common bean, inasmuch as it is capable of resisting the severest frost, and is ready for harvesting two months earlier.

There are several varieties of beans, which differ but little in their appearance. Experience is the best guide in choosing the seed which suits particular soils and situations. The small, round, regular-shaped beans are generally preferred, as obtaining the best prices in the markets, especially in large towns where there is a great consumption of beans by hard-working horses.

All the varieties thrive best on strong clay soils, heavy marls, and deep loams of a moist description. In such soils the produce is sometimes 30 to 60 bushels per acre, but an average crop on moderate land is about half that quantity. The Heligolands, and especially the Russian bean, have been found very productive when grown upon hazel moulds, and deep chalk soils intermixed with loam, as they do not require so close a soil as the other varieties. The last-named varieties seldom succeed sufficiently to repay the grower, if attempted to be raised on light lands; indeed, sandy soils or late climates are ill adapted to the successful cultivation of the bean. On very rich land, beans have produced extraordinary crops, by being sown broadcast and very thick, the stems being brought up to a great height in favourable seasons. A small field of very rich land, in the county of Sussex, was sown in the year 1832 with four bushels of the small tick bean, which came up so thick, that the proprietor thought of thinning out the plants by hoeing; but he was advised to see what the produce would be, and when they were thrashed out, there were ten quarters and one bushel of beans. He had the ground accurately measured, and it was found to be one acre and twenty-nine perches, which makes the crop above sixty-eight bushels per acre.

Beans are propagated by seed, which may be sown broadcast, drilled, or dibbled; if sown broadcast, three or four bushels of seed per acre will be required, which should be ploughed or harrowed in; if drilled, two and a half or three bushels per acre will be sufficient. Beans are tolerably hardy, and will bear moderate dry frosts; but they suffer much from alternate frosts and thaws, which in this

climate are so common in February. The end of February or the beginning of March is, therefore, generally preferred for bean sowing. When the season is remarkably mild, early sowing is a great advantage. As a general rule, spring beans may be sown from the middle of February to the middle of March. There are two modes of drilling beans. In one of these the lands or ridges are divided by the plough into ridgelets, or "one bout-stitches," at intervals of about twenty-seven inches.

If dung is applied to beans, the seed ought to be deposited first, as it is found inconvenient to run the drill machine afterwards. The dung may then be drawn out from the carts in small heaps, one row of heaps serving for three or five ridgelets; which is evenly spread and equally divided among them. The ridgelets are next split back or reversed, either by means of the common plough, or one with two mould-boards, which covers both the seed and the manure in the most perfect manner. When beans are sown by the other method in the bottom of a common furrow, the dung must be previously spread over the surface of the winter or spring ploughing. Three ploughs then start in succession, one immediately behind the other, and a drill-harrow either follows the third plough, or is attached to it, by which the beans are sown in every third furrow, or at from 24 to 27 inches asunder, according to the breadth of the furrow-slice.

Another improved mode of sowing beans when dung is applied at seed time, is to spread the dung and plough it down with a strong furrow; after this, shallow furrows are drawn, into which the seed is deposited by the drill machine. Whichever of these modes of sowing is followed, the whole field must be carefully laid dry, by means of channels formed by the plough, and when necessary, by the shovel; for neither then nor at any former period should water be allowed to stagnate on the land. It is a common practice with many farmers to mix and sow with beans a proportionate part of peas, about one-fourth, which, when growing, are called Polts, and are thus cultivated both on the drill and broadcast system. In either case the seed should be put into the ground by the latter end of January, or as soon after as the weather and state of the land will permit. By this intermixture of peas and beans, the straw or haulm is said to be greatly improved. In some places the peas are sown on the headlands, and the haulm is used to tie the beans with; but peas cling round the bean-stalks and impede the setting of the pods; they also interfere with the hoeing and weeding, so that the practice is not to be recommended. Peas require a lighter soil, and are best sown separately, except when they are sown broadcast, mixed with beans, in order to be mown in a green state as fodder for cattle or pigs. Sowing beans for this last-mentioned purpose is not much practised in England, but is found very useful on the Continent, especially in Flanders; in this case they are mown like tares, soon after the pods are formed. In order to have a succession of this green food, they should be sown at different times within a week or a fortnight of each other. By this

means a great deal of grass is saved, which may be reserved for hay. The cattle fed in the stables or yards thrive well on this food, and produce a quantity of rich manure, chiefly in a liquid state, which fills the tanks and reservoirs, which are indispensable appendages to every farm-yard. By having winter tares when the turnips are consumed, peas and beans after the first crop of clover, and summer tares to succeed them, cattle may be fed in the stables all the year round with great advantage; the land may be tilled at the best season of the year and prepared for wheat, as well as by a clear fallow, while the green crop will fully repay all the expenses. Three bushels of beans and two of peas, mixed together, are required per acre, when sown broadcast or drilled in each furrow after the plough. It is often advantageous to cut in a green state those beans which were sown for a general crop, when food for pigs is scarce. They will go nearly as far in this way in feeding store pigs, as the beans would have done when ripe: and the ground is left in a much better state for the following crop. (*Penny Cyclop.* vol. iv. p. 82.)

Many farmers have long and advantageously adopted the practice of dibbling in their beans, by which a great saving of seed is effected; neither are they required to be planted so early as by the old system. Besides being more evenly deposited in the soil, and properly covered over, they are better preserved from rooks, and other vermin that would destroy them. Drilling, however, is still preferred by most agriculturists, as being a less expensive course. Both drilling and dibbling have each great advantages over the broadcast system, as by the latter method the land cannot be kept clean.

Some parties recommend the topping of beans just as the blossoms are set, and assert that it not only improves the quality, but increases the quantity, and causes them to ripen sooner. They may be switched off with an old scythe-blade, set in a wooden handle, with which one man can easily top two acres a day. Others object, and with much justice, to this indiscriminate hacking and topping. The reason for doing this in garden culture is, that when a plant has borne pods a certain time, it is most advantageous to remove it, and the top blossoms, of course, never come to perfection. In the field this is not the case, there being no succession of plants; and, unless the top blossoms are very late, or the black dolphin (*aphis*) begins to appear, which is shown by the honey-dew on the upper shoots, no advantage is gained by topping the plants, and the labour is thrown away. The bean crop is generally harrowed to destroy annual weeds: sometimes just before the plants make their appearance, and sometimes after the beans have got their first green leaves, and are fairly above ground. After the beans have made some growth, the horse-hoe is employed in the intervals between the rows, and followed by the hand-hoe, for the purpose of cutting down such weeds as the horse-hoe cannot reach; all the weeds that grow among the beans should be pulled up with the hands. The same ope-

rations are repeated as often as the condition of the land in regard to cleanliness may require.

When the leaves of the beans begin to lose their green colour, and the pods to turn black, the crop should be reaped with the sickle, and made into small sheaves, tied with straw-bands or tarred twine, and set up in the field to dry. But if the haulm is short, as that of the long-pod and mazagan generally are, it is a more profitable course to pull them up by the roots, and lay them in sheaves, the same as if cut, by which means the lowest and earliest pods are better preserved and harvested. Mr. J. C. Curwen, M. P. (*Com. to the Board of Agr.*, vol. iv. p. 390) gives some details of the result of experiments made in 1803 and 1804, of cutting beans whilst in a perfectly green and fresh state. Forty acres of beans were drilled in February, 1804, and from May to the middle of July the ploughs and harrows were constantly at work in it. By the 10th of August, the beans had shot the black eye, which is the criterion of seeds being perfectly formed. The weather proving unfavourable, prevented their being reaped immediately, but they were eventually cut on the 20th of August, spread thinly, and exposed two days to the sun previous to binding and removing to an open pasture, where they remained three weeks, and were then found perfectly dry and fit for stacking. Mr. Curwen adds, as a strong proof of the benefit resulting from these early cuttings, that he was enabled, previous to drilling with wheat, to give the ground two ploughings, harrowings, &c., and in some parts three (the extreme foulness of this piece of land requiring what in few instances would be necessary); and to cart and spread sixty loads of compost per acre, and to complete the whole by the 20th of September. Mr. John Sherif, of Haddington (*Com. Board of Agr.*, vol. iv. p. 172), also says of harvesting beans, "This crop should be cut down as soon as the eye has attained its deepest dye, and instantly, if dry weather, sheaved. The sheaves of any grain or pulse ought not to exceed nine inches in diameter; and I think that sheaves from six to eight inches would be far safer in this variable climate. By cutting at this period of the state of the crop, the bean-straw will be of triple value of what stands till the leaves fall off; the grain too will be superior to that bleached by the weather for weeks, after the haulm and grain of the first is secured in the rick. Shocks of any crop of pulse or grain ought not to exceed six sheaves of the above-mentioned size." The Rev. John Ramsay, of Ayrshire, and Mr. John Boys, of Kent, also give the result of their observations on bean husbandry (*Com. Board of Agr.*, vol. vi. p. 141—146), which, though valuable, are of too confined and local a nature for me to notice.

The diseases to which beans are subject in England, are the rust, or mildew, which is a minute fungus that grows on the stems of leaves, attributed to cold fogs and frequent sudden transitions of weather, and the black dolphin or fly, also called the *collier*, an insect of the *aphis* tribe. For the mildew no remedy has yet been found. Whenever it has attacked

the plants, generally before the pods are filled, the best method is to cut down the crop in its green state; and if it cannot be consumed in the farm-yard, to plough it into the ground, where it will decay rapidly, and be an excellent manure for the succeeding crop of wheat. If allowed to stand, the crop will not only be unproductive, but the weeds will infest the ground, and spoil the wheat crop by their seeds and roots, which will remain in the soil. Whenever the tops of the beans begin to be moist and clammy to the feel, it is the forerunner of the aphid. They should then be immediately cut off, and this, if done in time, may save the crop from the ravages of the insects; but the most effectual way to prevent any disease from attacking the plants in their growth, is to have the ground in good heart, and well tilled; to drill the beans at a sufficient distance between the rows, to allow the use of the horse-hoe, and thus to accelerate the growth of the plants, and enable them to outgrow the effect of incipient disease, which seldom attacks any but weak plants. In the year 1831, there were imported from abroad 23,388 qrs. of beans. The largest proportion came from the following countries; Denmark, 1299 qrs.; Prussia, 1157 qrs.; Germany, 7664 qrs.; the Netherlands, 7070 qrs.; France, 1454 qrs.; Italy, 3691 qrs.; Malta, 1031 qrs. The total quantity of pulse (for beans and peas are included in the return) entered for home consumption in 1834, was 102,080 qrs.; in 1835, 94,540 qrs. (*Appendix to Second Agr. Report for 1836*, p. 282.; *Phillips's Cultivated Vegetables*; *Penny Cyc.* vol. iv.; *Baxter's Agr. Lib.*; *Prof. Low's work on Agr.*; *Com. Board of Agr.*, vols. iv. and vi.; *M'Culloch's Com. Dict.*)

Garden Beans.—The following varieties are those principally cultivated:—Early mazagan, a great bearer, and a good sort. Early Lisbon, or Portugal bean, a small and sweet kind. Common sword, and other long-pods, the most abundant bearers, and consequently more generally found in the cottager's garden than any other sort. Small Spanish. Broad Spanish. Toker, a good bearer, middling large. White and black blossomed, good sorts, and bear well; middling size: the seed, when old, is apt to degenerate if not saved with care. Windsor, one of our best-tasted beans when young; but not a hardy kind. Green nonpareil, smallish. Besides these, there are the Munford, Dwarf-cluster, or Fan, and the Red blossomed, varieties of little value. In some places the Fan is, however, much grown. It grows only from six to twelve inches high; the branches spread out like a fan, and the pods are produced in clusters. The soil should vary with the season. For the winter-standing and early crops, a moderately rich and dry soil is best adapted to them, since, if too moist, the seed is apt to decay, &c., whilst a moist aluminous one is best for the spring and summer insertions. Although the bean will succeed in much lighter soils than is generally imagined, yet, if such are allotted to it when thus late inserted, the produce is much diminished. The situation cannot be too unincumbered, but still a protection from violent winds is very beneficial, as no plant is more

liable to suffer if its leaves are much injured. It is propagated by seed. For the first production, in the following year, a small plantation may be made at the close of October, or during November, and a rather larger one in December. These should be inserted on a south border, in a row, about a foot from the fence, or in cross-rows. If intended for transplanting, the seed may be sown likewise during these months. Regular plantations may be continued to be made from the beginning of January to the end of June, once every three weeks. Early in July and August the two last crops must be inserted. The Windsor, which is the principal variety then planted, should have a south border allotted; it comes into production about Michaelmas.

The experiments of Bradley serve as a guide in some respects, whereby to apportion the extent of the plantations. He found that a rod of ground, containing fourteen rows, in pairs, at two feet distance, the plants in which are six inches apart, or thirty-four in number, will yield forty-seven quarts of broad beans. Smaller varieties only from one-half to one-third as many. (*General Treat. on Husband. and Garden.*, vol. iii. p. 16.) If the plants are intended to be transplanted, which is only practised for the early crops, the seed must be sown thick, about an inch apart, in a bed of light earth, in a sheltered situation, and of such extent as can be covered with a frame. If frames and hand-glasses are deficient, matting or litter, kept from pressing on and injuring the plants, by means of hooping, &c., are sometimes employed. These, however, afford such imperfect shelter, that there is scarce any advantage superior to the mode of sowing at once, where the plants are to remain, since the intention of this practice is to keep them in vigour, and to forward their growth, by securing them from ungenial weather. Care must be taken that they are not weakened from a deficiency of air or light; to guard against this, the lights should be taken entirely off every day that excessive wet or cold does not imperatively forbid their removal. The usual time for removing them into the open ground, in a south border, is February; if, however, the season is inclement, they may be kept under the frame until May; but then a week previous to their removal, Bradley informs us, they ought to be cut down within two inches of the ground. (*Gen. Treat. on Husband. and Garden.*) When removed, as much earth as possible should be retained round the roots of plants; and they must be set at similar distances as the main crops. No water is required, unless the season be very dry. When sown to remain, the seed may be inserted in rows, by a blunt dibble, or in drills, drawn by the hoe, from two and a half to three feet apart, from two to four inches apart in the row, and two deep, the earliest crops and shortest varieties being set at the smallest distances. These spaces may be considered as large by some gardeners; but the beans, Miller, from experience, asserts, are more productive than if set twice as close. Previous to sowing, in summer, if dry weather, the seed should be soaked for two or three hours in water, or if

sown in drills, these must be well watered immediately before the insertion. When advanced to a height of two inches, hoeing between, and drawing earth about the stems of the plants may commence. This must be often repeated, and even sooner begun to the early and late crops, as it affords considerable protection from frost and wind. As soon as the various crops come into blossom, two or three inches length of each stem is broken off; this, by preventing its increase in height, causes more sap to be afforded to the blossom, consequently causing it to advance with more rapidity, and set more abundantly. Some gardeners recommend the tops to be taken off when the plants are young, not more than six inches high, declaring it makes them branch, and be more productive. This may be ultimately the effect, but it is certainly incorrect to state that it brings them into production sooner: the effect in this respect is much the contrary. The winter-standing crops require, in the early stages of their growth, the shelter of dry litter, prevented touching the plants by small branches, &c. This is only requisite during very severe weather; it must be constantly removed in mild open days, otherwise the plants will be spindled and weakened. For the production of seed, plantations of the several varieties should be made about the end of February, in a soil lighter than that their produce is afterwards to be grown upon. No two varieties should be grown near each other; and in order to preserve the early ones as uncontaminated as possible, those plants only which blossom and produce their pods the first should be preserved. Water ought to be given two or three times a week, from the time of their blossoming until their pods have done swelling. None of the pods ought to be gathered for the table from them; the after-production of seed is never so fine, and the plants raised from it are always deficient in vigour. They are fit for harvesting when the leaves have become blackish, which occurs at the end of August or early in September. They must be thoroughly dried, being reared against a hedge until they are so, before the seed is thrashed out and stored; and those only should be preserved that are fine and perfect. Some gardeners even recommend the pods from the lower part of the stem alone to be selected. Seed beans will sometimes vegetate after being kept for eight or ten years, but are seldom good for any thing when more than two. The plants arising from seed of this age are not so apt to be superluxuriant as from that produced in the preceding year.

BEAN, KIDNEY (*Phaseolus vulgaris*, from its pods resembling a species of ship, supposed first to have been invented at Phaselis, a town of Pamphylia). Of this vegetable there are two species, the one being a dwarf bushy plant, the other a lofty climbing one.

Of the Dwarfs there are twelve varieties:—

Early liver-coloured.	Black speckled.
Early red-speckled.	Brown speckled.
Early white.	Streaked or striped.
Early negro, or black.	Large white.
Canterbury white.	Dun-coloured.
Battersea white.	Tawny.

Of the Runners there are six varieties:—

Scarlet runner.	Canterbury small white.
Large white.	Small white.
Large white Dutch.	Variable runner.

The soil for them may be any thing rather than wet or tenacious, for in such the greater part of the seed, in general, decays without germinating; whilst those plants which are produced are contracted in their produce and continuance. A very light mellow loam, even inclining to a sand, is the best for the earliest sowings, and one scarcely less silicious, though moister, is preferable for the late summer crops; but for the later ones a recurrence must be made to a soil as dry as for the early insertions. In all cases the subsoil must be open, as stagnat moisture is inevitably fatal to the plants or seed. For the early and late crops a sheltered border must always be allotted, or in a single row about a foot from a south fence, otherwise the situation cannot be too open.

Dwarfs.—The sowing commences with the year. They may be sown towards the end of January in pots, and placed upon the flues of the hot-house, or in rows in the mould of a hot-bed, for production in March; to be repeated once every three weeks in similar situations during February and March, for supplying the table during April, May, and June. At the end of March and April a small sowing may be performed, if fine open weather, under a frame without heat, for removal into a sheltered border early in May. During May, and thence until the first week in August, sowings may be made once every three weeks. In September, forcing recommences: at first merely under frames without bottom heat, but in October, and thence to the close of the year, in hot-beds, &c., as in January. Sowings, when a removal is intended, should always be performed in pots, the plants being less retarded, as the roots are less injured, than when the seed is inserted in patches or rows in the earth of the bed. It is a good practice likewise to repeat each sowing in the frames without heat after the lapse of a week, as the first will often fail, when a second, although after so short a lapse of time, will perfectly succeed. In every instance the seed is buried one and a half or two inches deep. The rows of the main crops, if of the smaller varieties, may be one and a half, if of the larger, two feet apart, the seed being inserted either in drills or by the dibble four inches apart; the plants, however, to be thinned to twice that distance.

If any considerable vacancy occurs, it may always be filled by plants which have been carefully removed by the trowel from where they stood too thick. A general remark, however, may be made, that the transplanted beans are never so productive or continue so long in bearing (although sometimes they are earlier) as those left where raised. The rows of the earlier crops are best ranged north and south. The seed inserted during the hottest period of summer, should be either soaked in water for five or six hours, laid in damp mould for a day or two, or the drills be well watered previous to sowing. The only after-cultivation required

's the destruction of weeds, and earth to be drawn up round the stems.

The pods of both species are always to be gathered while young; by thus doing, and care being had not to injure the stems in detaching them, the plants are rendered as prolific and long-lived as possible.

Forcing.—The hotbed must be of moderate size, and covered with earth eight or nine inches thick. When the heat has become regular, the seed may be inserted in drills a foot apart, and the plants allowed to stand six inches asunder in the rows. Some gardeners erroneously sow thick in a hotbed, moulded over about six or seven inches deep, and remove the plants, when two or three inches high, to the above-mentioned distances in another for producing, water and shade being afforded until they have rooted. Air must be admitted as freely as to the melon. The same precautions are likewise necessary as to keeping up the temperature, taking the chill off the water, &c., as for that plant. When the seed begins to sprout, the mould should be kept regularly moistened; and when grown up, water may be given moderately three times a week. The temperature should never be less than 60°, nor higher than 75°.

Some plants of the hotbed sowing at the end of March, are often, after being gradually hardened, planted in a warm border; this will at most hasten the plants in production a fortnight before those sown in the open ground in May.

Those sown under frames in March for transplanting into a border, when two or three inches in height, must in like manner be hardened gradually for the exposure, by the plentiful admission of air, and the total removal of the glasses during fine days. If any are raised in pots in the hot-house, they must in a like manner be prepared for the removal, by setting them outside in fine days, and there watering them with colder water. If the season is too ungenial after all to remove them even to a warm border, the plants are often inserted in patches, to have the protection of frames or hand-lights at night, or as the weather demands. It has been lately stated in a provincial paper, that kidney-beans appear of a perennial nature. In Somersetshire, they have been observed to vegetate for several years—the plants being in the vicinity of a steam-engine, and so situated that the frost could not penetrate to the roots. I have not yet had an opportunity of putting this statement to the test of experiment.

Runners.—As these are more tender, and the seed is more apt to decay than those of the Dwarfs, no open ground crop must be inserted before the close of April, or early in May, to be continued at intervals of four weeks through June and July, which will ensure a supply from the middle of this last month until October. Some gardeners force them in a similar manner to the Dwarfs: they certainly require similar treatment; but they will endure a higher temperature by a few degrees. They are so prolific, and such permanent bearers, that three open-ground sowing of a

size proportionate to the consumption will, in almost every instance, be sufficient.

The runners are inserted in drills, either singly, three feet apart, or in pairs, ten or twelve inches asunder, and each pair four feet distant from its neighbour. The seed is buried two inches deep and four inches apart in the rows, the plants being thinned to twice that distance. If grown in single rows, a row of poles must be set on the south side of each, being fixed firmly in the ground; they may be kept together by having a light pole tied horizontally along their tops, or a post fixed at each end of a row, united by a cross-bar at their tops; a string may be passed from this to each of the plants. If the rows are in pairs, a row of poles must be placed on each side, so fixed in the ground that their summits cross, and are tied together. They are sometimes sown in a single row down the sides of borders, or on each side of a walk, having the support of a trellis-work, or made to climb poles which are turned archwise over it.

As the plants advance to five or six inches in height, they should have the earth drawn about their stems. Weeds must be constantly cleared away as they appear. When they throw up their voluble stems, those that straggle away should be brought back to the poles, and twisted round them in a direction contrary to that of the sun: nothing will induce them to entwine in the contrary direction, or from left to right.

For the production of seed, forty or fifty plants of the Dwarf species will be sufficient for a moderate-sized family, or thirty of the Runner. They must be raised purposely in May, or a like number from the crop in that month may be left ungathered from; for the first pods always produce the finest seeds, and ripen more perfectly. In autumn, as soon as the plants decay, they must be pulled, and, when thoroughly dried, the seed beaten out and stored. (*G. W. Johnson's Kitchen Garden.*)

BEAN-FLY. A beautiful bluish black fly, generally found on bean flowers. It is sometimes called the *collier*. The aphides of beans are invariably brought on by very dry weather; they are most prevalent on the summits of the plants. (See **BEANS.**) The larvæ of the lady-bird, or lady-cow (*Coccinella septempunctata*), as well as the perfect insects, devour the aphids greedily, feeding almost entirely upon these insects. Several of the English summer birds also live upon them.

BEAR. A species of barley, called also winter barley, square barley, and big. It is sometimes written *bere*. This grain is chiefly cultivated in Scotland, the northern parts of England, and Ireland. It yields a very large return, but is not esteemed so good for malting as the common barley, for which reason it is very little cultivated in the southern parts of England.

BEAR-BIND. See **BLACK BIND-WEED.**

BEARD (Sax. *beard*). The same with the awn of a plant.

BEARD-GRASS (*Polypogon*). There are two sorts, the annual beard-grass (*P. monspeliensis*) and the perennial beard-grass (*P. litt-*

ralis). They are found in moist pastures and near the sea, in muddy salt-marshes, but are not often met with.

BEARDED OAT-GRASS. See WILD OATS.

BEAR'S-FOOT. See HELLEBORE.

BEAST (Su. Goth. *beest*, Ger. *bestie*, Fr. *beste*, Lat. *bestia*). A term generally applied to all such quadrupeds, or four-footed animals, as are made use of for food, or employed in labour; but farmers apply the term more particularly to neat cattle.

BED-STRAW, YELLOW, LADIES' (*Galium verum*). It is sometimes termed *cheesening* and *maid's hair*, or *petty muguet* or *mugwort*, and *yellow goose-grass*. A perennial weed, flowering from June till October, more common in the hedges and waysides than in the body of pastures. Its slender stalks rise to about a foot in height. The leaves come out in whorls, eight or nine together. They are long, narrow, and of a green colour. Two little branches generally come out near the top of the stalk, supporting a considerable number of small golden yellow flowers, consisting of one petal divided into four parts, and succeeded by two large kidney-shaped seeds. The flowers of this plant are said to coagulate boiling milk, and the better sorts of Cheshire cheese are sometimes prepared with them. A kind of vinegar is stated to have been distilled from the flowering tops. The French prescribe them in epileptic and hysteric cases; but they are of no value. Boiled in alum-water, they tinge wood yellow. The roots dye a fine red not inferior to madder, and are used for this purpose in the island of Jura. Sheep and goats eat the plant; horses and swine refuse it; cows are not fond of it. Smith enumerates seventeen species of bed-straw:—1. Cross-wort bed-straw, or mugweed; 2. White water bed-straw; 3. Rough heath bed-straw; 4. Smooth heath bed-straw; 5. Rough marsh bed-straw; 6. Upright bed-straw; 7. Gray spreading bed-straw; 8. Bearded bed straw; 9. Warty-fruited bed-straw; 10. Rough-fruited corn bed-straw, or three-flowered goose-grass; 11. Smooth-fruited corn bed-straw; 12. Least mountain bed-straw; 13. Yellow bed-straw; 14. Great hedge bed-straw; 15. Wall bed-straw; 16. Cross-leaved bed-straw; 17. Goose-grass, or cleavers. (*Hort. Gram. Wob.* p. 329; *Smith's Eng. Flora*, vol. i. pp. 199—210.)

Dr. Darlington, in his *Flora Cestrice*, enumerates twenty-one species of this plant found in Chester county, Pennsylvania. Among these are the wild madder (*Galium tinctorium*), sometimes called Dyer's goose-grass, frequent in low grounds. The roots of this and another species of galium (*boreale*) are used by the Indians in dyeing their porcupine quills, and other ornaments, of a red colour. Wild liquorice (*Galium Circæzans*), frequent in rich woodlands and having a sweet taste. Common cleavers, Robin-run-the-hedge, or Yellow goose-grass (Pl. 10, g), a troublesome weed.

BEECH (*Fagus sylvatica*, Sax. *bece* or *boc*). The beech is one of the handsomest of our native forest trees, and in stateliness and grandeur of outline vies even with the oak. Its silvery bark, contrasting with the sombre trunks of other trees, renders its beauties

conspicuous in our woods; while the gracefully spreading pendulous boughs, with their glossy foliage, mark its elegance in the park or paddock. There is only one species, the difference in the wood arising from the effects of soil and situation. The beech is a native of the greater part of the north of Europe and America. The finest beeches in England are said to grow in Hampshire. The tree is also much grown in Wiltshire, Surrey, Sussex, and Kent. The forest of St. Leonard's, near Horsham, Sussex, abounds with noble beech trees. The shade of the beech tree is very injurious to most sorts of plants that grow near it, but it is believed by the vulgar to be very salubrious to human bodies. The wood of this tree, which is hard, and rather handsome, Brande tells us (in his *Dict. of Science*, p. 139), is brittle and perishable, and liable to become worm-eaten. Phillips admits, that it is subject to worms, when exposed to the air without paint; but says, that the timber of these trees, in point of actual utility, follows next to the oak and the ash, and is little inferior to the elm for water-pipes. It is used, he adds (*Hist. of Fruits*, p. 60), by wheelwrights and chairmakers, and also by turners for making domestic wooden ware, such as bowls, shovels, churns, cheese-vats, dressers, shelves for dairies, &c. it being as white as deal, free from all disagreeable smell, and without any inconvenient softness. Bedsteads and other furniture are often made with this timber; and no wood splits so fine, or holds so well together, as beech, so that boxes, sword-sheaths, and a variety of other things, are made from it. The baskets called pottles, in which strawberries or raspberries are usually sold in London, are made from beech twigs and cuttings, and the wood is also much in use for poles, stakes, hoops, &c. Near large towns it is in great demand for billet wood. It affords a large quantity of potash and good charcoal. It is manufactured into a great variety of tools, for which its great hardness and uniform texture render it superior to all other sorts of wood. It is not much used in building, as it soon rots in damp places, but it is useful for piles in places which are constantly wet. The purple and copper beeches seen in plantations are seedling varieties of *Fagus sylvatica*. The beech-tree thrives best and attains to a great size on clayey loams incumbent on sand: silicious sandy soils are also well adapted for its growth, and it will prosper on chalky, stony, and barren soils, where many other timber trees will not prosper; and it is found to resist winds on the declivities of hills better than most other trees. Where the soil is tolerably good, beech will become fit to be felled in about twenty-five years. The tree bears topping, and may, therefore, be trained to form very lofty hedges.

The leaves of the beech, gathered in autumn before they are much injured by the frost, are said to make better mattresses than straw or chaff, as they remain sweet and continue soft for many years; they are also profitably employed in forcing sea-kale, asparagus, &c. in hot-beds. The beech is propagated by sowing the nuts, or mast, which should be gathered.

about the middle of September, when they are ripe, and begin to fall, and spread out on a mat in an airy place for a week to dry, when they may be sown. It is, however, recommended to keep them dry in sand until the spring, as there is less danger of their being then destroyed by field mice and other vermin. These nuts do not require to be covered more than an inch deep in mould, and it will be observed that only a part of them germinates the first year. Two or three bushels of seed are sufficient for an acre, to be sown mixed with sand, in the same manner as the ash.

The flowers of this tree come forth in May, and its kernels ripen in September. The Romans used beech leaves and honey to restore the growth of hair which had fallen off; but the moderns have not found it efficacious.

The nuts or seed of this tree, termed *beech mast*, are the food of hogs, and of various small quadrupeds. They are often called *buck-mast* in England, from the eagerness with which deer feed on them.

An oil, nearly equal in flavour to the best olive oil, with the advantage of keeping longer without becoming rancid, may be obtained from the nuts by pressure. It is very common in Picardy, and other parts of France, where the mast abounds; in Silesia it is used by the country people instead of butter. And in the reign of George I. we find a petition was presented, praying letters patent for making butter from beech nuts.

The cakes which remain from the pressure, after the oil is made, are given to fatten swine, oxen, or poultry. A bushel of mast is said to produce a gallon of clean oil; but the beech tree seldom produces a full crop of mast oftener than once in three years. This nut is palatable to the taste, but when eaten in great quantities occasions headache and giddiness; nevertheless, when dried and ground into meal, it makes a wholesome bread. Like acorns, the fruit of the beech was long the food of mankind before the use of corn. Roasted, the mast has been found a tolerable substitute for coffee. (*Phillips's Hist. of Fruits*, p. 56; *McCulloch's Com. Dict.*; *Baxter's Agr. Library*; *Brande's Diet. of Science*.)

In North America, as in Europe, the beech is one of the common trees of the forest. Two distinct species are found in the Northern States, which have been often treated by botanists as varieties. Michaux, who makes this distinction, calls one the white beech, (*Fagus sylvestris*), and the other the red beech (*Fagus ferruginea*), both the popular names being derived from the colour of the wood. In the Middle Western, and Southern States the red beech does not exist, or is very rare. A deep moist soil and a cool atmosphere are necessary to the utmost expansion of the white beech. In the Middle States, east of the mountains, it is insulated in the forests, whilst in the Northern parts of Pennsylvania, the Genessee district in New York, and in the states of Kentucky and Tennessee, it composes large masses of the primitive forests. The soils on which the beech mostly abounds have generally a stratum of clay or gravel, termed *hard-pan*, which prevents any roots from descending. This

forces the trees to obtain their subsistence from the upper soil, and the roots spread around the trees to a distance sometimes of a hundred feet or more, and so numerous withal as to be greatly in the way of the settler when he first clears his grounds. But he has the satisfaction of knowing that they soon rot away and yield to his plough. The white beech is more slender and less branchy than the red beech; but its foliage is superb, the green being of the most agreeable shade, and its general appearance very beautiful. On the banks of the Ohio and in some parts of Kentucky, where the oak is too rare to furnish enough bark for tanning, the deficiency is supplied by that of the white beech. The leather made with this is white and serviceable, though avowedly inferior to what is prepared with the bark of the oak.

The red beech bears a greater resemblance to that of Europe than the white species. It equals the white beech in thickness, but not in height, has a more massive and spreading summit, and more tufted foliage. The leaves are very similar, but those of the white beech are not quite so thick and large, with rather shorter teeth. To these differences must be added a more important one in the wood. The red beech 15 or 18 inches in diameter consists of 3 or 4 inches of white wood and 13 or 14 inches of red wood or heart, the inverse of which proportion is found in the white beech. The wood of the red beech is stronger, tougher, and more compact. In the state of Maine and in the British Provinces where oaks are rare, it is employed with the sugar maple and yellow birch for the lower part of the frame of vessels. As it is extremely liable to injury from worms, and speedily decays when exposed to alternate dryness and moisture, it is rarely used in the construction of houses. In the state of Maine the hickory is rare, and the white oak does not exist, and when the yellow birch and black ash cannot be procured in sufficient abundance the red beech is selected for hoops.

Experience has demonstrated the advantage of felling the beech in the summer, whilst the sap is in full circulation. Cut at this season it is very durable, but felled in winter, it decays in a few years. The logs are left several months in the shade before they are hewn, care being taken that they do not repose immediately upon the ground. After this they are hewn and laid in water for three months, which process, it is said, renders them inaccessible to worms.

The beech is very durable when preserved from moisture, and incorruptible when constantly in the water; but the white or exterior portion of the wood decays rapidly when exposed to alternations of dryness and dampness. The interior red wood, or heart, as it is usually called, is very durable. In the northern portion of the United States, the red beech constitutes a large proportion of the fuel consumed, and, as in Europe, the wood of the beech subserves a great variety of useful purposes.

The ashes of both species of beech yield a very large proportion of potash.

Michaux, who describes the process of extracting the oil, says that it equals one-sixth

of the nuts used. The quality of the oil depends upon the care with which it is made, and upon the purity of the vessels in which it is preserved. It should be twice drawn off during the first three months, without disturbing the dregs, and the third time at the end of six months. It arrives at perfection only when it becomes limpid, several months after its extraction. It improves by age, lasts unimpaired for ten years, and may be preserved longer than any other oil.

The manner of making beech nut oil most commonly pursued in the districts of the United States where the tree abounds, is somewhat different from that described in Michaux's *Sylva*. Instead of resorting to the rather tedious process of gathering the nuts and pressing them through screw-presses, the farmers turn out their hogs immediately after the first frost, who secrete the oil under their skin. In a favourable year they become perfect masses of blubber. Unless they be fed, sometime before killing, on Indian corn, the bacon has little solid consistency, becomes liquid upon the slightest application of heat, and keeps that state,—resembling in this respect the lard of hogs fed upon acorn mast. The nuts are only plentiful about every third or fourth year, and every farmer keeps a number of half-starved swine in the intervening period to take advantage of the happy event.

BEEF (Fr. *bœuf*), is used either fresh or salted. Beef is also sometimes used for the name of an ox, bull, or cow, considered as fit for food. Formerly it was usual for most families, at least in England, to supply themselves with a stock of salt beef in October or November, which served for their consumption until the ensuing summer; but in consequence of the universal establishment of markets where fresh beef may be at all times obtained, the practice is now nearly relinquished, and the quantity of salted beef made use of as compared with fresh beef is quite inconsiderable. Large quantities of salted beef are, however, prepared at Cork and other places for exportation to the East and West Indies. During the war large supplies were also required for victualling the navy. The vessels engaged in the coasting trade, and in short voyages, use only fresh provisions. The English have at all times been great consumers of beef; and at this moment more beef is used in London, as compared with the population, than anywhere else in Europe.

BEELD, or **BIELD** (Sax. *behlidan*; Icel. *boele*, a dwelling). A term provincially applied in the north of England to any thing which affords shelter, such as a clump or screen of trees planted for the protection of live-stock.

BEER (Welsh, *bir*; Germ. *bier*; Sax. *beap*; Goth. *bar*, *barley*). A liquor made from malt and hops, which is distinguished from ale either by being older or smaller. It may be prepared from any of the farinaceous grains, but barley is most commonly employed.

Beer is, properly speaking, the wine of barley. The meals of any of these grains being extracted by a sufficient quantity of water, and remaining at rest in a degree of heat requisite for this fermentation, are changed into a vinous

liquor. But as these matters render the water mucilaginous, fermentation proceeds slowly and imperfectly. On the other hand, if the quantity of farinaceous matter be so diminished that its extract or decoction may have a convenient degree of fluidity, this liquor will be impregnated with so small a quantity of fermentable matter, that the beer or wine of the grain will be weak, and have little taste. These inconveniences are therefore remedied by preliminary operations which the grain is made to undergo. These preparations consist in steeping it in cold water, that it may soak and swell to a certain degree; and in laying it in a heap with a suitable degree of heat, by means of which, and of the imbibed moisture, a germination begins, which is to be stopped by a quick drying, as soon as the bud shows itself. To accelerate this drying, and to prevent the farther vegetation of the grain, which would impair its saccharine qualities, the grain is slightly roasted, by means of a kiln, or making it pass down an inclined canal sufficiently heated. This germination, and this slight roasting, change considerably the nature of the mucilaginous fermentable matter of the grain, and it becomes the malt of commerce. This malt is then ground; and all its substance, which is fermentable and soluble in water, is extricated by means of hot water. This extract or infusion is evaporated by boiling in cauldrons; and some plant of an agreeable bitterness, such as hops, is added to heighten the taste of the beer, and to render it capable of being longer preserved. Lastly, this liquor is put into casks, and fermented, assisted by the addition of harm.

Beer is nutritious from the sugar and mucilage it contains, exhilarating from the spirit, and strengthening and narcotic from the hops. Mr. Brande obtained the following quantities of alcohol from 100 parts of different beers:—Burton ale, between 8 and 9; Edinburgh ale, 6 to 7; Dorchester ale, 5 to 6. The average of strong ale being between 6 and 7; brown stout, 6 to 7; London porter about 4 (average); London brewers' small beer between 1 and 2. (See **BREWING**.) "The distinction between ale and beer, or porter, has been," says Mr McCulloch, "ably elucidated by Dr. Thomas Thomson in his valuable article on brewing in the supplement to the *Encyc. Brit.*"

"Both ale and beer are in Great Britain obtained by fermentation from the malt of barley but they differ from each other in several particulars. Ale is light-coloured, brisk, and sweetish, or at least free from bitter; while beer is dark-coloured, bitter, and much less brisk. What is called *porter* in England is a species of beer; and the term 'porter,' at present signifies what was formerly called *strong beer*. The original difference between ale and beer was owing to the malt from which they were prepared; ale malt was dried at a very low heat, and consequently was of a pale colour, while beer or porter malt was dried at a higher temperature, and had of consequence acquired a brown colour. This incipient charring had developed a peculiar and agreeable bitter taste, which was communicated to the beer along with the dark colour. This bit

ter taste rendered beer more agreeable to the palate and less injurious to the constitution than ale. It was consequently manufactured in greater quantities, and soon became the common drink of the lower ranks in England. When malt became high priced, in consequence of the heavy taxes laid upon it, and the great increase in the price of barley which took place during the war of the French revolution, the brewers found out that a greater quantity of wort of a given strength could be prepared from pale malt than from brown malt. The consequence was, that a considerable proportion of pale malt was substituted for brown malt in the brewing of porter and beer. The wort, of course, was much paler than before, and it wanted that agreeable bitter flavour which characterized porter, and made it so much relished by most palates. At the same time various substitutes were tried to supply the place of the agreeable bitter communicated to porter by the use of brown malt; quassia, cocculus indicus, and we believe even opium, were employed in succession; but none of them was found to answer the purpose sufficiently." The use of the articles other than malt, referred to by Dr. Thomson, has been expressly forbidden under heavy penalties by repeated acts of parliament. In England, the classification of the different sorts of beer according to their strength, originated in the duties laid upon them; and now that these duties have been repealed, ale and beer may be brewed of any degree of strength.

The duty on beer being repealed in 1830, there are no later accounts of the quantity brewed.

The number of barrels of strong beer brewed in Scotland in the five years ending 1830, was 597,737; table beer, 1,283,490; amount of duty paid thereon, 393,136*l.* (*Parl. Paper*, No. 190, Sess. 1830.)

No account has been kept of the quantity of beer brewed in Ireland since 1809, when it amounted to 960,300 barrels. (*Morewood on Intoxicating Liquors*, p. 353.) Perhaps it may now amount to from 1,000,000 to 1,200,000 barrels. Ale or beer exported to foreign parts is allowed a drawback of 5*s.* the barrel of 36 gallons, Imperial measure. The number of barrels of strong beer annually exported is, from England, about 70,000 barrels; Ireland, 15,000, and Scotland, 3,000. (*McCulloch's Com. Dict.*)

BEES (*Sax.* *oeco*, *Lat.* *apies*). These industrious and useful insects are worthy the attention of all classes, and will repay the utmost care that can be taken in their management.

No farm or cottage garden is complete without a row of these busy little colonies, with their warm, neat straw roofs, and their own particular, fragrant bed of thyme, in which they especially delight. Select a sheltered part of the garden, screened by a wall or hedge from the cutting north and easterly winds; let them enjoy a southern sun, but do not place them facing his early beams, because bees must never be tempted to quit their hive in the heavy morning dew, which clogs their limbs and impedes their flight. Place them, if possible, near a running stream, as they de-

light in plenty of water; but if none is within their easy reach, place pans of fresh water near the hives, in which mix a little common salt; and let bits of stick float on the surface, to enable bees to drink safely, instead of slipping down the smooth sides of the vessel, and perish. Never place hives in a roofed stand: it heats them, and induces the bees frequently to form combs outside of their hives instead of swarming. Let the space before the hives be perfectly clear of bushes, trees, and every impediment to their movement, that they may wing their way easily to seek for food, and return without annoyance. Bees, returning heavily laden and wearied, are unable to bear up against any object, should they hit themselves and fall. Let their passage to and from their hives be clear; but trees and bushes in the vicinity of their residence are advisable, as they present convenient spots for swarms to settle which might otherwise go beyond sight or reach. A swarm seldom goes far from home, unless the garden is unprovided with resting-places, to attract the queen, who takes refuge in the nearest shelter. In the month of November remove your hives upon their stools, into a cool, dry, and shady room, outhouse, or cellar, where they will be protected as well from the winter sun as from the frosts. Warm days in winter often tempt bees to quit their cells, and the chilling air numbs and destroys them. Let them remain thus until February or March, should the spring be late and cold. Do not be satisfied with stopping the mouth of the hive with clay; the bees will soon make their way through it. *Remove them.* Bees are very subject to a disease in the spring, similar to dysentery. Before you place the hives in their summer quarters, examine the state of the bees by turning up the hive, and noticing the smell proceeding from it. If the bees are healthy, the odour will be that of heated wax; but if diseased, it will appear like that of putrefaction. In this case, a small quantity of port wine or brandy mixed with their food will restore them. In the early spring feed them, and do the same when the flowers pass away in autumn, until they are taken into the house; then disturb them no more. The proper food is beer and sugar, in the proportion of one pound to a quart; boil it five minutes only. In May, bees begin to swarm, if the weather is warm. New and dry hives must be prepared without any doorway; the entrance must be cut in the stool. This is recommended by "An Oxford Conservative Bee Keeper."

Sticks across the inside of the hive are useless, and very inconvenient. Let the hive be well washed with beer and sugar before you shake the bees into it. After swarming, place it upon a cloth with one side raised upon a stone; shade it with boughs, and let it alone till quite dusk, then remove it to the stool where it is to stand. The "Oxford Bee Keeper" advises food to be given to a swarm after hiving, for three or four days. Large hives are best: they do not consume more food than small ones; this is a fact, and the same writer mentions it. Smarts and casts are the second and third swarms from a hive: they seldom

live through the winter, and ought to be united to each other, or to a weak hive. This is the plan recommended by several writers; as also returning a smart or cast to the parent hive, if you have no hive weak enough to require an increase of numbers. In this last case, Huish recommends the following plan: Place the back of a chair parallel with the entrance of the hive, over which spread a sheet; then holding the hive containing the smart over it, give a few sharp knocks at the top, and the bees will immediately fall down on the cloth; proceed then, either with your finger or a stick, to guide a few of the bees to the entrance of the parent hive, and they will instantly crowd into it. The queen bee should be caught and secured as they proceed; if this is not done, they kill her, but in a less merciful way.

To form a junction of two weak hives, or a swarm and a hive, Huish discovered the following method: Smoke each hive, as if for taking, only with a less destructive fume, which will be mentioned presently. Spread all the bees of one hive upon a table, and search carefully for the queen; destroy her; sweep the bees of both hives together into one, sprinkling them with some beer and sugar mixed; replace the hive. The fungus used for smoking bees is that called frog's cheese, found in damp meadows; take the largest, and put it into a bag; squeeze it to half its size, then dry it in an oven or before the fire, but not by a very quick heat. Take a piece of this dried fungus, the size of two eggs, and put it in a stick split at one end, and sharp at the other, which is to be fixed into the bottom of an empty hive turned upside down, to receive the stupefied bees as they fall.

To prevent swarming, the "Oxford Bee Keeper" recommends this treatment:—

"You see in the following figure a wooden

bottom board, with the doorway *a a* cut in it. It has another doorway, *b b*, on the right side. The ring is meant to show where a hive stands on it. The other bottom board is just like it, only the second doorway is on the left hand, so as to fit exactly to the side entrance of the first board, when pushed close together. As soon as the bees begin to hang out, in May, push the two boards close together. In the evening, when they are all in, stop up the entrance *a a*, and open the right hand one *b b*. Put an empty hive on the new board, with a glass worked into the back for observation. Each doorway has a bit of tin laid over as much of it as juts out beyond the hive. The bees must then find their way out by the new doorway; rub it with a little honey, and they will soon take to it. When the second hive is full, remove it thus: in the heat of the day, when many bees are out, slip a piece of tin or card between the two doorways, shut up the doorway *c c*, and open

the old doorway *a a*. If the bees go on working quietly all day, you will be sure that the queen is in the old hive, and all is right. About half an hour before dusk, open again the doorway *c c*, and the bees, frightened by their long imprisonment, will hurry from one doorway to another to join the queen. As soon as they are gone, take away the full hive for yourself. If the old hive is very uneasy all day, you may be sure the queen is shut up in the new hive: if so, draw out the card or tin to join them again, and wait till another day."

Never destroy a bee; this is the first great principle in their treatment. Bees only live one year, therefore, by killing them in September, you destroy the young vigorous ones ready to work the following spring: the year-old bees die in August. When a hive is to be taken, smoke the bees as directed for joining hives; replace them in a fresh hive, taking care to ascertain that the queen is safe among them, and feed them through the autumn and spring; they will be ready to work with the rest, and a hive is thus added to the general stock. The queen is easily known from the working bees, as the size is larger.

By fumigating the bees with tobacco smoke while operating upon a hive, they are rendered perfectly harmless. It is well to protect the face, neck, and hands, to prevent alarm or the chance of accident. When stung, extract the sting, and apply Goulard water immediately, or laudanum, or sweet oil. In February bees first begin their labours. May is their busiest month. In November their labours end, and they remain torpid for the winter. For more particular instructions, see *Huish on Bees*; *The Conservative Bee Keeper's Letter to Cottagers*; *Wildman's Treatise on Bees*; *The Honey Bee*, by *Dr. Bevan*; *Penny Cyclo.*; *Quart. Journ. of Agr.* vol. ii. p. 594; *Baxter's Agr. Lib.* pp. 46—53.

Several of these treatises have been republished in the United States, where, besides separate works upon the subjects, the agricultural periodicals and newspapers abound with suggestions and instructions relative to the management of bees, &c.

Loudon, in his lately published *Encyclopædia of Agriculture*, says, that after all that has been done in England, France, and Italy, the bee is still more successfully managed and finer honey produced in Poland, by persons who never saw a work on the subject, or heard of the mode of depriving bees of their honey without taking their lives. Much as has been written in France and England upon this subject, it is, he observes, still found the best mode to destroy the bee in taking the honey, a practice for which he thinks unanswerable reasons are given by La Grenée, a French apianarian, and which is allowed to be conclusive as to profit even by Huish.

"*Suffocation* is performed when the season of flowers begins to decline, and generally in October. The smoke of paper, or rag soaked or smeared with melted sulphur, is introduced to the hive, by placing it in a hole in the ground where a few shreds of these articles are undergoing a smothering combustion; or the full hive may be placed on an empty one, inverted as in partial deprivation, and the sul

phurous smoke introduced by fumigating bellows, &c. The bees will fall from the upper to the lower hive in a few minutes, when they may be removed and buried to prevent resuscitation. Such a death seems one of the easiest, both to the insects themselves and to human feelings. Indeed, the mere deprivation of life, to animals not endowed with sentiment or reflection, is reduced to the precise pain of the moment, without reference to the past or the future; and as each pulsation of this pain increases in effect on the one hand, so, on the other, the susceptibility of feeling it diminishes. Civilized man is the only animal to whom death has terrors, and hence the origin of that false humanity which condemns the killing of bees in order to obtain their honey, but which might, with as much justice, be applied to the destruction of almost every other animal used in domestic economy, as fowls, game, fish, cattle, &c." (*Encyc. of Agriculture*, 7614.)

As to the best situation for bees during their working season, this must depend upon circumstances of climate and locality. In southerly latitudes and warm exposures,—where the climate will admit of the hives remaining upon the stands during winter,—it may still be advisable to give some shelter, and the principal object should be to ward off the sun, the warmth from which invites the bees to fly abroad at an unprofitable season, and makes them sensitive to the sudden spells of cold experienced throughout the United States. In summer, the extreme heat of the sun should certainly be warded off by sheds and suitable shades, although it is improper to oblige the bees to pass through barriers of boughs and bushes. The heat accumulated by objects exposed to the direct rays of the sun often increases to 130° or 140° of Fahrenheit, a temperature which must be injurious, not only to the bees themselves, but to their honey and wax. Whitewashing the hives and stands will tend much to prevent the accumulation of heat. The hives may front the east, south-east, or south-west, according to circumstances.

In the northerly portions of the United States, means are generally used to protect the swarms in winter, by removal to some cool and dry out-house or cellar. Some bury the hives either partly or entirely under ground, as is practised with many kinds of vegetables. The place should be very dry, and the hives set upon clean straw, without any bottom board to rest on, one side being raised about two inches by means of a stick or stone. An empty space must be left around, three times the size of the hive, covered over with bridging and earth, six, eight, or ten inches in depth, neaped up well so as to turn off water. They may remain thus covered about three months.

Whilst some persons contend for the necessity of protecting bees against the extreme cold of American winters, others deem it not only useless, but destructive to the health and welfare of swarms to remove the hives from their usual situations, however exposed these may be. Among apiarists who disapprove of the removal of hives in the winter, is Dr. J.

V. C. Smith, of Boston, who, in a neat little duodecimo volume of about a hundred pages, "On the Practicability of Cultivating the Honey Bee in Maritime Towns and Cities, as a source of Domestic Economy and Profit," holds the following testimony:—

"During the season of rest, from the first of October to the first or middle of April, the quantity of honey consumed by such a hive as has been spoken of, as worth keeping, varies according to the average temperature of the weather, from ten to twenty pounds. It is better that the bees should have too much than too little in store. They are very economical in the expenditure of food, and therefore there is no risk in trusting them with well stocked granaries. All hives should have the weight marked on the back, which will enable the manager to judge pretty accurately of the quantity of honey and wax on hand. Taking five pounds as the standard weight of the bees, and a half pound of wax to every fifteen pounds of honey, almost the exact quantity of honey can thus be ascertained. My rule has invariably been, to let the bees remain in winter, wherever they have stood through the summer; all attempts on my part to prepare them for the inclemencies of approaching cold were invariably anticipated, and seasonably attended to by the bees themselves.

"Feeling peculiar commiseration for a swarm, two years since, whose bleak locality, I feared, would be the certain destruction of the hive before spring, they were placed in the lobby of an adjacent building for comfort. In the month of March, discovering that thousands of them were dead on the floor, and that the bees were sickly, they were carried back to their old stand in the open air, at the summit of a high, exposed hill, where they were perfectly restored to health in about twelve days. If they are housed in winter, the torpidity which seems to be constitutionally requisite, both for the future health of the bee, and the saving of its honey, is obviated, and indisposition, in consequence of constantly feeding, without exercise, is the invariable result. The colder they are, the better: I am fully persuaded that bees, in their hive, cannot be frozen to death. Animation may be suspended several weeks or months with impunity—vitality may merely appertain to organized matter; but, when the genial warmth of spring comes gently on, the little spark of life is again rekindled into vigorous flame.

"On the 21st of March, 1831, in company with Mr. J. S. C. Greene, we examined a hive of bees that had, probably, died for want of proper ventilation. There were two thousand two hundred bees. A common flint tumbler contained one thousand, weighing six ounces and a half. It was obvious they did not die of starvation, as there was a good supply of beautiful honey, which, together with the comb, weighed twenty-two pounds. Allowing one half pound of cell comb for holding every fifteen pounds of honey, the quantity was easily ascertained. Taking this in connection with that which was taken from them in the autumn, and at the same time admitting that five hundred bees were lost by high autumnal winds,

storms, and early frosts, the whole colony consisted, originally, of thirty-two hundred bees, which, in eight weeks, or thereabouts, collected the wax, constructed the cells, and made over one hundred pounds of honey, in a garden on Pemberton's Hill, nearly in the centre of Boston! It should be remarked, that a bee answering the general description of the queen, as it relates to external appearance, was found in a cluster of dead ones. Not a drone was discovered, nor a young bee in any stage of infancy."

It is probable that bees can preserve their vitality in ordinary hives exposed to the most intense cold, so long as they remain in the torpid condition in which they are prepared for the worst. But when roused from this condition by the occurrence of a premature warm spell, they are then rendered sensitive to the effects of cold, and when this comes upon them suddenly and with severity, they perish under it. The great object therefore appears to be, to place the swarms during winter in some dry situation where they may be kept at a cool and equable temperature. A good dry and cool cellar must answer all the purposes admirably, and from such a situation it is easy to remove them occasionally, in good mild weather, and give them an airing.

Loudon, who adopts the views of Howison and Huish, says that the *best material and form* for hives is a straw thimble, or flower-pot, placed in an inverted position. Hives made of straw, as now in use, have a great advantage over those made of wood and other materials, from the effectual defence they afford against the extremes of heat in summer and cold in winter. A full-sized straw hive will hold three pecks; a small-sized, from one and a half to two pecks. (*Encyc. of Agric.*)

The *feeding of bees* is generally deferred till winter or spring; but this is a most erroneous practice: hives should be examined in the course of the month of September, or about the time of killing the drones; and if a large hive does not weigh thirty pounds, it will be necessary to allow it half a pound of honey, or the same quantity of soft sugar made into syrup, for every pound that is deficient of that weight; and in like proportion to smaller hives. This work must not be delayed, that time may be given for the bees to make the deposit in their empty cells before they are rendered torpid by the cold. Sugar simply dissolved in water (which is a common practice), and sugar boiled in water into a syrup, form compounds very differently suited for the winter store of bees. When the former is wanted for their immediate nourishment, as in spring, it will answer equally as a syrup; but if to be laid up as a store, the heat of the hive quickly evaporating the water, leaves the sugar in dry crystals, not to be acted upon by the trunks of the bees. Hives may be killed with hunger while some pounds' weight of sugar remain in this state in their cells. The boiling of sugar into syrup forms a closer combination with the water, by which it is prevented from flying off, and a consistence resembling that of honey retained. Howison has had frequent experience of hives, not containing a pound of honey,

preserved in perfect health through the winter with sugar so prepared, when given in proper time and in sufficient quantity.

In the article from Loudon, from which we are now quoting, it is recommended to *protect hives from cold*, by covering them with straw or rushes, about the end of September, or later, according to the climate and season. This perhaps only applies to board hives, as those made of thick rye-straw or rushes will do without additional covering. Well protected hives always prosper better the following season than such as have not been covered. In October, the aperture at which the bees enter should generally be narrowed, so that only one bee may pass at a time. Indeed, as a very small portion of air is necessary for bees in their torpid state, it were better during severe frosts to be entirely shut up, as numbers of them are often lost from being enticed to quit the hive by the sunshine of a winter day. It will, however, be proper at times to remove, by a crooked wire or similar instrument, the dead bees and other filth, which the living at this season are unable to perform of themselves. To hives whose stock of honey was sufficient for their maintenance, or those to which a proper quantity of sugar had been given for that purpose, no further attention will be necessary until the breeding season arrives. This, in warm situations, generally takes place about the beginning of May; and in cold, about a month after. The young bees, for a short time previous to their leaving their cells, and some after, require being fed with the same regularity that young birds are by their parents; and if the store in the hive be exhausted, and the weather such as not to admit of the working bees going abroad to collect food in sufficient quantity for themselves and their brood, the powerful principle of affection for their young compels them to part with what is not enough for their support, at the expense of their own lives. To prevent such accidents, it is advisable, if during the breeding season it rain for two successive days, to feed all the bees indiscriminately, as it would be difficult to ascertain those only which require it.

The *swarming of bees* generally commences in June, in some seasons earlier, and in cold climates or seasons later. The first swarming is so long preceded by the appearance of drones, and hanging out of working bees, that if the time of their leaving the hive is not observed, it must be owing to want of care. The signs of the second are, however, more equivocal, the most certain being that of the queen, a day or two before swarming, at intervals of a few minutes, giving out a sound a good deal resembling that of a cricket. It frequently happens that the swarm will leave the old hive, and return again several times, which is always owing to the queen not having accompanied them, or from having dropped on the ground, being too young to fly to a distance. Gooseberry, currant, or other low bushes, should be planted at a short distance from the hives, for the bees to swarm upon, otherwise they are apt to fly away; by attending to this, Howison has not lost a swarm by straying for

several years. When a hive yields more than two swarms, these should uniformly be joined to others that are weak, as, from the lateness of the season, and deficiency in number, they will otherwise perish. This junction is easily formed, by inverting at night the hive in which they are, and placing over it the one you intend them to enter. They soon ascend, and apparently with no opposition from the former possessors. Should the weather for some days after swarming be unfavourable for the bees going out, they must be fed with care until it clears up, otherwise the young swarm will run a great risk of dying.

The honey may be taken from hives of the common construction by three modes, partial deprivation, total deprivation, and suffocation.

Partial deprivation is performed about the beginning of September. Having ascertained the weight of the hive, and consequently the quantity of honeycomb which is to be extracted, begin the operation as soon as evening sets in, by inverting the full hive, and placing an empty one over it; particular care must be taken that the two hives are of the same diameter, for if they differ in their dimensions it will not be possible to effect the driving of the bees. The hives being placed on each other, a sheet or large table-cloth must be tied round them at their place of junction, in order to prevent the bees from molesting the operator. The hives being thus arranged, beat the sides gently with a stick or the hand, but particular caution must be used to beat it on those parts to which the combs are attached and which will be found parallel with the entrance of the hive. The ascent of the bees into the upper hive will be known by a loud humming noise; in a few minutes the whole community will have ascended, and the hive with the bees in it may be placed upon the pedestal from which the full hive was removed. The hive from which the bees have been driven must then be taken into the house, and the operation of cutting out the honeycomb commenced. Having extracted the requisite quantity of comb, this opportunity must be embraced of inspecting the hive, and of cleaning it of any noxious matter. In cutting the combs, however, particular attention should be paid not to cut into two or three combs at once, but having commenced the cutting of one, to pursue it to the top of the hive; and this caution is necessary for two reasons. If you begin the cutting of two or three combs at one time, were you to abstract the whole of them you would perhaps take too much; and secondly, to stop in the middle of a comb will be attended with very pernicious consequences, as the honey would drop from the cells which have been cut in two, and then the bees, on being returned to their native hive, might be drowned in their own sweets. The bees also, in their return to their natural domicile, being still under the impression of fear, would not give so much attention to the honey which flows from the divided cells; and as it would fall on the board, and from that on the ground, the bees belonging to the other hives would immediately scent the wasted treasure, and a general attack on the deprived hive might be the consequence. The

deprivation of the honeycomb being effected, the hive may be returned to its former position, and reversing the hive which contains the bees, and placing the deprived hive over it, they may be left in that situation till morning, when the bees will be found to have taken possession of their native hive, and, if the season proves fine, may replenish what they have lost. (*Huish's Treatise on Bees.*)

Total deprivation is effected in the same manner, but earlier in the season, immediately after the first swarm; and the bees, instead of being returned to a remnant of honey in their old hive, remain in the new empty one: which they will sometimes, though rarely, fill with comb. By this mode it is to be observed, very little honey is obtained, the bees in June and July being occupied chiefly in breeding, and one, if not two, swarms are lost. (*Loudon's Encyc. of Agriculture.*)

The mode of suffocation to be adopted by those who prefer destroying bees in taking honey, has already been given.

Particular attention should be paid to the culture of such plants as supply the bees with the best food and materials for making honey, such as thyme, clover, broom, and mustard, &c.

As a good deal of difference of opinion exists relative to the construction of hives and management of bees, we have endeavoured to condense the views upon the subject entertained by the most respectable authorities. It is a great desideratum that honey be brought to market without removal from the hive in which it is originally deposited, which enables the purchaser to keep it in fine condition for any length of time. Few persons will purchase the contents of a very large hive, when honey in small boxes generally sells readily. Hence one great advantage of having the hives constructed in sections, which, being of the same size, can always be fitted over or under each other. According to the views of Mr. Harasti, a skilful bee-cultivator, a good beehive ought to possess the following properties: First, it should be capable of enlargement or contraction according to the size of the swarm. Secondly, it should admit of being opened without disturbing the bees, either for the purpose of cleaning it from insects, increasing or dividing the swarm, &c. Thirdly, it should be so constructed, that the produce may be removed without injury to the bees. Fourthly,

Fig. 1.

it should be internally clean, smooth and free from cracks or flaws. All these properties seem best united in the section-hive, which is constituted of two, three, four, or more square boxes of similar size as to width, placed over each other. Such hives are cheap, and so simple that almost any one can construct them. (See Fig. 1.)

The boxes A, B, C, D, may be made from ten to fourteen inches square and about five inches in depth, inside measure. Every bee-keeper should have his boxes made of the same size, so as to fit on to each other. Every hive must have a common top-board, *a*, which should project over the sides of the hive. The top-board of each section should have about sixteen holes bored through at equal distances from each other, and not larger than $\frac{3}{4}$ or smaller than $\frac{1}{4}$ of an inch. Or, instead of such holes, chinks of proper size may be cut through to allow the bees to pass up and down. At the lower part of each box or section, in front, there must be an aperture or little door, *c, c, c, d*, just high enough to let the bees pass, and about an inch and a half wide. The lowermost aperture, *d*, is to be left open at first, and when the hive is filled the upper ones may be successively opened. By placing over the holes in the top of the upper section, glass globes, jars, tumblers, or boxes, the bees will rise into and fill them with honey. These may be removed at any time after being filled. The holes in the tops of the hive which do not open into the glasses or boxes should of course be plugged up. These glass jars, &c. must be covered over with a box so as to keep them in the dark. Every box or section, on the side opposite the little door, should have a narrow piece of glass inserted, with a sliding shutter, by drawing out which the condition of the hive can always be inspected. To make the bees place their combs in parallel lines, five or six sticks or bars may be placed at the top of every section, running from front to rear. The bees will at-

Fig. 2.

attach their combs to these bars, and the intermediate space will afford sufficient light to see them work. The slides covering the glasses should never be left open longer than is just necessary for purposes of inspection.

When one section is removed from the top, a wire or long thin knife must be previously run between this and the one immediately below, so as to destroy the attachments. Then remove the upper section, placing the top upon the one below, which is now the highest division of the hive. Another section is to be placed beneath, lifting up the whole hive for the purpose. Sometimes a second section has to be put under during a good season. If the swarm is not very large three or even two boxes will be sufficient for its accommodation. The boxes or sections may be secured upon each other by buttons, *b, b*, or rabbits, and the joints closed with cement.

A good swarm of bees should weigh five or six pounds, and one weighing eight pounds is

considered large. The weight diminishes to one pound. Such as are less than four pounds weight should be strengthened by a small additional swarm. The hives ought not to be too large, as bees are apt to lose time in filling up vacancies with wax instead of making honey.

Honey collected from flowers growing in meadows, pasture lands, trees, and cultivated crops, is almost as limpid as the purest oil, and the wax nearly as white as snow. Honey collected from buckwheat has a harsh taste. When taken once in two years, it is considered richer and more solid, and will keep better than what is taken every year.

Some of the plants from which bees collect their stores possess poisonous properties and impart these to the honey. The late Dr. B. S. Barton wrote an interesting and valuable paper upon this subject, which is published in the *Transactions of the American Philosophical Society*, volume 5th. The plants which, in the United States, most frequently, afford poisonous honey, are the dwarf laurel (*Kalmia angustifolia*), and the great laurel (*Kalmia latifolia*), the mountain laurel (*Rhododendron maximum*), wild honey-suckle (*Azalia nudiflora*), Jamestown weed, and broad-leaved moorwort of the south (*Andromeda mariana*). Most of these plants are known to produce poisonous honey, whilst a few of them are only suspicious. Of the trees and shrubs resorted to by bees, some furnish them with the farina or flower-dust which yields the spring food for their young, — some, the gummy or resinous exudations or secretions from which they derive the propolis or wax for sealing the hives of fresh swarms,—whilst others yield them honey in greater or less purity. The willow is much resorted to by bees for all the objects mentioned, furnishing the farina, the propolis, and honey-dew (the last from their aphides), in regular succession. When swarms are in the vicinity of the American sweet gum or styrax, they make their propolis from its fragrant gum. At other times they resort to the Athenian poplar. The sweet box myrtle blooms very early in the spring, and its flowers are always thickly beset by bees. The European, or sweet-flowered linden or lime tree, is likewise greatly resorted to by bees when in bloom, and also various kinds of fruit trees, especially the cherry and apple. The sweet juice exuded by the hickory is eagerly sought after by bees, but there is no American forest tree which affords them such ample supplies of the most limpid honey as the tulip poplar of the Middle States. This stupendous tree sometimes rises, in fertile bottom lands, above one hundred feet in height, having a trunk five or six feet in diameter. Such a tree, with every branch from the ground to the summit covered with splendid tulips is a magnificent sight, and a most valuable acquisition when within reach of the apiary.

Among the very great variety of plans which have been adopted by American ingenuity to improve the bee culture, there is one which has acquired much celebrity from its enabling the surplus honey to be taken without destroying the bees, which most persons prefer doing. The plan referred to, is that of

Mr. Luda, of Connecticut. By it the bees are made to build their cells and deposit their honey in the chamber of a dwelling-house appropriated for the purpose, in neat little drawers, from which it may be taken fresh by the owner, without killing the bees. The hive has the appearance of, and is in part, a mahogany bureau or sideboard, with drawers above and a closet below, with glass doors. This case or bureau is designed to be placed in the chamber of a house, or any other suitable building, and connected with the open air or outside of the house by a tube passing through the wall. The bees work and deposit their honey in drawers. When these or any of them are full, or it is desired to obtain honey, one or more of them may be taken out, the bees allowed to escape into the other part of the hive, and the honey taken away. The glass doors allow the working of the bees to be observed; and it is said that the spaciousness, cleanliness, and even the more regular temperature of such habitations, render them the more industrious and successful.

A recent plan called the "Kentucky Bee-house," has been highly commended for its successful adaptation, convenience and cheapness. One is described in the *Farmer's Cabinet*, for June, 1839, by Mr. F. C. Fisher.

"The building is twelve feet long, eight wide, and seven feet high from the floor to the plate or ceiling (the floor being eighteen inches from the ground), and consists of four posts, eleven feet six inches long, let in the ground three feet, which is weather-boarded round, and covered in so as to prevent the bees from getting in the house, they being confined in six boxes, three on either side of the house, placed fifteen inches one above another.

Fig. 3.

between the floor and ground, which are kept filled with water to prevent ants and other insects from getting in the house. Nos. 2, 3, and 4 are tubes eight inches wide, and one-eighth of an inch deep, to convey the bees through the wall into the long boxes, and entering them at the bottom, there being three to each long box. The drawing (fig. 4) represents one side of the house, viewed from the inside.

Fig. 4.

Nos. 1, 2 and 3 are long boxes, eighteen inches wide and twelve deep, extending the whole length of the house, with eight holes, four inches square, in each box, upon which is set two gallon caps, with two half inch holes in each, one near the top, the other about the centre of the cap, in which the smoke of a burning rag is blown to drive the bees from

the cap into the long box. When they are all in the long box,—which can be known by striking the caps,—a knife or wire should be drawn under the bottom of the cap to separate the comb from the box. The cap of honey may then be removed, and an empty one put in its place. Nos. 4 and 5 are tubes three inches square, to convey the bees from one box to another, that one swarm of bees may do the whole work, or if one or more swarms be put in each box, that they may become as one, as they will not permit more than one queen when put together, by which they are prevented from destroying themselves by fighting. A house of this description, when the long boxes are filled, will afford, at a moderate calculation, ninety-six gallons of honey in the comb annually."

A hive under the very pompous name of "Patent Fortified Transparent Royal Bee Palace," invented a few years since by Mr. William Groves, of Cleaveland, Ohio, is said to possess real merits, notwithstanding its unpromising and ridiculous name. It is so constructed that the bees never swarm, and are enabled to reject and roll off all offensive matters, besides defending themselves against intruders. For the preservation of the bees it is said to be preferable to any other hive, and it admits of the convenient removal of honey in any desirable quantity, at all times without disturbing the bees, which are kept clean, well-ventilated, and healthy.

A correspondent of the *Farmer's Cabinet* residing in Western Pennsylvania furnishes the following description of an improved hive, which he says embraces more advantages than any other he has ever seen. Among these are the following:—

"1. It prevents the ravages of the miller, whose worm is the bee's most fatal enemy. The miller deposits its eggs in the bee dirt; which in the common hive is constantly accumulating on the bottom. This difficulty is obviated by the slanting bottom of the stand; the dirt falling on this rolls out at D, and the bottom is kept clean.

"2. The cruel practice of destroying the bees is entirely superseded by the use of this hive. By blowing a small quantity of tobacco smoke into the upper box, through a hole made for that purpose, the bees will descend into the box next below; the upper box can be removed; fifty or sixty pounds of honey, entirely free from dead bees and dirt, can thus be taken from a good hive; and enough remain to winter the bees without any risk of loss.

"3. The swarming of the bees can be regulated by the rise of this hive, and the new swarms taken at the season of the year when they are most valuable. The bees can be prevented swarming again for the season, by additional boxes as the young bees increase.

"4. This hive is cheap and requires but little mechanical knowledge in its construction; any farmer with ordinary tools can make it from the following description:—

Fig. 5, A, is the stand of Mr. Groves's hive, the legs of which are sixteen inches high, the stand itself eighteen inches square. B represents a three-cornered box, open on the top, with a

slanting bottom *c, c*; a space is to be left open in the front of the hive the whole length at *D*, to admit the bees and allow the dirt to slide off the slanting bottom.

Fig. 5.

"1, 2, and 3, are boxes or hives, nineteen inches square, and seven inches high, with slats nailed across, a sufficient distance from each other to admit the free passage of the bees; bars are to be put across the hive to support the comb. The top is to be secured by a tight cover. The bees enter at *D*, and pass up the slanting bottom of the stand into the boxes above, and the boxes can be increased by adding others, always placing the additional boxes nearest the stand."

Mr. T. Afflick, of Cincinnati, has recently published an interesting pamphlet on bees and their hives, entitled "Bee-Breeding in the West," which contains much useful information. His plan for constructing and placing hives seems to combine economy, simplicity, and durability, with the great desideratum of securing the bees against the moth.

The invention is called the *Subtended hive*, and may be constructed by any farmer who can handle a saw, a plane, and a hammer, by pursuing the following directions. "The boxes of which it is to be composed, must be formed of well-seasoned boards, free from knots and wind-shakes, one inch thick; they may be ten, eleven, or twelve inches square in the clear, well-dressed on each side, and joined on the edges, so as to fit close, without being tongued or grooved. Before nailing together at the sides, lay a strip of thick white-lead paint on the edge, which will render the joint impervious to the ovipositor of the moth. In the top of each box cut two semicircular holes, at the front and back, one inch and a half in diameter, the straight side being in a line with the back and front of the box, so that the bees may have a straight road in their way from one story to the other; the top of the upper box must have an extra cover fixed with screws, that it may be easily removed in case of need, so as to form a second box when required: pour a little melted bees-wax over the in-

side of the top, which will enable the bees to attach their comb more firmly. We will suppose the boxes thus made, to be a cube of twelve inches inside measure; in that case, the tunnel-stand will be made thus:—take a piece of two-inch pine plank, free from knots and shakes, twenty-six inches long and eighteen inches broad; now, ten inches from one end, and two inches from the other and from each side, mark off a square of fourteen inches; from the outside of this square, the board is dressed off with an even slope until its thickness at the front edge is reduced to half an inch, and at the other three edges, to about an inch. The square is then to be reduced to twelve inches, in the centre of which is bored an inch auger-hole, and to this hole the inner square is gradually sloped to the depth of an inch—thus securing the bees from any possibility of wet lodging about their hive, and affording them free ventilation. There will then be a level, smooth strip, of one inch in width, surrounding the square of twelve inches, on which to set the box or hive. Two inches from the front edge of the stand, commence cutting a channel two inches in width, and of such a depth as to carry it out on an even slope half-way between the inner edge of the hive and the ventilating hole in the centre; and over this, fit in a strip of wood as neatly as possible, dressing it down even with the slope of the stand, so as to leave a tunnel two inches in width and a quarter of an inch deep. Under the centre hole, and over the outlet of the tunnel, hang small wire grates, the first to prevent the entrance of other insects, and the other to be thrown over to prevent the exit of the bees, or fastened down to keep them at home, in clear, sunny days in winter. For feet to the stand, use four or five inch screws, screwed in from below far enough to be firm; and the whole should have two coats of white paint, sometime before it is wanted, that the smell may be dissipated, as it is very offensive to the bees." (*Farmer's Cabinet*.)

A great variety of patent and fancy hives are from time to time vaunted for their very superior qualities, but in general the simplest construction answers best, and there is perhaps no hive which combines so many advantages as that composed of sections.

In most of the oldest settled parts of the United States, the larva or maggot of the bee-moth (*Phalæna cereana*), a small gray miller, commits great devastation among the swarms of bees. In many places in New England, the farmers have been induced to abandon the bee-culture entirely on account of the destruction caused by the bee-moth. These lay their eggs in the corners and other interior parts of the hive, which they enter at night. In due time these eggs are hatched out into maggots, and growing into worms with strong mandibles, they gnaw their way in any direction they choose to go, making destructive tracks through the honey-comb. After this destructive course, the worm envelopes itself in a thick, soft case or web, and there awaits the final change by which it is converted into the perfect winged miller. Numerous are the expedients resorted to and recommended to obviate the destruction

produced through the moth. Some of the most intelligent apiarians put their chief trust in the strength of the swarms, and when these become reduced and weak, unite them so as to enable the bees to defend their hive against intruders. Placing boxes for wrens near the apiary is also strongly recommended, and with good reason, since these little birds are very active in catching all kinds of moths. To enable the wren to get under the hive, it has been recommended to raise these an inch or an inch and a half above the stand, by means of small blocks.

Another plan frequently adopted, and, it is said, with much success, consists in placing, early in the evening, a burning lamp in a pail, near the hive-stand. Some fresh honey or molasses and water may be spread upon the bottom as a bait. A keg with only one head is thought preferable to a pail for this purpose, owing to the curvature of the staves, which serves to prevent the insect from flying out so readily, and before it has met its destruction from the flame of the lamp. A small fire kept up early in the evening near the apiary is also frequently resorted to for attracting and destroying the night-flying miller. Placing shallow vessels containing sweetened water, with one gill of vinegar added for each pint, is said to attract and drown the moths in great numbers. Shutting up the apertures for the exit and entrance of the bees, early in the evening, is also advised, as the moth intrudes itself in the evening and night. But when this is done the apertures must be opened again very early in the morning. When millers are numerous, each hive should be raised at least twice a week, upon one side, and the worms sought for and destroyed. In this operation a puff of smoke under the hive keeps the bees quiet during the search, which should be performed with as little jarring or disturbance to the swarm as possible.

A correspondent of the Farmer's Register recommends, that as soon as the bees commence working in the spring, the hives are to be examined, and with a piece of hoop-iron or other suitable implement, the stand well scraped immediately under the hive, especially around the inner edge of the box. The whole secret of keeping off the moth consists, he thinks, in keeping the hives free from the web formed by the moth. After this operation, four small blocks of wood are to be placed under each corner of the hive so as to raise it not quite half an inch from the stand. This will permit the hive and stand to be cleaned without raising the box. This scraping operation must be repeated every three or four days, especially if there be any appearance of web. In winter the blocks must be removed, and the hive let down upon the stand as a security against mice, and other depredators upon the honey. The person who recommends this plan as a certain security against the ravages of the worm, advises that an entrance be made for the bees, by cutting a perpendicular slit, one-eighth of an inch wide and two and a half inches long, situated about halfway from the bottom. Just under this a small

bees in going out and returning to the hive. The bees soon get accustomed to this new place of entrance. The plan has, it is said, often proved an effectual security against the worm, after every other remedy has failed.

Some persons have contrived drawers under the hives into which the millers enter by night. The drawers are slipped out every morning, and the moths found in them destroyed.

In the western country and in the new settlements of the Atlantic states, the bee-moth is rarely met with.

Some interesting views relative to the management of bees and construction of apiaries, by Henry Zollickoffer of Philadelphia, may be found in the Farmer's Cabinet for the year 1843.

BEE-MOTH. The following interesting details relative to the natural history of the bee-moth or wax-moth, are from Dr. Harris's Treatise on Destructive Insects. This pernicious insect belongs to a group called *Cambrians*, and was well known to the ancients, as it is mentioned under the name of *Tinea*, in the works of Virgil and Columella. "In the winged state, the male and female differ so much in size, colour, and in the form of their fore-wings, that they were supposed, by Linnæus and by some other naturalists, to be different species, and accordingly received two different names. (*Tortrix cereana*, the male; *Tinea mellonella*, the female.) To avoid confusion, it will be best to adopt the scientific name given to the bee-moth by Fabricius, who called it *Galleria cereana*, that is, the wax *Galleria*, because in its caterpillar state it eats beeswax. Doubtless it was first brought to this country, with the common hive-bee, from Europe, where it is very abundant, and does much mischief in hives. Very few of the *Tineæ* exceed or even equal it in size. In its perfect or adult state it is a winged moth or miller, measuring, from the head to the tip of the closed wings, from five-eighths to three quarters of an inch in length, and its wings expand from one inch and one-tenth to one inch and four-tenths. The male is of a dusty gray colour. The female is much larger than the male, and much darker coloured. There are two broods of these insects in the course of a year. Some winged moths of the first brood begin to appear towards the end of April, or early in May; those of the second brood are most abundant in August; but between these periods, and even later, others come to perfection, and consequently some of them may be found during the greater part of the summer. By day they remain quiet on the sides or in the crevices of the bee-house; but, if disturbed at this time, they open their wings a little, and spring or glide swiftly away, so that it is very difficult to seize or to hold them. In the evening they take wing, when the bees are at rest, and hover around the hive, till, having found the door, they go in and lay their eggs. Those that are prevented by the crowd, or by any other cause, from getting within the hive, lay their eggs on the outside, or on the stand, and the little worm-like caterpillars hatched therefrom easily creep into the hive through the cracks, or gnaw a passage for themselves under the edges of it. These cater-

pillars, at first are not thicker than a thread. they have sixteen legs. Their bodies are soft and tender, and of a yellowish white colour, sprinkled with a few little brownish dots, from each of which proceeds a short hair; their heads are brown and shelly, and there are two brown spots on the top of the first ring. Weak as they are, and unprovided with any natural means of defence, destined, too, to dwell in the midst of the populous hive, surrounded by watchful and well-armed enemies, at whose expense they live, they are taught how to shield themselves against the vengeance of the bees, and pass safely and unseen in every direction through the waxen cells, which they break down and destroy. Beeswax is their only food, and they prefer the old to the new comb, and are always found most numerous in the upper part of the hive, where the oldest honey-comb is lodged. It is not a little wonderful, that these insects should be able to get any nourishment from wax, a substance which other animals cannot digest at all; but they are created with an appetite for it, and with such extraordinary powers of digestion that they thrive well upon this kind of food. As soon as they are hatched they begin to spin; and each one makes for itself a tough silken tube, wherein it can easily turn around and move backwards and forwards at pleasure. During the day they remain concealed in their silken tubes; but at night, when the bees cannot see them, they come partly out, and devour the wax within their reach. As they increase in size, they lengthen and enlarge their dwellings, and cover them on the outside with a coating of grains of wax mixed with their own castings, which resemble gunpowder. Protected by this coating from the stings of the bees, they work their way through the combs, gnaw them to pieces, and fill the hive with their filthy webs; till at last the discouraged bees, whose diligence and skill are of no more use to them in contending with their unseen foes, than their superior size and powerful weapons, are compelled to abandon their perishing brood and their wasted stores, and leave the desolated hive to the sole possession of the miserable spoilers. These caterpillars grow to the length of an inch or a little more, and come to their full size in about three weeks. They then spin their cocoons, which are strong silken pods, of an oblong oval shape, and about one inch in length, and are often clustered together in great numbers in the top of the hive. Some time afterwards, the insects in these cocoons change to chrysalids of a light brown colour, rough on the back, and with an elevated dark brown line upon it from one end to the other. When this transformation happens in the autumn, the insects remain without further change till the spring, and then burst open their cocoons, and come forth with wings. Those which become chrysalids in the early part of summer are transformed to winged moths fourteen days afterwards, and immediately pair, lay their eggs, and die.

Bees suffer most from the depredations of these insects in hot and dry summers. Strong and healthy swarms, provided with a constant supply of food near home, more often escape

than small and weak ones. When the moth-worms have established themselves in a hive, their presence is made known to us by the little fragments of wax and the black grains scattered by them over the floor."

BEESTING or **BIESTING**, written also, **BEESTNING** (Flem. *biest*, *biestmelch*). The first milk taken from cows after calving. It is thick and yellow. This milk is commonly in part taken away from the cow upon her first calving, lest, when taken in too large a quantity by the calf, it should prove purgative.

BEET (Lat. *beta*; Celt. *hett*, red; also said to be so named from the Greek character *beta*, which its seeds resemble when they begin to swell). The sweet succulent root of *Beta vulgaris*, a chenopodiaceous plant of biennial duration. It is used in the winter as a salad, for which purpose the red and yellow beets of Castelnandari are the best; for the food of cattle, that which is named mangel worzel being most used; and for the extraction of sugar, a white-rooted variety with a purple crown is the most esteemed. Sea beet (*Beta maritima*) is a well known and excellent substitute for spinach. (*Brande's Diet. of Science*, p. 139.)

The genus *beta* comprehends several biennial species. Miller enumerates five. 1. The common white beet. 2. The common green beet. 3. The common red beet. 4. The turnip-rooted red beet. 5. The great red beet. 6. The yellow beet. 7. The Swiss, or chard beet. We have now nine varieties of this esculent, which are described with considerable discrimination by Mr. Morgan, gardener to H. Browne, Esq., Mimms Place, Herts. (*Hort. Trans.* vol. iii.) Of the red beet, Mr. Morgan enumerates seven varieties; of these, the three following are generally chosen for cultivation: 1. The long-rooted, which should be sown in a deep sandy soil. 2. The short or turnip-rooted, better adapted to a shallow soil. 3. The green-leaved, red-rooted, requiring a depth of soil equal to that of the long-rooted. There are two distinct species of beet commonly cultivated, each containing several varieties; the one called *Cicla* or *Hortensis*, or white beet, producing succulent leaves only, the other the red beet (*Beta vulgaris*); distinguished by its large fleshy roots.

The white beet is chiefly cultivated in gardens as a culinary vegetable, and forms one of the principal vegetables used by agricultural labourers, and small occupiers of land in many parts of Germany, France, and Switzerland. A variety known by the name of Swiss *chard* produces numerous large succulent leaves, which have a very solid rib running along the middle. The leafy part being stripped off and boiled is useful as a substitute for greens and spinach, and the rib and stalk are dressed like asparagus or scorzenera; they have a pleasant, sweet taste, and are more wholesome than the cabbage tribe. In a good soil the produce is very abundant; and if cultivated on a large scale in the field, this species would prove a valuable addition to the plants raised for cattle. By cultivating it in rows, and frequently hoeing and stirring the intervals, it would be an excellent substitute for a fallow on good light loams. All cattle are

fond of the leaves of this beet, which add much to the milk of cows, without giving it that bad taste which is unavoidable when they are fed with turnips or cabbages, and which is chiefly owing to the greater rapidity with which the latter undergoes the putrefactive fermentation. If sown in May, in drills two feet wide, and thinned out to the distance of a foot from plant to plant in the rows, they will produce an abundance of leaves, which may be gathered in August and September, and will grow again rapidly, provided a bunch of the centre leaves be left on each plant. They do not sensibly exhaust the soil. These leaves when boiled or steamed with bran, cut with chaff or refuse grain, are an excellent food for pigs or bullocks put up to fatten. (*Penny Cyclo.* vol. iv. p. 158.)

The white beet is an excellent root, and is preferred by many to the larger and more common intermediate varieties. It has lately been in great repute in France and Belgium, and indeed all over the continent of Europe, for the manufacture of sugar. The process is given in detail by Mr. Samuel Taylor in the sixth vol. of the *Gardener's Magazine*; and there are some able articles, entering extensively into detail on the subject, in the *Quart. Journ. Agr.* vol. i. p. 624, and vol. ii. pp. 892 and 907. (For an account of the common field beet for cattle, see MANGEL WURZEL.)

BEET, WHITE (*Beta cicla*). This is also known as the *chard*, or *carde*. We have two species in common cultivation, the green and the white. They receive their names from the colour of their footstalks; but the variation is considered by some as fugitive, and that both are produced from seed obtained of the same plant: but this the experience of Mr. Sinclair denies. The French have three varieties of the white—the white, the red, and the yellow—which only differ from ours in having a larger foliage, and thicker, fleshier stalks, but they are less capable of enduring frost. They are cultivated for their stalks, which are cooked as asparagus. Mangel wurzel is sometimes grown for the same purposes; but as it is much inferior, the notice that it may be thus employed, is sufficient. Beets require a rich, mouldy, deep soil; it should, however, be retentive of moisture, rather than light, without being tenacious, or having its alluminous constituent too much predominating. Its richness should preferably arise from previous application than from the addition of manure at the time of sowing; and to effect this, the compartment intended for the growth of these vegetables is advantageously prepared as directed for celery. On the soil depends the sweetness and tenderness of the red and yellow beets, for which they are estimated; and it may be remarked, that on poor, light soils, or heavy ones, the best sorts will taste earthy. Again, on some soils the better varieties will not attain any useful size, or even a tolerable flavour, whilst in the same compartment inferior ones will attain a very good taste. The situation should be open, and as free from the influence of trees as possible; but it is of advantage to have the bed shaded from the meridian sun in summer. I have always found it beneficial to dig the ground two spades deep for these deep-

rooting vegetables, and to turn in the whole or part of the manure intended to be applied, according to the richness of the soil near the surface, with the bottom split, so as to bury it ten or twelve inches within the ground. Salt is a beneficial application to this crop, one reason for which undoubtedly is, their being natives of the sea shore. Both species are propagated by seed, and may be sown from the close of February until the beginning of April: it being borne in mind that they must not be inserted until the severe frosts are over, which inevitably destroys them when in a young stage of growth. The best time for inserting the main crop of the beet root for winter supply is early in March; at the beginning of July or August, a successional crop of the white beet may be sown for supply in the winter and following spring.

It is best sown in drills a foot asunder, and an inch deep, or by dibble, at the same distance each way, and at a similar depth, two or three seeds being put in each hole: it may, however, be sown broadcast and well raked in.

During the early stages of its growth, the beds, which, for the convenience of cultivation, should not be more than four feet wide, must be looked over occasionally, and the largest of the weeds cleared away by hand. In the course of May, according to the advanced state of their growth, the beds must be cleared thoroughly of weeds, both by hand and small hoeing; the beet roots thinned to ten or twelve inches apart, and the white beet to eight or ten. The plants of this last species which are removed may be transplanted into rows at a similar distance, and will then often produce a finer and more succulent foliage than those remaining in the seed bed. Moist weather is to be preferred for performing this operation: otherwise, the plants must be watered occasionally until they take root: they must be frequently hoed and kept clear of weeds throughout the summer.

It is a great improvement to earth up the stalks of the white beet in the same manner as celery, when they are intended to be peeled, and eaten as asparagus.

In October, the beet-root may be taken up for use as wanted, but not entirely for preservation during the winter until November or the beginning of December, then to be buried in sand in alternate rows, under shelter; or, as some gardeners recommend, only part at this season, and the remainder in February; by this means they may be kept in a perfect state for use until May or June. If prevented running to seed, they will produce leaves during the succeeding year; but as this second year's production is never so fine or tender, an annual sowing is usually made. For the production of seed some roots must be left where grown, giving them the protection of litter in very severe weather, if unaccompanied with snow; or if this is neglected, some of the finest roots that have been stored in sand, and have not had the leaves cut away close, may be planted in February or March. Each species and variety must be kept as far away from the others as possible, and the plants set at least

two feet from each other. They flower in August, and ripen their seed at the close of September. Seed of the previous year is always to be preferred for sowing, but it will succeed, if carefully preserved, when two years old.

As a medicine, the seed of the beet is diuretic. The juice of beet-root snuffed up into the nostrils promotes sneezing, and is beneficial in headache and toothache.

BEETLE (*Scarabæidæ*; Sax. býtel). The generic name of a class of insects, of which there are a great many species, all of them having elytra or sheaths over their wings to defend them from hard bodies, which they may meet with in digging holes in the ground, or gnawing rotten wood with their teeth, to make themselves houses or nests. These insects are extremely destructive to many sorts of crops. The beetles most destructive to vegetables and animals are the *weevil beetle*, the *turnip-flea beetle*, the *wood-boring beetle*, and some others, which are described at length by Mr. J. Duncan in the *Quart. Journ. of Agr.* vol. ix. p. 394.

American beetles.—Passing over many groups into which the extensive beetle family is divided, such as the ground-beetles, earth-borers, and dung-beetles, which last, in all their states, are found in excrement; the skin-beetles, which inhabit dried animal substances, and the gigantic Hercules-beetles, which live in rotten wood or beneath old dung-heaps, we come to those groups which require more particular notice from their depredations upon plants, fruits, and trees.

One of the most common, and at the same time most beautiful of the tree beetles of the United States, is the Woolly Areoda, sometimes called the goldsmith (*Areoda lanigera*), which is thus described by Dr. Harris, in his highly interesting and valuable "Treatise upon Insects injurious to Vegetation."—

"It is about nine-tenths of an inch in length, broad oval in shape, of a lemon-yellow colour above, glittering like burnished gold on the top of the head and thorax; the under side of the body is copper-coloured, and thickly covered with whitish wool; and the legs are brownish-yellow, or brassy, shaded with green. These fine beetles begin to appear in Massachusetts about the middle of May, and continue generally till the twentieth of June. In the morning and evening twilights they come forth from their retreats, and fly about with a humming and rustling sound among the branches of trees, the tender leaves of which they devour. Pear-trees are particularly subject to their attacks, but the elm, hickory, poplar, oak, and probably also other kinds of trees, are frequented and injured by them. During the middle of the day they remain at rest upon the trees, clinging to the under-sides of the leaves; and endeavour to conceal themselves by drawing two or three leaves together, and holding them in this position with their long unequal claws. In some seasons they occur in profusion, and then may be obtained in great quantities by shaking the young trees on which they are lodged in the daytime, as they do not attempt to fly when thus disturbed out fall at once to the ground. The larvæ of these

insects are not known; probably they live in the ground upon the roots of plants."

Another member of the Rutilian tribe, to which the goldsmith belongs, is the Spotted Pelidnota, a large beetle found on the cultivated and wild grape-vine, sometimes in great abundance, in the summer months. "It is," says Dr. Harris, "of an oblong oval shape, and about an inch long. The wing-covers are tile-coloured, or dull brownish yellow, with three distinct black dots on each; the thorax is darker, and slightly bronzed, with a black dot on each side; the body beneath, and the legs, are of a deep bronzed green colour. These beetles fly by day, but may also be seen at the same time on the leaves of the grape, which are their only food. They sometimes prove very injurious to the vine. The only way to destroy them is to pick them off by hand, and crush them under foot. The larvæ live in rotten wood, stumps, and roots."

Among the tree-beetles, those commonly called dors, chafers, May-bugs, and rose-bugs, are the most interesting to the farmer and gardener, on account of their extensive ravages, both in the winged and larva states. Whilst the powerful and horny jaws possessed by most of these, are admirably fitted for cutting and grinding the leaves of plants upon which they subsist, their notched and double claws support them securely on the foliage; and their strong and jagged fore-legs, being formed for digging in the ground, point out the place of their transformations.

"The general habits and transformations of the common cock-chaffer of Europe have been carefully observed, and will serve," says Dr. Harris, "to exemplify those of the other insects of this family, which, as far as they are known, seem to be nearly the same. This insect devours the leaves of trees and shrubs. Its duration in the perfect state is very short, each individual living only about a week, and the species entirely disappearing in the course of a month. After the sexes have paired, the males perish, and the females enter the earth to the depth of six inches or more, making their way by means of the strong teeth which arm the fore-legs; here they deposit their eggs, amounting, according to some writers, to nearly one hundred, or, as others assert, to two hundred from each female, which are abandoned by the parent, who generally ascends again to the surface, and perishes in a short time.

"From the eggs are hatched, in the space of fourteen days, little whitish grubs, each provided with six legs near the head, and a mouth furnished with strong jaws. When in a state of rest, these grubs usually curl themselves in the shape of a crescent. They subsist on the tender roots of various plants, committing ravages among these vegetable substances, on some occasions of the most deplorable kind, so as totally to disappoint the best founded hopes of the husbandman. During the summer, they live under the thin coat of vegetable mould near the surface, but, as winter approaches, they descend below the reach of frost, and remain torpid until the succeeding spring, at which time they change

their skins, and reascend to the surface for food. At the close of their third summer, (or, as some say, of the fourth or fifth), they cease eating, and penetrate about two feet deep into the earth; there, by its motions from side to side, each grub forms an oval cavity, which is lined by some glutinous substance thrown from its mouth. In this cavity it is changed to a pupa by casting off its skin. In this state the legs, antennæ, and wing-cases of the future beetle are visible through the transparent skin which envelopes them, but appear of a yellowish white colour; and thus it remains until the month of February, when the thin film which encloses the body is rent, and three months afterwards the perfected beetle digs its way to the surface, from which it finally emerges during the night."

Some account of the destruction occasionally wrought by these insects may be found under the head of **COCK-CHAFFER**.

In their winged state, many species of tree-beetles act as conspicuous a part in injuring trees as their grubs do in destroying herbage. "During the month of May they come forth from the ground, whence they have received the name of May-bugs or May-beetles. They pass the greater part of the day upon trees, clinging to the under-sides of the leaves, in a state of repose. As soon as evening approaches, they begin to buzz about among the branches, and continue on the wing till towards midnight. In their droning flight they move very irregularly, darting hither and thither with an uncertain aim, hitting against objects in their way with a force that often causes them to fall to the ground. They frequently enter houses in the night, apparently attracted, as well as dazzled and bewildered, by the lights. Their vagaries, in which, without having the power to harm, they seem to threaten an attack, have caused them to be called dars, that is, darers; while their seeming blindness and stupidity have become proverbial in the expressions 'blind as a beetle,' and 'beetle-headed.' Besides the leaves of fruit-trees they devour those of various forest-trees and shrubs, with an avidity not much less than that of the locust, so that in certain seasons, and in particular districts, they become an oppressive scourge, and the source of much misery to the inhabitants. Mouffet relates that, in the year 1574, such a number of them fell into the river Severn, as to stop the wheels of the water-mills; and, in the Philosophical Transactions, it is stated that, in the year 1688, they filled the hedges and trees of Galway in such infinite numbers as to cling to each other like bees when swarming; and, when on the wing, darkened the air, annoyed travellers, and produced a sound like distant drums. In a short time the leaves of all the trees, for some miles round, were so totally consumed by them, that at midsummer the country wore the aspect of the depth of winter."

The animals and birds appointed to check the ravages of these and other insects so destructive to vegetation, are different in different countries. In Europe, according to the great French naturalist Latreille, they are the badger, weasel, martin, bats, rats, common

dung-hill fowl, and the goat-sucker, or night-hawk. In the United States, various birds may be always seen in the spring of the year following the plough, among which the black-bird family is by far the most numerous. These ought to meet with the utmost protection, and by no means to be stoned, shot at, killed, and frightened away, as is too often done by the idle and inconsiderate. The following view of the subject will serve to set the subject in the important light it deserves. In "Anderson's Recreations," it is stated that "a cautious observer, having found a nest of five young jays, remarked that each of these birds, while yet very young, consumed at least fifteen of these full-sized grubs in one day, and of course would require many more of a smaller size. Say that, on an average of sizes, they consumed twenty a-piece, these for the five make one hundred. Each of the parents consume, say fifty; so that the pair and family devour two hundred every day. This, in three months, amounts to twenty thousand in one season. But, as the grub continues in that state four seasons, this single pair, with their family alone, without reckoning their descendants after the first year, would destroy eighty thousand grubs. Let us suppose that the half, namely forty thousand, are females, and it is known that they usually lay about two hundred eggs each; it will appear that no less than eight millions have been destroyed, or prevented from being hatched, by the labours of a single family of jays. It is by reasoning in this way that we learn to know of what importance it is to attend to the economy of nature, and to be cautious how we derange it by our short-sighted and futile operations." Our own country abounds with insect-eating beasts and birds, and without doubt the more than abundant *Melolonthæ* form a portion of their nourishment. (*Harris*.)

The very numerous varieties of the beetle family may be imagined from the fact taught us by naturalists, that of the genus *Melolontha* to which the beetles belong, more than two hundred have been described. Several of these found in the United States, produce injuries in the perfect grub state which rival those of the European cock-chaffer. The May-beetle, as it is generally called (*Phyllophaga quercina*), is the most common species.

"It is of a chestnut-brown colour, smooth, but finely punctured, that is, covered with little impressed dots, as if pricked with the point of a needle; each wing-case has two or three slightly elevated longitudinal lines; the breast is clothed with yellowish down. The knob of its antennæ contains only three leaf-like joints. Its average length is nine-tenths of an inch. In its perfect state it feeds on the leaves of trees, particularly on those of the cherry-tree. It flies with a humming noise in the night, from the middle of May to the end of June, and frequently enters houses, attracted by the light. In the course of the spring, these beetles are often thrown from the earth by the spade and plough, in various states of maturity, some being soft and nearly white, their superabundant juices not having evaporated, while others exhibit the true colour and texture of the per-

fect insect. The grubs devour the roots of grass and of other plants, and in many places the turf may be turned up like a carpet in consequence of the destruction of the roots. The grub is a white worm with a brownish head, and, when fully grown, is nearly as thick as the little finger. It is eaten greedily by crows and fowls. There is a grub, somewhat resembling this, which is frequently found under old manure heaps, and is commonly called muck-worm. It differs, however, in some respects from that of the May-beetle, or dor-bug, and is transformed to a dung-beetle called *Scarabæus relictus* by Mr. Say. The beetles are devoured by the skunk, whose beneficial foraging is detected in our gardens by its abundant excrement filled with the wing-cases of these insects. A writer in the 'New York Evening Post,' says that the beetles, which frequently commit serious ravages on fruit-trees, may be effectually exterminated by shaking them from the trees every evening. In this way two pailsful of beetles were collected on the first experiment; the number caught regularly decreased until the fifth evening, when only two beetles were to be found. The best time, however, for shaking trees on which the May-beetles are lodged is in the morning, when the insects do not attempt to fly. They are most easily collected in a cloth spread under the trees to receive them when they fall, after which they should be thrown into boiling water to kill them, and may then be given as food to swine." (Harris.)

In some parts of Massachusetts the beetle called the Georgian leaf-eater takes the place of the *quercina*. It is extremely common in some places in May and June. Its colour is a bay-brown. The upper side is entirely covered with very short yellowish gray hairs, and measures seven-tenths of an inch, or more, in length. These beetles, with some others of the same genus, are commonly found in American gardens, nurseries, orchards, and fields, where they are more or less injurious depredators. They also devour the leaves of various forest-trees, such as the elm, maple, oak, &c. They are all nocturnal insects, never appearing, except by accident, in the day, during which they remain under shelter of the foliage of trees and shrubs, or concealed in the grass. (Harris.)

Of the American diurnal or day-flying beetles, which belong to the Melolonthians, one is described by Professor Gemar, which he proposes to call *cælebs*. It resembles the vine-chaffer of Europe in its habits, and is found in the months of June and July on the cultivated and wild grape-vines, the leaves of which it devours. During the same period these chaffers may be seen in still greater numbers on various kinds of sumach, which they often completely despoil of their leaves. They are very variable in colour. The head and thorax of the male are greenish black, margined with dull ochre or tile-red, and thickly punctured; the wing-covers are clay-yellow, with punctured furrows. The males are sometimes entirely black, and they commonly measure nearly, and the females rather more than seven-tenths of an inch in length. Should these beetles increase

in numbers, Dr. Harris thinks they will be found as difficult to check and extirpate as the destructive vine-chaffers of Europe.

An account of the natural history and habits of the *Rose-bug* or *chaffer*, which belongs to the family of day-fliers, will be found under the head *ROSE-BUG*.

Very few of the beetle tribes which usually subsist upon flowers are injurious to vegetation. Some of them are said to eat leaves, but the greater number live on the pollen and the honey of flowers, or upon the sap which oozes from the wounds of plants. The flower-beetles belong chiefly to a group called *Citronians*. They are easily distinguished from other beetles by their lower jaws, which are generally soft on the inside, and are often provided with a flat brush of hairs that serves to collect the pollen and juices on which they subsist. Most of the bright-coloured kinds are day-fliers; those of dark and plain tints are generally night-fliers. Some of them are of immense size, and have been styled the princes of the beetle tribes; such are the *Incas* of South America, and the Goliath beetle of Guinea, the latter being more than four inches long, two inches broad, and thick and heavy in proportion. (Harris.)

A family of beetles called the *Lucanians*, includes the insects called stag-beetles, horn-bugs, and flying-bulls, vulgar names derived from the great size and peculiar form of their upper jaws, which are sometimes curved like the horns of cattle, and sometimes branched like the antlers of a stag. "These beetles," says Dr. Harris, "fly abroad during the night, and frequently enter houses at that time, somewhat to the alarm of the occupants; but they are not venomous, and never attempt to bite without provocation. They pass the day on the trunks of trees, and live upon the sap, for procuring which the brushes of their jaws and lip seem to be designed. They are said also occasionally to bite and seize caterpillars and other soft-bodied insects, for the purpose of sucking out their juices. They lay their eggs in crevices of the bark of trees, especially near the roots, where they may sometimes be seen thus employed. The larvæ hatched from these eggs resemble the grubs of the *Scarabæians* in colour and form, but they are smoother, or not so much wrinkled. The grubs of the large kinds are said to be six years in coming to their growth, living all this time in the trunks and roots of trees, boring into the solid wood, and reducing it to a substance resembling very coarse sawdust; and the injury thus caused by them is frequently very considerable. When they have arrived at their full size, they enclose themselves in egg-shaped pods, composed of gnawed particles of wood and bark, stuck together and lined with a kind of glue; within these pods they are transformed to pupæ, of a yellowish-white colour, having the body and all the limbs of the future beetle encased in a whitish film, which being thrown off in due time, the insects appear in the beetle form, burst the walls of their prison, crawl through the passages the larvæ had gnawed, and come forth on the outside of the trees.

"The largest of these beetles in the New England States, was first described by Linnaeus under the name of *Lucanus capreolus*, signifying the young roe-buck; but here it is called the horn-bug. Its colour is a deep mahogany-brown; the surface is smooth and polished; the upper jaws of the male are long, curved like a sickle, and furnished internally beyond the middle with a little tooth; those of the female are much shorter, and also toothed; the head of the male is broad and smooth, that of the other sex narrower and rough with punctures. The body of this beetle measures from one inch to an inch and a quarter, exclusive of the jaws. The time of its appearance is in July and the beginning of August. The grubs live in the trunks and roots of various kinds of trees, but particularly in those of old apple-trees, willows, and oaks.

"Several other and smaller kinds of stag-beetles are found in New England, but their habits are much the same as those of the more common horn-bug."

Another great tribe of beetles is described by naturalists under the name of *serricorn*, or *saw-horned* beetles, because the tips of the joints of their antennæ usually project more or less on the inside, somewhat like the teeth of a saw. The beetles belonging to the family of *Buprestians* have antennæ of this kind. The popular name for these in England is burn-cow, a very inappropriate appellation for a perfectly harmless insect. The French call them *richards*, on account of the rich and brilliant colours wherewith many of them are adorned. These beetles are frequently seen on the trunks and limbs of trees, basking in the sun. They walk slowly, and at the approach of danger, fold up their legs and antennæ and fall to the ground. Their flight is swift, and attended with a whizzing noise. They keep concealed in the night, and are in motion only during the day. (*Harris*.)

The larvæ of these saw-horned beetles, are wood-eaters or borers, and orchards and forest trees are more or less subject to their attacks, especially after trees have passed the prime of life. The transformations of these insects take place in the trunks and limbs of trees. The larvæ that are known have a close resemblance to each other; a general idea of them can be formed from a description of that which attacks the pig-nut hickory. These grubs are found under the bark and in the solid wood of trees and sometimes in great numbers. They frequently rest with the body bent side-wise, so that the head and tail approach each other. They appear to pass several years in this larvæ state, before they cast off the pupa-coat and cut out through the bark in the form of a beetle.

"Some of these beetles are known to eat leaves and flowers, and of this nature is probably the food of all of them. The injury they may thus commit is not very apparent, and cannot bear any comparison with the extensive ravages of their larvæ. The solid trunks and limbs of sound and vigorous trees are often bored through in various directions by these insects, which, during a long-continued life, derive their only nourishment from

the woody fragments they devour. Pines and firs seem particularly subject to their attacks, but other forest-trees do not escape, and even fruit-trees are frequently injured by these borers. The means to be used for destroying them are similar to those employed against other borers, and will be explained in a subsequent part of this essay. It may not be amiss, however, here to remark, that wood-peckers are much more successful in discovering the retreats of these borers, and in dragging out the defenceless culprits from their burrows, than the most skilful gardener or nurseryman.

"Until within a few years the Buprestians were all included in three or four genera. A great number of kinds have now become known, probably six hundred or more."

The largest of these beetles known to Dr. Harris, is called the Virginian Buprestis, or saw-horn beetle. It is of an oblong shape, brassy, or copper-coloured; sometimes almost black, with hardly any metallic reflections. On each wing-cover are two small square impressed spots. It measures eight-tenths of an inch to one inch or more in length. This beetle appears in Massachusetts towards the end of May, and through the month of June, on pine trees and on fences. In the larvæ state, it bores into the trunks of the different kinds of pines, and is often times very injurious to these trees. (*Harris*.)

The wild-cherry tree (*Prunus serotina*) and also the garden cherry and peach trees, suffer severely from the attacks of borers, which are transformed to beetles called *Buprestis divaricata*, from the wing-covers parting a little at the tips. These beetles are copper-coloured, sometimes brassy above, and thickly covered with little punctures. They measure from seven to nine-tenths of an inch.

Other species of American wood-eaters or borers are described by Dr. Harris, among which are those attacking the hickory, oak, and white pine. When trees are found to be very much infested by borers, and are going to decay in consequence of their ravages, it will be better to cut them down and burn them immediately, rather than to suffer them to stand until the borers have completed their transformations and made their escape. (*Harris*.)

The family of *Spring-beetles*, or *Elaters*, are closely related to the Buprestians. They derive their name from the well known faculty of throwing themselves up with a jerk when laid on their backs, the legs being too short to enable them to turn over by their assistance.

"The larvæ or grubs of the *Elaters*," says Dr. Harris, "live upon wood and roots, and are often very injurious to vegetation. Some are confined to old or decaying trees, others devour the roots of herbaceous plants. In England they are called wire-worms from their slenderness and uncommon hardness. They are not to be confounded with the American wire-worm, a species of *Iulus*, which is not a true insect, but belongs to the class *Myriapoda*, a name derived from the great number of feet with which most of the animals included in it are furnished; whereas the English wire-worm has only six feet. The European wire-worm is said to live, in its feeding or larva state, not less than five

years; during the greater part of which time it is supported by devouring the roots of wheat, rye, oats, and grass, annually causing a large diminution of the produce, and sometimes destroying whole crops. It is said to be particularly injurious in gardens recently converted from pasture lands. We have several grubs allied to this destructive insect, which are quite common in land newly broken up; but fortunately, as yet, their ravages are inconsiderable. We may expect these to increase in proportion as we disturb them and deprive them of their usual articles of food, while we continue also to persecute and destroy their natural enemies, the birds, and may then be obliged to resort to the ingenious method adopted by European farmers and gardeners for alluring and capturing these grubs. This method consists in strewing sliced potatoes or turnips in rows through the garden or field; women and boys are employed to examine the slices every morning, and collect the insects which readily come to feed on the bait. Some of these destructive insects, which I have found in the ground among the roots of plants, were long, slender, worm-like grubs, closely resembling the common meal-worm; they were nearly cylindrical, with a hard and smooth skin, of a buff or brownish yellow colour, the head and tail only being a little darker; each of the first three rings was provided with a pair of short legs: the hindmost ring was longer than the preceding one, was pointed at the end, and had a little pit on each side of the extremity; beneath this part there was a short retractile wart, or prop-leg, serving to support the extremity of the body, and prevent it from trailing on the ground. Other grubs of Elaters differ from the foregoing in being proportionally broader, not cylindrical, but somewhat flattened, with a deep notch at the extremity of the last ring, the sides of which are beset with little teeth. Such grubs are mostly wood-eaters, devouring the woody parts of roots, or living under the bark and in the trunks of old trees.

"After their last transformation, Elaters or spring-beetles make their appearance upon trees and fences, and some are found on flowers. They creep slowly, and generally fall to the ground on being touched. They fly both by day and night. Their food, in the beetle state, appears to be chiefly derived from flowers; but some devour the tender leaves of plants."

The largest of the American springing-beetles is of a black colour, covered with a whitish powder, and having a large oval velvet-black spot, like an eye, on each side of the middle, from which the insect derives its name of *Oculatus*, or eyed. This large beetle measures from one inch and a quarter to one inch and three quarters in length. It undergoes its transformations in the trunks of trees, and Dr. Harris has found many in old apple trees. These larvæ or worms are reddish yellow grubs. One of them found in April fully grown, measured no less than two inches and a half in length. Soon after this grub was found, it cast its skin and became a pupa, and in due time the latter was transformed to a beetle. (*Harris*.)

Among the night-shining Elaters is the celebrated *Cucurio*, or fire-beetle, of the West Indies, from whence it is often brought alive to this country as a curiosity. It resembles considerably the insect just described, being an inch or more in length. It gives out, even by day, a strong light from two transparent eye-like spots on the thorax, and from the segments of its body beneath. It feeds upon the sugar-cane, and its grub is said to be very injurious to this plant, by devouring its roots.

Dr. Harris states that above sixty different kinds of spring-beetles are now known to inhabit Massachusetts.

The utility of a knowledge of the natural history of insects in the practical arts of life, was perhaps never more strikingly and triumphantly displayed than by the great Linnæus himself, who, while giving to natural science its language and its laws, neglected no opportunity to point out its economical advantages. On one occasion, this great naturalist was consulted by the King of Sweden, upon the cause of the decay and destruction of the ship-timber in the royal dock-yards, and, having traced it to the depredations of insects, and ascertained the history of the depredators, by directing the timber to be sunk under water during the season when these insects made their appearance in the winged state, and were busied in laying their eggs, he effectually secured it from future attacks. The name of these insects is *Lymexylon navale*, or the naval timber-destroyer, which Dr. Harris thinks cannot be far removed from the tribe of spring-beetles. The odd-looking, long, and slender grubs of the *Lymexylon*, inhabit oaks, and make long cylindrical burrows in the solid wood. They are also found in some other kinds of trees. Dr. Harris considers insects of this family rather rare in New England, and describes only two kinds of American timber-borers. (See his *Treatise*.)

BETTER. A large wooden instrument in the form of a mallet, with one, two, or three handles for as many persons, used in driving piles, wedges, hedge-stakes, and in splitting wood, &c.

BETTER, CLODDING. A sort of implement made use of in reducing the clods of tillage-lands, in clayey and other stiff tenacious soils, to a fine powdery condition. This business may be much sooner performed, and at less expense, by means of rollers constructed for the purpose. (See **ROLLER**.)

BEEVES. The plural of beef. A general name employed by farmers for oxen or black cattle.

BEGGAR'S LICE (*Echinasperrum Virginicum*). An obnoxious weed found along the borders of woods, bearing a small bluish-white flower, frequent in pastures and along fence-rows, the bur-like fruit or nuts of which are furnished with hooked prickles, and often form a matting in the fleeces of sheep, and the manes and tails of horses. (*Flor. Cestrica*.)

BELLADONNA (*Atropa belladonna*). In botany, the Deadly Nightshade. It is an acro-narcotic poison. This name, *belladonna* (signifying Handsome Lady), according to Ray,

was given to it by the Italians, because the Italian ladies make a cosmetic of the juice.

The belladonna, although perennial in reference to the root, is annual in its herbage, which is of quick growth, branching, and shrub-like. The leaves are lateral, generally two together, ovate, acute, entire, smooth, and clammy. The flowers are solitary, stalked, rising in the axillæ of the leaves, bell-shaped, and of a lurid purple colour. The fruit is a shining, black, sweetish berry, seated in the permanent calyx, about the size of a cherry. The plant is poisonous, having a peculiar alkali, named *atropia*, which, in combination with malic acid, is found in every part of the plant. Its influence is chiefly exerted on the brain and nervous system, causing delirium, movements of the body resembling intoxication, confused speech, uttered with pain, and other symptoms of narcotic poisoning. Buchanan, the Scottish historian, informs us, that the Scots under Macbeth intoxicated the Danes under Sweno by mixing their wine with the juice of the berries of belladonna during a truce, which enabled Macbeth readily to overcome them. Shakspeare alludes to it in the interview between Macbeth and the witches, when the former says—

Or have we drank
Of the insane root which takes the reason prisoner?
Macbeth, Act 1.

The beauty of the berries frequently entices children to eat them; and, although not often fatal, they cause very distressing effects to the little sufferers. In such cases, the stomach should be quickly emptied by an emetic, and afterwards vegetable acids and decoction of nut-galls should be given. Belladonna is an excellent medicine; but it should not be entrusted to the ignorant.

BELL-WETHER. A sheep which leads the flock, with a bell on his neck.

BELT. To *belt*, in some districts, signifies to shear the buttocks and tails of sheep.

BELT. In planting, a strip or portion of land planted with trees for the purpose of ornament, or warmth and shelter. Much advantage may be derived in this way in improving the climate of the district. (See **PLANTATION**.)

BENE PLANT (*Sesamum orientale*). The bene or sesamum has been introduced into Jamaica and other West India islands, where it is quite extensively cultivated in many places. It is commonly called *Vanglo* or oil-plant, from the oil which it yields to pressure. The seeds are frequently used in broths, and by some introduced into cakes. Many of the Oriental nations look upon the seed as a hearty and wholesome food, and express an oil from them, not unlike, or inferior to, the oil of almonds. Attempts have even been made to manufacture oil from it in England, but with little success.

Sesamum orientale, or bene, is frequently cultivated in the eastern parts of the Mediterranean as a garden vegetable. The seeds have been introduced into the Carolinas, and other Southern States, by the African negroes. The seeds are used by the blacks for food; they parch them over the fire, then mix them with water, and then stew them up with other ingredients. A kind of pudding is also made

of them, similar to such as are made of rice or millet. The oil pressed from the seeds will keep many years without acquiring any rancid taste, but in two years becomes quite mild, so that the warm taste of the oil when first drawn is worn off, and it can be used for salads and all the ordinary purposes of sweet oil. In Japan, China, and Cochin-China, where they have no butter, they use the oil for frying fish, and preparing other dishes; as a varnish, and for some medicinal purposes. Nine pounds of seed are said to yield upwards of two pounds of fine oil.

The sesamum is an annual plant. It grows like cotton, from three to six feet high, bearing numerous square pods about an inch and a half long, filled with seeds about the size of flaxseeds. In its growth it requires no sticks, or other support. The product of seed is about twelve or fifteen bushels per acre, and the proportion of oil yielded to pressure has been estimated as equal to one-half the measure of the seed, and some estimate the proportion as far greater. The oil may be extracted by bruising the seed and immersing them in hot water, when the oil rises on the surface and may be skimmed off. But the usual mode of extraction is similar to that practised in the expression of linseed oil. In the Southern States many planters cultivate the bene largely, sowing in drills about four feet apart, in the month of April, and gathering the crop of seed in September. The pods ripen successively, and not all at one time. Bene has been raised in Virginia, Maryland, and the lower part of the peninsula between the Delaware and Chesapeake Bays, just as far north as cotton admits of cultivation. In higher latitudes, even in the vicinity of Philadelphia, the plant will grow, but seldom ripens its seed. The leaves of the plant are in great repute as a remedy in dysentery, and especially the cholera infantum or summer complaint of children. The freshly gathered leaves are merely dipped into a tumbler of cold water, which immediately becomes ropy, without losing its transparency or acquiring any unpleasant taste, on which account it is readily and even gratefully received by the little sufferers, who are allowed to sip it in moderate quantities instead of other drinks. Sesamum is indeed a valuable plant, and should be cultivated wherever it will grow, for its medicinal and domestic uses, if not for its oil; which last, however, must, under proper management, prove a profitable product of the soil.

BENT, or **STARR**. Names applied in England to the common reed (the *Arundo prugmites* of Dr. Darlington, and the *A. arenaria* of some other botanists). Sinclair calls the upright sea lyme grass, starr, or bent. (See Plate 7, l.) One of the chief uses this coarse grass is made to subserve in the United States, as well as in European countries, is to protect banks and sea-dykes exposed to the washings of waves and currents. See **ARUNDO ARENARIA**.

BENT-GRASS. A species of *Agrostis* very common in pasture grounds, the bent or creeping stems of which are very difficult to eradicate. (See **AGROSTIS**.)

BENTS. The withered stalks of grass standing in a pasture after the seeds have dropped. It also sometimes signifies a species of rush (*Juncus squarrosus*), which grows on moorland hills.

BERBEREN. A yellow bitter principle contained in the alcoholic extract of the root of the barberry tree.

BERBERRY (*Berberis*). See **BARBERRY**.

BERE (Goth. *bur*; Sax. *berne*). The common name for a species of barley, which is also frequently termed big, bear, and square barley. Thus, in Huloet, an old writer, we find "beer-corn, barley-bygge, or moncorne."

BERGAMOT (Fr. *bergamotte*). A species of citron, the fruit of the *Citrus bergamia* (Risso). This tree is cultivated in the south of Europe. It is a moderate-sized tree with oblong, acute, or obtuse leaves, with a pale underside, and supported on winged footstalks. The flowers are small and white; the fruit is pyriform, of a pale yellow colour, and the rind studded with oil vesicles; the pulp is slightly acidulous. The oil, which is procured from the rind, is imported from the south of Europe, under the name of *oil or essence of bergamot*. It is of a pale greenish colour, lighter than water, and used merely as an agreeable perfume. A species of mint, having a highly agreeable odour (*Mentha odorata*, Smith), is popularly called bergamot in the United States.

BERRY (*Bacca*). A succulent pulpy fruit, which contains one or more seeds, or granules, imbedded in the juice.

BETHLEHEM, STAR OF (*Ornithogalum*). Smith points out four varieties of this flower: the yellow star of Bethlehem, *O. luteum*; the common star of Bethlehem, *O. umbellatum*, (commonly called ten o'clock); the tall star of Bethlehem, *O. pyrenaicum*; and the drooping star of Bethlehem, *O. nutans*. The first is met with sometimes, but not very frequently, in grove pastures. The second is found in meadows, pastures, and groves in various parts of England. The last is found mostly in fields and orchards, probably naturalized. All are elegant spring flowers. The last is common in country gardens, whence it may have escaped into the fields. Yet the plant may as well be a native of England as of Denmark, Austria, or other parts of Europe and America, where it is found in similar situations. One of the species, commonly called ten o'clock (*Ornithogalum umbellatum*), Dr. Darlington says, is a foreigner that has escaped from gardens, and has become a nuisance on many farms in the Middle States. Although it rarely perfects its seed, it propagates itself with great rapidity by means of lateral bulbs. These bulbs are extremely difficult to eradicate. (*Flor. Cestricea*.) An American species of the star of Bethlehem (*O. virens*) was found by Lindley on the Delaware Bay. The sea-squill, so extensively used in medicine, belongs to this bulbous-rooted family of plants. (*Smith's Eng. Flora*, vol. ii. p. 141—145.)

BEVER (Ital. *bevere*; old French, *beivre*). To drink: a word now almost obsolete, but from which we derive beverage. The provincial term amongst labourers for the meal between dinner and tea.

BIENNIAL (Lat. *biennis*). Any thing that continues or endures two years. This term is usually applied to plants which grow one year and flower the next, after which they perish. They only differ from annuals in requiring a longer period to fruit in. Most biennials, if sown early in the spring, will flower in the autumn and then perish, thus actually becoming annuals. (*Brande's Dict. of Science*.)

BIG. A term sometimes applied in England to bere or square barley.

BILBERRY, or **BLEABERRY**. See **WHORTLEBERRY**.

BILL (*Bille*; Sax. *table*, a two-edged axe). A kind of hatchet with a hooked point, and a handle shorter or longer, according to the particular uses for which it is intended. It is mostly employed by husbandmen for cutting hedges and felling underwood; and Johnson tells us it takes its name from its resemblance, in form, to the beak of a bird of prey.

BILLET (Fr. *bilot*). A small log of wood for the chimney.

BIN (Sax. *binne*). A small box or other contrivance in which grain of any kind is kept. It is sometimes written binn. Bin also signifies a sort of crib for containing straw or other bulky fodder in farm-yards.

BIN, CORN-. A sort of convenient box or chest fixed in the stable for the purpose of containing grain or other provender for horses. We have also hop-bins, wine-bins, &c.

BIND-WEED (Lat. *convolvulus*). A troublesome genus of weeds, of which there are in England three species, the smaller, the great, and the sea bind-weed. The climbing buckwheat (*Polygonum convolvulus*) is also known by the name of black bind-weed. The first or smaller bind-weed (*C. urvensis*), frequently called grave bind-weed, is very common in hedges, fields, and gardens, and upon dry banks and gravelly ground in most districts, and is an almost unconquerable weed. Its presence is generally a sign of gravel lying near the surface. Its branching, creeping roots penetrate to a great depth in the soil. The flowers are fragrant like the heliotrope, but fainter, very beautiful, of every shade of pink, with paler or yellowish plaits, and stains of crimson in the lower part; sometimes they are nearly white. They close before rain. The second kind, or great bind-weed (*C. sepium*), is also an equally troublesome and injurious weed to the husbandman. It grows luxuriantly in moist hedges, osier holts, and thickets. In an open, clear spot of ground, when the plants are kept constantly hoed down for three or four months, it may sometimes be effectually destroyed; as when the stalks are broken or cut, a milky juice exudes, by which the roots are exhausted and decay. Every portion of the root will grow. The roots of this species are long, creeping extensively, and rather fleshy; the stems twining, several feet long, leafy, smooth, and slightly branched. Flowers solitary, large, purely white for the most part, occasionally of a uniform flesh or rose colour. It is a perennial, flowering in July and August in England, and a month earlier in Pennsylvania, where it is occasionally found. It is so injurious to crops that farmers should try all means to get rid of it. The black bind-weed,

(Plate 10, *d*), called also climbing buck-wheat, and bear-bind, is an annual, flowering in June and September. Its root is small and tapering, and the stem twines from left to right, round every thing in its way to the height of five or six feet. The flowers are drooping, greenish white, or reddish.

Several plants of the convolvulus family are highly valuable for the food and medicines they furnish. That most active purgative scammony is obtained from *C. scammonia*, and jalap from a species of *Ipomœa*. Occasionally the purgative principle is so much diffused among the fæcula of the root, as to be almost inappreciable, as is the case in the *C. batatas*, or sweet potato of America. The root of the great bind-weed is a strong purgative, fresh gathered and boiled in a little warm liquid, being near akin to the acrid and violent scammony. The humbler classes boil it in beer or ale, and find it a never-failing remedy. Among delicate constitutions it should be taken with caution, as its effects are very powerful. In Northamptonshire it grows most abundantly. A decoction of the roots also causes perspiration.

BIRCH (Sax. *birce*; Lat. *betula*). The English word birch seems, however, to be derived from the German *birke*, or the Dutch *berk*. All the European languages are similar in the pronunciation of the name of this tree. A very hardy, ornamental, and, in some respects, a useful tree, inhabiting the north of Europe, Asia, and America. There are many species of birch, but that best known, and most generally cultivated in this country, is the common birch (*Betula alba*). The common birch is valuable for its capability of resisting extremes of both heat and cold: its timber is chiefly employed for fire-wood. Its bark is extremely durable: it consists of an accumulation of ten or twelve skins, which are white and thin like paper, the use of which it supplied to the ancients; and as a proof of its imperishable nature, we are told that the books which Numa composed, about 700 years before Christ, which were written on the bark of the birch tree, were found in a perfect state of preservation in the tomb of that great king, where they had remained 400 years. Although this species is not much valued for its timber, it is extremely useful for many other purposes. Russia skins are said to be tanned with its bark, from which the peculiar odour of such leather is derived; and it is said to be useful in dyeing wool yellow, and fixing fugacious colours. The Highlanders weave it into ropes for their well-buckets. The poor people of Sweden were formerly accustomed to grind the bark to mingle with their bread corn. And in Denmark, Christopher III. received the unjust surname of *Berka Kanung* (king of bark), because in his reign there was such a scarcity, that the peasants were obliged to mix the bark of this tree with their flour. Cordage is obtained from it by the Laplanders, who also prepare a red dye from it; the young shoots serve to nourish their cattle, and the leaves are said to afford good fodder for horses, kine, sheep, and goats. The vernal sap of these trees is well known to have a saccharine quality, and from

it the forest housewife makes an agreeable and wholesome wine. During the siege of Ham-burgh, in 1814, by the Russians, almost all the birch trees of the neighbourhood were destroyed by the Bashkirs and other barbarian soldiers in the Russian service, by being tapped for their juice. Vinegar is obtained from the fermented sap. The inhabitants of Finland use the leaves for tea; and both in Lapland and Greenland, strips of the young and tender bark are used for food. From the timber are manufactured gates and rails, packing-cases, hoops, yokes for cattle, turners' ware, such as bowls, wooden spoons, wooden shoes and clogs, and other articles in which lightness without much durability is sufficient. Baskets, hurdles, and brooms are often made of part of its shoots. The broom-makers are constant customers for birch in all places in the vicinity of London, or where it is near water-carriage; but in most other parts the hoop-benders are the purchasers. The larger trees are often bought by the turners. In some of the northern parts of Europe, the wood of this tree is likewise greatly used for making of carriages and wheels, being hard and of long duration. The most general and the most profitable use to which birch at present can be turned is, unquestionably, the manufacture of small casks, as herring barrels, butter tubs, &c. For the latter purpose it is admirably suited, because it is stout, clean, and easily wrought, and communicates no particular taste or smell to the butter. The timber of the birch was more used and more valued in former times. It was not so strong as the ash for harrows and other farming implements, but it was not so ready to split, and for roofing cottages it is still held in estimation. In Russia, Poland, and other northern countries, the twigs of this tree cover the dwellings of the peasant, instead of tile or thatch. It afforded our ancestors arrows, bolts, and shafts, for their war implements. The whole tree is adapted for burning into charcoal of the best quality, and suited for the manufacture of gunpowder.

The birch will grow in any soil, but best in shady places. It may, therefore, in some situations, be turned to good account, since it will grow to advantage upon land where other timber will not thrive. Miller says, it loves a dry barren soil, where scarcely any thing else will grow; and will thrive on any sort of land, dry or wet, gravelly, sandy, rocky, or boggy, and those barren, heathy lands which will scarcely bear grass. It is said to attain sometimes the height of seventy feet, with a diameter of two feet; in England it does not acquire such considerable dimensions. The birch is propagated by seeds, which are easily taken from bearing trees, by cutting the branches in August, before they are quite ripe. The seed may be thrashed out like corn, as soon as the branches dry a little; they should be then kept in dry cool sand until they are sown, either in the autumn or spring. A great deal of nicety and attention is required in rearing the birch from the seed; they must be sown in the shade, and covered very lightly with soil made as fine as possible, and watered according to the wetness or dryness of the season. The planting out

of this tree is performed in the same manner as in the ash. If planted for underwood, it should be felled before March to prevent its bleeding. The tree bears removing with safety, after it has attained the height of six or seven feet; and is ready to plash as hedges in four years after planting. When old they are transplanted with considerable difficulty.

The other European birches are the weeping birch (*Betula pendula*), which is very common in different parts of Europe, along with the last, in the properties of which it appears to participate, and with which it is often improperly confounded. It differs from the common birch not only in its weeping habit, but also in its young shoots being quite smooth, bright chestnut brown when ripe, and then covered with little white warts. The *Betula pontica* of the nurseries is a slight variety, of a less drooping habit.

The third species is the downy birch (*Betula pubescens*), a smaller species than the first, found in the bogs of Germany; a variety of it is called *Betula urticifolia* in gardens.

The fourth and last European species is the dwarf birch (*Betula nana*), a small bush found in Lapland and the mountainous parts of other northern countries. To the people of the south this plant has no value, but to the Laplanders it affords a large part of their fuel, and its winged fruits are reported to be the favourite food of the ptarmigan. The Asiatic species are the Indian paper birch (*B. Bhojpaltra*); tapering-leaved birch (*B. acuminata*); shining birch (*B. nitida*); cylindrical spiked birch (*B. cylindrostachya*). The principal American birches are, 1. The poplar-leaved or white American birch (*B. populifolia*). It is very like the European *B. pendula*. 2. The red birch (*B. nigra*). In this country it is generally called *B. angulata*, and by some *B. rubra*. The Messrs. Loddiges, of Hackney, were the first importers of this fine but little known species. 3. The yellow birch (*B. excelsa*). 4. The paper or canoe birch (*B. papyracea*), which is employed by the North American Indians for a variety of useful purposes. 5. The soft black or cherry birch (*B. lenta*). None of the American birches produce timber so valuable as this, whence one of its American names is mountain mahogany. Its wood is hard, close-grained, and of a reddish brown; it is imported into England in considerable quantities, under the name of American birch, for forming the sides of dining tables, and for similar purposes. It is rarely seen in England, although it is perhaps one of the best suited to that climate. All the species of birches, except the common and weeping, are multiplied by layers in the usual way.

The juice of the birch tree, produced from punctures in the spring of the year, is diuretic. The wine made from this sap is said to be aperitive, and detersive. Old medical writers tell us that the wood was esteemed the best to burn in times of pestilence and contagious distempers; but, like many old medical saws, that opinion is of no value. (*Phillips's Syl. Flor.* vol. i. p. 123; *Pen. Syc.* vol. iv. p. 348; *Baxter's Agr. Lib.*)

BIRDS. A few of the feathered tribes may

be regarded as mischievous depredators upon the farmer and gardener, eating his fruit, as the robin; pulling up the corn when just sprouted, or eating it from the ear when nearly matured, as is so often done by the crow, the black-bird or grackle. But if account be made of all the services derived from birds in destroying those insects which in their larva or worm state, or their more perfect winged state, commit such serious depredations upon orchards and fields, it will be found that we owe the feathered family a very large balance. Upon this subject we must refer for further illustration to the articles **BETLE**, **BORERS**, **APHIS**, and others relating to destructive insects. That distinguished naturalist, Mr. Nuttall, has the following beautiful tribute to birds in his interesting *Manual of the Ornithology of the United States*.

"In whatever way we view the feathered tribes which surround us, we shall find much both to amuse and instruct. We hearken to their songs with renewed delight, as the harbingers and associates of the season they accompany. Their return, after a long absence, is hailed with gratitude to the Author of all existence; and the cheerless solitude of inanimate nature is, by their presence, attuned to life and harmony. Nor do they alone administer to the amusements and luxury of life; faithful aids as well as messengers of the seasons, they associate round our tenements, and defend the various productions of the earth, on which we rely for subsistence from the destructive depredations of myriads of insects, which, but for timely riddance by unnumbered birds would be followed by a general failure and famine. Public economy and utility, then, no less than humanity plead for the protection of the feathered race, and the wanton destruction of birds, so useful, beautiful, and amusing, if not treated as such by law, ought to be considered as a crime by every moral, feeling, and reflecting mind."

BIRD-BOLT. A short arrow, having a ball of wood at the end of it, and sometimes an iron point, formerly used for shooting birds.

BIRD-CHERRY (*Prunus padus*). The berries are eagerly sought after by birds, and as the leaf and fruit resemble that of the cherry tree, hence the name of bird-cherry. In Scotland it is called hogberry. This aboriginal of our English woods possesses beauties that should oftener secure it a situation in the shrubbery, and more frequently a place in ornamental hedge-rows. The bird-cherry rises from ten to fifteen feet in height, spreading to a considerable distance its branches, which are covered with a purplish bark. It flowers in April and May, and the small black fruit, which hangs in bunches, ripen in August. Although the fruit is austere, and bitter to the taste, it gives an agreeable flavour to brandy, and many persons add it, for the same reason, to their made wines. Birds soon devour the fruit, which is nauseous and probably dangerous, though perhaps, like that of the cherry laurel, not of so deadly a quality as the essential oil, or distilled water of the leaves, which is highly dangerous from containing much Prussic acid. The wood is hard and close-grained, and is used for whip and knife handles.

Linnæus says, that kine, sheep, goats, and swine eat the leaves, but that horses refuse them. The scent of the leaves, when bruised, resembles rue. The variety with red fruit, commonly called the Cornish cherry, flowers two or three weeks earlier, and is therefore not so desirable for the shrubbery. The bird-cherry may be propagated by layers, which should be performed in autumn, but the handsomest trees are raised from seed, which may be sown at the same season. A wet soil is not congenial to this tree. (*Phillips's Syl. Flor.* vol. i. p. 134; *Smith's Eng. Flor.* vol. ii. p. 354.)

BIRD'S EYE (*Veronica chamædrys*). The Germander Speedwell, or wild germander. A troublesome weed in fields. It is found very commonly in groves, meadows, pastures, and hedges. It is a perennial, flowering in May and June. Herbage light green. Flowers numerous, transient, but very beautiful, bright blue with dark streaks and a white centre; their outside pale and flesh coloured. The flowers expand in fine weather only. Some take this for the German "forget-me-not." It vies in beauty with the true one, *Myosotis palustris*. (*Smith's Eng. Flor.* vol. i. p. 23.) See **SPEEDWELL**.

BIRD'S FOOT, COMMON (*Ornithopus perpusillus*). A weed found most generally in sandy or gravelly pastures. Root fibrous, annual, though it is sometimes propagated by subterraneous lateral knobs in the manner of a potato, in which case the seeds are abortive. The stems, often numerous, are procumbent, from three to ten or twelve inches long. Leaves alternate, of from five to ten or twelve pair, of small uniform elliptical leaflets. Flowers three or four in each little head or tuft.

The species of bird's foot are curious on account of their jointed pods, but not worth culture as plants of ornament. *O. sativus* is, however, a most valuable agricultural plant.

BIRD'S-FOOT TREFOIL, or CLOVER (*Lotus*). The common name of a genus of plants that flourishes in a singular manner in the most exposed and dry situations. On bowling-greens and mown lawns it forms a fine green close herbage, even in hot seasons; and in meadow and pasture grounds it is frequently abundant. Its very strong deep tap root is the cause of its resisting drought. Smith describes four species:—1. Common bird's-foot trefoil (*L. corniculatus*), a perennial, flowering in the second week of June, and ripening the seed about the end of July, and successively to the end of autumn; common in open grassy pastures. [Pl. 9, g.] Some botanists have considered the following species (*L. major*) to be a variety of the *corniculatus*, but the difference between them is obvious at first sight; and this difference remains permanent when the plant is raised from seed, and cultivated on different soils. What renders a specific distinction here of most importance to the farmer, is the difference which exists between them in an agricultural point of view. Heads depressed, of few flowers, root branching, somewhat woody; the fibres beset with small granulations; stems several, spreading on the

ground in every direction, varying in length from three to ten inches, simple or branched. Flower stalks erect or recumbent, five times as long as the leaves, each bearing from two to five bright yellow flowers, dark green when dried, and they change to orange when verging towards decay. This species is recommended for cultivation, though under the erroneous names of milk-vech and *Astragalus glycyphyllos*, by the late Dr. Anderson, in his *Agricultural Essays*, as being excellent for fodder as well as for hay. Mr. Curtis and Mr. Wood also recommended it. Linnæus says that cows, goats, and horses eat it; and that sheep and swine are not fond of it. With regard to sheep (says the late Mr. G. Sinclair, *Hort. Gram. Wob.* p. 310), as far as my observations have extended, they eat it in common with the herbage with which it is usually combined; the flowers, it is true, appeared always untouched, and in dry pastures little of the plant is seen or presented to the cattle, except the flowers, on account of its diminutive growth in such situations. This, however, is nearly the case with white or Dutch clover; sheep seldom touch the flowers while any foliage is to be found. Mr. Woodward informs us that it makes extremely good hay in moist meadows, where it grows to a greater height than the trefoils, and seems to be of a quality equal, if not superior, to most of them. Professor Martyn observes, that, in common with several other leguminous plants, it gives a substance to hay, and perhaps renders it more palatable and wholesome to cattle. The clovers contain more bitter extractive and saline matter than the proper natural grasses, and the bird's foot trefoils contain more of these vegetable principles than the clovers. In pastures and meadows, therefore, where the clovers happen to be in small quantities, a portion of the trefoil (*L. corniculatus*) would doubtless be of advantage; but it appears to contain too much of the bitter extractive and saline matters to be cultivated by itself, or without a large intermixture of other plants. It does not spring early in the season, but continues to vegetate late in the autumn. In irrigated meadows, where the produce is generally more succulent than in dry pastures, this plant cannot with safety be recommended, at least in any considerable quantity. It is more partial to dry soils than the next species (*L. major*); it attains to a considerable height when growing among shrubs, and seems to lose its prostrate or trailing habit of growth entirely in such situations. 2. The greater bird's-foot trefoil (*L. major*) flourishes in wet bushy places, osier holts and hedges; very different from the foregoing species in general habit, and now technically distinguished by several clear and sufficient characters. The stems are from one to two or three feet high, upright, clothed more or less with long loosely-spreading hairs. Leaves fringed with similar hairs; flowers from six to twelve in each head, of a duller orange than the former. The weight of green food or hay is triple that of the foregoing species, and its nutritive powers are very little inferior, being only as 9 to 8. These two species of bird's-foot trefoil may be compared to each

other with respect to habits in the same manner as the white clover and perennial red clover; and were the latter unknown, there appear to be no plants of the leguminous order, that, in point of habits, would so well supply their place as the common and greater bird's-foot trefoil. They are, however, greatly inferior to the clovers. The white clover is superior to the common bird's-foot trefoil in the quantity of nutritive matter it affords, in the proportion of 5 to 4. It is much less productive of herbage, and is much more difficult of cultivation, the seed being afforded in much smaller quantities. The produce of the greater bird's-foot trefoil is superior to that of the perennial red clover on tenacious or moist soils, and on drier and on richer soils of the first quality; but the produce is inferior in the proportion of nutritive matter it contains as 5 to 4. The nutritive matter is extremely bitter to the taste. It does not appear to be eaten by any cattle when in a green state, but when made into hay, sheep, oxen, and deer, all eat it without reluctance, and rather with desire. It does not seem to perfect so much seed as the former species, but this is abundantly remedied in its propagation by the creeping or stoloniferous roots which it spreads out in all directions. In moist clayey soils it would doubtless be a most profitable substitute for red clover; but the excess of bitter extractive and saline matters it contains seems to forbid its adoption without a considerable admixture of other plants. It flowers about the third week of June, and the seed is ripe about the end of the following month. The following analysis will show the comparative value of the two species:—

	Green Prod.	Dry Prod.	Nutrient
	per acre.	per acre.	per acre.
	lbs.	lbs.	lbs.
<i>Lotus corniculatus</i>	10,209 6 0	3,190 6 0	358 4 9
— <i>major</i>	21,780 0 0	8,142 8 0	660 10 0

3. Spreading bird's-foot trefoil (*L. decumbens*) is, like the two preceding species, a perennial, flowering in England in July. It is found in fields and meadows. The flower-stalks are four or five times the length of the leaves, smooth, stout, and firm, each bearing an umbel of from three to six bright yellow flowers. 4. Slender bird's-foot trefoil (*L. angustissimus*) is an annual flowering in May and June, found in meadows towards the sea on the south and western coasts of England. It is smaller, in general, than any of the foregoing species. A species of trifolium (*T. ornithopodioides*) also bears the name of bird's-foot trefoil; but Sir J. Smith very justly observes (*Engl. Flor.* vol. iii. p. 298), it can scarcely, without violence, be retained in the genus *Trifolium*; yet no one has thought fit to make it a distinct one, however plausible might be the reasons for such a measure. It is an annual plant flowering in June and July, found in barren, gravelly, grassy pastures; root fibrous, stems several, spreading flat on the ground, flowers two or three, long, pale, reddish. (*Smith's Eng. Flor.* vol. iii. pp. 298, 312; *Sinclair's Hort. Gram. Wob.*)

Two species of lotus, not referred to in the preceding account, are a good deal cultivated

in France, on light soils. These are the villosus (*L. villosus*) and the cultivated lotus (*Lotier cultivé*, or *Lotus tetragonolobus*, Pl. 9, h). The last is an annual sown in gardens.

BIRDLIME. This glutinous vegetable product is procured either by boiling mistletoe berries in water until they break, pounding them in a mortar, and washing away the husky refuse with other portions of water; or, which is the chief mode in which it is made (chiefly in Scotland) for the purposes of bird-catching, &c., from the middle bark of the holly. The bark is stripped in June or July, and boiled for six or eight hours in water, until it becomes tender; the water is then separated from it, and it is left to ferment for two or three weeks, until it becomes a mucilage, which is pounded in a mortar into a mass, and then thoroughly rubbed by the hands in running water till all the branny matters and other impurities are washed away; the birdlime is then suffered to remain fermenting by itself in an earthen vessel for some weeks. (The bird-catchers, when they make their own, place the vessel in a dunghill.) The bark of the wayfaring tree is sometimes employed. The fragrant gum which exudes from the *Styrax*, or American Sweet Gum, a large tree, growing in the Middle and Southern States, also makes a good birdlime, being extremely tenacious. (*Gray's Supplement*, p. 226; *Nich. Journ.* b. xiii. p. 145; *Thomson*, vol. iv. p. 119.)

BIRD'S NEST, YELLOW (*Monotropa hypopitys*). A weed occasionally met with in poor and gravelly soils. It is also found sometimes about the roots of beeches and firs, in woods, frequent in all the midland counties. Root fibrous, much branched, and somewhat creeping, growing among dead leaves, or in half decayed vegetable mould. Stem solitary, five or six inches high, flowers in a drooping cluster. (*Smith's Engl. Flor.* vol. ii. p. 249.)

The species of this plant found in the Middle States, are, that called the Indian Pipe (*M. uniflora*), and the woolly monotropa, Pine-sap, or False Beach-drops. Both these singular plants are called parasitic. (See *Flor. Cestric.*)

BIRD PEPPER. A species of small *capsicum*, which affords the best Cayenne pepper. See **CAPSICUM**.

BISCUIT (Lat. *bis*, twice; Fr. *cuit*, baked, Ital. *biscoto*). A kind of hard dry bread cake Biscuits are more easily kept than other kinds of bread, and as they contain no ferment, they are better fitted than loaf bread for persons of weak stomachs, and for the pap of infants, who are under the misfortune of being brought up by hand.

The best biscuits and the most wholesome, are those prepared for the use of the navy. They are of two kinds, *captains'* and *seamen's* biscuit. The latter are composed of wheaten flour, from which the bran only has been taken; consequently they are more nutritive than the finer sort. In the government bake-houses at Weevil and Deptford, the biscuits are preferable to those baked by ordinary bakers, owing to the extent of the operations, and the purity of the wheat-meal: 102 lbs. of perfectly dry biscuits are procured from 112 lbs. of meal.

BISHOPING. A cant term made use of

among horse-jockeys, implying the practices employed to conceal the age of an old horse, or the ill properties of a bad one. See AGE OF HORSES.

BISON, AMERICAN (*Bos Americanus*). This species of the ox kind is peculiar to the temperate latitudes of North America, where it is universally, though incorrectly called the Buffalo, a name properly belonging to a different species of the ox tribe common to Eastern Asia. The bison was found by the first colonists of the Carolinas, and other of the Southern and Middle States, from which parts of the North American Continent they have long been exterminated or frightened away. So late as the year 1766, they were seen in a wild state in Kentucky. At present none are to be met with east of the Mississippi river, having retired beyond this great stream, and concentrated in the prairies of the Missouri and other rivers of the far west. Here they often unite in immense flocks, some of which, travellers and hunters inform us, contain eight or ten thousand. Generally speaking, the bison is rather timid, flying from the hunter, except in the rutting season, about the middle of June, when the males become very fierce, and often kill each other in their terrible combats.

The qualities of buffalo beef are highly extolled, and the hump upon the shoulders is regarded as a particularly choice morsel. The tongues, which constitute a regular article of trade, are exceedingly rich and tender. The thick and rough hairy skins of the bison are tanned by the Indians and trappers, and then sold to be formed into buffalo robes and other articles of comfort, so useful during the severe winters of the United States.

The following highly interesting account of the American Bison is taken from the *American Farmer*, (vol. vi. p. 260), under the head of *Buffalo Oxen*.

"The animal known by the name of the Buffalo throughout the valleys of Missouri and Mississippi differs materially from the buffalo of the Old World. At first view, his red fiery eyes, his shaggy mane, and long beard, the long lustrous hair upon his shoulders and fore-quarters, and the comparative nakedness of his hind-quarters, strongly remind a spectator of the lion.

"In the size of his head, in bulk, in stature, and in fierceness, he resembles the buffalo of Buffon; but the humps or protuberance between his shoulders, the shape of his head, his curled forehead, short thick arms, and long hind legs, mark a much stronger affinity to the bison.

"He carries his head low like the buffalo, and this circumstance, together with his short muscular neck, broad chest, and short thick arms, designate him as peculiarly qualified for drawing: the whole weight of his body would thus be applied in the most advantageous manner to the weight drawn. The milk of the female is equal in quality to that of the cow, but deficient in quantity. It has been supposed that the smallness of the udders is more remarkable in those that have the hump large, and that the diminished size of the hump is evidence of a more abundant secretion of milk. The hump, when dressed, tastes like

the udder of a cow, and is deemed a delicacy by the Indians. But there is one other particular which distinguishes the buffalo of the New World from its eastern namesake more distinctly than any variety of conformation could do. The cow refuses to breed with the buffalo of Europe; and such is the fixed aversion between these creatures, that they always keep separate, although bred under the same roof and feeding in the same pasture. The American buffalo, on the contrary, breeds freely with the domestic cattle, and propagates a race that continues its kind. Many of the landholders in Louisiana, like the patriarchs of old, possess thousands of cattle which graze at liberty in the uncultivated prairies. These herds cost their owners little more than the trouble of marking them, and the expense of salting once or twice in a month, to prevent them from becoming wild. By occupying the same pastures, they have become so much intermixed with the buffalo that it is difficult to say to which race they are most nearly allied.

"In procuring the cross, it is necessary to observe one precaution. The domestic breed must furnish the male, and the buffalo the female. The wild bull and the cow can be brought together without difficulty, and the impregnation is perfect; but the pelvis of the cow is not sufficiently capacious to allow the passage of the buffalo's fœtus with its hump. The pelvis is the circular bone which connects the spine with the thigh bones, and when the fœtus, from disease or any other cause, is too large to pass through it, the female must necessarily die in labour. This fact constitutes the principal obstacle to the introduction of the half breed in the old settlements. It would be easy to catch and tame a single male of the wild breed, and to obtain any number of impregnations from him; but it is difficult to procure, and still more to confine a sufficient number of wild females. The amazing strength of the head and breast enables them to upset the strongest fences by running against them; and unless they are caught very young, they can never be effectually tamed. Nevertheless, some enterprising farmers in this state and Missouri are introducing the breed. Captain Jenkins of Rutherford county, has one three years old and one two years old of the half blood, and several calves of the quarter blood, all of which are large for their age, and promise well. The advantages proposed by the introduction of this breed are, that the oxen thus raised will be stronger, less sluggish, more hardy, and more easily kept, and (if it be true that the buffalo goes twelve months with young) they will probably last longer than the common breed. In addition to these considerations, the hides are larger and applicable to a greater number of uses, and the leather is thicker, softer, and more impervious to water. The full grown buffalo on the Missouri are said to be from sixteen to eighteen hands high, and as the body is larger in proportion to the height, than in the domestic cattle, they must greatly exceed the finest of the imported breed in strength and weight. In the neighbourhood of the settlements, the hunter's dogs and

prairie flies conspire to prevent them from attaining either full size or mature age."

BISSLINGS. A provincial word, applied, like beestings, to the first milk of the newly calved cow. See **BEESTING**.

BITTER PRINCIPLE. This term has been applied to certain products of the action of nitric acid upon animal and vegetable matters of an intensely bitter taste. (*Brande's Dict. of Science*.) The most important of the plants cultivated with us for their bitter principle are the hop, the common broom, mugwort, ground ivy, marsh trefoil or buck-bean, and the gentian family of plants. Quassia, the wood of a tree, is also a very intense bitter, and is used in medicine, and clandestinely in the brewing of beer. The chief combinations of the bitter principle used in medicine are narcotic, aromatic, astringent, acid, and purgative bitters. (*Lowe's El. of Ag.* pp. 371—373.)

BITTERS. A spirituous liquor in which bitter herbs or roots are steeped. An excessive habit of taking bitters may finally prove detrimental to the stomach, by over-excitement, or by inducing a kind of artificial demand for food in greater quantity than is salutary to the general health. Habitual drunkenness has often been the sequel of the insidious practice of taking bitters.

BITTER-SWEET, or WOODY NIGHTSHADE (*Solanum dulcamara*). This wild plant loves moist places, therefore grows most freely in hedges and thickets, near ditches, rivers, and damp situations. It flowers in June and July, and ripens its berries in August, which are of a red colour, juicy, bitter, and poisonous. Its flowers are an elegant purple, with yellow threads in their middle, and the berries are oval or oblong in shape. The stalks are shrubby, and run, when supported, to ten feet in length; of a bluish colour, and when bruised or broken have an odour not very fragrant or desirable, savouring of rotten eggs. A decoction of its wood, and the young shoots sliced, is a valuable medicine, but not to be trifled with. (*Eng. Flor.*, vol. i. p. 317.)

BITTERWORT. The old English name for the yellow gentian. See **GENTIAN**.

BIXA. See **ANNOTTA**.

BLACK. (Sax.) A common colour in horses. Horses of this colour are most esteemed when they are of a shining jet black, and well marked, without having white on their legs. The English black horses have generally more white about them than the black horses of other countries. Those that partake most of the brown are said to be the strongest in constitution; for the English black cart horses are found not to be so hardy as the bays or chestnuts.

BLACKBERRY. See **BRAMBLE**.

BLACKBIRD. This is a species of bird so generally known, that but little need be said of its habits or its haunts. Numbers are bred in England every season, and those thus reared, it is believed, do not migrate. Its food varies considerably with the season. In spring and early summer, larvæ of insects, worms, and snails; as the season advances, fruit of various sorts. When the enormous number of insects and their larvæ, with the abundance

of snails and slugs, all injurious to vegetation, be duly considered, it may fairly be doubted whether the value of the fruit is not counterbalanced by the services performed.

The American blackbird differs considerably from the European. The species found in the United States bear the names of the great crow, the common crow, the cow, the red-winged, and the rusty. The following interesting details relative to birds which so often occupy attention in rural life, are from Mr. Nuttall's Manual of the Ornithology of the United States. Treating of the great crow blackbird, (*The Quiscalis major* of Bonaparte) Mr. Nuttall says:

"This large and crow-like species, sometimes called the jackdaw, inhabits the southern maritime parts of the Union only, particularly the states of Georgia and Florida, where they are seen as early as the close of January or beginning of February, but do not begin to pair before March, previously to which season the sexes are seen in separate flocks. But about the latter end of November, they quit even the mild climate of Florida, generally, and seek winter quarters probably in the West Indies, where they are known to be numerous, as well as in Mexico, Louisiana, and Texas; but they do not ever extend their northern migrations as far as the Middle States. Previous to their departure, at the approach of winter, they are seen to assemble in large flocks, and every morning flights of them, at a great height, are seen moving away to the south.

"Like most gregarious birds, they are of a very sociable disposition, and are frequently observed to mingle with the common crow-blackbirds. They assemble in great numbers among the sea islands, and neighbouring marshes on the main land, where they feed at low water, on the oyster-beds and sand-flats. Like crows, they are omnivorous, their food consisting of insects, small shell-fish, corn, and small grain, so that by turns they may be viewed as the friend or plunderer of the planter.

"The note of this species is louder than that of the common kind, according to Audubon, resembling a loud shrill whistle, often accompanied by a cry like *crick crick cree*, and in breeding season changing almost into a war. They are only heard to sing in the spring, their concert, though inclining to sadness, not altogether disagreeable. Their nests are built in company, on reeds and bushes, in the neighbourhood of salt marshes and ponds, they lay about three to five eggs which are whitish, blotched and lined nearly all over with dusky olive. They begin to lay about the beginning of April; soon after which the males leave their mates not only with the care of incubation, but with the rearing of the young, moving about in separate flocks, like the cow birds, without taking any interest in the fate of their progeny.

"The general appearance of the male is black, but the head and neck have bluish-purple reflections; the rest presents shades of steel-blue, excepting the back, rump, and middling wing coverts, which are glossed with copper-green; the vent, inferior tail coverts

and thighs are plain black. The tail, wedge-shaped, is nearly eight inches in length, and like that of the common species, is capable of assuming a boat-shaped appearance. Iris pale yellow. The bill and feet black. The *female* is of a light dusky brown, with some feeble greenish reflections, and beneath of a dull brownish white. The *young*, at first, resemble the female, but have the irids brown, and gradually acquire their appropriate plumage."

Of the Common Crow-Blackbird, (*The Quiscalis versicolor* of Audubon), Mr. Nuttall says: "This very common bird is an occasional or constant resident in every part of America, from Hudson's Bay and the Northern interior to the great Antilles, within the tropic. In most parts of this wide region they also breed, at least from Nova Scotia to Louisiana, and probably farther south. In the states north of Virginia they begin to migrate from the beginning of March to May, leaving those countries again in numerous troops about the middle of November. Thus assembled, from the north and west in increasing numbers, they wholly overrun, at times, the warmer maritime regions, where they assemble to pass the winter in the company of their well known cousins the red-winged troopials or blackbirds; for both, impelled by the same predatory appetite, and love of comfortable winter quarters, are often thus accidentally associated in the plundering and gleanings of the plantations. The amazing numbers in which the present species associate are almost incredible. Wilson relates that on the 20th of January, a few miles from the banks of the Roanoke, in Virginia, he met with one of those prodigious armies of blackbirds, which, as he approached, rose from the surrounding fields with a noise like thunder, and descending on the stretch of road before him, covered it and the fences completely with black: rising again, after a few evolutions, they descended on the skirt of a leafless wood, so thick as to give the whole forest, for a considerable extent, the appearance of being shrouded in mourning, the numbers amounting probably to many hundreds of thousands. Their notes and screams resembled the distant sound of a mighty cataract, but strangely attuned into a musical cadence, which rose and fell with the fluctuation of the breeze, like the magic harp of Æolus.

"Their depredations on the maize crop or Indian corn commence almost with the planting. The infant blades no sooner appear than they are hailed by the greedy blackbird as the signal for a feast; and, without hesitation, they descend on the fields, and regale themselves with the sweet and sprouted seed, rejecting and scattering the blades around as an evidence of their mischief and audacity. Again, about the beginning of August, while the grain is in the milky state, their attacks are renewed with the most destructive effect, as they now assemble as it were in clouds, and pillage the fields to such a degree that in some low and sheltered situations, in the vicinity of rivers, where they delight to roam, one-fourth of the crop is devoured by these vexatious visitors. The gun, also, notwithstanding the havoc it produces, has little more effect than to chase

them from one part of the field to the other. In the Southern States, in winter, they hover round the corn-cribs in swarms, and boldly peck the hard grain from the cob through the air-openings of the magazine. In consequence of these reiterated depredations they are detested by the farmer as a pest to his industry; though, on their arrival, their food for a long time consists wholly of those insects which are calculated to do the most essential injury to the crops. They, at this season, frequent swamps and meadows, and familiarly following the furrows of the plough, sweep up all the grub-worms, and other noxious animals, as soon as they appear, even scratching up the loose soil, that nothing of this kind may escape them. Up to the time of harvest, I have uniformly, on dissection, found their food to consist of these larvæ, caterpillars, moths, and beetles, of which they devour such numbers, that but for this providential economy, the whole crop of grain, in many places, would probably be destroyed by the time it began to germinate. In winter they collect the mast of the beech and oak for food, and may be seen assembled in large bodies in the woods for this purpose. In the spring season the blackbirds roost in the cedars and pine trees, to which in the evening they retire with friendly and mutual chatter. On the tallest of these trees, as well as in bushes, they generally build their nests, which work, like all their movements, is commonly performed in society, so that ten or fifteen of them are often seen in the same tree, and sometimes they have been known to thrust their nests into the interstices of the fish-hawk's eyry, as if for safety and protection. Occasionally they breed in tall poplars near to habitations, and, if not molested, continue to resort to the same place for several years in succession. They begin their breeding operations from the commencement of April to May. The nest is composed outwardly of mud, mixed with stalks and knotty roots of grass, and lined with fine dry grass and horse-hair. The eggs, usually five or six, are of a dull green, like those of the crow, blotched and spotted with dark olive, more particularly towards the larger end. According to Audubon, the same species in the Southern States nests in the hollows of decayed trees, after the manner of the woodpecker, lining the cavity with grass and mud. They seldom produce more than a single brood in the season. In the autumn, and at the approach of winter, numerous flocks after foraging through the day, return from considerable distances to their general roosts among the reeds. On approaching their station, each detachment as it arrives, in straggling groups like crows, sweeps round the marsh in waving flight, forming circles; amidst these bodies, the note of the old reconnoitring leader may be heard, and no sooner has he fixed upon the intended spot, than they all descend and take their stations in an instant. At this time they are also frequently accompanied by the ferruginous species, with which they associate in a friendly manner.

"The blackbird is easily tamed, sings in confinement, and may be taught to articulate some few words pretty distinctly. Among the

variety of its natural notes, the peculiarly affected sibilation of the starling is heard in the *wöttishee*, *wöttishee*, and whistle, which often accompanies this note. Their intestines and stomach are frequently infested by long, cylindric, tapering worms, which probably increase sometimes in such numbers as to destroy the bird.

"The male is twelve inches long, and eighteen in alar extent. The prevailing black colour of the body is relieved by glossy reflections of steel blue, dark violet, and green; the violet is most conspicuous on the head and breast, and the green on the hind part of the neck. The back, rump, and whole lower parts, with the exception of the breast, reflect a cupreous gloss. The wing-coverts, secondaries, and coverts of the tail, are light violet, with much of the red; the rest of the wings and rounded tail are black, with a steel-blue gloss. Iris silvery. The *female* is rather less, but very similar in colour, and glossy particoloured reflections."

The Rusty Blackbird. "This species," says Mr. Nuttall, "less frequent than the preceding, is often associated with it, or with the red-winged troopial or the cow-pen bird, and, according to the season, they are found throughout America, from Hudson's Bay to Florida and westward to the Pacific ocean. Early in April, according to Wilson, they pass hastily through Pennsylvania, on their return to the north to breed. In the month of March he observed them on the banks of the Ohio, near Kentucky river, during a snow-storm. They arrive in the vicinity of Hudson's Bay about the beginning of May, and feed much in the manner of the common crow-blackbird on insects, which they find on or near the ground. Dr. Richardson saw them in the winter as far as the latitude of 53°, and in the summer they range to the 68th parallel or to the extremity of the wooded region. They sing in the pairing season, but become nearly silent while rearing their young; though when their brood release them from care they again resume their lay, and may occasionally be heard until the approach of winter. Their song is quite as agreeable and musical as that of the starling, and greatly surpasses that of any of the other species. I have heard them singing until the middle of October.

"They are said to build in trees and bushes, at no great distance from the ground, making a nest similar to the other species, and lay five eggs, of a pale blue spotted with black. The young and old, now assembling in large troops, retire from the northern regions in September. From the beginning of October to the middle of November, they are seen in flocks through the Eastern States. During their stay in this vicinity, they assemble towards night to roost in or round the reed marshes of Fresh Pond, near Cambridge. Sometimes they select the willows by the water for their lodging, in preference to the reeds, which they give up to their companions the crow-blackbirds. Early in October they feed chiefly on grasshoppers and berries, and at a later period pay a transient visit to the corn-field. They pass the winter in the Southern States, and like their

darker relatives, make familiar visits to the barn-yard and corn-cribs. Wilson remarks, that they are easily domesticated, and in a few days become quite familiar, being reconciled to any quarters while supplied with plenty of food.

"The male is about nine inches in length, and fourteen in alar extent; black, glossed with dark green; with the tail somewhat rounded; iris silvery. The *female* is of about the same size with the male, and the *young* of the first season, of both sexes, are nearly of the same colour."

BLACK CANKER. A disease in turnip and other crops, produced by a species of caterpillar. See BONE DUST.

BLACK COUCH GRASS, or BLACK TWITCH. Provincial names for the marsh bent grass, or *Agrostis alba*. See AGROSTIS.

BLACK DOLPHIN. A term applied to a small insect which is frequently very destructive to bean, turnip, and some other green crops.

BLACK FLY. An insect of the beetle tribe, very injurious to turnips in their early stage. See FLY.

BLACK GUM (*Nyssa sylvatica*). This North American tree is variously designated in different parts of the United States by the names of the *Black gum*, *Yellow gum*, and *Sour gum*, the last of which appellation is doubtless derived from the extremely acid taste of its fruit. This consists of deep blue berries of an oval shape. Each stem has twin-berries, and each berry contains a very hard slightly convex stone. The leaves are five or six inches long, entire, of an elongated oval shape, with downy stems. The river Schuylkill, in the vicinity of Philadelphia, may be assumed as the northern limit of the black gum, which is very common in Delaware, Maryland, and other Middle and Southern States, both east and west of the Alleghany mountains. In Maryland, Virginia, and the Western States, Michaux informs us, it grows without any peculiar form on high and level grounds, with the oaks and walnuts. In the lower parts of the Carolinas and Georgia, where it is found only in wet places, with the small magnolia or white-bay, the red-bay, the loblolly-bay, and the water-oak, it has a pyramidal base resembling a sugar-loaf.

The black gum frequently attains a height of sixty or seventy feet, with a diameter of eighteen or twenty inches, being larger in the upper part of Virginia, in Kentucky and Tennessee, than in the marshy grounds of the maritime parts of the Southern states.

The bark of the trunk is whitish and similar to that of the young white oak. The wood is fine-grained but tender, and its fibres are interwoven and collected in bundles; an arrangement characteristic of the genus. The albumen or sap part, as it is commonly designated, of stocks growing upon dry and elevated lands is yellow. This complexion is considered by wheel-wrights as a proof of the superior quality of the wood, and has probably given the tree one of its popular names. It is extensively employed in Richmond, Baltimore, and Philadelphia, for the naves or hubs of

coach and wagon wheels, as well as for hatters' blocks, being so little liable to split; a quality which also causes it to be chosen by shipwrights for the cap, or piece which receives the top-mast.

Tupelo.—The black gum is often confounded with another tree of the same genus, the *Tupelo* or *Nyssa aquatica*, also called gum tree, sour gum, and peperidge. The first of these appellations, Michaux says, is most common, the second is wholly misapplied, as no self-condensing fluid distils from the tree, and the third which more appropriately belongs to the common barberry-bush, is used only by the descendents of the Dutch settlers in the neighbourhood of New York. The tupelo extends much higher north than the black gum, appearing in the lower part of New Hampshire near the sea; but it is most abundant in the southern parts of New York, New Jersey, and Pennsylvania. It grows only in wet grounds. In Delaware, where the black gum and tupelo are found together, the former name is universally applied to both. In New Jersey it is constantly seen on the borders of the swamps with the sweet gum, the swamp white-oak, the chestnut white-oak, and the white elm. It rarely exceeds forty or forty-five feet in height, and its limbs, which spring at five or six feet from the ground, grow in a horizontal direction. The trunk is of a uniform size from its base. While it is less than ten inches in diameter the bark is not remarkable, but on full-grown and vigorous stocks it is thick, deeply-furrowed, and, unlike the bark of any other tree, divided into hexagons, which are sometimes nearly regular.

The leaves are about half the length of those of the black gum, viz.: three inches long, ob-oval, smooth, alternate, and often united in bunches at the extremity of the young lateral shoots. The flowers are small and scarcely apparent. The fruit, which is abundant, is, like that of the black gum, of a deep blue colour, about the size of a pea, and attached in pairs. It is ripe towards the beginning of November, and remaining after the falling of the leaf, it forms a part of the nourishment of the robins and other birds in their autumnal migration to the south. The stone is flattened on one side, a little convex on the other, and striated lengthwise. Bruised in water the berries yield an unctuous, greenish juice, of a slightly bitter taste, which is not easily mingled with the fluid.

The tupelo holds a middle place between trees with soft and those with hard wood. When perfectly seasoned, the sap part is of a light reddish tint, and the heart, of a deep brown. Of trees exceeding fifteen or eighteen inches in diameter more than half the trunk is generally hollow.

The woody fibres which compose the body of trees in general are closely united, and usually ascend in a perpendicular direction. By a caprice of nature, they sometimes pursue an undulating course, as in the red and sugar maples, or, as in the last mentioned species, form riplings so fine, that the curves are only one, two, or three lines in diameter; or lastly, they ascend spirally, as in the twisted elm

(*Orme tortillard*) following the same bent for four or five feet. In these species, however, the deviation is only accidental, and to be sure of obtaining this form it must be perpetuated by grafting or by transplanting young stocks from the shade of the parent tree. The genus which we are considering exhibits, on the contrary, a constant peculiarity of organization; the fibres are united in bundles, and interwoven like a braided cord. Hence the wood is extremely difficult to split unless cut into short billets; a property which gives it a decided superiority for certain uses. In New York, New Jersey, and particularly at Philadelphia, the wood of the tupelo is almost exclusively employed for the hubs of wheels. In a very few places white oak is used for this purpose, probably because the tupelo is of a bad quality or cannot be readily obtained. Michaux thinks that from its limited size and strength, the tupelo can never be substituted for the twisted elm, where very large naves or hubs are required for wagons destined to support immense burdens. In France, he says, the wheels of their heavy vehicles have naves twenty inches in diameter at the insertion of the spokes, with an axle-tree of three hundred and fifty pounds weight, and are laden for distant transportation with nine thousand pounds. If, to its own organization, the tupelo joined the solidity of the elm, a more rapid vegetation and the faculty of growing on dry and elevated lands, and of expanding to three or four times its present size, it would be the most precious to the mechanical arts of all the forest-trees of Europe and North America. In New Jersey and Pennsylvania, many farmers prefer the tupelo for the *side-boards* and bottom of carts, as experience has proved its durability. Wooden bowls are made of it, and also the mortars in which Indian corn is beaten with an iron pestle in the process of preparing hominy. It burns slowly and throws out a good heat, which makes it a favourite with those who keep wood fires, especially for the back log, a purpose to which it is almost exclusively devoted. (*American Sylva*.) See TUPELO.

BLACK LEGS. A provincial name given in some places to a disease frequent among calves and sheep. In Staffordshire it is called the *wood evil*. It is a bloody gelatinous humour, settling in their legs, and often in the neck between the skin and the flesh, making them carry their necks awry.

BLACK MUZZLE. See SHEEP, DISEASES OF.

BLACK OATS. A species of oats much cultivated in some parts of England. The oats of this habit have the corolla very dark, are awned, and the seeds are small. They are rather an inferior class of oats, but are hardy and ripen early, and it is this property which suits them for cultivation in cold and elevated climates. (*Prof. Low. Ele. Ag.*, p. 256.) See OATS.

BLACK THORN, or SLOE (*Prunus spinosa*). This rigid bushy shrub is well known, growing commonly in hedges and thickets. It is frequently used in making fences, especially in exposed situations. But it is not reckoned so good for this purpose as the white thorn, because it is apt to run more into the ground.

and is not so certain of growing; however, when cut, the bushes are much the best, and most lasting of any for dead hedges, or to mend gaps; cattle are not so apt to crop fences of this kind as those of the white thorn.

The fruit is well known in the country, and from its acid, astringent, and very austere flavour, it is not eatable except when baked, or boiled with a large proportion of sugar, and then it is not good. The juice, when inspissated over a slow fire, is a substitute for the Egyptian acacia, or Indian catechu. In some form or other this juice is used in adulterating port wine. The leaves also are reckoned among the adulterated substitutes for tea in England. A water distilled from the blossoms of the sloe is said to be used medicinally in Switzerland and Germany.

The juice of sloes checks purgings when no inflammation is present. (*Smith's Eng. Flor.* vol. ii. p. 357.)

What is commonly called the black thorn in the United States is not the sloe or black haw, (a species of *viburnum*), but the *yellow Crataegus* of botanists, one of the species of thorn commonly used for hedges. (See *Flor. Cestrica*.)

BLACK TWITCH (*Agrostis alba*). A noxious weed of the sub-aquatic marsh bent genus. It chokes up drains and underwood, and flourishes even in extremely dry situations, proving very injurious to many crops. It is also known under the names of *black couch* and *black wrack*. See **MARSH BENT GRASS**.

BLACK WALNUT. See **WALNUT**.

BLACK WASH. A lotion composed of calomel and lime water.

BLACK WATER. See **SHEEP, DISEASES OF**.

BLADE (Sax. *blaed*, *bled*; Fr. *bled*; Low Lat. *bladus*). The spire of grass before it grows to seed; the green shoots of corn which rise from the seed. (*Todd*.)

BLADE-BONE. In farriery, the popular name for the shoulder-blade (*scapula*), of an animal.

BLAIN (Sax. *blezene*; Dutch, *bleyne*, from the Icelandic *blina*, a pustule). In farriery, inflammation of the tongue, a disease in cattle, which frequently affects them in the spring of the year or beginning of summer. The disease (says Clater) is neither so frequent nor so fatal in the horse as it is in cattle; but it does sometimes occur, and the nature of it is frequently misunderstood. The horse will refuse his food, hang his head, and a considerable quantity of ropy fluid will be discharged from the mouth. On examining the mouth, the tongue will be found considerably enlarged, and, running along the side of it, there will be a reddish or darkish purple bladder, and which sometimes protrudes between the teeth. The neighbouring salivary glands are enlarged, and the discharge of saliva is very great, while the soreness of the swelled and blistered part causes the horse obstinately to resist every motion of the jaws. The cure is very simple: the bladder must be deeply lanced from end to end: there will not be any great flow of blood. This will relieve or cure the horse in twenty-four hours. If he can be spared from his work, a dose of physic will remove the stomach affection and any slight

degree of fever that may have existed. If the disease is neglected, the swelling will at length burst, and corroding ulcers will eat deeply into the tongue, and prove very difficult to heal. (*Clater's Farriery*, p. 64.)

BLAST. A vegetable disease, the same as blight. In farriery, it is also a vulgar name for any circumscribed swelling or inflammation in the body of an animal. See **MILDEW**.

BLASTING OF STONES. The operation of tearing asunder large stones or rocks which are in the way of the plough, or other instrument employed in breaking up ground, by means of gunpowder. Logs of wood, the roots of trees, and other obstructions, are removed by the same agent. In stone quarries, blasting is a necessary business. Perhaps one of the greatest and most successful blasts ever effected was at Craigleith quarry, Scotland, on the 18th of October, 1834, when, by 500 lbs. of Sir Henry Bridge's double-strong blasting powder, a mass of upwards of 20,000 tons of solid rock was displaced. (*Quart. Journ. of Agr.* vol. vi. p. 463.)

BLAZE. A white mark or star in the face of a horse.

BLEEDING (Sax. *bleðan*). An operation frequently necessary in the disorders of different kinds of cattle, particularly horses. Such horses as stand much in the stable, and are full-fed, require bleeding more than those which are in constant exercise; but especially when their eyes look heavy and dull, or red and inflamed; and when they look yellow, and the horse is inflamed in his lips and the inside of his mouth; or when he seems hotter than usual, and mangles his hay. These indications not only show that bleeding is required, but likewise the lowering of the diet. The spring is the common season for bleeding horses; but periodical bleeding, without its necessity being indicated, should never be practised. In summer, it is often necessary to prevent fevers, always choosing the cool of the morning for the operation, and keeping them cool the remaining part of the day. Some farriers bleed horses three or four times a year, or even oftener, by way of prevention, taking only a very small quantity at a time, as a pint or a pint and a half. There is, however, this inconvenience from frequent bleeding, that it grows into a habit, which, in some cases, cannot be easily broken off without hazard; and besides, horses become weak from frequent bleeding.

BLEMISH. In farriery, any kind of imperfection in a horse or other animal.

In horses, they consist of broken knees, loss of hair in the cutting places, mallenders and salenders, cracked heels, false quarters, splents, or excrescences which do not occasion lameness; and wind-galls and bog-spavins, where they prevail to any great degree.

In *planting*, the knots on the outside of trees, and shakes internally, are termed blemishes.

BLENDINGS. A provincial word applied to mixed crops, such as peas and beans when grown together.

BLEND-WATER. In farriery, the name of a distemper incident to neat or black cattle, in which the liver is affected.

BLIGHT. The general name for various injuries received by, and diseases incident to, corn, fruit-trees, plants, &c. The terms blight and blast, are indiscriminately applied to plants injured by fungi, insects, disease, frost, &c. *Blight originating in cold*, which, congealing the sap of the tender shoots and leaves of plants, causes these to perish from the bursting of their sap-vessels. Blight sometimes results from causes the very opposite of this, namely during *the prevalence of very sultry, or very dry winds*, the effects of which are popularly termed *fire-blights*, and are similar to those which sometimes injure the vineyards of Italy, and the hop-grounds of England. What is called in England the *white blight* is supposed to originate from *want of nourishment*. It is most commonly met with in grain fields during very dry spells of weather, especially on thin gravelly soils, when the plants get into head or blossom prematurely, and the head or seed-pod ripens without filling.

The *mildew*, one of the greatest enemies that the agriculturist has to contend with, is nothing more than several species of parasitical fungi, or very minute plants of the mushroom species, which attack different kinds of plants, grain, &c. It varies in its nature and appearance, according to the plants attacked. (See Pl. 2, *l, m, n, &c.*)

Blight originating in fungi, attacks the leaves or stems both of herbaceous and woody plants, such as the common barberry and buckthorn, but more generally grasses, and particularly our most useful grains, wheat, barley, and oats. It always appears in the least ventilated parts of a field and has generally been preceded by cold, moist weather, which happening in the warm month of July, suddenly chills and checks vegetation. It generally assumes the appearance of a rusty-looking powder that soils the finger when touched. In March, 1807, some blades of wheat attacked by this species of blight were examined by Keith; the appearance was that of a number of rusty-looking spots or patches dispersed over the surface of the leaf, exactly like that of the seeds of dorsiferous ferns bursting their indusium. Upon more minute inspection, these patches were found to consist of thousands of small globules collected into groups beneath the epidermis, which they raised up in a sort of blister, and at last burst. Some of the globules seemed as if embedded even in the longitudinal vessels of the blade. They were of a yellowish or rusty brown, and somewhat transparent. But these groups of globules have been ascertained by Sir J. Banks to be patches of a minute fungus, the seeds of which, as they float in the air, enter the pores of the epidermis of the leaf, particularly if the plant is sickly; or they exist in the manure or soil, and enter by the pores of the root. (*Sir J. Banks on Blight.*) This fungus has been figured by Sowerby and by F. Bauer and Grew. It is known among farmers by the name of red rust, and chiefly affects the stalks and leaves. But there is another species of fungus known to the European farmer by the name of red gum, which attacks the ear only, and is extremely prejudicial. In the aggregate it consists of groups of minute globules interspersed with

transparent fibres. The globules are filled with a fine powder, which explodes when they are put into water. It is very generally accompanied with a maggot of a yellow colour, which preys also upon the grain, and increases the amount of injury. Grisenthwaite conjectures that in many cases in which the blight and mildew attack corn crops, it may be for want of the peculiar food requisite for perfecting the grain; it being known that the fruit or seeds of many plants contain primitive principles not found in the rest of the plant. Thus the grain of wheat contains gluten and phosphate of lime, and where these are wanting in the soil, that is, in the manured earths in which the plant grows, it will be unable to perfect its fruit, which of consequence becomes more liable to disease. (*New Theory of Agr.*)

Smut is a disease incidental to cultivated corn, by which the farina of the grain, together with its proper integuments and even part of the husk, is converted into a black soot-like powder. If the injured ear be struck with the finger, the powder will be dispersed like a cloud of black smoke; and if a portion of the powder be wetted by a drop of water and put under the microscope, it will be found to consist of millions of minute and transparent globules, which seem to be composed of a clear and glairy fluid encompassed by a thin and skinny membrane. This disease does not affect the whole body of the crop, but the smutted ears are sometimes very numerously dispersed throughout it. Some have attributed it to the soil in which the grain is sown, and others have attributed it to the seed itself, alleging that smutted seed will produce a smutted crop; but in all this there seems to be a great deal of doubt. Willdenow regards it as originating in a small fungus, which multiplies and extends till it occupies the whole ear (*Princip. of Bot.* p. 356): but F. Bauer, of Kew, seems to have ascertained it to be merely a morbid swelling of the ear, and not at all connected with the growth of a fungus. (*Smith's Introduct.* p. 282.) It is said to be prevented by steeping the grain, before sowing, in a weak solution of arsenic. But, besides the disease called smut, there is also a disease analogous to it, or a different stage of the same disease, known to the farmer by the names of bags or smut balls, in which the nucleus of the seed only is converted into a black powder, whilst the ovary, as well as the husk, remains sound. The ear is not much altered in its external appearance, and the diseased grain contained in it will even bear the operation of thrashing, and consequently mingle with the bulk; but it is always readily detected by the experienced buyer, and fatal to the character of the sample. It is said to be prevented as in the case of smut. This disorder, so very fatal to the character of wheat from the injury it does to flour, is known in some of the United States by the very homely name of *bust*.

Mildew is a thin and whitish coating with which the leaves of vegetables are sometimes covered, occasioning their decay and death, and injuring the health of the plant. It is frequently found on the leaves of hops, hazelnut, and the white and yellow dead-nettle. It is

found also on wheat in the shape of a glutinous exudation, particularly when the days are hot and the nights without dew. J. Robertson (*Hort. Trans.* v. 178), considers it as a minute fungus, of which different species attack different plants. Sulphur he has found to be a specific cure.

In cultivated crops mildew is said to be prevented by manuring with soot; though by some this is denied, and soot, by rendering the crop more luxuriant, is said to be an encourager of mildew, the richest part of a field being always most infected by it. As it is least common in airy situations, thinning and ventilation may be considered as preventives. See MILDEW. (*Loudon's Encyc. of Agricult.*)

Mr. Haggerston, who obtained a premium from the Massachusetts Horticultural Society for the discovery of a mode of destroying the rose-slug, says—that a weak solution of *whale-oil soap*, in the proportion of two pounds of soap to about fifteen gallons of water, or weaker, will check and entirely destroy the mildew on the gooseberry, peach, grape vine, &c. &c. For further particulars in regard to the application of this remedy see APUS, RUSK, and SMUT.

BLIND, MOON- In farriery, a disease in the eyes of horses, which is commonly the forerunner of cataract, and generally ends in blindness.

BLINDNESS. A deprivation or want of sight, originating from various causes; a complaint more frequent in horses than in neat-cattle or sheep.

Blindness in horses may be discerned by the walk or step being uncertain and unequal, so that they dare not set down their feet boldly; but when they are mounted by an expert horseman, the fear of the spurs will frequently make them go resolutely and freely, so that their blindness can hardly be perceived. Another mark by which horses that have lost their sight may be known, is, that when they hear anybody enter the stable, they prick up their ears, and move them backwards and forwards in a particular manner.

Blindness in sheep. A complaint that sometimes occurs in these animals, from their being much exposed to either great dampness or long continued snows.

BLIND NETTLE. A provincial term for the wild hemp plant.

BLINDWORM. A term sometimes applied to the slow-worm (*Anguis fragilis*). See SLOW WORM.

BLINKERS. Expansions of the sides of the bridle of a horse, intended to prevent him from seeing objects on either side, but at the same time not to obstruct his vision in front.

BLISTERING (Dutch, *bluyster*). In farriery, the operation of stimulating the surface of some part of the body of an animal, by means of acrid applications, so as to raise small vesications upon it. It is frequently employed for the purpose of removing local affections of different kinds, such as hard indolent tumours.

BLISTER FLY. The *Cantharis*, or Spanish fly.

BLISTER LIQUID is composed of pow-

dered alkanet two ounces, and a gallon of spirit of turpentine; adding, on the fourth day, a pound of powdered Spanish flies; and macerating the whole for a month, when the clear fluid will form a strong liquid blister. If so powerful an external stimulant be not required, this liquid may be diluted with an equal part of spermaceti oil. (*Clater's Farriery*.)

BLISTER OINTMENT. One ounce of powdered Spanish flies; half an ounce of powdered euphorbium; four ounces of lard. One ounce of this well rubbed in is sufficient to blister a horse's leg. That commonly sold by farriers generally contains oil of vitriol (sulphuric acid), to make it raise the blister without the trouble of rubbing in the ointment; and, in consequence, a blemish is produced.

BLOOD (Sax. blod; old French, *bloed*). The fluid which circulates in the bodies of all animals. Blood, when drawn from the body, and allowed to rest, speedily separates into two portions, viz. the fluid, or serum, and the solid clot, crassamentum, or cruor.

In quadrupeds, in general, the temperature of the blood is higher than in man. In the sheep, it ranges from 102° to 103°; in man it is 98° in a state of health. The equal distribution of the blood in the animal system is as essential to the health of quadrupeds as of man. When it is irregularly circulated, and more sent to any organ than it should share, that part becomes oppressed, diseased action is set up in it; and if the organ be a vital one, life is endangered or destroyed through the violence of inflammation.

Blood is an excellent manure for fruit trees; and, mixed with earth, forms a very rich compost. (*Ann. of Phil.* vol. ii. p. 202.)

BLOOD-ROOT. See BLOODWORT.

BLOOD-SHOT. In farriery, a popular term for that red appearance which the eye exhibits when inflamed. The best treatment is to bathe the eye with a lotion composed of one drachm of white vitriol (sulphate of zinc) dissolved in half a pint of water.

BLOOD-SPAVIN or **BOG-SPAVIN.** In farriery, a swelling of the vein that runs along the inside of the hock of the horse, forming a little soft tumour in the hollow part, often attended with weakness or lameness of the hock. Clater (*Farriery*, p. 272) says, a blister is the proper application.

BLOODWORT (*Sanguinaria canadensis*). A hardy American perennial, flowering in April. It loves a shady situation and bog soil; and may be propagated by parting the roots in spring or autumn. The root of bloodwort throws out a bright red juice, when pressed, which the Indians paint themselves with. It operates as an emetic and narcotic.

BLOODWORT (*Rumex sanguineus*). This is a beautiful dock, growing wild in many parts of England, but introduced lately into gardens, for its fine deep-red appearance. It grows from two to three feet high, and the stalks are firm, stiff, reddish, and branched. The leaves are long and narrow, heart-shaped at the base, and taper gradually towards their point. Sometimes the leaves are a deep green, only stained, or veined with red; sometimes they are entirely a deep blood colour, which

gives them a beautiful appearance. The flowers are in terminal clusters, small and numerous. They blow in June and July, and the seed ripens in August. The dried root, either in powder or in decoction, is astringent; and may be used in spitting of blood, and violent purgings.

BLOOM or **BLOSSOM**. A general name for the flowers of plants, but more especially of fruit-trees. The office of the blossom is partly to afford protection, and partly to draw or supply nourishment to the fertilizing organs of the plant, for the perfecting of the embryo, fruit, or seed.

Bloom is a term applied to the delicate powder which coats the outer surface of such smooth-skinned fruits as the grape and plum. In gathering such fruits, care should always be observed to prevent this bloom from being removed by handling or otherwise, as it injures the appearance.

BLOSSOM. A colour in horses, formed by the intermixture of white hairs with sorrel and bay ones.

BLOW-BALL. A local name for the flower of the dandelion.

BLOW-FLY. The large flesh-fly (*Musca carnaria*).

BLOW-MILK. The milk from which the cream has been blown off.

BLOWN. In farriery, a diseased state of the stomach and bowels of cattle, caused by the sudden extrication of air in large quantities from some of the grosser kinds of green food. See **HOVEN**.

BLOWS. A provincial term used to signify the blossoms of beans, &c.

BLUBBER. See **FISH**.

BLUE-BELLS (*Scilla nutans*). A common name given to a bulbous-rooted plant of the hyacinth kind, frequently met with in woods and other places. Its bulb is globular, white, and coated; its leaves linear, channelled, shining, and drooping in their upper half; the flowers form a cluster on an upright stalk, drooping in the upper half; they are blue, pendulous, nearly an inch long, and scented. The bulb is acrid, but loses its acrimony in drying, in which state it answers as a substitute for gum-arabic in the art of dyeing, by being simply dried and powdered.

BLUE-BIRD. Mr. Nuttall describes three species of the blue-bird (*Sialia*), found in America. That which is most familiarly known in the United States (the *Sylvia sialis* of Wilson), is an insectivorous bird, inhabiting almost every section of the continent east of the Rocky Mountains, from the forty-eighth degree of latitude to the tropics. Although they generally spend their winters in the Southern States, they sometimes remain in well-protected warm situations in the southern parts of Pennsylvania. They breed and pass the summer from Labrador to Natchez. "In the Middle and Northern States," says Mr. Nuttall, "the return of the blue-bird to his old haunts round the barn and the orchard is hailed as the first agreeable presage of returning spring, and he is no less a messenger of grateful tidings to the farmer, than an agreeable, familiar, and useful companion to all. Though sometimes

he makes a still earlier fitting visit, from the 3d to the middle of March, he comes hither as a permanent resident, and is now accompanied by his mate, who immediately visits the box in the garden, or the hollow in the decayed orchard-tree, which has served as the cradle of preceding generations of his kindred. Affection and jealousy, as in the contending and related thrushes, have considerable influence over the blue-bird. He seeks perpetually the company of his mate, caresses and soothes her with his amorous song, to which she faintly replies; and, like the faithful rook, seeks occasion to show his gallantry by feeding her with some favourite insect. If a rival makes his appearance, the attack is instantaneous, the intruder is driven with angry chattering from the precincts he has chosen, and he now returns to warble out his notes of triumph by the side of his cherished consort. The business of preparing and cleaning out the old nest or box now commences; and even in October, before they bid farewell to their favourite mansion, on fine days, influenced by the anticipation of the season, they are often observed to go in and out of the box as if examining and planning out their future domicile. Little pains, however, are requisite for the protection of the hardy young; and a substantial lining of hay, and now and then a few feathers, is all that is prepared for the brood beyond the natural shelter of the chosen situation. As the martin and house-wren seek out the favour and convenience of the box, contests are not unfrequent with the parties for exclusive possession; and the latter, in various clandestine ways, exhibits his envy and hostility to the favoured blue-bird. The eggs are five or six, of a very pale blue, and without spots. As they are very prolific, and constantly paired, they often raise two and sometimes probably three broods in the season; the male taking the youngest under his affectionate charge, while the female is engaged in the act of incubation.

"Their principal food consists of insects, particularly beetles, and other shelly kinds; they are also fond of spiders and grasshoppers, for which they often, in company with their young, in autumn, descend to the earth, in open pasture-fields or waste grounds. Like our thrushes, they, early in spring, also collect the common wire-worm, or *Iulus*, for food, as well as other kinds of insects, which they commonly watch for, while perched on the fences or low boughs of trees, and dart after them to the ground as soon as perceived. They are not, however, flycatchers, like the *Sylvicolas* and *Muscicapas*, but are rather industrious searchers for subsistence, like the thrushes, whose habits they wholly resemble in their mode of feeding. In the autumn, they regale themselves on various kinds of berries, as those of the sour-gum, wild-cherry, and others; and later in the season, as winter approaches, they frequent the red cedars and several species of sumach for their berries, eat persimmons in the Middle States, and many other kinds of fruits, and even seeds, the latter of which never enter into the diet of the proper flycatchers. They have also, occasionally, in a state of confinement,

been reared and fed on soaked bread and vegetable diet, on which they thrive as well as the robin." (*Nuttall's Ornithology*.)

The Western Blue-bird (*Sialia occidentalis* of Townsend), is found along the Pacific coast west of the Rocky Mountains. It possesses many of the habits of the common kind, his song being, however, described as more varied, sweet, and tender than that of the common blue-bird of the Atlantic states.

The Arctic Blue-bird (the *Sialia arctica* of Audubon), is a beautiful species found in the highest latitudes of the North Western portions of the American continent. See *Nuttall's Ornithology of American Land Birds*, Audubon, Wilson, &c.

BLUE-BOTTLE (*Centaurea*). This is a large herbaceous genus, which contains several species known as weeds; that, however, which is peculiar to corn-fields is the corn blue-bottle (*Centaurea cyanus*). It grows amongst corn, and its presence indicates careless farming. It is an annual, ripening its seeds in autumn. It is also known by the names of knapweed, matfellow, centaury, corn-flower, and hurt-sickle. The expressed juice of its blue flower, when mixed with cold alum-water, may be used as a water colour for painting, being a permanent colour. See **CENTAURY**.

This pretty wild flower has been introduced into our gardens for its elegance. The blue-bottle grows a foot high; the stalk is firm and white, and the leaves are narrow, and of a whitish-green. The root is hard and fibrous. A decoction of the flowers with galls and copperas affords a good writing ink. This plant is sometimes known among the common people by the name of "wound herb." Any reliance on the styptic properties of the leaves might prove dangerous by losing time, and a consequent waste of blood, before proper assistance can be procured in extensive wounds. Small wounds can unite without its aid. An infusion of the flowers is slightly diuretic.

BLUE-GRASS, wire-grass (*Poa compressa*, compressed or flattened poa. Plate 7, *h*). A very common perennial grass in the United States, found in fields, pastures, &c. It affords a good nutritious pasture for cattle, but is not so much esteemed as the green meadow-grass, (*Poa pratensis*). Its great tenacity of life makes it sometimes very troublesome in the tillage of certain crops. (*Flor. Cæstrica*.)

The famous Kentucky blue-grass, Dr. Darlington says, is the *Poa pratensis*, smooth-stalked meadow-grass; green grass; (Plate 5, *h*) decidedly the most valuable of all the American pasture grasses. It comes in spontaneously, in all rich, calcareous soils.

The best time for sowing, says a writer in the *Western Farmer and Gardener*, is as soon as you can get ready after October; or any time before the middle of March.

Old fields, on which the sun can exert full power, produce blue grass in the greatest abundance, and of the best quality. Animals feeding thereon without grain, keep better and become fatter than on any other treatment; but even wood-lands will produce good grass.

If intended for old or permanent pasture, the

fields should be broken up in February or March, and sown in oats. Then sow ten pound of blue-grass seed, half a gallon of red clover-seed, and if a little timothy or orchard-grass be sprinkled on, so much the better. The timothy or orchard-grass will give a quick pasture, and afford protection to the blue-grass until it gets a strong foot-hold, after which no other grass can contend with it. The rains will cover the seed sufficiently to insure vegetation.

The following account of the blue grass is from the *Franklin Farmer*.

"This grass, which constitutes the glory of Kentucky pastures, is esteemed superior to all others for grazing. It flourishes only on calcareous soils. Opinions and practice vary here, as to the best time of sowing it—some preferring September, for the same reasons, chiefly, which relate to timothy or other grasses, others preferring February or March, to obviate the danger of the tender roots being winter-killed. It is sown either on wood-land or open ground—in the latter case most generally after a succession of exhausting crops in old fields. If sown on woodland, the leaves, brush, and trash must be raked off or burnt. It is particularly important to burn the leaves, else the seed may be blown away with them by the wind, or if not blown away, the leaves may prevent the seed reaching the earth and thus defeat their germination. Many of those who sow in winter, prefer casting the seed on the snow, as it enables them to effect the operation with more neatness and uniformity. In woodlands, the grass must not be grazed the first year, or at all events till after the seeds have matured. In open land, the practice has been adopted by some, of mixing timothy and clover with blue grass, in which case, half a bushel of the latter seed to the acre is sufficient. The advantage resulting from this is, that it secures at once, a well-covered pasture that will bear considerable grazing the first year. The blue grass, in a few years, expels the other grasses, and takes entire possession of the field. On open ground, it is frequently sown in March upon wheat, rye, or oats. If the season is favourable, it may be sown in April; but should the weather prove dry, a great portion of the seed will be lost. It is the practice, we believe, of most graziers, to put upon a given pasture as much stock as it will maintain, without shifting them during the season, as, besides saving labour, it renders the cattle more quiet and contented. Others, however, fence off their pastures into separate divisions, to undergo a regular succession of periodical grazings. This plan secures a constant supply of fresh grass, very grateful to the animals, and is believed to be more economical, as much less is trampled and rejected by the cattle. The number of animals to the acre must depend upon their size and the quality and quantity of grass. The grass on open ground is much more abundant, sweet and nutritious, than on woodland, and consequently will maintain much more stock, perhaps nearly twice as much; while open woodland will produce much more and better grass than that which is deeply shaded. The best grazier"

extirpate, as fast as possible, every tree not valuable for timber or wanted for fuel, and some even prune the branches of those which are allowed to remain." (*Farmer's Register*.)

BLUE MILK. Milk that has been skimmed, or had the cream taken off. In large dairies it is chiefly used for feeding hogs.

BLUE STONE. The common name for blue vitriol, or sulphate of copper.

BOAR (Sax. *bar*; Dutch, *beer*). The male of the swine-tribe of animals. See **HOG** and **SWINE**.

In *horsemanship*, a horse is said to boar when he shoots out his nose level with his ears, and tosses his nose in the wind.

BOARD OF AGRICULTURE. A society established in London in 1794, under the patronage of his Majesty, Geo. III., "For the Encouragement of Agriculture, and Internal Improvement," consisting of a president, and thirty ordinary members, with proper officers for conducting the business of the institution. The plan and design of this highly useful establishment, though previously suggested by several writers on rural improvements, was chiefly brought forward, and carried into execution by the unwearied efforts and persevering industry of Sir John Sinclair, to whom the nation is certainly under much obligation. It was discontinued about the year 1812, in consequence of the withdrawal by government of the annual parliamentary grant of 3000*l.* for its support, chiefly owing to the society's interference with political themes, foreign to the improvement of agriculture. A full account of the nature, origin, and plan, with the charter of incorporation of this excellent institution, may be seen in the first volume of the "Communications" published by the Board, which extended to seven vols.; and these contain some excellent papers on various important matters connected with husbandry and agriculture in general.

BOG, and **BOG GRASSES.** See **PEAT SOILS**.

BOG-BEAN. See **BUCK-BEAN**.

BOG-RUSH, BLACK (*Scheenus nigricans*). Is found on turfy bogs. Root scarcely creeping, of very long, strong fibres, crowned with black, shining, erect, folded sheaths, a few of which bear very narrow, acute, upright leaves, and embrace the bottom of the otherwise naked stem, which is from eight to twelve inches high. Head black. Anth. long, yellow. Stigm. three, dark purple. Seed white and polished. (*Smith's Engl. Flor.* vol. i. p. 50.)

Nuttall, in his *Genera of North American Plants*, mentions three species of the bog-rush or *saw-grass*. This remarkable grass, as he calls it, was discovered in the West Indies by Schwartz, and extends a considerable distance northward beyond Wilmington, North Carolina, often almost exclusively occupying considerable ponds. The leaves are almost as sharply serrated as those of a Bromelia, and hence it is very properly called *saw-grass*. The genuine species of this genus are principally confined to Europe and Barbary.

BOG-SPAVIN. See **BLOOD-SPAVIN**.

BOIL (Sax. *bile*). In farriery, an inflammatory suppurating tumour affecting cattle or

sheep. In order to cure this sort of tumour, it will be necessary to bring it to a head by the application of plasters composed of wheat-flour and tar; and when the boil feels soft under the finger, to open it with a lancet, and let out the matter or pus.

BOLE. A term signifying the body or trunk of a tree, and sometimes the stalk or stem of corn. This word is written and pronounced in the north of England *boll*, and "bollings" is the name for pollards, trees whose tops and branches are lopped off.

BOLE, or **BOLL** (Lat. *bolla*). In Scotland, a common measure of grain, containing four bushels. In the old measure of Scotland, for oats and barley,

4 lippies	=	1 peck.
4 pecks	=	1 firloft.
4 firlofts	=	1 boll.
16 bolls	=	1 chaldier.

The boll of oatmeal weighs 140 lbs. For wheat, peas, and rye, three oat firlofts make one boll. (*Brit. Husb.* vol. ii. p. 500.)

BOLE OF SALT. A measure that contains two bushels.

BOLETUS. A genus of mushroom, of which several species have been subjected to chemical analysis, by the French chemists Braconnot and La Grange. They yield bolitic acid.

BOLSTERS. In horsemanship, those parts of a great saddle which are raised on the bows both before and behind, to rest the rider's thighs, and keep him in a posture to withstand the irregular motions of the horse.

BOLT and **BOLTING.** Terms provincially applied to the trussing of straw.

BOLTER. A sort of framed sieve, having its bottom made of linen stuff, hair, or wire, according to circumstances. The bakers employ bolters that may be worked by the hand, but millers have larger ones that move by the machinery of the mill. It is sometimes called *boulter*.

BOLTING, or **BOULTING.** The operation of separating flour or meal of any kind from the husks or bran, by means of a bolter.

BOLTING CLOTH. Linen or hair-cloth made for the purpose of sifting meal or flour through. They are made of different degrees of fineness, and numbered accordingly; hence we have cloths of No. 2, No. 3, &c.

BOLTING FOOD. This is a very common vice in greedy horses, especially when they feed out of the same manger. The only remedy is not to let them fast too long, and to mix chaff in their corn. The teeth of such horses ought to be examined, to see whether the bolting of the corn arises from any unevenness of the grinders.

BOLTING MILL. A mill or machine having much lateral or circular motion, by which means the business of sifting meal or flour can be performed with great facility and expedition. The framed sieve that moves within it is termed a bolter.

BOLUS. See **BALL**.

BONASUS. A kind of buffalo, or wild bull.

BONES (Sax. *ban*; Su. Goth. *been*; Germ. *bein*). The more solid parts of the body of animals. When crushed, a valuable manure.

The introduction of bones as a fertilizer is perhaps one of the most important and successful agricultural efforts of modern days, and has been certainly one great means of sufficiently increasing the national production of corn to keep pace with an annually enlarging population. It required, however, like all other agricultural improvements, much perseverance and unshaken energy in the promoters of this manure, to induce its general adoption; many a long and stubborn argument had to be answered; many hundred loads of the bone refuse of Sheffield and Birmingham had to be given away, before the cautious and suspicious Yorkshire farmers could be generally persuaded of the fallacy of the assertion, that "there is no good in bones." To this tardy conviction the erroneous mode of employing them originally adopted mainly contributed, for they were at first used without even roughly breaking them, and, in consequence, they decomposed so very slowly in the soil that the farmer's patience was naturally exhausted: he sought in vain for immediate and striking results.*

The introduction of machinery, however, by enabling the cultivator to procure them in a crushed state, did away with this objection, for when crushed, they decompose with much greater rapidity; and this has long since induced a consumption of this manure more than adequate to the national produce of bones. It has been necessary, in consequence, to search in other countries for a supply; and for the last fifteen years the quantity of bones imported from abroad has been steadily increasing. Thus the declared value of all the bones imported into England—

In the year	1821 was	£	s.	d.
—	1824	15,898	12	11
—	1827	43,910	17	11
—	1830	77,956	6	8
—	1833	58,223	16	8
—	1835	97,900	6	4
—	1836	127,131	14	10
—	1837	171,806	0	0
—	1837	254,600	0	0

Into the port of Hull alone, in 1815, were imported about 8000 tons; this had increased to 17,500 tons in 1833, and to 25,700 tons in 1835. These came principally from the Netherlands, Denmark, and the Baltic, but they have been imported from much more distant places, such as Buenos Ayres and the Mediterranean; and I am confident that if the seal fishermen of North America and other distant stations were aware of the fact that the bones of fish are nearly, if not quite, as valuable for the farmer as those of other animals, they would not suffer any falling off in the supply. By the 3 & 4 W. 4, c. 56, a duty of one pound per cent. on the declared value is payable on all bones imported for farming or other purposes.

The following table, extracted from one by Richard Tottie, Esq., of Hull, will show to the

* It is said, in the Doncaster Agricultural Society's Report upon the use of bones, "Colonel St. Leger, then residing at Warmsworth, was the first person who is known to have used them, and his introduction of them was in 1775; the early progress does not seem to have been rapid, from the practice of laying them on almost unbroken, and in very large quantities."

farmer from whence the great supply of foreign bones is derived. This table contains the imports during 1827, in which year the following number of vessels entered the port of Hull loaded with bones:—

From	Vessels.	Tons of Bones
Russia - - - -	6	carrying 822
— Prussia - - - -	9	1174
— Sweden and Norway - - - -	6	362
— Denmark - - - -	57	3778
— Hanseatic towns - - - -	61	3760
— Netherlands - - - -	76	6110
— Mecklenberg } - - - -	33	1702
— Hanover } - - - -		
— Oldenberg } - - - -		
	<hr/> 248	<hr/> 17,718

The import of bones into Hull has since been regularly increasing: it was, according to a letter with which Mr. Tottie favoured me, equal to 23,900 tons in 1834, and to 25,700 in 1835. It would certainly be well to look to other quarters besides the Continent for a future supply, since in some of the German states a duty on their export has been recently imposed. So considerable, indeed, has the demand become, that by many unprincipled dealers several kinds of adulterations are used. These, according to Mr. Halkett (*Quar. Journ. of Agric.* vol. ii. p. 181), are the lime that has been used in tan-works to take off the wool and hair, old plaster lime, soap boilers' waste, saw-dust, rotten wood, oyster-shells, &c. The best remedy for these frauds is for the farmer to deal with only respectable crushers, and to pay a fair price for the bones.

There is, perhaps, no manure of whose powers the chemical explanation is more easy; for of the earthy and purely animal matters of which bones are composed, there is not a single particle which is not a direct constituent or food of vegetables; thus, if carbon, hydrogen, and oxygen, are found in the abounding oil and cartilage of bones, they are equally common, nay, ever present, in all vegetable matters: and if carbonate and phosphate of lime are almost equally common in plants, they are still more universally present in all bones.

The bones of animals do not vary much in composition; they all contain phosphate and carbonate of lime, with a portion of cartilage or animal matter, with other minor ingredients. The bone of the ox has been analyzed by M. Berzelius: he found that, by calcining these bones, every 100 lbs. lost 38 lbs. in weight. 100 parts of these bones, before calcination, consisted of—

Cartilage - - - - -	33.3
Phosphate of lime - - - - -	55.35
Fluate of lime (Derbyshire spar) - - - - -	3.
Carbonate of lime (chalk) - - - - -	3.85
Phosphate of magnesia - - - - -	2.05
Soda, with a little common salt - - - - -	2.45
	<hr/> 100

Bones, however, vary slightly in composition, according to the age and condition of the animal, for MM. Fourcroy and Vauquelin found some ox bones which they analyzed, to be composed of—

	Parts.
Gelatine and oil - - - -	51
Phosphate of lime - - - -	37.7
Carbonate of lime - - - -	10
Phosphate of magnesia - - - -	1.3
	<hr/> 100

The enamel of teeth is the only portion of bones hitherto analyzed, which is entirely destitute of cartilage. It is true that fossil bones contain none; but these have probably, in a former state of the earth, been acted upon by fire; for Mr. Hatchett found in some bones from Hythe in Kent, taken out of a Saxon tomb, the same proportion of cartilage as in a recent bone. Teeth have been analyzed by Mr. Pepys: he found them to be composed of

	Adults.	Children's.
Phosphate of lime - - - -	64	62
Carbonate of lime - - - -	6	6
Cartilage - - - -	20	20
Loss - - - -	10	12
	<hr/> 100	<hr/> 100

M. Merat Guillot has furnished us with a statement of the earthy constituents of 100 parts of the bones of different animals; from which the farmer will perceive that the composition of the bones of all animals is very similar.

Be e.	Phosphate of Lime.	Carbonate of Lime.	Animal Matter.
Calf -	54	—	46
Horse -	67.5	1.25	31.25
Sheep -	70	5	25
Elk -	90	1	9
Hog -	52	1	47
Hare -	85	1	14
Pullet -	72	1.5	26.5
Pike -	64	1	35
Carp -	45	5	50
Teeth of the			
Horse -	85.5	2.05	—
Ivory -	64	1	.35

Lobster shells, egg shells, &c., are all composed of the same ingredients as bone. The poor of Dublin are often employed for the purpose of pounding oyster shells for the use of the cultivators of the soil; and a similar plan might, I should imagine, be very advantageously adopted in some of the populous districts of this country: for, although such shells do not contain the same proportion of phosphate of lime as bone, yet they contain a sufficient quantity to render them highly valuable as fertilizing substances. 100 parts of lobster shells yield—

	Parts.
Carbonate of lime (chalk) - - - -	60
Phosphate of lime - - - -	14
Cartilage - - - -	26
	<hr/> 100

100 parts of cray-fish shells contain—

	Parts.
Carbonate of lime - - - -	60
Phosphate of lime - - - -	12
Cartilage - - - -	28
	<hr/> 100

100 parts of hens' egg-shells contain—

	Parts.
Carbonate of lime - - - -	89.6
Phosphate of lime - - - -	5.7
Animal matter - - - -	4.7
	<hr/> 100

There is yet another source from whence the phosphate of lime might be obtained in large quantities for the use of the farmer, viz., the fossil bones or native phosphate of lime, which is found in various districts of this country, in very considerable quantities, and would only require crushing or powdering to render it nearly as useful to the farmer as the recent bones. That the cartilage or oily matter of the bone does not constitute the chief fertilizing quality is shown by the fact, that the farmers who use bone dust will as readily employ that which has first been steamed, and all its fatty portion extracted by the preparers of cart grease, as they will the unused fresh bones. It is acknowledged, says the *Doncaster Agr. Soc.* in their Report, to be a prevalent opinion amongst intelligent farmers, that manufactured bones are equal, in their effects, to the raw bones. Mr. Short, in the year 1812, "boned twenty-four acres, at the rate of fifty bushels an acre. On one part of the field he put London bones, which had the oil stewed out of them; and another part was tilled with bones collected from Nottingham, which were full of marrow, and a third part with horses bones, having much flesh upon them. He could not see any difference in the turnips produced from these: they all produced a good crop. But the next crop was not so good where the fleshy bones had been laid." And Mr. Horn-castle adds, "A strong fermentation takes place in the boiled bones; when thrown in a heap they become extremely offensive, and when they obtain this bad smell, I consider they are in a state to break up for manure."—And, says Mr. Halkett, of New Scone, in Perthshire, "After numerous trials between what we call green bones with all the marrow and fat in them, and dry ones free from it, I have always found that the latter raised by far the best crops. Therefore, I have arrived at the conclusion that the less animal fat in them the better, and that the boiling of them before crushing, instead of impairing them is a benefit." (*Quar. Journ. of Agric.* vol. ii. p. 180.)

The mineral substance called the Apatite, found in the Cornish tin mines, is nothing but phosphate of lime; 100 parts being composed of—

	Parts.
Phosphoric acid - - - -	45
Lime - - - -	55
	<hr/> 100

The phosphate of lime is also found in many parts of the north of England, in Hungary, and, in immense beds, in Spanish Estremadura, where it is said to be so common in many places, that the peasants make their walls and fences of it. 100 parts of this substance, called by mineralogists the phosphorite, contain—

	Parts.
Phosphoric acid and lime - - - -	93
Carbonate acid - - - -	1
Muriatic acid - - - -	0.5
Fluoric acid - - - -	2.5
Silica - - - -	2
Oxide of iron - - - -	1
	<hr/> 100

The horns of the deer are similar in composition to bones; but those of black cattle are totally different; they approach nearer in composition to animal muscle, as may be seen by the following analysis of Dr. John; 100 parts of the horns of black cattle yielding this chemist—

	Parts.
Albumen - - - - -	90
Ditto with Gelatine - - - - -	8
Fat - - - - -	1
Various salts, &c., &c. - - - - -	1
	100

100 parts, however, of a fossil horn, analyzed by M. Braconnot, yielded—

	Parts.
Phosphate of lime - - - - -	69.2
Water - - - - -	11
Gelatine - - - - -	4.6
Carbonate of lime - - - - -	4.5
Bitumen - - - - -	4.4
Silica - - - - -	4
Phosphate of magnesia - - - - -	1
Alumina - - - - -	0.7
Oxide of iron - - - - -	0.5
	100

The excrements of those birds and animals which feed upon animal matters approach very nearly to bone in chemical composition; and I have little doubt but that the dung of sea birds might be profitably collected from some of the rocky islands on our coasts. This is actually done among the South Sea Islands by the Peruvian farmers, and to such an extent, that, according to M. Humboldt, fifty vessels, each carrying from fifteen hundred to two thousand cubic feet, are annually loaded with this manure at the island of Chinche alone. This manure is known in South America under the name of Guano, and is too powerful to be used in large quantities. It abounds in phosphate of lime. (A quantity has recently been imported into England: it contains 36 per cent. of phosphate of lime.) Some of the dung of sea-fowl collected on a rock on the coast of Merionethshire, was tried at the request of Sir Humphry Davy, at Nannau, by Sir Robert Vaughan, and produced a very powerful, though transient effect, on some grass land. The very soil of some of the rocks, which have been for so many ages tenanted by these water-fowls, must be completely impregnated with the earthy matters of bones. See GUANO.

All the constituent parts of bones are found in vegetable substances. The cartilage of bones is composed, according to the examinations of Mr. Hatchett, of a substance nearly identical in all its properties with solid albumen. Now, 100 parts of albumen are composed of—

Carbon - - - - -	52.888
Oxygen - - - - -	23.872
Hydrogen - - - - -	7.54
Azote - - - - -	15.705
	100

“The primary sources from which the bones of animals are derived, are the hay, straw, or other substances which they take as food. Now if we admit that bones contain 55 per cent of the phosphates of lime and magnesia

(Berzelius), and that hay contains as much of them as wheat-straw, it will follow that 8 lbs. of bones contain as much phosphate of lime as 1000 lbs. of hay or wheat-straw, and 2 lbs. of it as much as 1000 lbs. of the grain of wheat or oats. These numbers express pretty exactly the quantity of phosphates which a soil yields annually on the growth of hay and corn. Now the manure of an acre of land with 40 lbs. of bone dust is sufficient to supply three crops of wheat, clover, potatoes, turnips, &c., with phosphates. But the form in which they are restored to a soil does not appear to be a matter of indifference. For the more finely the bones are reduced to powder, and the more intimately they are mixed with the soil, the more easily are they assimilated.” (Liebig’s *Organ. Chem.*)

It is perfectly needless to specify any vegetable substances into which the three first of these substances enter, for the vegetable world is almost entirely composed of them, and occasionally a portion of azote is also found in vegetable substances, but the three first are invariably present. The flour of wheat, the poison of the deadly night-shade, the oxalic acid of the wild sorrel, the narcotic milk of the lettuce, the stinking odour of the garlic, and the perfume of the violet, are, by the contrivance of their divine architect, only some of the results of the mixture of carbon, oxygen, and hydrogen.

But the chief constituent present in all bones we have already seen is the phosphate of lime; and how absolutely necessary this substance is for the healthy vegetation of plants, will be apparent from the following table, which contains the results of the examination by MM. Saussure, Vauquelin, and a few other distinguished chemists, of the ashes or solid contents of a number of vegetable substances:—

	Parts.
100 parts of the ashes of the grain of the oat yielded	
of phosphate of lime - - - - -	39.3
straw of wheat yielded of phosphates	
of lime and magnesia - - - - -	6.2
— seeds of wheat - - - - -	44.5
— bran - - - - -	46.5
— seeds of vetches - - - - -	27.99
— golden rod (<i>Solidago virgaurea</i>) - - - - -	11.
— plants of turnsole (<i>Helianthus annuus</i>),	
bearing ripe seeds - - - - -	22.5
— chaff of barley - - - - -	7.75
— seeds of barley - - - - -	32.5
— seeds of oats - - - - -	24.
— leaves of oak - - - - -	24.
— wood of oak - - - - -	4.5
— bark of oak - - - - -	4.5
— leaves of poplar - - - - -	13.
— wood of poplar - - - - -	16.75
— leaves of hazel - - - - -	23.
— wood of hazel - - - - -	35.
— bark of hazel - - - - -	5.5
— wood of mulberry - - - - -	2.25
— bark of mulberry - - - - -	6.5
— wood of hornbeam - - - - -	23.
— bark of hornbeam - - - - -	4.5
— seeds of peas - - - - -	17.5
— bulbs of garlic - - - - -	8.9

Phosphate of lime has also been found in the marsh bean (*Vicia faba*), and in the pea-pod or husk, by Einhof; in rice, by Braconnot; in the Scottish fir, by Dr. John; in the quinquina of St. Domingo, by Fourcroy; in the fuci, by Gaultier de Claubry, and in many others; in short, as Dr. Thomson remarks

(*System of Chem.* vol. iv. p. 319), "phosphate of lime is a constant ingredient in plants."

The cultivator of the soil will not be incredulous as to the power of vegetables to dissolve and feed upon the hard substance of the crushed bones of animals, when he is reminded that the ashes of the straw of wheat are composed of 61½ per cent. of silica (flint), a still harder substance than the hardest bone. And this is not a solitary instance; for the same earth abounds in a still greater proportion in the straw of other grain. Vauquelin found 60¾ per cent. of it in the ashes of the seeds of the oat; and the Dutch rush contains it in such abundance that it is employed by the turner to polish wood and even brass.

To the mode and effect of applying bones as a manure, either whole, broken, or in a state of powder, the Doncaster Agricultural Association paid considerable attention, and they have made a very valuable report of the result of their inquiries, in which they say:—"The returns received by the Association satisfactorily establish the great value of bones as a manure. Our correspondents, with only two exceptions, all concur in stating them to be a highly valuable manure, and on light dry soils superior to farm-yard dung and all other manures. In copying the language of one of them, in reference to dry sandy soils, we express the opinions repeated in a far greater number—"I consider bone tillage one of the most useful manures which has ever been discovered for the farmer's benefit. The lightness of carriage, its suitability for the drill, and its general fertilizing properties, render it peculiarly valuable in those parts where distance from towns renders it impossible to procure manures of a heavier and more bulky description." For, as stated by another farmer, the carting of six, eight, or ten loads of manure per acre is no trifling expense. The use of bones diminishes labour at a season of the year when time is of the first importance; for one wagon load, or 120 bushels of small drill bone-dust is equal to forty or fifty loads of fold manure. Upon very thin sand land its value is not to be estimated; it not only is found to benefit the particular crop to which it is applied, but extends through the whole course of crops." The report adds, that bones have been found highly beneficial on the limestone soils near Doncaster, on peaty soils, and on light loams; but that on the heavy soils and on clay they produce no benefit. The late Mr. George Sinclair, of New Cross, has given (*Trans. High. Soc.* vol. i. p. 78), the analysis of two soils on which bone manure produced very opposite results. 400 parts of the soil on which the bone manure had very beneficial effects consisted of—

	Parts.
Silicious sand - - - - -	167
Calcareous sand - - - - -	43
Water of absorption - - - - -	99
Animal and vegetable matter - - - - -	24
Carbonate of lime - - - - -	25
Silica (flint) - - - - -	23
Alumina (clay) - - - - -	9
Oxide of iron - - - - -	3
Soluble vegetable and animal matter - - - - -	5
Moisture and loss - - - - -	2
	400

The soil on which the bone manure had no such beneficial effect, contained, in 400 parts,

	Parts.
Calcareous sand and gravel (nearly pure carbonate of lime) - - - - -	217
Animal and vegetable matters - - - - -	17
Carbonate of lime - - - - -	39
Silica - - - - -	85
Alumina - - - - -	20
Oxide of iron - - - - -	5
Soluble matter with gypsum - - - - -	4
Moisture or loss - - - - -	13
	400

The mode of applying them, adds the *Doncaster Report*, is either by sowing broadcast or by the drill; either by themselves, or, what is much better, previously mixed with earth and fermented. Bones which have been thus fermented are decidedly superior to those which have not been so. Mr. Turner, of Tring, adopted the practice of mixing with his bone-dust an equal quantity of the dung of the sheep, collected for the express purpose, at an expense of 2½d. per bushel for labour. He prepared the mixture in winter, by laying the sheep-dung in heaps with the crushed bones, and allowing them to ferment together for some months. By this plan the two manures are thoroughly incorporated, and he considers that thirty-five bushels of the mixture are fully equal in effect to twenty-five bushels of the bones. (*My Essay on Crushed Bones*, p. 14.) The quantity applied per acre is about twenty-five bushels of bone-dust and forty bushels of large broken bones. The dust is best for immediate profit; the broken half-inch bones for more continued improvement. Mr. Birks says, "If I were to till for early profit, I would use bones powdered as small as saw-dust; if I wished to keep my land in good heart, I would use principally half-inch bones, and in breaking these I should prefer some remaining considerably larger." The reason for this is very obvious; the larger the pieces of bone, the more gradually will a given bulk dissolve in the soil.

Crushed bones are employed with decided success for turnips. The ease with which they are applied by the drill, the ample nourishment they afford the young plants, on the very poorest soils, and the avidity with which the roots of the turnip encircle and mat themselves around the fragments of crushed bone, clearly evinces how grateful the manure is to this valuable crop. The evidence in its favour is copious, and decisive of its merits. In a recent report of the East Lothian Agricultural Society, Mr. John Brodie, of Aimsfield Mains, has given the result of his experiments upon the comparative cost of crushed bones and other commonly employed manure for turnips, which is worthy of attention:—

	£	s.
1st exp.—20 cart loads of street dung, per Scotch acre, at 5s. 6d. per load - - - - -	5	10
2d exp.—half a ton of rape-dust, at 110s. - - - - -	2	15
three quarters crushed bones, at 19s. - - - - -	2	17
	5	12
3d exp.—16 loads of farm-yard dung at 7s. - - - - -	5	12

"The whole turnips," says Mr. Brodie, "braided beautifully, and from the first to the time of lifting, it was impossible to decide which was the weightiest crop I therefore

determined, in the last week in November, to take up alternate rows of the whole, and weigh each separately after the roots and tops were taken off, and the result was found to be as follows:—

	cwt.	lbs.
1st exp.—The portion examined of a Scotch acre, manured with the street dung, produced of common globe turnip	301	92
2d exp.—The same quantity of ground manured with the rape and bone-dust, produced	301	99
3d exp.—Ditto with farm-yard dung	312	30

“Mr. Watson, of Keilor,” says the Hon. Capt. Ogilvy, of Airlie (*Trans. High. Soc.* vol. iv. p. 238), “introduced the use of bone manure in Strathmore. The great deficiency of farm-yard dung in 1827 (consequent on the almost failure of the crop of the previous year), first induced me to try four acres of turnip without other manure, sown with fifteen bushels of bone-dust per acre: it cost 3s. per bushel, or 2l. 5s. per acre. The crop of turnips on these four acres was, at least, equal to the rest raised with farm-yard manure; but as the whole of the turnips were pulled, and the land received some dung before the succeeding crop, much stress cannot be laid on the circumstance of the following white crop and grass being good.

“Next year, 1828, eight acres were sown with turnip, solely with bone-dust; the soil a light sandy loam; the subsoil gravel and sand, coming in some places nearly to the surface, which is very irregular, but in general has a south exposure. This field had been broken up with a crop of oats in 1827, after having been depastured six years, principally by sheep. The quantity of bone-dust applied was twenty bushels per acre, and cost 2s. 6d. per bushel, or 2l. 10s. per acre. The turnip crop was so heavy, that, notwithstanding the very light nature of the soil, it was judged advisable to pull one-third for the feeding cattle, two drills pulled, and four left to be eaten on the ground by sheep. The following year, 1829, these eight acres were sown with barley and grass-seeds; and the produce was fifty-seven bolls one bushel, or seven bolls one bushel nearly per acre, of grain equal in quality to the best in the Dundee market, both in weight and colour. Next year, a fair crop of hay for that description of land was cut, about 150 stones an acre; and though I am now convinced that the field should rather have been depastured the first year, yet the pasture was better than it had ever been known before for the two following seasons, 1831 and 1832. It is worthy of remark, as a proof of the efficacy of the bone manure, that in a small angle of this field, in which I had permitted a cottager to plant potatoes, well dunged, and which, after their removal, was included in one of the flakings of sheep, and had (one might have supposed) thereby had at least an equal advantage with the adjacent bone-dust turnip land, both the barley and grass crops were evidently inferior, and this continued to be observable until the field was again ploughed up. A very bulky crop of oats has been reaped this season, probably upwards of eight bolls per acre, but no part of it is yet thrashed.

“Having detailed what may be considered a

fair experiment, during the whole rotation of the above eight acres, I may add, that turnip raised with bone manure and fed off with sheep, has now become a regular part of the system on this farm. Fifteen, twenty, and last year twenty-five acres were fed off, and invariably with the same favourable results, with the prospect of being able to adopt a five-shift rotation, and to continue it without injury to the land. Every person in the least acquainted with the management of a farm, of which a considerable portion consists of light, dry, sandy loam, at a distance from town manure, must be aware of the importance of this, from knowing the expense at which such land was formerly kept in a fair state of cultivation: indeed, the prices of corn, for some years past, would not warrant the necessary outlay; and large tracts of land, capable of producing barley little inferior to that of Norfolk, must speedily have been converted into sheep pasture, but for the introduction of bone manure.”

In the valuable experiments of Mr Robert Turner, of Tring, in Hertfordshire, the soil on which they were made, hitherto a common, producing only furze, is sandy, with a substratum of clay, and then chalk. He began the use of bone manure in 1831 on this land, and has continued its employment for the last three years on a very bold scale, and with unvaried success. The quantity generally employed was from twenty-four to thirty bushels per acre, of the description of half-inch and dust, and the bones were invariably applied to the turnip crop. The bones were usually drilled with the seed at a distance of eighteen inches, and the turnips were always horse-hoed. The year 1831 was a peculiarly good season for this crop generally. The turnips manured with bone-dust, like most others in the district, were very luxuriant. About 2000 bushels of bone manure were this year used by Mr. Turner. In 1832, the turnips were, in general, a very bad plant, the fly committing general devastation; many cultivators unsuccessfully sowing four or five times. On the turnip land of Mr. Turner, seventy-four acres were manured with bones, and of this breadth only the last sown four acres were a failure, and there was, in no instance, any necessity to repeat the sowing. The turnips were a much better crop than in 1831. In 1833, the turnips in the neighbourhood of Tring were a very partial crop. On the farm of Mr. Turner, about fifty acres were manured with bones. The effect, with the exception of the very last sown turnips, was again most excellent, the crop being very heavy, and that too on land now first cultivated. In 1835 and 1836, Mr. Turner continued the use of bones for his turnips, to the same extent, and with equal success. These experiments the cultivator will deem of the very first importance. The soil was not manured with any other fertilizer except bones, and in drilling, every now and then, for the drill's breadth, the bones were omitted.

On the soil not boned, the failure of the turnips was general and complete: they vegetated, it is true, and came up, but they were wretchedly small, and of no use. The turnips being fed off, and the sheep folded on the soil

without any distinction between boned and unboned land, the comparative experiments upon the succeeding crop were rendered uncertain. The experience of two more years, Mr. Turner informs me (1836-7), has confirmed all his former experiments: he continues the use of this valuable fertilizer, with the most satisfactory results; his plot of turnips drilled with bones having been, in that dry season, most excellent.

In no part of England is the use of bone dust more extensive, and more absolutely essential to the growth of turnips than in Lincolnshire. A brief account of its introduction will be found in the following extract from a letter with which I was favoured in the spring of 1836, from Thomas Brailsford, Esq., of Barkwith.

"The use of bones crushed small enough to pass the drill, began in Lincolnshire about twenty or twenty-five years ago, and may now be considered as *general* over the greatest part of the county, and *universal* over the great natural divisions—the heath, and (the corn brash and upper oolite) the cliff, and the wolds (the chalk and green sand-stone measures of geologists). The effect produced has been wonderful: it has converted large tracts of thin-skinned and weak lands into the most fertile districts. The quantity now drilled varies from twenty strikes of half-inch bone, *with the dust in it*, per acre; and it is used almost exclusively for turnips, experience having proved that it is more profitably adapted to the cultivation of that crop than any other. It may be right to add, that, in this county, it is considered that the feeding quality of turnips raised from bones exceeds that produced by dung. Last year," adds Mr. Brailsford, "I used sulphur with my crushed bones, mixing 7 lbs. of the former with 100 lbs. of the latter: a few days before I drilled them with the turnip seed, a moderate fermentation took place, which rendered the sulphur active, and produced a pretty considerably smell of brimstone, and had the effect of *most effectually* defending the young turnip plants from the fly."

An opinion has been sometimes entertained, that the black grub or caterpillar, which has for the last two or three years been so destructive of the turnip crop, has been introduced in the bones imported from abroad for manure; and many equally idle and learned papers have appeared to warn the farmer of the dangers he was incurring by their use. A more absurd supposition, perhaps, was never entertained; for, saying nothing of the total absence of every thing like proof of a single black grub being discovered in an imported bone, all the accurate experiments, and long experience of those who have used bones, render the supposition laughable.

In the numerous experiments at which I have assisted and witnessed, it has been always found that the black grub appeared equally numerous among the boned and unboned turnips: that in those portions of the field, or in the entire field, where bones were drilled with the turnips, the grubs were not more numerous than on those lands which

were manured with common manure, or drilled without any manure at all.

Again, the very habits of this black grub betray the fact that he is not of animal origin; he lives, he feeds upon, he is composed of vegetable matter. The farmer well knows that the grub or caterpillar which is bred on a cabbage or turnip cannot sustain life, nay, cannot eat animal matters; it would perish if placed on the most dainty bone. And on the contrary, if a grub bred in a bone is placed, however cautiously and skilfully, on a turnip or cabbage, he dies of absolute starvation, for vegetable matters are not food for him; his habits, his very nature, make him revolt from the novel food presented to him.

And again, if he really be imported from Belgium in the bones, he must be able to resist a very considerable temperature; for it has been clearly established, that the turnip fields which have been manured with the refuse *boiled* bones of the size and cart-grease makers have been just as much covered with the black caterpillars as those which have been manured with fresh bones. He can live, therefore, even in boiling hot water: or, if he come in the shape of caterpillar eggs, then the believers in this absurd doctrine must be convinced that caterpillar eggs can be hatched even after they have been boiled for hours in a temperature of 212°.

But grubs and black caterpillars are not the first living substances which have been supposed to have been imported in the foreign bones. Thus, the Nottingham and Lincolnshire farmers, many years since, found that, by the use of bones, the growth of white clover was surprisingly encouraged; and that, in fact, wherever a load of crushed bones was spread, in that place the clover sprung up as if by magic. "They appeared," says his Grace the Duke of Portland, in a letter with which he honoured me in February 1836, "so much to encourage the growth of white clover, that I had almost formed the opinion that it was superfluous to sow the seed." The honest farmers of that fine district naturally had many a puzzling learned cogitation upon this strange yet regular appearance of the white clover, wherever bones were applied; but then, they recollected that the bones came from the very land of fine white clover seed; and that the seed must, therefore, as a natural consequence, come hid in the bones. The Lancastrian and Cheshire farmers, however, did not fall into this mistake, since they found that the white clover sprung up just as copiously after the use of the boiled bones, as upon the lands manured with those in a fresh or green state.

The chemical explanation will occur to every scientific farmer. The white clover abounds in phosphate of lime; it cannot, therefore, grow vigorously in soils which do not contain it. Bones supply this necessary food, or constituent; and enable the white clover to contend successfully in the turf with other and coarser grasses, and finally extirpate them. There are few soils in England which do not contain the seeds of this plant; it has been noticed to spring up in the most unlikely situ-

ations, even in London, *after a fire*; and for precisely the same reason—the ashes of wood abound in phosphate of lime. Bones have been hitherto principally employed upon the turnip crop, but there is another, the potato plant, to which they seem admirably adapted; and of this opinion was Mr. Knight, the late President of the Horticultural Society; he observed to me in a communication dated March 26, 1836, written with his usual anxious solicitude to assist on every occasion in any researches which tended to the improved cultivation of the earth,—“I have one large farm, upon which rises a sufficient quantity of spring water to work a thrashing machine and a bone mill, at all seasons; and upon that I have erected a machine for crushing bones, which my tenant has used largely. The soil is generally strong and argillaceous, but upon this the bone manure operates well, and it is applied by a drill to the turnip ground. My tenant finds that it acts according to the quantity of oleaginous matter which it contains; and I cannot help thinking, that taking away that part must destroy to a very great extent the operation of the manure during at least one year; particularly if the bones be crushed nearly to dust before boiling. I have tried other animal substances, such as hair, feathers, and the parings and dust of white leather, and none of these have operated till they have had some weeks to decompose. The white leather parings, being almost entirely composed of gelatine, I expect operate very soon, but I found that turnips drilled in over a very sufficient quantity of it did not begin to grow kindly till September; and I do not entertain a shadow of a doubt but that if bones, after being crushed, were mixed with four or five times their weight of earth, their operation, as a manure, immediately, would be greatly increased. It could not, however, then be conveniently drilled in with the seed, and that process, whenever the soil is poor, is very important, because by being placed close to the seedling plant, that gets well nourished while young. I cannot doubt but the bone manure must continue to operate as long as decomposition of the original substance continues, and under this impression I am willing to find capital to purchase it, upon the tenant's paying a fair amount of increased rent. Much would, of course, depend upon the bones being more or less crushed; but I cannot think that a good manuring of bone-dust can, under any circumstances, be soon entirely expended. I have seen bone-dust applied in considerable quantities in planting stone fruit trees, as peaches and plums, with good effect, though such are always greatly injured or destroyed by the application of stable-yard dung in the same way. My tenant applies his bone manure wholly to his turnips, and the stable-yard manure to the wheat field, in opposition certainly to my opinion; as I think wheat crops yield best when the soil is firm, and turnip crops best when it is hollow, and he purposes to try the effect of reversing the process. If the turnip plant is capable of deriving nourishment from fragments of bones, which have been boiled, after being crushed, their roots must, I conceive,

have a power of decomposing the substance of the bone; which appears very improbable, though many plants appear to exercise such power on silicious earth. I have somewhere read an account of experiments, which appeared to prove that the silex found in the epidermis of the different species of *Equisetum*, grapes, &c., is really dissolved and taken up from the soil, and subsequently deposited in an organic form; but as the plants which were subjected to experiment might, owing to having been feeble and sickly, not have deposited any, or the usual portion of silex, I am not satisfied that the remaining half of flint, after its oxygen has been driven off, is a simple substance. The number of simple elements (admitting the existence of matter) I suspect to be very small; such was the opinion of my late lamented friend, Sir H. Davy. I think it probable that quicklime, if applied to bones containing much oily matter, would operate powerfully by reducing such oil to the state of soap, readily soluble in water; but a part of the ammonia might by this process be dissipated and lost. Valuable as bone-dust certainly is as a manure to the turnips, I doubt whether it may not be employed with more advantage as a manure for the potato; and my tenant is inclined to think that the potato crop, though wholly consumed upon the farm, will best repay him. The bone manure, when employed to nourish the potato plant, might be buried in the soil two months before it would be materially wanted; and the crops of barley and oats, upon all except light soils, are much better after potatoes than after turnips, both being carted off the ground. Early varieties which do not blossom are the most valuable, as they afford the most certain crops, and will be quite ready to be taken up in August, after which the ground may be well prepared for wheat. Of such potatoes I have obtained a produce equivalent to 963½ bushels of 80 lbs., and 1248¾ bushels of 60 lbs. But early potatoes vegetate again late in autumn, and they then become much better food without being steamed, than previously.”

The way in which bone-dust is usually employed as a manure for potatoes is decidedly wrong; it is used in much too fresh a state. This error long deceived and perplexed the turnip growers of the east of England, who now invariably let the bone-dust ferment, either by itself, or mixed with earth, for some weeks before it is applied to the soil. And all my experiments have concurred in their result with those of my neighbours in Essex, that if the bones are mixed with five or six times their bulk of earth, and are turned over and mixed together some weeks before they are spread on the potato ground, the more valuable is the application. And this remark is not confined to its use for potatoes; oats and barley are proportionally benefitted by the previous fermentation and partial dissolution of the bones in the mixed earth. The same observation must apply to Indian corn.

It is impossible, in any agricultural experiment, to give very minute directions for the farmer's guidance, since soil, climate, and situation, as regards temperature and easy access;

to the proposed fertilizer, must be of necessity taken into the agriculturist's consideration; and these observations particularly apply to those manures of a purely animal nature, whose value I have been endeavouring to illustrate. Thus, with regard to bones, the quantity applied per acre must of necessity vary with circumstances; but, by many carefully conducted experiments, at some of which I have personally assisted, it has been found that the bones remain in the soil for a length of time proportionate to the size of the pieces, the dust producing the most immediate effect, the larger description showing the longest advantage; thus, on arable lands, the good effects of the half-inch or inch bones are observable for four or five years; while, on pasture land, the advantage derived from their application is observable for eight or nine. But, as practical experience is alone the substitute for our want of general scientific knowledge founded on experiments, the farmer should, in experimenting upon all manures, for the sake of correct information, apply them in varying quantities per acre, and on no account omit to leave, by way of comparison, a fair portion of the field without any manure.

There is no delusion more common than that a correct agricultural experiment is easily accomplished—that it may be taken up as a mere amusement, carried on without care, and concluded without any laborious attempts at accuracy. Some experience in these delightful pursuits, amongst some of the most talented farmers of the east of England, has long convinced me of the folly of such a conclusion, and of the extreme care and caution necessary for such valuable researches; for, otherwise, all kinds of errors are almost sure to arise. In applying weight and measure, also, to the crop, there is no need for the farmer to weigh and measure large plots; a square rod or two carefully examined, furnishes results nearly as accurate and valuable as the examination of acres.

The application of bones to grass land is very common in Cheshire and Lancashire. I have already noticed its effect in the production of white clover, a phenomenon well known to the farmers in the neighbourhood of Manchester, who are also fully aware of the amazingly increased produce of their grass lands by the application of the refuse bones of the size makers. The quantity which they employ is very large, varying from forty-five to eighty bushels per acre. The result, however, is fully commensurate with the outlay, for they calculate that the produce of their grass fields is nearly doubled by the application.

I cannot give a better account of its application for grass than that very kindly communicated to me in March, 1836, by Dr. Stanley, the present Bishop of Norwich. "Bone-dust has been used in Cheshire," said his lordship, "as a manure, to a very considerable extent, for the last seven years, but partially for a much longer period. Formerly, it was laid on pasture ground only, and in large quantities, and in large pieces, which rendered it very expensive, and the advantage comparatively

twenty years ago now show, almost to a yard, where this manure was applied. Bones are now used on every description of soil in England with the best results, provided the wet sands are first effectually drained. Some thousands of tons are annually consumed, and the demand is daily increasing. The quantity per statute acre varies; but the average may be, on pasture, from 30 to 40 cwt. of Manchester or calcined bones or 20 cwt. of raw or ground bones, to the statute acre. For turnips, from 20 to 30 cwt. of calcined bones. For oats or barley (of this latter, however, the quantity grown in Cheshire is very trifling), with clover and grass seeds, 20 to 30 cwt. of calcined bones, or one ton of raw or ground bones. Pasture ground should be well scarified or harrowed previous to sowing the bones, and immediately afterward rolled with a heavy roller. For turnips the bones should be pounded, or ground very small, and drilled in with the seed. With spring grain they should be rolled in with clover and seeds. It should be here remarked, that raw bones particularly should be allowed to remain for some days in heaps to ferment before they are applied. They have been used for potatoes; but experienced persons say they prefer dung. I am also informed, though my informant states his observations to be limited, that on old meadows the result has not been found to be so satisfactory as on pastures. On clover, bones have a most extraordinary effect. On old pastures that have been boned, although previously the clover was not to be seen, luxuriant crops have soon shown themselves. The best proof, indeed, of their beneficial effect, is the fact, that the farmers, six years ago, in this immediate neighbourhood, had so strong a prejudice against bones that it was with some difficulty they were induced to use them, although given by way of reduction of rent; but, for the last three years, they have been most anxious to obtain them, and are now quite willing to be at half the expense. The rents have latterly been well paid, and there is good reason for believing that it is in a great measure owing to the advantage they are deriving from the boned land. On some estates in the county, the proprietors have boned a considerable quantity of the pasture land, the tenants willingly agreeing to pay, as an increased rent, from eight to ten per cent. on the cost of bones. There is some difference of opinion as to the most advantageous sorts of bones for use, some preferring the dust to the ground bones. The dust, or calcined bones, are 3*l.* per ton, and the ground bones 7*l.* per ton. For turnips, the dust is generally preferred, as being more immediate in its effects. On a very poor peat soil, about 35 cwt. of bone-dust was applied to a statute acre for Swedish turnips. The crop was a fair average one. The turnips were carted off, and the ground sown with wheat, which produced nearly twenty-five measures (of 75 lbs. per measure) to the statute acre. Oats succeeded with seed, principally red clover, a most excellent crop of oats ensuing. The clover, also, proved a very heavy full crop, and was mown twice. No manure was applied for this course, except the first set of

bones for the turnips. The remainder of the field, of exactly the same description of soil, was well manured with farm-yard dung, for potatoes, mangel wurzel, and vetches, to be used for soiling. This was then sown with wheat; but, being first well set over with a compost of lime and soil, the wheat plant on this part during winter and spring looked much better than the boned part of the field, but did not prove so good a crop; but the difference in favour of the bones was not much. Oats succeeded here, also, with seeds, but the oat crop did not prove half so productive anywhere as on the part boned; and the clover was still more inferior, and mowed only once, the second crop not being considered worth mowing, while the part boned, alongside of it, was as much as could be well mown."

There appears to be on many grass soils some care requisite to ensure the greatest advantage from the application of the bones; and this observation is not confined to any particular district, since it is strongly alluded to in the following extract from a letter of Mr. William Lewis, of Trentham in Staffordshire, transmitted to me in September last, in an obliging communication of his Grace the Duke of Sutherland:—

"I have never," says this intelligent farmer, "applied less than one ton of crushed bones per acre for turnips drilled in, and have been generally successful in growing that crop; and their good effects (I mean the bones) are most conspicuously shown and felt on the grass crop that follows the turnips, showing to an inch how far the ground has been manured with them. I have no genuine fertile land, it being nearly all of a light, dry, sandy, hungry nature; but I have now excellent pastures for sheep, which I greatly ascribe to the use of bones; for the pastures following barley which have been manured with dung I find very inferior to that manured with bones—(the difference in the barley crop not being perceivable)—so much so, that I am upon the eve of breaking up some of my pasture fields which have lain three years, and were intended for permanent pasture; for those manured at the same time with bones are still looking beautiful, with a close, fine, even bottom. I have also applied bones to pastures, and they have generally improved the herbage and verdure very greatly. The top-dressing with the bones I would recommend to be done in moist weather, when the ground is pretty well covered with grass. I consider from one and a half to two tons per acre to be a fair dressing. After sowing them, the ground should be well brushed, harrowed length and breadthways, then heavily rolled, and all stock taken from the field for at least ten days. I have seen bones applied to bare pastures, with little or no covering, done in hot, dry weather, showing no beneficial effects whatever afterwards." There is no doubt of the superior advantage of rolling the bones into the soil; for fresh, or *green* bones, as they are called in Cheshire, when they are exposed to the atmosphere for some time, lose from one fifth to one fourth of their weight; and even boiled bones, under similar circumstances, are reduced one third in weight. A

bushel of crushed green bones, of the three-quarter of an inch size, weighs about 45 lbs.—the same bulk of bone-dust 54 lbs.: 75 bushels of crushed green bones weigh about one ton and a half, the same bulk of boiled bones about two tons. The average weight of the bones of an ox is about 2 cwt., or about one fourth of the carcase free from offal; the bones of a sheep about 21 lbs., supposing the carcase to average 84 lbs. So that, according to this calculation, allowing twenty bushels of crushed bones to manure an acre, the bones of five bullocks or horses, or fifty sheep, are requisite to supply the necessary dressing.

Liebig recommends the following method as the one by which the benefits may be most speedily derived from bone applications. "The most easy and practical mode of effecting their division is," he says, "to pour over the bones, in a state of fine powder, half of their weight of sulphuric acid diluted with three or four parts of water, and after they have been digested for some time, to add one hundred parts of water, and sprinkle this mixture over the field before the plough. In a few seconds, the free acids unite with the bases contained in the earth, and a neutral salt is formed in a very fine state of division."

A convenient mode of preparing vitriolized bones, or *super-phosphate of lime*, is to make a hollow in the centre of a heap of fine mould, and place in this crater the bones to be dissolved. Upon these apply, gradually, sulphuric acid, in weight equal to half the weight of the bones. These will soon be dissolved, after which the heap of mould and bones is to be thoroughly mixed by shovelling together.

Another method is described by Mr. Spooner, in which the ground bones, being placed in a hogshead, have poured upon them one-third of their weight of oil of vitriol; that is to say, 60 lbs. of the sulphuric acid, to 180 lbs. or about 4 bushels of bones. The acid, mixed with half its bulk or measure of water, previously to putting upon the bones, will suddenly produce very great heat, equal to about 300° of Fahrenheit's thermometer. Too much care cannot be taken to prevent the acid from burning the clothes or skin of those employed in this work. After the bones are sufficiently dissolved, they are mixed with ashes, so as to bring them to a state convenient for application by the drill or otherwise. Prepared in this way, the fertilizing properties of bones are rendered much more soluble. Mr. Spooner cites a case in which two bushels of the vitriolized bones, with ashes, gave as good a crop as sixty bushels of common ground bones.

In manuring the light lands, cultivated on the four-course system, with bones and with bones only, for a long series of years, I would advise the farmer, whenever he finds any symptoms of his ground failing to produce clover so well as it was once used to do, to add in that case a dressing of gypsum, either with the bones or with the grass seeds. The value of this latter manure, which is amply sufficient, when applied in quantities of not exceeding 2 cwt. per acre, being in most situations trifling. There is every reason to believe

that in those cases which have puzzled some farmers, where land, after a long course of successful bone-dressing, has at last refused to produce clover, the gradual exhaustion of sulphate of lime, and perhaps of potash and other elements of fertility, removed by previous crops, may account for the failure.

For ornamental plantations of trees there can be no manure more advantageous than bones. There is a considerable portion of phosphate of lime in all timber trees, and there is no manure of a mixed animal, earthy, and saline nature which remains so long in the soil, mixed with earth; and thus previously fermented bones are an excellent dressing for vines, and have been used with decided advantage. As a manure for the use of the conservatory and the flower-garden, there is no fertilizer more useful than bone-dust; or, what is a still more elegant application, the turnings and chippings of the bone turners. Their use not only promotes the luxuriance of the plant, but the beauty of the flowers. The Sheffield florists are well aware of the value of bone turnings.

As it is desirable that American farmers should be instructed in the various and most simple modes of preparing vitriolized bones or *superphosphate of lime*—mentioned in a preceding paragraph—we subjoin a few more of the plans adopted in England.

The bones, in the form of bone-dust, or, where bone-mills are not at hand, simply broken in pieces with a hammer, may be put into a cast-iron, stone, earthenware, or strong wooden trough, cask, or other vessel, mixed with half their weight of boiling water, and then with half their weight of the strong oil of vitriol of the shops, stirring constantly while the latter is slowly poured in. A powerful boiling up, or effervescence at first takes place, but which gradually subsides. By occasional stirring, the whole assumes the appearance of a thick paste; the pieces of bone disappear by degrees, and after a week or ten days the whole may be taken out and mixed with a little sawdust, charcoal-powder, charred peat, or fine dry earth, to make it dry enough to pass through the drill, and thus be immediately applied to the land. It would be better to prepare the bones a month at least before using them, and to lay them up in a heap for awhile, with a view to their more perfect decomposition. Where the pieces of bone are large this is especially desirable, as otherwise they will not be fully decomposed without a larger addition both of water and of acid. Or, the mixture of acid and bones, as above, may after a couple of days be further mixed with a quantity of light friable soil, and laid up into a heap for seven or eight weeks, with occasional turning; the bones thus heat, decompose, and dry up, so as to be ready for putting into the drill without further preparation. This method, however, requires more acid, and it is not unusual, in employing it, to take equal weights of acid and of bones. Professor J. F. W. Johnston recommends the following plan for preparing bones into a liquid manure: Take equal weights of bone-dust, of boiling water, and of acid, and mix together, occasionally stirring them for a week or ten days; when the particles of bone have nearly disappeared, from 50 to 100 times more water may be added to the mixture, and the liquid thus diluted applied by a water cart. If

it is to be used upon grass land, in the spring, or to young grain, it will be safer to dilute it with 200 waters, but 50 waters (by weight) will be enough if it be applied to the turnip drills.

Mr. Tennant thus describes the method he adopts:—"I put 25 bushels into three old boilers, and next pour in two bottles of acid of about 170 lbs. each, and 36 Scotch pints (18 imperial gallons) of boiling water into each boiler. It boils away at a great rate for some time, and in a day or two we empty the boilers into two cart loads of light mould, and turn the mixture over. At this stage the bones are only partially dissolved, but they heat and decompose in the heap, after being turned over three or four times; and in the course of seven or eight weeks the compost becomes dry, and breaks down with a shovel."

It is important to know that oil of vitriol varies in strength, from water added purposely or attracted from the atmosphere, as will always be the case when left in open vessels, which, when partly empty, will soon become full again from the water attracted. The purest oil of vitriol has a specific gravity of about 1.85, one gallon weighing as much as 1.7 or 1.8 gallons of water. That of commerce ought to have a specific gravity of about 1.45 or 1.5, that is to say, be about half as heavy again as water, so that one gallon of oil of vitriol shall weigh as much as a gallon and a half of water. More of it must be used if weak. The price varies with the strength, from 2½ to 3 cts. per lb. The great heat produced by the mixing of oil of vitriol and water, acting on the animal portions of the bones, makes these of a dark colour; but, if a small quantity of acid only be employed, the mixture is white, from the carbonate of lime which then predominates. The fat, gristle, and other organic matter united with bones, in the state in which these are usually employed by farmers, constitutes about 1-3 of their weight. Mr. Hannum reckons the soft parts of bone, when very fresh, at 45 per cent. Four bushels of ground bones, which may be considered a fair allowance for an acre, will weigh, in a fine state, from 168 to 180 lbs. This last-named quantity contains 12½ lbs. of carbonate of lime, and the first action of the acid is to seize upon this, displace its carbonic acid, and convert the lime into sulphate of lime or gypsum. The quantity of the acid required for this first change is 10 lbs. The acid having thus decomposed the carbonate of lime in the bones and converted it into plaster of Paris, next turns upon the phosphates, of which the 4 bushels contains about 106 lbs., 47 lbs. being lime and 59 lbs. phosphoric acid. 33 lbs. of the vitriolic acid unites with half the lime, or 23½ lbs., to form more gypsum. The other half of the lime unites with a double portion of phosphoric acid to produce the desired *super-phosphate*. Thus about 43 lbs. of acid will be required to effect the necessary changes in the 4 bushels of bones.

Instead of the sulphuric acid, muriatic acid has been substituted in similar quantity, diluted and treated in the same manner. The cost per acre and the produce obtained were very much the same. Where no manure was applied, and the produce per acre was only about 7 tons of turnips, the superphosphate of lime made from 4 bushels of bones increased the produce to 17½ tons. See PHOSPHATES.

It is hardly necessary for us to add more authorities in favour of bone manure. The reader may refer, however, to the experiments of Captain Ogilvy, of Airlie Castle (*Trans. of High. Soc.* vol. iv. p. 238); of Mr. Watson, of Keillor, Cupar-Angus (*Quart. Journ. of Agr.* vol. vi. p. 41—43); and of Mr. Boswell, of Kingcaussie (*Trans. of High. Soc.* vol. i. p. 73; Comparative Trial of Bones, Farm-yard Manure, and Rape Cake): to those of Mr. Billyse on their use for the pastures of Cheshire (*Journ. of Roy. Agr. Soc. of Eng.* vol. ii. p. 91.) See also Johnson, *On Fertilizers*, p. 125. (*Brit. Farm. Mag.* vol. vi. p. 308.) The bone mill is described by Mr. Anderson, of Dundee (*Trans. of High. Soc.* vol. i. p. 401), and again in the *Penny Cyclopædia*.

BONE SPAVIN (Fr. *espavent*; Ital. *spavano*), in horses, is a disease of the hock joint, usually brought on by over-exertion, accelerated by bad shoeing. When this is forming, there is commonly lameness, but this diminishes or ceases when the bony matter, whose deposit causes the spavin, is completely formed, at least when the horse is warm with exercise. It impedes his rising when down, and in consequence spavined horses lie down with reluctance. A spavined horse generally does slow work well enough, and when used in the farm, his disease is commonly ameliorated or cured. Repeated blisters will either entirely remove or ameliorate the symptoms. It is only as a last resort that the hot iron should be used.

BOOK-KEEPING. As the merchant, the manufacturer, and the tradesman all find it necessary to keep a set of account books which shall show them the amount of capital employed, the debts owing to and by them, and the profit or loss arising from their different transactions, so to the farmer is this good practice equally essential. The Dutch have a proverb, that no one ever goes to ruin who keeps a correct set of accounts. There is great truth in this sagacious observation of the plodding Dutchmen; for by consulting correct accounts the farmer will be either warned to retrace his steps, or to persevere in the path he is pursuing. The time required for keeping these books is always to be found of an evening after the labours of the day are over. The necessary books to give him this information are, first, a cash book, in which shall be entered on one side all the moneys received, and from whom; and on the other side, all payments, and to whom made; secondly, a journal, in which should be entered all deliveries, and articles received; and, thirdly, a stock book, in which should be every week entered all addition to or subtraction from the stock of the farm; fourthly, an invoice book, to receive all bills of account; fifthly, a wages book, to keep each labourer's time and wages; and, sixthly, a ledger, which should contain every person's account with whom the farmer has transactions. With these statements carefully kept, and an account and valuation of his stock in trade made annually, as if he were about to quit the farm, no farmer's affairs can reasonably go wrong; for not only by good book-keeping is fraud prevented, and economy pro-

moted, but by this means the farmer always knows his real position. I am supported in these opinions by a very considerable farmer and land-agent, Mr. Hewitt Davis, of Spring Park, in Surrey.

BORAGE (*Borago officinalis*). Supposed to be derived from *corago*, or *cor*, the heart, and *ago*, to give, alluding to the renovating power of which it was supposed to be possessed. This is a well-known plant in all gardens, growing two feet high, with large leaves, and bright blue flowers. The stalks are round, juicy, and thick, and so hairy that they are almost prickly to touch. The leaves are broad, rough, wrinkled, and hairy. The flowers have five bright blue petals or parts, with a black centre; they blow all through the summer, and continue till late in autumn. They will begin to flower about June, and when their seed is perfectly ripe, the stalks must be gathered and dried completely before it is rubbed out. (*G. W. Johnson's Kitch. Gard.*) Borage was formerly considered cordial. The leaves and flowers tied in a bundle, and warmed up in beer, is a great remedy in England among the poor. They consider them cordial, opening, and cooling; and in many parts of England they make borage one of their materials in brewing. The whole plant, says Smith (*Eng. Flor.* vol. i. p. 265), has an odour approaching to cucumber and burnet, which gives a flavour to a cool tankard; but its supposed exhilarating qualities, which caused borage to be reckoned one of the four cordial flowers along with alkanet, roses, and violets, may justly be doubted. The flavour is nauseous in any other beverage.

BORDER (Germ. and Fr. *bord*; Sax. *borþ*). A term which signifies the portion of land next the hedges in fields; but in ploughed grounds is mostly applied to the parts at the ends on which the teams turn.

BORECOLE (*Brassica oleracea fimbriata*.) A species of winter cabbage, of which the following are the principal varieties commonly cultivated in the garden:—1. Brussels borecole. 2. Green borecole (*Brassica oleracea selenisia*). 3. Purple borecole (*B. o. laciniata*). 4. Variegated borecole. 5. German, or curled kale or curlies. 6. Scotch or Siberian kale (*B. o. sabellica*). 7. Chou de Milan. 8. Egyptian, or Rabi kale. 9. Ragged Jack. 10. Jerusalem kale. 11. Buda, Russian, Prussian, or Manchester kale. 12. Anjou kale. Like the other members of the cabbage tribe, it is propagated by seed. The first crop to be sown about the close of March, or early in April; the seedlings of which are fit for pricking out towards the end of April, and for final planting at the close of May, for production late in autumn and at the commencement of winter; the sowing must be repeated about the middle of May, for final planting during July, and lastly in August, for use during winter and early spring. If transplanting is adopted, their fitness for pricking out is known when their leaves are about two inches in breadth; they must be set six inches apart each way, and watered frequently until established. In four or five weeks they will be of sufficient growth for final removal. When planted, they must be set in

rows two feet and a half apart each way; the last plantations may be six inches closer. They must be watered and weeded, as directed for the other crops; as they are of large spreading growth, the earth can only be drawn about their stems during their early growth. If, during stormy weather, any of those which acquire a tall growth are blown down, they must be supported in their erect posture by stakes, when they will soon firmly re-establish themselves. For the production of seed, such plants of each variety as are of the finest growth, and are true to the characteristics primarily given, must be selected, and either left where grown, or removed during open weather in November, or before the close of February, the earlier the better, into rows three feet apart each way, and buried down to their heads. The seed ripens about the beginning of August. (*G. W. Johnson's Kitchen Garden.*)

BORER. See **AUGER.**

BORERS. The wood-eating worms called *borers*, are grubs of various species of the beetle tribe, several of which have been already referred to. Some live altogether in the trunks of trees, boring into the most solid wood; others take up their residence in the limbs. Some devour the wood, others the pith; some are found only in shrubs, some in stems of herbaceous plants, and others confine themselves to the roots. Certain kinds restrict themselves to plants of one species, others live indiscriminately upon several plants, provided these belong to the same natural family; for the same borer is not known to inhabit plants differing essentially from each other in their natural characters. The beetles produced from these worm-borers are of very many kinds, nearly one hundred species having been already found by Dr. Harris in Massachusetts, belonging to the *Capricorn family* alone. This family of beetles derive their name from their long and tapering antennæ, which are curved like the horns of a goat. The head is short and armed with powerful jaws. Most of this family remain upon trees and shrubs during the daytime, and fly abroad at night. Some, however, fly by day, and may be found on flowers feeding on the pollen and even the blossoms. When annoyed or taken into the hands, they make a squeaking sound by rubbing the joints of the thorax and abdomen together. "The females are generally larger and more robust than the males, and have rather shorter antennæ. Moreover they are provided with a jointed tube at the end of the body, capable of being extended or drawn in like the joints of a telescope, by means of which they convey their eggs into the holes and chinks of the bark of plants.

"The larvæ hatched from these eggs are long, whitish, fleshy grubs, with the transverse incisions of the body very deeply marked, so that the rings are very convex or hunched both above and below. The body tapers a little behind, and is blunt-pointed. The head is much smaller than the first ring, slightly bent downwards, of a horny consistence, and is provided with short but very powerful jaws, by means whereof the insect can bore, as with a centre-bit, a cylindrical passage through the

most solid wood. Some of these borers have six very small legs, namely, one pair under each of the first three rings; but most of them want even these short and imperfect limbs, and move through their burrows by the alternate extension and contraction of their bodies, on each or on most of the rings of which, both above and below, there is an oval space covered with little elevations, somewhat like the teeth of a fine rasp; and these little oval rasps, which are designed to aid the grubs in their motions, fully make up to them the want of proper feet. Some of these borers always keep one end of their burrows open, out of which, from time to time, they cast their chips, resembling coarse saw-dust; others, as fast as they proceed, fill up the passages behind them with their castings, well known here by the name of powder-post. These borers live from one year to three, or perhaps more years before they come to their growth. They undergo their transformations at the furthest extremity of their burrows, many of them previously gnawing a passage through the wood to the inside of the bark, for their future escape. The pupa is at first soft and whitish, and it exhibits all the parts of the future beetle under a filmy veil which inwraps every limb. The wings and legs are folded upon the breast, the long antennæ are turned back against the sides of the body, and then bent forwards between the legs. When the beetle has thrown off its pupa-skin, it gnaws away the thin coat of bark that covers the mouth of its burrow, and comes out of its dark and confined retreat to breathe the fresh air, and to enjoy for the first time the pleasure of sight, and the use of the legs and wings with which it is provided (*Harris's Treatise on Insects.*)

One family of the capricorn or goat-horned beetles, derives its name of *Prionidæ* from a Greek word signifying saw. It is said that some of these saw-beetles can saw off large limbs by seizing them between their jaws, and flying or whirling sidewise round the enclosed branch, till it is completely divided. One of the largest species is the broad-necked *prionus*. It is from one inch and a quarter, to an inch and three-quarters in length, of an oval form and pitchy black colour. The grubs of this beetle, when fully grown, are as thick as a man's thumb. They live in the trunks and roots of the balm of Gilead, Lombardy poplar, and probably in other kinds of poplar.

In the second family of the Capricorn beetle, called the *Cerambycians*, there is one which inhabits the hickory, in its larva state forming long galleries in the trunk of this tree in the direction of the fibres of the wood.

"The ground beneath black and white oaks," says Dr. Harris, "is often observed to be strewn with small branches, neatly severed from these trees as if cut off with a saw. Upon splitting open the cut end of a branch, in the autumn or winter after it has fallen, it will be found to be perforated to the extent of six or eight inches in the course of the pith, and a slender grub, the author of the mischief, will be discovered therein. In the spring this grub is transformed to a pupa, and in June or July it is changed to a beetle, and comes out of the

branch. The history of this insect was first made public by Professor Peck, who called it the oak-pruner, or *Stenocorus (Elaphidion) putator*. In its adult state it is a slender long-horned beetle, of a dull brown colour, sprinkled with gray spots, composed of very short close hairs; the antennæ are longer than the body, in the males, and equal to it in length in the other sex, and the third and fourth joints are tipped with a small spine or thorn; the thorax is barrel-shaped, and not spined at the sides; and the scutellum is yellowish white. It varies in length from four and a half to six-tenths of an inch. It lays its eggs in July. Each egg is placed close to the axilla or joint of a leaf-stalk or of a small twig, near the extremity of a branch. The grub hatched from it penetrates at that spot to the pith, and then continues its course towards the body of the tree, devouring the pith, and thereby forming a cylindrical burrow, several inches in length, in the centre of the branch. Having reached its full size, which it does towards the end of the summer, it divides the branch at the lower end of its burrow, by gnawing away the wood transversely from within, leaving only the ring of bark untouched. It then retires backwards, stops up the end of its hole, near the transverse section, with fibres of the wood, and awaits the fall of the branch, which is usually broken off and precipitated to the ground by the autumnal winds. The leaves of the oak are rarely shed before the branch falls, and thus serve to break the shock. Branches of five or six feet in length and an inch in diameter are thus severed by these insects, a kind of pruning that must be injurious to the trees, and should be guarded against if possible. By collecting the fallen branches in the autumn, and burning them before the spring, we prevent the development of the beetles, while we derive some benefit from the branches as fuel.

"It is somewhat remarkable that, while the pine and fir tribes rarely suffer to any extent from the depredations of caterpillars and other leaf-eating insects, the resinous odour of these trees, offensive as it is to such insects, does not prevent many kinds of borers from burrowing into and destroying their trunks. Several of the Capricorn-beetles, while in the grub state, live only in pine and fir trees, or in timber of these kinds of wood. They belong chiefly to the genus *Callidium*, a name of unknown or obscure origin. The larvæ are of moderate length, more flattened than the grubs of the other Capricorn-beetles, have a very broad and horny head, small but powerful jaws, and are provided with six extremely small legs. They undermine the bark, and perforate the wood in various directions, often doing immense injury to the trees, and to new buildings, in the lumber composing which they may happen to be concealed. Their burrows are wide and not cylindrical, are very winding, and are filled up with a kind of compact sawdust as fast as the insects advance. The larva state is said to continue two years, during which period the insects cast their skins several times. The sides of the body in the pupa are thin-edged, and finely notched, and the tail is forked.

"One of the most common kinds of *Callidium* found here is a flattish, rusty black beetle, with some downy whitish spots across the middle of the wing-covers; the thorax is nearly circular, is covered with fine whitish down, and has two elevated polished black points upon it; and the wing-covers are very coarsely punctured. It measures from four-tenths to three-quarters of an inch in length. This insect is the *Callidium bojulus*; the second name, meaning a porter, was given to it by Linnæus on account of the whitish patch which it bears on its back. It inhabits fir, spruce, and hemlock wood and lumber, and may often be seen on wooden buildings and fences in July and August. We are informed by Kirby and Spence that the grubs sometimes greatly injure the wood-work of houses in London, piercing the rafters of the roofs in every direction, and, when arrived at maturity, even penetrating through sheets of lead which covered the place of their exit. One piece of lead, only eight inches long and four broad, contained twelve oval holes made by these insects, and fragments of the lead were found in their stomachs. As this insect is now common in the maritime parts of the United States, it was probably first brought to this country by vessels from Europe." (Harris.)

The violet *Callidium*, is of a Prussian blue or violet colour, its length varying from four to six-tenths of an inch. It is found in great numbers on piles of pine wood, from the middle of May to the first of June, and the maggots and pupæ are often met with in splitting the wood. They live mostly just under the bark, where their broad and winding tracks may be traced by the hardened sawdust with which they are crammed. Just before they are about to be transformed, the larva or worms bore into the solid wood to the depth of several inches. In Maine and other places they are said to be very injurious to the sapling pines. Professor Peck supposed this species of borer to have been introduced into Europe in timber sent from this country, as it is found in most parts of that continent that have been much connected with North America by navigation. It is somewhat singular that Europe and America should have thus interchanged the porter and violet *Callidium*, which, by means of shipping, have now become common to the two continents. (Harris.)

Sugar Maple Borer.—The sugar-maple, one of the most beautiful and noble trees of the American forest, suffers much from the attacks of a borer, the largest known species of *Clytus*, by which it is sometimes entirely destroyed. In order to check the devastations of these borers they should be sought for in the spring, when they may be readily detected by the sawdust thrown out of their burrows; and, by a judicious use of a knife and stiff wire, they may be cut out or destroyed before they have gone deeply into the wood. (Harris.)

Locust-tree Borer.—The locust tree or acacia, is also preyed upon by a borer of the *Clytus* family, the larva of a painted beetle often seen in abundance feeding by day upon the blossoms of the golden rod (*Solidago*), in the month

of September. If the trunks of the common locust-tree are examined at this time, a still greater number of these beetles will be found upon them, and most often paired. This Capricorn-beetle has the form of the beautiful maple Clytus. It is velvet-black, and ornamented with transverse yellow bands. The legs are rusty red, and the length of the insect is from about half an inch to three quarters of an inch. "In the month of September," says Dr. Harris, "these beetles gather on the locust trees, where they may be seen glittering in the sunbeams with their gorgeous livery of black velvet and gold, coursing up and down the trunks in pursuit of their mates, or to drive away their rivals, and stopping every now and then to salute those they meet with a rapid bowing of the shoulders, accompanied by a creaking sound, indicative of recognition or defiance. Having paired, the female, attended by her partner, creeps over the bark, searching the crevices with her antennæ, and dropping therein her snow-white eggs, in clusters of seven or eight together, and at intervals of five or six minutes, till her whole stock is safely stored. The eggs are soon hatched, and the grubs immediately burrow into the bark, devouring the soft inner substance that suffices for their nourishment till the approach of winter, during which they remain at rest in a torpid state. In the spring they bore through the sap-wood, more or less deeply into the trunk, the general course of their winding and irregular passages being in an upward direction from the place of their entrance. For a time they cast their chips out of their holes as fast as they are made, but after a while the passage becomes clogged, and the burrow more or less filled with the coarse and fibrous fragments of wood, to get rid of which the grubs are often obliged to open new holes through the bark. The seat of their operations is known by the oozing of the sap and the dropping of the sawdust from the holes. The bark around the part attacked begins to swell, and in a few years the trunks and limbs will become disfigured and weakened by large porous tumours, caused by the efforts of the trees to repair the injuries they have suffered. According to the observations of General H. A. S. Dearborn, who has given an excellent account (*Mass. Agric. Repos. and Journ.* vol. vi. p. 272), of this insect, the grubs attain their full size by the twentieth of July, soon become pupæ, and are changed to beetles and leave the trees early in September. Thus the existence of this species is limited to one year.

"Whitewashing, and covering the trunks of the trees with grafting composition, may prevent the female from depositing her eggs upon them; but this practice cannot be carried to any great extent in plantations or large nurseries of the trees. Perhaps it will be useful to head down young trees to the ground, with the view of destroying the grubs contained in them, as well as to promote a more vigorous growth. Much evil might be prevented by employing children to collect the beetles while in the act of providing for the continuation of their kind. A common black bottle, containing a little water, would be a suitable vessel

to receive the beetles as fast as they were gathered, and should be emptied into the fire in order to destroy the insects. The gathering should be begun as soon as the beetles first appear, and should be continued as long as any are found on the trees, and furthermore, should be made a general business for several years in succession. I have no doubt, should this be done, that, by devoting one hour every day to this object, we may, in the course of a few years, rid ourselves of this destructive insect."

In noticing the locust-borer, Mr. Coleman states, that Allen C. Metcalf, of Lennox, Massachusetts, washed his locust trees with spirits of turpentine, and in that way, as he believes, compelled the borer to leave them, after they had made severe ravages. The trees were examined by Mr. Coleman, who found them much perforated, but without any signs indicating the presence of the worm. (See Mr. Coleman's *Second Report*.)

The poplar tribe of trees, both in Europe and America, are subject to the attacks of certain kinds of borers, differing essentially from all the foregoing when arrived at maturity. They belong to the genus *Saperda*. The largest kind found in America is the *Saperda calcarata* of Say, so called because the tips of the wing-covers end with a little sharp point or spur. It is covered all over with a short and close nap, which gives it a fine blue-gray colour; it is finely punctured with brown; there are four ochre-yellow lines on the head, and three on the top of the thorax. It is from one inch to an inch and a quarter in length. The grubs of this beetle, with those of the broad-necked *Prionus*, already mentioned, have in some parts of the United States, in the vicinity of Boston, for instance, almost entirely destroyed the Lombardy poplar. They also live in the trunk of American poplars. These grubs are of a yellowish-white colour, and, when fully grown, measure nearly two inches in length. The beetles proceeding from these may be found on the trunks and branches of the various kinds of poplars, in August and September; they fly by night, and sometimes enter the open windows of houses in the evening.

Apple-tree Borer.—"The borers of the apple tree," says Dr. Harris, "have become notorious, throughout the New England and Middle States, for their extensive ravages. They are the larvæ of a beetle called *Saperda bivitata* by Mr. Say, the two-striped, or the brown and white striped *Saperda*; the upper side of its body being marked with two longitudinal white stripes between three of a light brown colour, while the face, the antennæ, the underside of the body, and the legs are white. This beetle varies in length from a little more than one-half to three-quarters of an inch. It comes forth from the trunks of the trees, in its perfected state, early in June, making its escape in the night, during which time only it uses its ample wings in going from tree to tree in search of companions and food. In the daytime it keeps at rest among the leaves of the plants which it devours. The trees and shrubs principally attacked by this borer are the apple tree, the quince, mountain ash, haw-

thorn and other thorn bushes, the June-berry or shad-bush, and other kinds of *Amelanchier* and *Aronia*. Our native thorns and Aronias are its natural food; for I have discovered the larvæ in the stems of these shrubs, and have repeatedly found the beetles upon them, eating the leaves, in June and July. It is in these months that the eggs are deposited, being laid upon the bark near the root, during the night. The larvæ hatched therefrom are fleshy whitish grubs."

The larva or grub state continues two or three years, during which the borer will be found to have penetrated eight or ten inches upwards in the trunk of the tree, its burrow, at the end approaching to, and being covered only by, the bark. Here its transformation from larva to pupa takes place, and its final change from pupa to beetle or winged insect, which occurs about the first of June, soon after which the beetle gnaws through the bark that covers the end of its burrow, and leaves its place of confinement in the night.

"Notwithstanding," says Dr. Harris, "the pains that have been taken by some persons to destroy and exterminate these pernicious borers, they continue to reappear in our orchards and nurseries every season. The reasons of this are to be found in the habits of the insects, and in individual carelessness. Many orchards suffer deplorably from the want of proper attention; the trees are permitted to remain, year after year, without any pains being taken to destroy the numerous and various insects that infest them; old orchards, especially, are neglected, and not only the rugged trunks of the trees, but even a forest of unpruned suckers around them, are left to the undisturbed possession and perpetual inheritance of the Saperda. On the means that have been used to destroy this borer, a few remarks only need to be made; for it is evident that they can be fully successful only when generally adopted. Killing it by a wire thrust into the holes it has made, is one of the oldest, safest, and most successful methods. Cutting out the grub with a knife or gouge is the most common practice; but it is feared that these tools have sometimes been used without sufficient caution. A third method, which has more than once been suggested, consists in plugging the holes with soft wood. If a little camphor be previously inserted, this practice promises to be more effectual; but experiments are wanting to confirm its expediency."

The zealous and able naturalist who has furnished the foregoing information relative to insects which so frequently carry destruction among the forest, fruit, and ornamental trees of the United States, has also described many others of the beetle tribe which attack trees and plants not yet named. Among these may be mentioned the borers which infest the pitch pine tree, and even the blackberry and raspberry bushes; together with various leaf-beetles which prey upon the foliage of fruit-trees, the linden-tree, potato, cucumber, and pumpkin vines, the leaves of turnips, horse-radish, milk-weed, &c., most of which will be referred to in noticing the several trees and plants named, together with the best means

known of destroying them or preventing their ravages.

BORING. A practice sometimes employed in order to ascertain the nature of the different strata that lie beneath the soil; and also for the purpose of discovering springs, and tapping them, so as to draw off the water, that injures the grounds below or in the neighbourhood. See **DRAINING**.

BOS. The generic name for quadrupeds whose horns are in the form of a crescent. See **CATTLE**.

BOSCAGE. A word borrowed from the French, signifying a woody grove, or woodland.

BOTANY (from the Gr. *βότανον*, an herb), in the most confined sense of the term, is the science which teaches us the arrangement of the members of the vegetable kingdom in a certain order or system, by which we are enabled to ascertain the name of any individual plant with facility and precision. Such arrangement is only to be considered as useful in proportion as it facilitates the acquirement of a knowledge of their economical and medicinal qualities, which cannot be perfectly ascertained without an acquaintance with vegetable physiology, the parts of plants, their functions, and uses. Botany, in its most comprehensive form, teaches us the names, arrangement, parts, functions, qualities, and uses of plants.

This science may be consulted by the agriculturist with considerable benefit. For instance (and several other advantages will readily suggest themselves to the intelligent farmer), the plants growing wild on a soil ever afford some tolerable indication of the nature of the soil and its subsoil. Thus, the heath on elevations indicates a dry soil; the fern that it is deep as well as dry. The deer hair (*Scirpus cæspitosus*) grows commonly over bogs, resting on clay. In the lower situations the broom (*Spartium scoparium*) tenants the deep light gravels. The whin, coarser gravels upon a clay subsoil. The rush (*Juncus conglomeratus*) tells the negligent farmer that good land is rendered useless for want of drainage. The common sprit (*Juncus articulatus*), that the land is not fertile. Sweet gale (*Myrica Gale*), that it is still worse. The rag weed (*Senecio jacobæa*) in arable land betrays an ill-cultivated loam. The marsh marigold (*Caltha palustris*) or the wild water-cress in water meadows, tells the owner that the land is fully irrigated. The common rattle (*Rhinanthus christi*), that a meadow is exhausted. The pry (*Carex dioica*), that water is stagnating beneath its surface, and these are only a few of the truths which wild flowers teach the intelligent cultivator. Botanists have, indeed, long been at work for the farmer—a fact no one will be willing to dispute who remembers that the sloe, the blackberry, and the crab are nearly all the fruits indigenous to England; and that hardly a grass, a flower, or a vegetable that is now cultivated is a native of the island.

In 1825 and 1827, the Highland Society of Scotland offered as a prize theme, "The indications to be formed regarding the nature and qualities of soils and subsoils, according to the plants growing upon them, having regard

to elevation, exposure, climate, &c." And in the first volume of their transactions will be found several valuable essays on the subject, by Mr. Macgillivray, p. 81, Mr. Gorie, p. 113, Dr. Singer, p. 264, Mr. Hogg, p. 271, all ably illustrating the value of the study of plants to the cultivator.

The definition of a plant to a superficial observer may appear easy; but those who have studied natural history are aware of the difficulty of drawing a just line of distinction between the animal and the vegetable kingdoms. It is easy to distinguish a horse, or even a worm, from a rose-tree or a fungus; but to distinguish a sensitive plant, &c., by descriptive marks from many zoophytes, has hitherto baffled the acutest botanists. Many plants, as will be presently seen, are gifted with spontaneous motion; whilst many animals, as the corallines, are devoid of locomotion; so that neither of these qualities avails us in distinguishing the two kingdoms. In short, whilst the zoophytes, most of which take root, grow up into stems, and multiply by buds and slips, must still be considered as animals, no one can correctly define how plants differ from them. It is, however, fortunate, that the student is seldom placed in a situation where these nice distinctions are to be made. Where specimens are to be examined which admit of the doubt whether they belong to the lower classes of animals or to the vegetable tribes, chemistry may be called to our aid; if, when burnt, they omit an ammoniacal smell resembling that of feathers, similarly treated, we need not hesitate to consider them as animal products; if that of burning wood, we may consider them as fit objects for our botanical researches.

A few facts will demonstrate that it is impossible to deny that vegetables possess some degree of sensation. The Venus's fly-trap (*Dionæa muscipula*) has jointed appendages to the leaves, which are furnished on their edges with a row of strong prickles. Flies, attracted by honey, which is secreted in glands on their surface, venture to alight upon them; no sooner do their legs touch these parts than the sides of the leaves spring up, and locking their rows of prickles together, squeeze the insects to death. The well-known sensitive plant (*Mimosa sensitiva* and *putida*) shrink from the slightest touch. *Oxalis sensitiva* and *Smilthia sensitiva* are similarly irritable; as also are the stamens of the flower of the barberry. One of this tribe (*Hedysarum gyrans*) has a spontaneous motion—its leaves are frequently moving in various directions without order or co-operation. When an insect inserts its proboscis between the converging anthers of a kind of dog's bane (*Apocynum androsæmifolium*), they close with a power usually sufficient to detain the intruder until his death. If from these, and many other considerations which we shall notice as we pursue our study, we conclude that plants are endowed with a certain degree of sensation, or at least of irritability, we can pursue that path of the science no further. Such are the results of life; what constitutes the living principle no human eye can discover.

We gaze on a rose as it waves in the plente of its vigour, admire the tints of its petals, the verdure of its foliage, the gracefulness of its form, the delicacy of its fragrance. We may come on the morrow, and it has been blasted—those petals are scattered on the borders—those leaves are withered and sapless—and scarcely a vestige of its loveliness remains. Wherefore is this change? The same components remain—the same food was ready for its nourishment; but some invisible governing principle—some unknown agent—has silently departed, without one vacancy to point out where it had resided, but a total ruin, to show that it had pervaded the whole. Let a few more hours pass away, when the air, and moisture, and heat, external agents which were subservient to its welfare, now concur in completing its destruction—it is partly dissipated in pestilential exhalations, partly reduced to a few earthy and saline particles. Life, whilst it continued, prevented this ruin; but still, like its Great Author, "no one hath seen it at any time."

To explore our path satisfactorily, and that one step may naturally explain the way to the succeeding, we had better first consider the most obvious parts of plants, and their functions.

The root and its uses.—A root usually consists of two parts, the *caudex* or body, and the fibres or *radicula*. The last only are essential for the imbibing of nourishment, but the whole serves to steady or fix the plant firmly in a commodious situation and position. Roots are annual, biennial, or perennial. The first belong to those plants whose term of existence is confined to a portion of a year, as barley; the second to such as, being raised during one year, survive its winter, and produce flowers during a succeeding year, as wheat. Perennial roots belong to such plants as live for several years. All plants are considered as biennial; that are raised from seed one year, and flower during another, whether that year is the next, or whether the flowering is deferred during several, provided the flowers occur but once. This is often the case with the tree mallow (*Lavatera arborea*), &c. Attention must be paid to these circumstances, or we may often mistake the natural term of a plant's existence. Mignonette (*Reseda odorata*), in our borders, is an annual; but in the shelter of a room or green-house, it may be made, by proper management, to blossom during several successive seasons. The nasturtium (*Tropæolum*), naturally a shrubby perennial, is an annual in our gardens.

Plants search for food by means of their roots, and to obtain it have been known, by their aid, to overturn walls by piercing their foundations. A tree growing on the top of a wall has been observed to extend its roots down the sides, until they reached the earth at its bottom. If a flower-pot, divided by a perpendicular section, be on one side filled with common earth, and on the other with similar earth mixed with a little potash, the roots of a geranium or other plant, growing in it, will, by degrees, all move into the alkaline portion. It has also been proved that the root is gifted

with the power of rejecting what is hurtful, and selecting what is beneficial to its parent plant, from any mixed solution of substances not corrosive or poisonous.

Botanists distinguish seven kinds of roots.

1. The fibrous root (*radix fibrosa*), consisting of fibres alone, either branched or undivided, as that of the *Poa annua*, that species of grass so troublesome in gravel walks, &c.

2. The creeping root (*R. repens*). This spreads and branches horizontally, throwing out fibres in its course, as some kinds of mint (*Mentha*), and the couch-grass, or twitch (*Triticum repens*).

3. Tapering root (*R. fusiformis*), as that of the carrot, &c.

4. Abrupt root (*R. præmorsa*), appears inclined to be a tapering one, but, from some natural decay or habit, becomes abrupt, or apparently bitten off, as in the devil's-bit scabious (*Scabiosa succisa*), and several of the hawk-weeds.

5. Tuberous root (*R. tuberosa*), consists of fleshy tubers connected by fibres, as in the potato (*Solanum tuberosum*). It is the premature formation of the tubers which prevents the blooming of the Jerusalem artichoke, and some of the early varieties of the potato. If the tubers are removed as soon as they are formed, the plants blossom.

6. Bulbous root (*R. bulbosa*), is solid, as in the crocus; tunicate, composed of concentric layers, as in the Onion (*Allium cepa*); or scaly, as in the lilies.

7. Jointed or granulated root (*R. articulata* or *granulata*), is a cluster of either little bulbs or scales, connected by a common fibre, as in the wood-sorrel (*Oxalis acetosella*), and white saxifrage (*Saxifraga granulata*).

The roots of plants sometimes change their form with the situation in which they grow. Those of some grasses are bulbous in a dry situation, and fibrous in a moist one. Thus we see the care of Providence is manifested even in providing for the welfare of a weed; bulbous roots being, as it were, reservoirs of moisture, enable such plants to perfect their seed in the driest season. Again, the fibrous roots of grasses growing in sandy sterile places are remarkably downy; by this means they retain firmly their hold in so yielding a medium, and their absorbing surfaces are likewise increased, not unnecessarily, where nourishment is so scanty.

Seven kinds of stalks or stems are distinguished by botanists;—1. A stem (*caulis*) is confined to such as bear both leaves and flowers, which is the case with the trunks of all trees. It is either simple, as in the white lily, or branched, as in most cases. In general it grows upright, but sometimes it is more or less recumbent. Some cling to other bodies by fibres for support, as the ivy (*Hedera helix*); or by tendrils, as the vine. Others twine round such plants as come in their way. A remarkable distinction is to be observed in twining plants. Honeysuckles, &c., twine from left to right; whilst others, as the kidney-bean, twine from right to left, nor can any art induce them to alter their course. Some trail along the ground; some are jointed, as in the samphire

and Indian fig. They are of various forms, round, three-sided, square, &c. Their surfaces are smooth, viscid, rough, bristly, hairy, &c. Internally they are solid or hollow. Plants without stems are termed *acaules*.

2. A culm or straw (*culmus*), is only a variety of the caulis, but, being peculiar to the grasses, rushes, and other plants nearly allied to them, has been deemed worthy of a separate name. It is without joints, as in the common rushes; jointed, as in wheat, &c.; bent like a knee, as in *Alopecurus geniculatus*. It varies in being hollow, solid, hairy, &c.

3. A stalk (*scapus*), springing from the root, bears only flowers and fruit, as that of the primrose (*Primula vulgaris*), and cowslip (*P. veris*). In the first it is simple, in the latter subdivided and many-flowered. It is sometimes scaly; in which case the scales are apt to sport into leaves, and thus render it a proper caulis. It greatly varies as to length, manner of growth, &c.

4. A flower stalk (*pedunculus*), springing from the stem, bears only fruit and flowers. A partial flower stalk (*pedicellis*), is the ultimate division of a general one, as in the cowslip before instanced. Flowers without stalks are termed *sessile*, as the dodders, &c.

5. The leaf stalk (*petiolus*), signifies the stalk of a leaf only. It is solitary or simple, as in the lilac, and all other simple leaves. It is common in the rose, &c. It is usually channelled on its upper side.

6. A frond (*frons*), is now used only in describing the class *Cryptogamia*, and signifies a leaf which produces both flowers and fruit, as in the ferns, lichens, &c.

7. A stipe (*stipes*), is the stem of a frond.

It will be better to defer the consideration of the functions of roots and stems until we take a connected view of the phenomena of vegetable life.

Leaves are a very general, but not a universal part of the vegetable body; they are wanting in the samphires, creeping cereus, &c. Such plants are called *plantæaphyllæ* (leafless plants). The situations, forms, insertions, and surfaces of leaves are of great use in botanic descriptions; a few must at present suffice:—

Folia radicularia spring from the root, as in the primrose.

Folia caulina and *ramea* spring respectively from the stem or branch.

Folia bina terna, &c., leaves in pairs, or three together, &c.

Folia verticillata, whorled, several opposite, or growing in a circle round the stem.

Folia peltata, peltate, having the foot-stalk in the centre, as the nasturtium.

Folia sessilia, sessile, having no foot-stalk.

Folia perfoliata, perfoliate, when the stem runs through their centre.

Leaves are nearly circular, roundish, egg shaped or ovate, oblong, lanceolate, &c.; they terminate abruptly, or are sharp, jagged, pointed, cirrhose (*i. e.* tipped with a tendril), &c. Their margins are entire, spinous, toothed, wavy, &c. Their surfaces are dotted, rugged, veiny, coloured (*i. e.* tinted with any colour

but green, white, or yellow; in the two latter cases they are termed variegated), &c. They are tubular, awl-shaped, three-edged, evergreen, &c. Compound leaves consist of two or more leaflets, combined by a common foot-stalk, as in the rose; they are binate when they consist of two leaflets; ternate, of three, &c.; pinnate when several proceed sideways or laterally from the common footstalk, as in the rose. Leaves are sometimes twice and thrice compounded.

The *flower* is the most essential, yet the most transitory part of plants. By means of the seed, which it is the great agent in producing, plants may be indefinitely multiplied and perpetually renewed; whereas all other modes of propagation, by cuttings, grafts, &c., are but extensions of an individual. Hence, though many plants, from unfavourable modes of cultivation, &c., are seldom known to blossom, yet Providence has wisely ordained that no plant is incapable of producing and perfecting seed. As our systems of botany are founded chiefly upon the flower, we will proceed to consider it at large. A flower is divided into seven parts:—

1. The *calyx*, or outer covering, resembling leaves in texture; is not present in many flowers, as the tulip.

There are six kinds of calyx:—1. The *perianth* is close to, and forms part of, the flower, as in the rose, and is, in fact, the only true calyx. 2. The *involucre* is an appendage to the one form of inflorescence, namely the umbel. It is remote from the corolla, as in all the umbelliferous plants, carrot, &c. 3. The *spathe* is a floral appendage which bursts longitudinally, being more or less remote from the flower, as in the snow-drop, narcissus, &c. 4. The *glume*, or *husk*, is the peculiar calyx or chaff of the grasses, as in wheat, &c. 5. *Perechatium*, a scaly sheath, enclosing the fertile flowers of some mosses. 6. *Volva* is the membrane that covers the parts of fructification or gills of the fungi, as in the common mushroom; but it is also applied to the fleshy covering which encloses some fungi when young.

2. The *corolla*, or more delicate coloured leaves or leaf, properly called petals, is situated within the calyx. This is absent in many flowers. It comprehends both the *petal* and the *nectary*. By petal is meant what are commonly called the coloured leaves of a flower. By nectary is meant an appendage to the corolla, supposed to be for the purpose of secreting honey. The little cells, for example, at the bottom of the flower of the crown imperial, each full of a sweet liquid, are called nectaries, but they vary in form and situation in different flowers. When a corolla is formed of one petal, it is said to be *monopetalous*. It may be *bell-shaped*, as in the Canterbury bell; *funnel-shaped*, as in lungwort (*Pulmonaria*); *salver-shaped*, as in the primrose; *wheel-shaped*, the same as the preceding, only with a short tube, as in the borage; *ringent*, like the mouth of an animal, as in the dead nettle; *personate*, like the mask of an animal, as in snap-dragon. Corollas of more than one petal are termed *polypetalous*. It is *cruciform*, as in the wall-flower; *rosaceous*, as in the rose; *papilionaceous*,

as in the pea; *incomplete*, when some part, found in kindred flowers, is wanting.

3. The *stamen* or stamens are essential for the perfecting of the seed, and are only absent in double flowers, in which they are changed into petals. They vary in different species, from a single one to several hundreds, and surround the pistil or pistils, which occupy the centre of the flower. A stamen usually consists of two parts; the *filament*, or slender stem, which is sometimes absent, bearing otherwise on its summit the *anther*, a cellular organ of various forms in different species of plants, being the part for holding the pollen.

4. The *pistil* or pistils are in the centre of the flower, and usually fewer in number than the stamens. They are sometimes situated in flowers distinct from the stamen, and even on different plants. No seed can be perfected without the pistil, which consists of the *germen*, or rudiment of the fruit and seed, and, of course, is never absent. The *style*, or little stem proceeding from the germen, which is not essential, serving chiefly to elevate the *stigma*—this must always be present: it varies in form and size, being either scarcely more than a point, or forming an orbicular head, or being variously lobed.

5. The *seed-vessel* is the germen enlarged, varying in form, texture, and size in almost every species. What old botanists called naked seeds are seed-vessels or carpels containing only one seed, and which do not open when ripe; the strawberry, wheat, maize, are examples. The only naked seeds are those of the fir cones, and the *Cycadææ*.

There are seven kinds of seed-vessels:—1. A *capsule* is woody or membranous, containing one or more cells, as in the poppy. 2. A *pod* is long, dry, and solitary, formed of two valves, divided by a linear partition into two cells, as in the wall-flower. 3. A *legume* is solitary, formed of two oblong valves without any partition, consequently is one-celled, as the pea. 4. A *drupe* has a fleshy coat, closely enclosed in a hard nut, as the cherry, peach, &c. 5. A *pome* has a fleshy coat, enclosing a capsule, as the apple, pear, &c. 6. A *berry* is fleshy, containing its seed or seeds within its pulp, without valves, as the currant. A compound berry is instanced in the blackberry, &c. 7. A *cone* is a catkin hardened into a seed-vessel, as in the fir, birch, &c.

6. The *seed*. To the perfecting of this part all the other parts of the fructification, and even of the whole plant, are subservient; annuals perish immediately after it is perfected, and in our climate even perennials begin to droop as soon as it is ripe. A seed consists of several parts:—1. The *embryo* is the part the welfare of which all the other parts unite in promoting. It is the rudiment of the future plant. It is very apparent in the bean, pea, &c., and has the form of a heart in the walnut. It is usually within the substance of the seed, as in the above instance; in the grasses, however, it is on the outside.

Upon removing the skin of a pea or bean, it divides easily into two parts; these are the *cotyledons*: this is the usual number. In the pine tribe they are four; in the grasses, &c.,

only one; hence the last are called *monocotyledons*. The cotyledons, when the seed has sprouted, usually rise, in the course of germination, out of the ground, and perform the functions of leaves for a while: this is never the case in wheat, or any other of the monocotyledons; their seeds consist chiefly of the *albumen* or white, which is either farinaceous, horny, or fleshy, and remains in the ground nourishing the embryo, until its leaves and roots are sufficiently perfected for that purpose. Although the albumen is wanting in a distinct form in several tribes, as those with compound and cruciform flowers, &c., yet the farinaceous matter lodged in the cotyledons is evidently intended to supply the embryo with nourishment during the first efforts of germination. Many plants have it distinct from the cotyledons. *Vitellus*, the yolk, like the albumen, serves to nourish the embryo in the commencement of germination. If the albumen, as a distinct organ, is present also, the vitellus is situated between it and the embryo.

Testa, the skin, envelopes all the preceding parts, and gives them their form, being itself of a permanent shape, whilst they are in a liquid state. It is of various textures and substance; sometimes single, but usually lined with a finer membrane. *Hilum*, or scar, marks where the seed was connected with the seed-vessel or receptacle. In describing the form or external parts of a seed, it is always to be considered as the base.

There are several occasional appendages to seeds, which may as well be considered in this place. The *pellicle* closely adheres to some seeds, so as to conceal their actual skin. It varies, being downy, membranous, and mucilaginous, or not perceptible until moistened. The *tunic* envelopes the seed more or less loosely, being attached only at the base. The *seed-down* is the chaffy, bristly, or feathery crown, originating from the partial calyx remaining attached to the summit of a seed, somewhat resembling a parachute, which we see bearing along the seed of the dandelion, thistle, &c. A *tail* is the permanent style which remains as an elongated, feathery termination to some seeds, as clematis. A *wing*, a membranous appendage, serving, as the seed-down, to transport the seed it is attached to through the air. It is solitary, except in some umbelliferous plants.

We may now proceed to the last division of the flower, which is, 7thly, the *receptacle*.—This is the common base or point of connection of the other parts. In compound flowers it serves as a distinguishing mark, and therefore is of importance. In the daisy it is conical; in the chrysanthemum, convex; carduus has it hairy; chamomile, scaly; picris, naked; onopordum, cellular.

A compound flower is formed by the union of several sessile florets, or lesser flowers, within a common calyx; each, however, must possess five stamens, their filaments divided, but their anthers united into a cylinder, through which passes the style of a solitary pistil, much longer than the stamens, and having a stigma divided into two parts, which

roll backwards. There are various forms, as the thistle, daisy, sunflower, &c.

When the flowers are collected round a stem in a complete ring, or merely on two of its sides, it is denominated a *whorl*, as in the dead nettle (*Lamium*). Flowers on their own stalks, standing somewhat distant from each other on a common one, or axis, are denominated a *raceme*, as a bunch of currants. When they are placed together on one common axis, they form a *spike*, as in lavender (*Lavandula*). If flowers standing on a common stalk have, in proportion as they stand on it lower down, longer foot-stalks, so that the flowers all stand nearly on a level, it is denominated a *corymb*, as in *Spiræa opulifolia*, common in our gardens; in the common cabbage, a corymb of flowers becomes a raceme of fruit. Flowers on partial stalks variously divided and inserted, collected closely together and level at top, is a *fascicle*, as in the Sweet William (*Dianthus barbatus*). Sessile flowers collected together in a globular figure form a *head* or *tuft*, as in *Statice armeria*. When several flowers on stalks of nearly equal length spring from a common centre on a general stalk, they form an *umbel*, as in the parsley. This is either general or partial; the latter is termed an *umbellule*. When flowers on separate foot-stalks, springing from a common centre, have their foot-stalks variously subdivided, it is termed a *cyme*, as in the elder (*Sambucus*). Flowers growing on partial foot-stalks without any order, but loosely spread on a common one, form a *panicle*, as in the oat (*Avena*). When the flowers of a panicle grow closely together, somewhat approaching an ovate form, as a bunch of grapes, the lilac, &c., it is termed a *thyrsus*, or bunch. When the flowers are all barren and sessile upon a common axis, it forms the *amentum*.

The exterior covering of plants is called the *epidermis* or *cuticle*, answering the same purpose as the scarf-skin or cuticle of animals, viz. protecting the interior and more tender parts from the injuries that might arise from excessive heat, cold, &c.; yet, being porous, it allows the absorption and emission of moisture and air, and the admission of light. It cannot but have been observed how the epidermis varies in different plants; how smooth it is over the petals of most flowers—how downy on the fruit of the peach—how rough on the oak—on the nettle, clothed with perforated poisonous hairs. The cuticle peels off in some plants, as in the cork tree. In some plants, especially the Dutch rush (*Equisetum hyemale*), it is so impregnated with silicious or flinty matter as to serve as a polish for the cabinet-maker, &c.

Immediately beneath the epidermis is the *cellular integument*; this is usually the seat of colour, being red in the petals of the red rose, blue in the common violet, &c. Leaves appear to be little else than masses of cellular integument, enclosed in a case of epidermis, and traversed by numerous sap-vessels. Next to the cellular integument occurs the *bark*. In stems and branches but one year old this consists but of one layer; in older ones there are to be

observed a layer for every year of age; these, however, are of little import to the plant, the vital functions for the time being are carried on in the layer immediately in contact with the wood. This innermost ring is termed the *liber*. The bark is very conspicuous in some roots, as the parsnip, carrot, &c.; the thick outer ring, observable when these are cut transversely, is the bark. The bark consists of woody fibres, chiefly running longitudinally, but beautifully interwoven. In one of the *mezereon* tribe, a native of Jamaica, and called the lace bark, it may be separated into elegant layers of lace-work. In the bark the peculiar properties of the plant principally reside; witness the resin in the pine, the fragrant oil of the cinnamon, &c.

Next to the *liber* occurs the *wood*, which forms the chief bulk of trees. A layer or more of this occurs in all exogenous plants, for in the portion of it which adjoins the *liber*, and is named the *alburnum*, are the sap-vessels which convey the fluid from the root to the leaves, whence it descends into vessels situated in the *liber*, as we shall see hereafter. In trees, a fresh layer of wood is deposited every year adjoining the *liber*, from which it is formed or deposited; hence the age of a tree may be known by counting the concentric rings. In the middle of the wood occurs the *medulla* or *pith*, commonly a porous, juicy, yellowish or greenish substance; even the hollow stems of the onion, &c., are lined with a film of it. It seems to be an extra reservoir of nourishment, required for the formation of the leaves and more recent parts of plants; at all events, in old stems and branches it is usually obliterated. Botanists are not determined as to its uses.

When a seed is committed to the ground, if moisture, air, and heat are not all present in certain favourable proportions, it refuses to germinate. (See *WATER*, its uses to vegetation.) No seed will vegetate in dry earth, nor in a temperature at or below the freezing point; all require a free admission of air. These circumstances being favourable, the seed swells—the skin bursts—and the radicle, or embryo root, makes its appearance, and sinks into the earth. The cotyledons, if the seed has more than one, by degrees develop themselves, and rise above the surface, affording nourishment to the embryo stem, situated between them, until the radicle has become sufficiently a root to supply food for its growth; when thus rendered useless, they decay.

Animal and vegetable matters rendered soluble in water by putrefaction, various salts and earths, and water, are the chief nourishment plants derive from the soil; but it is also certain that the roots absorb air, which in part accounts for the benefit afforded to them by loosening the soil about them, and for planting them near the surface. When a plant has got its leaves developed, it possesses another source of acquiring nourishment from the atmosphere. See *GASES*, their use to vegetation.

The atmosphere, which to our eyes appears a simple uniform fluid, has been demonstrated by chemists to be composed of three different gases or airs with which is constantly mixed

the vapour of water. The gases are known as oxygen, carbonic acid, and azote or nitrogen. Carbonic acid gas is carbon or charcoal combined with oxygen. Water is composed of hydrogen and oxygen gases. These facts, by a little attention, will be easily remembered, and render all that follows comprehensible. The nourishment which is absorbed by the roots being in a fluid state, proceeds along the sap-vessels situated in the *alburnum* of the wood, and spreads through the leaves, flowers, &c. Here, and during its course up the stem, by the varied absorption and decomposition of water and carbonic acid, and the emission of oxygen, the sap is converted into various substances, varying in every species of plants; gum is formed in the cherry, resin in the fir, &c.; these are deposited as the sap descends through the vessels of the *liber*. From the sap likewise is derived the nourishment from whence is formed the wood, &c.; in fact, it is the source of the growth of the parts. Our knowledge of chemistry and vegetable physiology is yet too imperfect to enable us to mark the various shades of difference in the processes of each plant with any degree of precision. We know that in the light all plants absorb carbonic acid gas, and emit oxygen whilst in the dark; on the contrary, they absorb the latter and give out the former by the same surfaces; but we are utterly unable to point out how the same organs secrete a poison in the nightshade and a wholesome food in the potato, which so closely resembles the first in form. A few very simple experiments will serve to fix the above facts upon our memories. We may prove that the sap rises through the *alburnum*, and descends through the bark, by placing the cut end of a leafy twig of the fig tree in an infusion of Brazil wood; after some hours cut off about half an inch of the extremity, when a circle of red dots will mark where the infusion ascended, and an outer circle of white dots will show where the juices descend.

That leaves throw off moisture, or perspire, is demonstrated by inverting a tumbler over two or three leaves placed in the light; the inside of the glass will soon be perceptibly covered with dew.

That leaves throw off gas from their surfaces is demonstrated by plunging one in a vessel of water; air-bubbles will soon be perceived to be emitted by and attached to it.

In due course of time the flowers of a plant open; the anthers of the stamens swell, burst, and scatter a dust, termed *pollen*, secreted by them, and which is caught immediately by the moist stigmas of the pistils, or is carried to them by the wind, or accidental contact of some insect. This contact of the pollen with the stigma is found to be absolutely necessary before the seed can be perfected. This course of vegetation is repeated for a series of years in perennials, but the plant decays as soon as the seed is perfected in annuals.

Botanists at present are acquainted with nearly 100,000 species of plants; and the care with which Providence has provided for the well-being of plants is an earnest of their importance. That they may never become ex

ting, the number of their seeds is often immense: Ray counted 32,000 in one poppy-head! Where the seeds are less numerous, their safety is secured by the extra strength of the seed-vessel, their nauseous, poisonous nature, and other means. The various modes in which they are spread over the face of the country is equal evidence of a peculiar providential care. The seed-down bears some through the air to a distance; some cling by their rough appendages to the coats of animals; others are borne by neighbouring streams, or by the winds, to an immense distance; cocoa-nuts float from the tropics to the shores of Norway; African seeds are blown over the southern coasts of Spain; birds, animals, and even the seed-vessels themselves, by an ejective power, all perform a part in the office of dissemination. Then, again, the various kinds of defence with which they are endowed: cuticles, woolly, and thorny, and flinty, to preserve an equable temperature and to prevent injurious wounds. The buds which contain the embryo of leaves to appear the following year, how enveloped are they in scales, and often coated with resin or gum!

Independent of any general arrangement, plants are divided into species, genera, and varieties.

By species is to be understood a plant which by certain permanent signs can be distinguished from all others; for instance, every one can determine that the damask rose differs from every other; and botanists, having shown by what specific marks it may always be distinguished, have determined it to be a *species*: but there are many other roses which, though having specific points of difference, very closely resemble the damask rose; these, botanists have therefore collected into one family, which they term a genus, under the general name of *Rosa*. *Rosa*, then, is the generic or family name; but, to distinguish the species, every one has a separate second or *specific* name:—thus, the damask rose is *Rosa centifolia*; the dog rose, *Rosa canina*; these second names are therefore termed the *specific names*. By variety is meant a plant varying in an established species, but which cannot produce an exact resemblance of itself by seed. Thus, all our apples are varieties of one species, the crab (*Pyrus*); and all plants raised from their seed invariably differ from each other and their parent. The whole vegetable kingdom, then, is divided into families, or *genera*, composed of a greater or less number of species. In botany the varieties are little noticed. These genera are distributed by Linnæus into *classes*, in what, from him, is denominated the Linnæan System of Botany.

These classes are twenty-four in number, founded on the number, situation, or proportion of the stamens.

The plants of the twenty-four classes are further arranged in subdivisions, denominated *orders*. The orders of the first thirteen classes are founded on the number of pistils the plants belonging to them contain.

The orders of the 14th class are distinguished by their *seed-vessels*.

The two orders of the 15th class are distinguished by the *form of the seed-vessels*.

The orders of the 16th, 17th, and 18th classes are founded on the *number of the stamens*, that is, on the characters of the first thirteen classes.

The orders of the 19th class (*Syngenesia*) are marked by the *nature of the florets*.

The orders of the 20th, 21st, and 22d classes are distinguished by the characters of some of the classes that preceded them: that is, by the number or proportion of the stamens, the union of the anthers not being attended to.

The orders of the 23d class are distinguished upon the principles of the two preceding classes.

The 24th class (*Cryptogamia*) is divided into five orders:—

1. Ferns,
2. Mosses,
3. Liverworts,
4. Algæ,
5. Mushrooms.

The natural system of M. Jussieu.—Every person must have observed, that plants in many instances are arranged by nature in families; for instance, the grasses, liliaceous plants, the umbelliferous plants, mosses, sea-weeds, ferns, &c., are composed of individuals bearing a very striking resemblance to each other in their forms. The same resemblance holds in their internal qualities, between such plants as resemble one another in configuration. Thus the grasses are all nutritious; the liliaceous plants in general poisonous; umbelliferous plants growing on high dry soils are generally wholesome; those of wet situations are generally poisonous. The importance of keeping these families undivided in a botanical classification is evident; and if plants were universally separable into such distinct families as those above mentioned, a natural system would be easy and perfect. But plants are too diversified; they approach each other in such various shades, that it is certain a complete natural system can never be perfected, or must be too intricate for general use. Jussieu's system, with all its merit, is open to both these objections; it is imperfect, were it only from being founded upon the structure of the seed, that part of plants which is, perhaps, more seldom than any other capable of being observed by the botanist.

There are fifteen classes and one hundred orders. The classes have no particular names, but are distinguished by numbers, with a short statement of essential characters. The orders are named after some principal genus in each. There are some inaccuracies in the arrangement; many plants, considered by Jussieu as monocotyledonous, are now known to be without any cotyledons.

At the end Jussieu places a large assemblage of genera, consisting of plants, the construction of whose seed is undetermined. This, of course, is an imperfection, but not peculiar to Jussieu's system. It must be the case with all systems founded on nature, unless their contrivers could have at once before them a specimen of every species of plant that the various portions of our globe produce. This system has been greatly modified and improved by Decandolle, Lindley, and others; and it is now justly preferred to the artificial system of Linnæus. (*G. W. Johnson; Dr. Lindley; G. Sinclair; Trans. High. Soc. vol. i. p. 81.*)

BOTS. In farriery, a kind of worms very

troublesome to horses. Bots are the larvæ or maggots of a species of gad-fly (the *Æstrus equi*), which deposits its eggs on the legs, mane, or those parts of the horse that the animal is most apt to lick. The egg is immediately hatched by the warmth and moisture of the tongue, and the little worm conveyed into the mouth, whence it crawls down the œsophagus into the stomach. It adheres to the cuticular coat of the stomach by means of little hooks, with which its mouth is furnished; and there it remains from the summer of one year to the spring of the next, nourished by the mucus of the stomach, or the food which it contains. Then having attained its full size as a maggot, it loosens its hold, and is carried along the intestines with the other contents of the stomach, and evacuated with the fæces. Before it drops, it generally clings for a while to the verge of the anus, and tickles and teases the horse to a very great degree. Except they exist in most unusual numbers, bots do neither good nor harm during their residence in the stomach of the horse. It is the habitation which nature has assigned to them; and the safety of so noble an animal as the horse would not have been compromised for the sake of a maggot and a fly. The best advice that can be given, therefore, is to let them alone, or at most to be content with picking them off when they appear under the tail. There are two good reasons for this. The first is, that there is not any medicine that will expel them; the strongest and even the most dangerous purgative is insufficient. The second reason is, that if the bots are let alone, they will, in due time, come all away without our help or meddling. (*Clater's Farriery*, p. 168—170.) Green food, however, expels them readily, as does common salt in the proportion of two to four ounces to a quart of water. The most simple and efficient remedy is a quart of milk, mixed well with a quarter of a pound of honey or brown sugar, given fasting. This is much better than aloes.

BOT-FLIES. The various insects, improperly called *bot-bees*, are two-winged flies, belonging to the order Diptera and the family *Æstridæ*. Bot-flies do not seem to have any mouth or proboscis; for, although these parts do really exist in them, the opening of the mouth is extremely small, and the proboscis is very short, and is entirely concealed in it, so that these insects, while in the winged state, do not appear able to take any nourishment. The larvæ or young of bot-flies live in various parts of the bodies of animals. They are thick, fleshy, whitish maggots, without feet, tapering towards the head, which is generally armed with two hooks, and the rings of the body are surrounded with rows of smaller hooks or prickles. When fully grown, they drop to the ground and burrow in it a short distance. After this, the skin of the maggot becomes a hard and brownish shell, within which the insect turns to a pupa, and finally to a fly, and comes out by pushing a little piece like a lid from the small end of the shell.

More than twenty different kinds of bot-flies are already known, and several of them are found in the United States. Some of them have been brought here with our domesticated ani-

mals from abroad, and have multiplied and increased. Three of them attack the horse. The large bot-fly of the horse (*Gasterophilus equi*) has spotted wings. She lays her eggs about his knees; the small red-tailed species (*G. hamorrhoidalis*), on his lips; and the brown farrier bot-fly (*G. veterinus*), under his throat, according to Dr. Roland Green. By rubbing and biting the parts where the eggs are laid, the horse gets the maggots into his mouth, and swallows them with his food. The insects then fasten themselves in clusters to the inside of his stomach, and live there till they are fully grown. The following are stated to be the symptoms shown by the horse when he is much infested by these insects. He loses flesh, coughs, eats sparingly, and bites his sides; at length he has a discharge from his nose; and these symptoms are followed by a stiffness of his legs and neck, staggering, difficulty in breathing, convulsions, and death. No sure and safe remedy has yet been found sufficient to remove bots from the stomach of the horse. The preventive means are very simple, consisting only in scraping off the eggs or nits of the fly every day. Bracy Clark, Esq., who has published some very interesting remarks on the bots of horses and of other animals, maintains that bots are rather beneficial than injurious to the animals they infest. (*Dr. Harris.*)

If a piece of the maw or stomach of a horse that has died while affected with bots be cut out, it may be held under the jet of the strongest fountain or hydrant, without the maggots or bots leaving go, or loosing their hooks. Experiments have been made to destroy them out of the body with spirits of turpentine, alcohol, and a great many of the most stimulating and acrimonious substances, in liquid and other forms, all, however, with little apparent effect upon an insect so very tenacious of life. The bot-maggot is even said to live a considerable length of time in oil of vitriol and nitric acid or aquafortis. After such results, the chance of destroying them in the body must be small, through means which would not destroy the horse. The following ingenious method has, however, been pursued with success. A full drench has been administered, consisting of a mixture of milk sweetened with molasses, followed soon after by an active purgative drench. The milk and molasses tempt the bot-maggots to let go their holds in order the better to partake of the milk, in which condition they are worked off quickly by the brisk operation of the medicine.

The maggots of the *Æstrus bovis*, or ox bot-fly, live in large open boils, sometimes called wornils or wurmals, that is, worm-holes, on the backs of cattle. The fly is rather smaller than the horse bot-fly, although it comes from a much larger maggot. The sheep bot-fly (*Cephalomyia ovis*) lays its eggs in the nostrils of sheep, and the maggots crawl from thence into the hollows in the bones of the forehead. Deer are also afflicted by bots peculiar to them. Our native hare, or rabbit, as it is commonly called, sometimes has very large bots, which live under the skin of his back. The fly (*Æstrus buccatus*) is as big as our largest humble-bee, but is not hairy. It is of a reddish-

black colour; the face and the sides of the hind-body are covered with a bluish-white bloom; there are many small black dots on the latter, and six or eight on the face. This fly measures seven-eighths of an inch or more in length, and its wings expand about three-quarters of an inch. It is rarely seen; and my only specimen was taken in the month of July, many years ago.

At the very end of this order is to be placed a remarkable group of insects, which seems to connect the flies with the true ticks and spiders. Some of these insects have wings; but others have neither wings nor poisons. Of the winged kinds there is one (*Hippobosca equina*) that nestles in the hair of the horse; others are bird-flies (*Ornithomyia*), and live in the plumage of almost all kinds of birds. The wingless kinds have sometimes been called spider-flies, from their shape; such are sheep-ticks (*Melophagus ovis*) and bat-ticks (*Nycteria*). These singular creatures are not produced from eggs, in the usual way among insects, but are brought forth in the pupa state, enclosed in the egg-shaped skin of the larva, which is nearly as large as the body of the parent insect. This egg-like body is soft and white at first, but soon becomes hard and brown. It is notched at one end, and out of this notched part the enclosed insect makes its way, when it arrives at maturity. (*Dr. Harris.*)

BOUND (Sax. *bunde*, from *bindan*, to bind). In veterinary medicine, a term of various application. Any part of an animal that is embraced with an unnatural force is said to be bound: thus horses are liable to be *hoof-bound*, *hide-bound*, &c. Or the bowels may be constricted so as not to part with the fæces, in which case the belly is said to be *bound*.

BOWEL DISEASES (Mod. Fr. *boyaux*; old Fr. *boailles*). The horse and other quadrupeds are liable to various diseases affecting the bowels. Of inflammation of the bowels there are two kinds; that of the external and that of the internal coat. The former is a very frequent and fatal disease, and is recognised by the farrier under the name of *red colic*. It is frequently caused by the application of cold to the belly of the horse, either by taking him into the water, or washing him about the belly with cold water, or suffering him to drink plentifully of it when he is heated, or by exposure to rain, over-exertion on a full stomach, &c. From whatever cause it arises, it runs its course with fearful rapidity, and sometimes destroys the horse in less than twenty-four hours. The symptoms should be carefully studied. One of the earliest is the expression of very acute pain. The animal paws, rolls, struggles violently, lies upon his back, groans; his legs and mouth are cold, the flanks heave violently, the horse shivers and sweats, &c. The violence of the symptoms soon abates, and the horse becomes weak, and scarcely able to stand. Prompt and copious bleeding should be at first resorted to, until fainting nearly or quite succeeds; and mild aperients may be next administered. The whole of the belly should be stimulated with the strong blistering liquid, or with spirit of turpentine; and these appliances should be rubbed in as hardly

and thoroughly as the tender state of the belly will allow. The horse should be kept quiet, warmly clothed, and his legs bandaged. Inflammation of the *inner* coat of the bowels is usually the consequence of physic, either of bad quality or given in an over-dose; or the horse may have been ridden or driven far and fast with nothing but green meat in his belly. This disease can scarcely be confounded with the foregoing. The horse does not roll so violently nor kick so desperately, nor is there any heat nor much tenderness of the belly. At the same time he is purged, instead of exhibiting the obstinate costiveness which generally accompanies the former. Plenty of tolerably thick gruel or starch should be forced down, which will possibly sheathe the coats of the stomach from the effect either of some portion of the physic or the acrimony of the secretion, and the purging will gradually stop. If this should have no effect, bleeding, carefully watched, and stopped when the pulse falters, must be resorted to; and thicker gruel and astringent medicine must be administered. As in the last species, warm clothing and bandages about the legs will be of essential service. (*Clater's Farriery*, p. 173—178.)

BOWLERS, or BOULDERS. A term in geology, implying rounded masses of rock; it is also provincially applied to a kind of round stone, common in the soils of the midland districts. In the north of England it is pronounced sometimes *bowder* or *booder*, and also *boother*.

BOWLER-WALL. A wall generally on the sea-coast, constructed of large pebbles or bowlders of flint, which have been rounded by the action of water.

BOW-LEGGED. In horsemanship, is a defective conformation or posture of the fore-legs of a horse.

BOWS OF A SADDLE are two pieces of wood laid archwise to receive the upper part of the horse's back, to give the saddle its due form, and keep it steady.

BOX DRAIN. An underground drain, regularly built, with upright sides, and a flat stone or brick cover; so that the close section has the appearance of a square box. See **DRAINS** and **DRAINING**.

BOX TREE (Sax. *box*; It. *bosso*; Fr. *buis*; Lat. *Buxus sempervirens*). We consider the English name of this plant to be a corruption of the Latin word *buxus*, or from the Spanish *box*, and that it gave the name to the wooden cases made by the carpenter and turner, rather than derived its own from these cases. The box was formerly much more plentiful in England than at present. Boxwel, in Gloucestershire, was named from this tree, and it also gave the name of Boxhill to those delightful downs near Dorking, in Surry, where this shrub seems to have grown naturally, as it is known to have abounded there long before the time that the Earl of Arundel retired to that spot, and, as it is stated, planted the box. In 1815 the box trees cut down on Boxhill produced upwards of 10,000. This evergreen bush, or small tree, is found all over Europe, as well as upon the chalk hills of England; but it acquires its largest dimensions in the south. The duty on box-wood is quite appres-

sive; being 5*l.* a ton if brought from a foreign country, and 1*l.* a ton if from a British possession. It is from Turkey that the principal part of the wood is imported into England; whether or not all this is really furnished by *Buzus sempervirens* is not known. It is not improbable that *Buzus balearica*, a larger species, too tender to thrive in this country, may furnish a part, at least, of that which comes from the Mediterranean. It is said, that the wood of this species is coarser, and of a brighter yellow than that of the common species. At an average of the three years ending with 1831, the entries of box-wood for home consumption amounted to 382 tons a year. In 1832, the duty produced 1867*l.* 17*s.* 4*d.* Turkey box-wood sells in the London market for from 7*l.* to 14*l.* a ton, duty included. Box is a very valuable wood. It is of a yellowish colour, close-grained, very hard, and heavy; it cuts better than any other wood, is susceptible of a very fine polish, and is very durable. In consequence it is much used by turners and mathematical and musical instrument makers. It is too heavy for furniture. It is the only wood used by the engravers of wood-cuts for books; and, provided due care be exercised, the number of impressions that may be taken from a box-wood cut is very great. In France, box-wood is extensively used for combs, knife handles, and button moulds. The value of the box-wood sent from Spain to Paris is reported to amount to 10,000 fr. a year.

Where box trees are required, they should be raised from seed, which should be sown soon after it is ripe, in a shady border of light loam, or sand; but it is generally propagated by cuttings planted in the autumn, and kept moist, until they have taken root. The box plant is best known for its use in gardens as hedgings to borders; the kind so employed is a dwarf variety. It is very useful, as it grows freely under the drip and shade of trees. Dwarf box is increased by parting the roots, or planting the slips. The best time for transplanting this shrub is October; though it may be removed almost at any time, except summer, if it be taken up with a good ball of earth.

With respect to its medicinal properties, box-wood has been substituted for *guaiacum* as a sudorific in rheumatism; but is now seldom prescribed. Oil of box root is a popular remedy for the toothache, when dropped on cotton, and put into a carious tooth. (*Phillips's Sylv. Flor.* vol. i. p. 44; *Brande's Dict. of Science; M'Culloch's Com. Dict.*)

BOX of a Wheel. The aperture wherein the axis turns.

BOX of a Plough. The cross-piece in the head of the plough which supports the two crow-staves.

BRACE. The general name for a couple, or pair, of such animals as bucks, hounds, partridges, &c. It is also applied to any thing that serves to strengthen or support.

BRACKEN. It is written also *braken*, and sometimes pronounced *breckin* in the north of England. The same with brake or fern. See **FERN.**

BRAIRD. In the agriculture and gardening

of Scotland, the term braird is applied to the springing up of seeds, which, when they come up well, are said to have a fine braird.

BRAKE. The name of a wooden instrument for dressing hemp and flax, used to bruise or break the bun or stem, &c. in order to separate the cortical part or rind from it. It is sometimes applied to a thicket, or the place where fern grows; and is another name for the barnacles, or pincers, used by farriers. Brake is also a sharp bit, or snaffle for horses. A smith's brake is a machine in which horses unwilling to be shod are confined during that operation. Some species of large heavy harrows are frequently called brakes. See **HARROW.**

BRAMBLE, FLOWERING (*Rubus odoratus*). A hardy exotic shrub, five or six feet in height, blowing a pinkish violet-coloured flower in June and August. It loves shade and moisture, and is propagated by suckers. It is known also as the flowering raspberry.

BRAMBLE or BRAMBLE-BERRY (*Sax. bræmbel*, formerly written *bremble*; Lat. *Rubus*). The bramble, or blackberry, the generic name of a large family of shrubs which creep along the hedge in every soil. The common bramble (*Rubus fruticosus*) derives both its Latin and English common name from the colour of its fruit at different stages of ripeness. However generally the bramble is reprobated as a troublesome weed, we must acknowledge that, when either in fruit or flower, it forms a principal among the numberless hedgerow beauties, and is not without its utility in particular soils, especially in poor sandy lands, where the growth of other hedges is slow, and where, by reason of the looseness of the soil, the ditch is no defence. When planted in such situations, it will, by its quick growth, soon entwine its thorny branches in the dead hedge, and form an almost impervious fence against the invasions of cattle, sheep, and other trespassers. Brambles mixed with other hedge plants will render them thicker and stronger. The objections urged against the more general adoption of bramble fences are, that, by the yearly decay of a portion of the shoots, they soon fill the hedge with dead wood, which has not only an unsightly appearance, but is also hurtful to the other plants; and again it is said, that the leaves are so broad and numerous as to smother every other plant, by depriving it of both sun and air. When brambles are in considerable abundance, as is often the case in waste and other lands that require to be brought into cultivation, they should always be grubbed or hoed up; and if the land be afterwards ploughed with a good furrow, the remaining roots will be torn up, and the plants at length destroyed. This shrub, which is only used by the chance passenger occasionally plucking its fruit, possesses, however, several advantages which deserve our attention. Its long branches can, in case of need, be employed as cords; and its fruit produces an excellent wine, the mode of making which is as follows:—Five measures of the ripe fruit, with one of honey and six of wine, are taken and boiled; the froth is skimmed off, the fire removed, and the mixture being

passed through a linen cloth, is left to ferment. It is then boiled anew, and allowed to ferment in a suitable cask. In Provence bramble-berries are used to give a deep colour to particular wines. (*Allgem. Forst und Jagd-Zeitung*, Feb. 1828, p. 104.) The juice of the blackberry, mixed with raisin wine before it has fermented, will give it both the colour and flavour of claret. "The berries," says Pliny, "have a desiccative and astringent virtue, and are a most appropriate remedy for the gums and inflammation of the tonsils." The flowers as well as the berries of the bramble were ignorantly considered by the ancients as remedies against the most dangerous serpents. They are diuretic; and the juice pressed out of the tendrils, or young shoots, and afterwards reduced to the consistency of honey by standing in the sun, is, adds the above author, "a singularly efficacious medicine, taken inwardly or applied outwardly, for all the diseases of the mouth and eyes, as well as for the quincy, &c." But Pliny has lost his celebrity as a medical authority, if he ever had any; and modern blackberries have also lost their virtue. Boerhaave affirms, that the roots taken out of the earth in February or March, and boiled with honey, are an excellent remedy against the dropsy.

Syrup of blackberries, picked when only red, is cooling and astringent in common purgings or fluxes. The bruised leaves, stalks, and unripe fruit, applied outwardly, are said to cure ringworm.

Billington, in his work on Planting, says, "To the poor in the vicinity of Newcastle it is of great importance; many of whom go a great number of miles to gather blackberries while they are in season, and carry them from ten to twenty miles, to Newcastle, Shields, and Sunderland, where they sometimes sell them as high as 3*d.* and 4*d.* per quart, for puddings, tarts, preserves, or jellies, and even making of wines." The fruit is, in particular, much esteemed and sought after by the wives and mothers of sailors, to send on board the ships, as it is found to be very healthful to the men to eat with their biscuits, as well as for puddings, much more so than their common fare of salt beef and pork. All through the season, after the gooseberries are over (for apples, plums, &c., are often scarce and dear), the people are regaled with the fruit of the bramble as the greatest domestic luxury, and would probably lay in a store for future consumption if sugar were cheaper. The leaves of the dwarf crimson bramble (*Rubus arcticus*) are often used to adulterate tea. See WHORTLEBERRY.

Of the *Rubus fruticosus*, or common bramble, we have (says Phillips) five varieties; and as one has been discovered in a hedge near Oxford by Bobart which produces a white fruit, it will be necessary to adopt the proper name of bramble-berry for this fruit, to avoid the contradictory appellation of *white blackberry*. The variety with a double flower is now one of the ornaments of the shrubbery; the other varieties are, one with variegated leaves, one with cut leaves, and the bramble without thorns. Smith, in his *English Flora*, describes fourteen species of bramble (*Rubus*); which

include the raspberry, cloudberry, and dew-berry. Several reputed varieties of the common bramble have also been observed in Britain (says Smith, vol. ii. p. 400), differing in the shape and pubescence of their leaflets, not to mention other characters. These have recently been proposed as species in a very able work, with excellent plates partially coloured, by Dr. A. Weihe and Prof. Ch. G. Nees ab Esenbeck of Bonn, under the title of *Rubi Germanica*. Notwithstanding the colour of the flowers, I cannot suppose the British *R. fruticosus* to differ from theirs. (*Smith's Engl. Flora*, vol. ii.; *Phillips's Hist. of Fruits*, p. 63; *Quarterly Journ. of Agr.* vol. i. p. 816; vol. iii. p. 182.)

The *Rubus* brier, or bramble genus, consists of about fifty species, which are very widely dispersed over the various continents, extending from the arctic circle to the equatorial limits. Mr. Nuttall enumerates twenty species as found in America, among which are the following: *Rubus Idæus*, indigenous, according to Pursh and others, throughout Upper Canada and the northern parts of the United States. Dr. Darlington calls this the Antwerp raspberry, so advantageously known from its large and finely flavoured berries which are cultivated in most gardens. He doubts its being a native of America. There are several varieties of this species of *Rubus*. The *Rubus occidentalis*, common black raspberry, or thimble-berry, is common in the Middle States and other portions of the Union, growing along fence-rows, borders of woods, &c. *Rubus villosus*, common brier, or black-berry bush, is often a great nuisance on farms, from the rapidity with which it spreads and takes possession of neglected fields. *R. Cuneifolius*, or wedge-leaved rubus or brier, bearing an oval-shaped, small, and well-flavoured blackberry, very common in New Jersey. *R. Trivialis*, dewberry, or running brier. The black, sweet, and succulent fruit of this species of rubus is a very great favourite. It is not, however, the same as the English dew-berry, which is produced by the *Rubus Cæsius*. In treating of the American dewberry, or running brier, Dr. Darlington says, "the plough-boy is apt to get well acquainted with this species,—by the long trailing stems, with their recurved prickles, drawing across his naked ankles!" *R. odoratus*, found on the banks of the Wisahickon, near Philadelphia, abundant in mountainous districts, always among rocks.

The tall blackberry (*R. Villosus*) is sometimes cultivated near Boston and other large cities, for the sake of its fruit, and richly repays the care bestowed upon it. Dr. Harris, in his report to the Massachusetts legislature upon destructive insects, says, that this plant and its near relation, the raspberry, suffer from borers that live in the pith of the stems, a fact which does not appear to be generally known. The beetle is a species of *Saperda*, and finishes its transformations towards the end of July, laying its eggs early in August, one by one, on the stems of the blackberry and raspberry, near a leaf or small twig. The grubs proceeding from these eggs burrow directly into the pith, which they consume as they proceed, so

that the stem for several inches is completely deprived of its pith, and consequently withers and dies before the end of the summer. In Europe, one of these slender sapers attack the hazle-nut bush, and another the pear tree in a similar manner.

The dewberry and blackberry are very pleasant fruits and make fine jelly. All the species are readily propagated both by seed and layers, and are wonderfully improved by culture.

There is a double white flowering bramble (*Rubus albo-pleno*) which is a beautiful and ornamental variety.

BRAN (Old Fr. *bren*; Ital. *brenna*). The thin skin or husks of corn, particularly wheat, ground and separated from the meal by a sieve or boulder. It is generally laxative; owing to the mechanical irritation it excites. An infusion of it, under the name of bran tea, is frequently used as a domestic remedy for coughs and hoarseness. Infusions of bran also remove scurf and dandriff. Calico-printers employ bran and warm water with great success, to remove colouring matter from those parts of their goods that are not mordanted. Bran is a useful ingredient, when well scalded, and employed occasionally in moderate quantities, in mashes for horses; but the constant use of it, whether raw or scalded, is prejudicial, as it is apt to weaken the horse's bowels, and therefore expose him to many disorders. It is also highly useful in stall-feeding cattle, and for sheep, when given as a dry food. According to the analysis of M. Saussure, 100 parts of the ashes of the bran of wheat contain (*Chem. Rec. Veg.*),—

	Parts.
Soluble salts - - - -	44.15
Earthy phosphates - - - -	46.5
Silica - - - -	0.5
Metallic oxides - - - -	0.25
Loss - - - -	8.6

BRAND-GOOSE, or **BRENT-GOOSE**. A kind of wildfowl, less than a common goose, having its breast and wings of a dark colour. See **GOOSE**.

BRANK. A provincial name sometimes applied to buckwheat, which see.

BRAWN. The flesh of the boar, after being boned, rolled up, or collared, boiled, and pickled. Brawn is made of the flitches, and some other parts, the oldest boars being chosen for the purpose, it being a rule that the older the boar the more horny the brawn.

The method of making it is generally as follows:—The bones being taken out of the flitches, or other parts, the flesh is sprinkled with salt, and laid in a tray, that the blood may drain off; after which it is salted a little, and rolled up as hard as possible. The length of the collar of brawn should be as much as one side of the boar will bear; so that, when rolled up, it may be nine or ten inches in diameter. After being thus rolled up, it is boiled in a copper or large kettle, till it is so tender that you may almost run a stiff straw through it; when it is set by till thoroughly cold, and then put into a pickle composed of water, salt, and wheat-bran, in the proportion of two handfuls of each of the latter to every gallon of water; which, after being well boiled together, is strained off as clear as possible from the bran,

and when quite cold, the brawn put into it. (*Willich's Dom. Encycl.*)

BREACHY, or **BREECHY WOOL**, is the short coarse wool of a sheep, such as that which comes from the breech of the animal.

BREAD (Sax. *bræod*; Ger. *brod*). This forms an important and principal article in the food of most civilized nations, and consists of a paste or dough formed of the flour or meal of different sorts of grain, mixed with water, with or without yeast or ferment, and baked.

Bread may be divided, in the first instance, into *leavened* and *unleavened* bread. When stale dough or yeast is added to the fresh dough of flour and water to make it swell, it is said to be leavened; when nothing of this sort is added, the bread is said to be unleavened. These may again be subdivided into various kinds and qualities. The principal sorts in use are *white*, *wheaten*, *household*, and *brown* bread, which differ from each other in their degrees of purity. In the first, all the bran is separated from the flour; in the second, only the coarser parts of it; and in the third scarcely any at all; so that fine bread is made only of flour; wheaten bread of flour, with a mixture of fine bran; and household bread of the whole substance of the grain, without taking out scarcely any either of the coarse bran or the fine flour. We have also manchet or roll-bread, and French bread, which are fine white breads made of the purest flour; in roll-bread there is sometimes an addition of milk, and in French bread butter is used. There is likewise ginger-bread, maslin-bread, made of wheat and rye, or sometimes of wheat and barley; and other breads made with various substitutes for flour, as oat-bread, rye-bread, pea and bean-bread, &c.

The President de Gouget has endeavoured (*Origin of Laws, &c.*, vol. i. pp. 95—105, Eng. trans.) to trace the successive steps by which it is probable men were led to discover the art of making bread; but nothing positive is known on the subject. It is certain, however, from the statements in the sacred writings, that the use of unleavened bread was common in the days of Abraham (Gen. xviii. 8); and that leavened bread was used in the time of Moses (Exod. xii. 15). The method of grinding corn by hand-mills was practised in Egypt and Greece from a very remote epoch; but for a lengthened period, the Romans had no other method of making flour than by beating roasted corn in mortars. The conquests of the Romans diffused, amongst many other useful discoveries, a knowledge of the art of preparing bread, as followed in Rome, through the whole south of Europe.

The use of yeast in the raising of bread seems, however, from a passage of Pliny (lib. xviii. c. 7), to have been taken advantage of by the Germans and Gauls before it was practised by the Romans; the latter, like the Greeks, having leavened their bread by intermixing the fresh dough with that which had become stale. The Roman custom seems to have superseded that which was previously in use in France and Spain; for the art of raising bread by an admixture of yeast was not practised in France in modern times till towards the end of the seventeenth century.

For the formation of bread, a certain degree of fermentation, not unlike vinous fermentation, is requisite, care being taken to avoid the acetous fermentation, which renders the bread sour, and, to most persons, disagreeable. This fermentation is called *panary*. If dough be left to itself in a moderately warm place (between 80° and 120°), a degree of fermentation comes on, which, however, is sluggish, or, if rapid, is apt to run into the *acetous*; so that, to effect that kind of fermentation requisite for the production of the best bread, a ferment is added, which is either *leaven*, or dough in an already fermenting state, which tends to accelerate the process of the mass to which it is added, or *yeast*, the peculiar matter which collects in the form of scum upon beer in the act of fermentation. See YEAST. Of these ferments, leaven is slow and uncertain in its effects, and gives a sour and often slightly putrid flavour to the bread. Yeast is more effective, and, when clean and good, it rapidly induces panary fermentation; but it is often bitter, and sometimes has a peculiarly disagreeable smell and taste. Bread well raised and baked differs from unfermented bread, not only in being spongy, less compact, lighter, and of a more agreeable taste, but also in being more easily miscible with water, with which it does not form a viscous mass; and this circumstance is of great importance to health. All, then, that is essential to make a loaf of bread, is dough to which a certain quantity of yeast has been added. This mass, or *sponge*, in the language of the baker, is put into any convenient mould or form, or it is merely shaped into one mass; and, after being kept for a short time in rather a warm place, so that fermentation may have begun, it is subjected to the process of baking in a proper oven. Carbonic acid is generated, and the viscosity or texture of the dough preventing the immediate escape of that gas from the innumerable points where it forms, the whole mass is puffed up by it, and a light porous bread is the result. Along with the carbonic acid alcohol is evolved, but the quantity is so insignificant and the spirit so impure as not to be worth notice; thence the attempts which have been made to collect it upon a large scale have entirely failed in an economical point of view.

The general process of making household bread is this:—To a peck of meal or flour is to be added about three ounces of salt, half a pint of yeast, and three quarts of water, cold in summer, but warm in winter, and temperate between the two: the whole being then well kneaded in a bowl or trough, and being set by in a proper temperature, rises in about an hour, according to the season. It is then moulded into loaves, and put into the oven to be baked. In placing the dough aside, it is proper to cover it; this is termed *setting the sponge*, and it undergoes a second kneading before it is baked.

For French bread, take half a bushel of fine flour, ten eggs, a pound and a half of fresh butter (the eggs and butter, however, are very seldom used), and the same quantity of yeast used in making the finest rolls or manchet; and, tempering the whole mass with new milk, pretty hot, let it lie half an hour to rise; which

done, make it into loaves or rolls, and wash these over with an egg beaten with milk, taking care that the oven is not too hot.

Other flour, besides that of wheat, will, under similar circumstances, undergo panary fermentation; but the result is a heavy, unpalatable, and often indigestible bread; so that the addition of a certain quantity of wheat flour is almost always had recourse to. It is the gluten in wheat which thus peculiarly fits it for the manufacture of bread, chiefly in consequence of the tough and elastic viscosity which it confers upon the dough.

Wheat flour is composed chiefly of starch and gluten; the proportion of these and other substances which it contains, according to Vogel, are—

	Parts.
Starch - - - - -	68.0
Gluten - - - - -	24.0
Gummy sugar - - - - -	5.0
Vegetable albumen - - - - -	1.5

Sir H. Davy states, that wheat sown in autumn contains 77 per cent. of starch, and 19 of gluten; while that sown in spring yields 70 of starch and 24 of gluten. The wheat of the south of Europe contains a larger proportion of gluten than that of the north; and hence its peculiar fitness for making macaroni and vermicelli. Oats yielded, according to Davy's analysis, 59 of starch, 6 of gluten, and 2 of saccharine matter; while the same quantity of rye gave only 6.1 parts of starch, and half a part of gluten.

Like all other farinaceous substances, bread is very nourishing, on account of the gluten which it contains; but if eaten too freely, it is productive of acidity, which deranges the intestines, and lays the foundation of dyspepsia. Stale bread, in every respect, deserves the preference over that which is newly baked; and persons troubled with flatulency, cramp of the stomach, or indigestion, should abstain from new bread, and particularly from hot rolls. Bread made from the best flour is necessarily costly, but is more wholesome for those persons who are liable to a relaxed state of the bowels. Brown bread, on the contrary, is the cheapest and most desirable for persons whose habit of body is of the contrary nature: but there is an intermediate kind made from flour, in which the finer portion of the bran is retained, called locally "seconds," which is preferable to either of the above. (*Quar. Jour. Agr.* vol. ix. p. 585.) It is a prevailing idea that yeast reproduces itself, just as seeds reproduce similar seeds. But chemical investigation has shown that such an opinion is not to be entertained. See YEAST.

The species of bread in common use in a country depends partly on the taste of the inhabitants, but more on the sort of grain suitable for its soil. The superiority of wheat to all other farinaceous plants in the manufacture of bread is so very great, that wherever it is easily and successfully cultivated, wheaten bread is used to the nearly total exclusion of most others. Where, however, the soil or climate is less favourable to its growth, rye, oats, &c., are used in its stead. A very great change for the better has, in this respect, taken place in Great Britain within the last century. It is

mentioned by Harrison, in his *Description of England* (p. 168), that in the reign of Henry VIII. the gentry had wheat sufficient for their own tables, but that their households and poor neighbours were usually obliged to content themselves with rye, barley, and oats. It appears from the household-book of Sir Edward Coke, that in 1596 rye bread and oatmeal formed a considerable part of the diet of servants, even in great families, in the southern counties. In 1626 barley bread was the usual ordinary food of the great bulk of the people. At the Revolution, the wheat produced in England and Wales was estimated by Mr. King and Dr. Davenant to amount to 1,750,000 quarters. (*Davenant's Works*, vol. ii. p. 217.) Mr. Charles Smith, the very well informed author of the *Tracts on the Corn Trade*, originally published in 1758, states that in his time wheat had become much more generally the food of the common people than it had been in 1689; but he adds (2d edit. p. 182. Lond. 1766), that, notwithstanding this increase, some very intelligent inquirers were of opinion that even then not more than *half* the people of England fed on wheat. Mr. Smith's own estimate, which is very carefully drawn up, is a little higher; for, taking the population of England and Wales, in 1760, at 6,000,000, he supposes that 3,750,000 were consumers of wheat, 739,000 of barley, 888,000 of rye, and 623,000 of oat bread. He further supposed that they individually consumed—the first class, 1 qr. of wheat; the second, 1 qr. and 3 bushels of barley; the third, 1 qr. and 1 bushel of rye; and the fourth, 2 qrs. and 7 bushels of oats. About the middle of last century, hardly any wheat was used in the northern counties of England. In Cumberland the principal families used only a small quantity about Christmas. The crust of the goose-pie, with which almost every table in the county is then supplied, was, at the period referred to, almost uniformly made of barley meal. (*Eden, On the Poor*, vol. i. p. 564.)

Every one knows how inapplicable these statements are to the condition of the people of England at the present time. Wheat bread is now almost universally made use of in towns and villages, and almost everywhere in the country. Barley is no longer used; oats are employed for bread only in the northern parts of the island; and the consumption of rye bread is comparatively inconsiderable. The produce of the wheat crops has been, at the very least, *trebled* since 1760. And if to this immense increase in the supply of wheat we add the still more extraordinary increase in the supply of butcher's meat (see CATTLE), the fact of a very signal improvement in the condition of the population, in respect of food, will be obvious. When flour is converted into bread, it is found, on weighing it when taken from the oven, that it has increased from 28 to 34 per cent. in weight (3 lbs. of flour make 3 lbs. 10 oz. of dough); but when it has been kept thirty-six hours, that which had gained 28 will lose about 4 per cent. There are, however, several circumstances which influence the quantity of bread obtained from a given weight of flour, such as the season in which the wheat was grown and the age of the

flour: the better the flour is, and the older, within certain limits, the larger is the quantity of the bread produced.

According to the assize acts, a sack of flour weighing 280 lbs. is supposed capable of being baked into 80 quarter loaves; one-fifth of the loaf being supposed to consist of water and salt, and four-fifths of flour. But the number of loaves that may be made from a sack of flour depends entirely on its goodness. Good flour requires more water than bad flour. Sometimes 82, 83, and even 86 loaves have been made from a sack of flour, and sometimes hardly 80: 96 are generally made, at 4 lbs. 6 oz. before going into the oven, by the London bakers.

It is well known that *home-made bread* and *baker's bread* are very different; the former is usually sweeter, lighter, and more retentive of moisture, and will keep well for three weeks, especially if a little rye meal is mixed with it; the latter, if eaten soon after it has cooled, is pleasant and spongy; but if kept more than two or three days, it becomes harsh and unpalatable, and mouldy. Small quantities of alum are invariably used by the London bakers, with the view of whitening or bleaching the bread; for it will be observed, that whatever may be the quality of the flour which is used, home-made bread is always of a comparatively dingy hue. By some respectable bakers it was formerly in extensive use, and might still be used, with perfect safety; for in so small a quantity as a quarter of a pound of alum to 1 cwt. of flour, it could not be in the least degree injurious. According to Mr. Accum (*On the Adulteration of Food*), the requisite quantity of alum for this purpose depends upon the quality of the flour. The mealman, he says, makes different sorts of flour from the same kind of grain. The best flour is chiefly used for biscuits and pastry, and the inferior kinds for bread. In London, no fewer than five kinds of wheaten flour are brought into the market; they are called fine flour, seconds, middlings, coarse middlings, and twenty-penny.

Beans and peas are also, according to the same authority, frequently ground up with London flour. The smallest quantity of alum used is from three to four ounces to the sack of flour of 240 lbs. Alum may easily be detected in bread, by pouring boiling water on it, pressing out the water, boiling it away to one-third, allowing it to cool, filtering it through paper, and adding to the clear liquor some solution of muriate of lime (*chloride of calcium*). If considerable muddiness now appear, it is proof of adulteration, and none other can well be suspected than alum. Another article occasionally employed in bread and ginger-bread making is carbonate of ammonia. As it is wholly dissipated by the heat of the oven, none remains in the baked loaf. It renders the bread light, and perhaps neutralizes any acid that may have been formed (exclusive of carbonic acid); but it is too dear to be much employed. To some kinds of biscuits it gives a peculiar shortness, and a few of the most celebrated manufacturers use it largely. According to Mr. E. Davy, bread, especially that

of indifferent flour, is materially improved by the addition of a little carbonate of magnesia, in the proportion of twenty to thirty grains to the pound of flour; it requires to be very intimately mixed with the flour. Salt, which, in small quantity, is absolutely necessary to the flavour of the bread, is used by fraudulent persons as an adulteration; for a large portion of it added to dough imparts to it the quality of absorbing and retaining a much greater quantity of water than it otherwise would, thus making the loaf heavier. The taste of such bread is a sufficient index to its bad quality. It is rough in its grain. (*Domestic Economy*, vol. i.) A long list of other articles which are said to be used in the adulteration of bread might be given, but no advantage could result from such a statement.

Making bread at home is an operation very easy of acquirement; and, doubtless, most of our farming friends are fortunate in possessing worthy helpmates or experienced servants who provide the families with this daily necessary. To such a practical method of performing the art would be deemed needless; but others of our readers, who may not have considered the expediency of this bread, its superior salubrity, its decided economy, and the feasibility of its preparation, may be pleased to meet with its details. We may refer them, therefore, to the *Quar. Journ. of Agr.* (vol. ix. pp. 289 and 583), a work which is probably in the hands of the greater number of the British farmers; or they may consult with advantage any of the works cited at the end of this article, for our limits will not permit us to go into the particulars. The writer there states, that the addition of potatoes is wholly unnecessary, unless it be the intention of a housewife that her product shall resemble that of the baker in insipidity and whiteness; both qualities will result from the use of that root, which enters largely into the composition of all bread that is purchased. Notwithstanding the prejudice in favour of the use of potatoes, it has been proved, by careful calculation, that although even a third part of the flour be exchanged for potatoes, so immense is the quantity of water which they contain, that the substitute would cause a loss rather than a gain.

Substitute for wheat flour.—Various substances have been used for bread, instead of wheat. In the year 1629–30, when there was a dearth in England, bread was made in London of turnips. And again in 1693, when corn was very dear, a great quantity of turnip bread was made in several parts of the kingdom, but particularly in Essex. The process is, to put the turnips into a kettle over a slow fire, till they become soft; they are then taken out, squeezed, and drained as dry as possible, and afterwards mashed and mixed with an equal weight of flour, and kneaded with yeast, salt, and a little warm water. A series of interesting experiments were made some years ago by the Board of Agriculture to determine what were the best substitutes for wheaten flour in the composition of different kinds of bread. For this purpose, all the sorts of grain, &c. commonly sold in the markets in London

were procured, ground into meal, and baked in various proportions into bread; such as wheat, rye, rice, barley, buckwheat, maize, oats, peas, beans, and potatoes. Many of these form the principal nourishment of mankind in various countries. Buckwheat, made into thin cakes, is the chief article of food in Bretagne and parts of Normandy. Rice nourishes, probably, more human beings in the East than all other articles of food taken together; and, for its bulk, is supposed to be the most nutritious of all the sorts of grain. Maize is a principal article throughout the south of Europe, and is made into bread in Italy and in America. Peas and beans have rarely, it is believed, been used alone as bread; but, it is suspected, they enter largely, though clandestinely, into its composition in various districts.

To ascertain the respective qualities of all these grains, and to discover their operation on each other, in correcting by means of one the defects of another, would be an inquiry deserving great attention, but it has not yet been experimentally investigated. With almost all the several kinds of grain enumerated, experiments were made on seventy sorts of bread. But as all these sorts were made at once, by several bakers, in order to be examined at the same time, the execution, it is observed, was by no means such as gave the Board of Agriculture, who instituted the inquiry, satisfaction. One general result, however, was, that very few, if any, of the loaves then exhibited, were too bad for human food in times of scarcity; and it may be observed, that though at first a change may prove disagreeable, yet the practice of a few days soon reconciles the stomach to almost any species of food, by which, at least in the same country, other individuals can be supported. These experiments were followed by others, which I will explain under distinct heads.

Rice.—Of all the mixtures, none has made bread equally good with rice, not ground, but boiled quite soft, and then mixed with wheaten flour. One-third rice and two-thirds wheat make good bread; but one-fourth rice makes a bread superior to any that can be eaten, better even than all of wheat; and as the gain in baking is more than of wheat alone (since rice contains 85 per cent. of starch), there can be no doubt of its nutritive quality. Rice bread thus formed is sweetish to the taste, and very agreeable; but, as the proportion of gluten is considerably less than in wheaten bread, it is less nutritive. Excellent biscuits are formed of the mixture.

Potatoes.—The experiments made with this root were similar. It makes a pleasant palatable bread with wheat in the proportion of one-third, but one-fourth still lighter and better. Specimens of barley and potatoes, and also of oats and the same root, made into bread, were submitted to the Board, which promise well. In some cases the potato was not boiled, but merely grated down into a pulp and mixed with wheaten flour, in which mode it made excellent bread. It has been found by other trials, that good bread may be made from equal quantities of flour and potato meal, which has been greatly the practice in those

countries most remarkable for the plentiful culture of the potato.

Various experiments have been made to combine the meal of wheat, barley, oat, bean, and pea flour with vegetable substances, and which have been found to produce very wholesome and nutritive bread.

Using the potatoes after boiling, steaming, or baking, and reducing them into a sort of powder, seems, however, to be the most ready method of making them into bread.

Oats.—It appears, from some experiments made by Dr. Richard Pearson of Birmingham, that oats answer better mixed with potatoes than has been commonly apprehended.

He found that three pints (dry measure) of fine oatmeal, three pints of seconds flour, and one quart of potato pulp kneaded into a dough, with a proper quantity of yeast, salt, and milk and water, made a bread of excellent quality.

Barley.—Mixed with an equal proportion of wheat, or one-fourth potatoes and three-fourths barley, barley bread is good. The following method of making bread of wheat and barley flour has been strongly recommended. To four bushels of wheat ground to one sort of flour, extracting only a very small quantity of the coarser bran, add $3\frac{1}{2}$ bushels of barley flour. The oven should be hotter than when bread is made of wheat alone; and the loaves should remain in the oven about two hours or more. The offal of the barley is good food for hogs. This bread appears to be improved by being baked in half-gallon loaves.

Rye.—In several parts of the kingdom a mixture of rye and wheat is reckoned an excellent species of bread. In Nottinghamshire even opulent farmers consume one-third wheat, one-third rye, and one-third barley; but their labourers do not relish it. As rye is well known to be a wholesome and nutritious grain, its consumption cannot be too strongly recommended. The astringent quality of rice, mixed with rye, corrects the laxative quality of the latter, and makes it equally strong and nourishing with the same weight of common wheaten bread. The principal objection to rye is the circumstance of the grain being sometimes ergotted, which renders the bread unwholesome.

Indian Corn.—The flour of maize or Indian corn, by itself, makes a heavy bread. The right mode of manufacturing it is to boil the flour to the consistency of paste, and then, when mixed with wheat flour, it makes a most excellent bread. If used by itself, it is said to have at first a laxative effect, but that diminishes by use, and at any rate can easily be corrected by a mixture either of barley or rice. It is stated, on very respectable authority, as the general opinion of the inhabitants of the United States, but more particularly of the people of Virginia, Maryland, Delaware, and Kentucky, where Indian corn is raised in the largest quantity, and applied to the greatest variety of uses, that rather more nutriment is contained in a bushel of Indian corn than of wheat. In the four states above-mentioned it constitutes the almost entire food of the labouring class of the people, and has supplanted the use of wheaten bread

There are several sorts of Indian corn in America. The yellow flinty corn is reckoned the sweetest and most nutritive. The white ground corn of the southern states makes the fairest, but considerably the weakest flour. Of this last species there is one variety called the flour-corn, which is scarce, but very valuable.

Buckwheat.—This is not kiln-dried, but dried in the sun, being reaped in October, a month remarkably dry and serene in America. The husk is taken off by what is called running it through the mill-stones. The farinaceous part of the grain is then easily separated from the husk by winnowing; and, being afterwards ground fine, forms an agreeable and nutritive aliment, and may be made into bread with wheat flour or other substances.

Beans and peas.—When these are used as bread, in some places the flour is steeped in water to take off the harsh flavour, and afterwards, when mixed with wheat flour, the taste is hardly to be perceived. Specimens of very good bread have been produced, mixed as follows:—1 lb. bean flour, 1 lb. potatoes, and 4 lbs. of wheat flour. The flour or meal both of beans and peas, by being boiled, previous to its being mixed with wheaten flour, incorporates more easily with that article, and is probably much more wholesome than it otherwise would be.

Eran may in times of scarcity be advantageously employed in the making of common household bread; this is effected by previously boiling the bran in water, and then adding the whole decoction in the dough; thus the bran will be sufficiently softened and divested of its dry husky quality, while the nutritive part, which is supposed to contain an essential oil, is duly prepared for food. It is asserted, that the increase in the quantity of bread, by the addition of one-fourth bran, or 14 lbs. 14 oz. of bran to 56 lbs. of flour, is from 34 lbs. to 36 lbs. of bread beyond what is produced by the common mode.

Dr. Davison considers that there are many vegetables which would afford wholesome nutriment either by boiling or drying and grinding them, or by both these processes. Amongst these may be reckoned, perhaps, the tops and bark of gooseberry trees, holly, hawthorn, and gorse. The inner bark of the elm may be converted into a kind of gruel; and the roots of fern, and probably those of many other plants, such as some of the grasses, and clovers, might yield nourishment, either by boiling, baking, and separating the fibres from the pulp, or by extracting the starch from those which possess an acrid mucilage, such as the white bryony. If, in these days of improved chemical knowledge, a quarter loaf of very good bread can be made out of a deal board (see *Quart. Rev.* No. civ., quoted also in *Quart. Journ. of Agr.* vol. v. p. 626), there is no reason why many of our native herbs and shrubs, which are now comparatively useless, should not, as their various nutritive properties become better known, be turned to considerable advantage in the production of a greater or less proportion of cheap and wholesome food. There are many other substances

which may be formed, by a proportionate admixture of wheat flour, into palatable bread, and advantageously employed in the manufacture of this indispensable article of human sustenance. (*Brand's Dict. of Science and Art*; *McCulloch's Com. Dict.*; *Penny Cyc.* vol. v.; *Willich's Domes. Encyc.*)

BREAD-ROOT (*Psoralea esculenta*). A shrubby or herbaceous perennial plant found on the elevated plains of the Missouri. Its roots are eaten both raw and boiled, the latter being the most common way of cooking it adopted by the Indians. By cultivation it is made to produce abundant crops. The taste of the root is rather insipid, its texture being laminated, always tenacious, solid, but never farinaceous, like the potato. It is somewhat medicinal, operating as a diuretic.

Other species of *Psoralea* are also found on the Missouri and tributaries, among which are the *P. canescens*, and *P. cuspidata*, both of which are described as having large, tuberous, and ramified roots. The last species is known among the Canadian boatmen by the name of "Pomme de Prairie," or meadow potato. The *P. lanceolata*, or *elliptica*, grows in great quantities together on the sandy banks of the Missouri, from the river Platte to the mountains, flowering in July and August. It sends up shoots in every direction through the sand, in which soil it is exclusively met with. The stem is about a foot high and the leaves aromatic when bruised. The *P. lupinellus* is found from South Carolina to Florida, though not in abundance. It is a very singular plant, the leaves being so narrow as scarcely to be distinguished from the petiole, and two or three inches long, extremely deciduous when dry. The *P. virgata* is met with in West Florida. With very few exceptions, says Nuttall, this genus of plants producing esculent roots is indigenous to North America and the Cape of Good Hope.

BREAKING (Goth. *brikan*; Sax. *bræccæn*). In rural economy, the bringing of an animal under subjection. The breaking of a colt is commonly, especially for race-horses, commenced when he is much too young; for this, as for all other breeds of horses, too much caution and gentleness can hardly be used. (*Darvill. On Training*). Of dogs, spaniels should begin to be broken in at five or six months old. The water-spaniel, according to old Markham, as soon as "even when you first weane him;" and, according to Blaine (*Encyc. of Rural Sports*), the education of a pointer or a setter should commence at five or six months.

BREAKING UP. A term that is often applied to such lands as are ploughed for leys, or which are cut or pared for the purpose of being burned.

BREAST-PLATE. The strap of leather that runs from one side of the saddle to the other over the horse's breast, in order to keep the saddle tight, and hinder it from sliding backwards.

BREASTS. Part of the bows of a saddle.

BREED (Sax. *bræðan*). A sort or variety of any kind of live-stock. The breeds of most domestic animals are numerous, and distinguished by certain invariable marks or ap-

pearances peculiar to each, as in cattle, sheep, horses, and swine. See these different heads.

BREEDER. In agriculture, a farmer who is much employed in breeding and rearing animals of any of the domestic kinds.

BREEDING IN AND IN. The breeding from close relations. "This plan," says Professor Youatt (*Cattle*, p. 525), "has many advantages to a certain extent. It may be pursued until the excellent form and quality of the breed are developed and established. It was the source whence sprung the fine cattle and sheep of Bakewell, and the superior cattle of Colling; but disadvantages attend breeding 'in and in,' and to it must be traced the speedy degeneracy, the absolute disappearance of the new Leicester cattle, and in the hands of many an agriculturist, the impairment of constitution and decreased value of the new Leicester sheep and the short-horned beasts. It has therefore become a kind of principle with the agriculturist to effect some change in his stock every second or third year: and that change is most conveniently effected by introducing a new bull or ram. These should be as nearly as possible of the same sort, coming from a similar pasturage and climate, but possessing no relationship, or at most a very distant one, to the stock to which he is introduced." These remarks apply to all descriptions of live-stock. In cattle, as well as in the human species, defects of organization and permanent derangements of function obtain, and are handed down when the relationship is close. In Spain the deformed and feeble state of the aristocracy arises from the alliances being confined to the same class; whilst in England, which can boast the finest aristocracy in the world, the higher classes are improved by constant alliances being formed with the daughters of inferior classes, where wealth has been accumulated. See the heads, **CATTLE**, **HORSE**, **SHEEP**, &c.

BREEDING-PONDS. Such ponds as are employed for breeding fish. The qualities of a pond, to make it profitable for breeding fish, are very different from those which are sufficient for the feeding of them; inasmuch as some particular ponds serve only for one of these purposes, and others for the other; and scarcely ever the same pond is found to answer for both. In general it is much more rare to find a good breeding-pond than a good feeding one. The indications of a good breeding-pond are these,—a considerable quantity of rushes and grass about its sides, with gravelly shoals, such as horse-ponds usually have. The spawn of fish is prodigiously great in quantity; and where it succeeds, one fish is able to produce some millions. Thus, in one of these breeding-ponds, two or three melters, and as many spawners will, in a very little time, stock the whole country. When these ponds are not meant entirely for breeding, but the owner wishes to have the fish grow to some size in them, the method is to thin their numbers; for they would otherwise starve one another. It may also be necessary to put in other fish that will prey upon the young, and thin them in the quickest manner. Eels and perch are the most useful on this account. See

cause they prey not only upon the spawn itself, but upon the young fry from the first hatching to the time they are of a considerable size. Some fish are observed to breed indifferently in all kinds of waters; of this nature are the roach, pike, and perch.

The introduction of certain voracious fish, such as the pike or pickarel, into ponds or lakes well stocked with trout, white and yellow perch, &c., has been attended with serious consequences, and even led to the total extinction of some kinds and the diminution of all. The mischief in such cases has perhaps been less owing to the exceeding voracity of the pike or pickarel, than to its habits of thrusting itself into the shallows and retired breeding places of other fish, and there breaking up the spawn or devouring the small-fry, without allowing them a chance to live or increase. The trout contents itself with preying upon such bait as it can catch away from the shallows, leaving the breeding places and spawn of other fish undisturbed. Hence, in lakes where plenty of bait is seen along the shores, trout may be found in abundance and in fine condition. Trout and perch both multiply in the same ponds or lakes, provided no pike or pickarel be present.

BREWING. The process of obtaining the saccharine solution from malt, or other matters, and converting this solution into spirituous liquors, ale, porter, or beer. There is little doubt of the antiquity of this art. The Egyptians are said to have been the inventors of beer. The early Germans, and our Saxon forefathers, were as fond of beer as the modern citizens of Lubec and Rostock are now, or the English of all ages. It is hardly necessary, in this work, to go deeply into the description of a process which most country persons understand so well. The directions may be divided into several heads. 1. The grinding of the malt: in this there is, as in many other parts of brewing, considerable difference of opinion; some prefer it ground between stones, others crushed by rollers; some prefer a fine grist, others a coarse one. 2. The mashing is usually performed in a vessel of wood, with a false bottom pierced full of holes; on this bottom the malt is laid; the water is then admitted, which, for pale ale, or pale spirits, should be of the temperature of from 170° to 185°, according to the quantity mashed; the heat being increased as the mass diminishes. For porter, not higher than 165°, or lower than 156°. For the second mash, an increased temperature of 15° or 20° will be advisable. For the first mash: for every quarter of malt, a barrel and a half of water may be used, and the grist well mixed with the water. The mash is permitted to rest for some time, and then allowed to run off into an auderback, whence it is pumped into the boiler, where it is raised to the boiling temperature. When the wort is sufficiently drained from the mash-tub, another portion of hot water is added for a second mash. The hops are next added, and the boiling is completed, which in general requires an hour and a half, "or until the wort breaks bright from the hops, when a sample is taken from the

copper." The wort is let off into coolers, either of wood or iron; where, when sufficiently cooled, or else in proper fermenting tuns, the yeast or barm is added. The fermentation speedily begins; and when it is thought that a sufficient quantity of alcohol is formed, the fermentation is stopped, and the yeast is separated by running it into smaller vessels, and skimming off the barm; or else by allowing it to run off from the bung-holes of the casks, which are, for this purpose, kept completely filled. A small portion of salt is commonly added, and, occasionally, especially by the professional brewer, a portion of isinglass or other finings. In all these operations, cleanliness is a most essential part, for without this it is impossible to have good beer.

The quantity of hops to be added varies with the quality of the beer. 4 lbs. to the quarter of malt is sufficient for beer for present use, and from this to 28 lbs. have been used for beer for long keeping, as for exportation, &c.

The temperature of the fermentation should range between 56° and 62°. Not more than 60° for ale wort, nor more than 62° for porter. Great care should be taken to have good, sound, healthy, and new yeast,—and of this about 2 lbs. per barrel are commonly needed. Good malt and hops, of course, are requisite; but the quality of the water is not of so much consequence as is very often considered to be the case. Some of the best ales in England are brewed either with soft or with hard water, and from rivers, or springs, or ponds. From those issuing from the limestones of Nottinghamshire, the chalks of Dorsetshire, the clays of Staffordshire, the gravels and sands of Surrey and Middlesex, is made some of the most excellent beer in the United Kingdom. The quantity of alcohol, upon an average, in stout is about 6·80, in ale 8·88, and in small beer from 2 to 3 per cent. (*Erande.*) Beer came under the excise in the year 1643, but the duties were repealed in 1830. The exportation of beer from England was in—

	Tons.
1830 - - - -	10,212
1832 - - - -	11,330
1834 - - - -	10,406

The specific gravity of the wort, when it is placed in the fermenting vessels, varies from 1·060, when it contains 14·25 per cent. of solid matter, to 1·127, when it contains 28·2 per cent. That of small beer varies from 1·015 to 1·040, the first containing about 3·5 per cent. of solid matter, the latter about 9·5 per cent. The chief use of the hops (ground ivy and other herbs were used by our Saxon ancestors for this purpose) is to communicate the peculiar bitter flavour from the oil which is contained in them; partly to hide the sweetness of the saccharine matter, and partly to counteract the tendency which wort has to run into acidity. (*Thomson's Chem.* vol. iv. p. 376.)

"Hops," says Dr. Lardner (*Domestic Economy*, vol. i.), "are by no means the only bitter which may be made use of for preparing and flavouring ales; others can be much more conveniently procured in certain situations. Mixtures, in various proportions, of worm-

wood, powdered bitter oranges, gentian root, and the rind of Seville oranges, will afford an excellent bitter, perhaps more wholesome than hops, and, if skilfully combined, to the full as palatable; in this position the brewers cannot refuse to bear me out." Strasburg beer, which is much prized on the continent, owes much of its excellence to the use of avens (*Geum urbanum*). It has been shown by Mr. Dubrunfaut, that a good beer can be produced from potatoes grated to a pulp, mixed with barley malt. In Ireland, beer is made from parsnips. Cane sugar answers admirably (14 lbs. of cane sugar, dissolved in ten gallons of boiling water, with 1½ lbs. of hops). The beer made in this way is pale coloured, it is true; but colour may be given readily by scorched treacle, or the raspings of an over-baked loaf. (*Quart. Journ. of Agr.* vol. ii. p. 634.) Beer "which would not disgrace a nobleman's table" has also been made from mangel wurzel 150 lbs., and 1 lb. of hops in sixteen gallons of water. (*Mechanic's Mag.*) It may also be made from the seeds of the Fiorin grass (Donovon, *Domestic Economy*), Indian and other corn. (*Baxter's Lib. of Agriculture*.)

BRICKS are building materials often employed by the farmer for the construction of drains, besides the ordinary purposes, for which they answer very well; but they are more expensive than draining tiles, which see. By the 17 G. 3, c. 42, under a penalty of 20s., and 10s. per 1000, all bricks made in England for sale shall be 8½ inches long, four inches wide, and 2½ inches thick; and all pantiles 13½ inches long, 9½ inches wide, and ½ an inch thick. If the farmer wishes to make his own bricks, the London plan is to mix fifty chaldrons of coal ashes, or breeze, with 240 cubic yards of clay, which makes 100,000 bricks; and to burn these, fifteen chaldrons of coarse sifted breeze are required. The soils called brick earths vary much in their composition; they contain alumina in different proportions. Pottery's clay is perhaps the richest in that earth, being composed, according to M. Vauquelin, (*Bull. Phil.* xxvi.) of—

Silica (flint)	-	-	-	Parts.
Alumina	-	-	-	43·5
Lime	-	-	-	33·2
Oxide of iron	-	-	-	3·5
Water	-	-	-	1·0
Loss	-	-	-	18·0
				0·8
				100·0

BRIDLE. A contrivance made of straps or thongs of leather, and pieces of iron, in order to keep a horse in subjection, and direct him in travelling. The several parts of a bridle are, the bit or snaffle; the head-stall, or leather from the top of the head to the rings of the bit; the fillet, over the forehead and under the fore-top; the throat-band, which buckles from the head-band under the throat; the nose-bands, going through the loops at the back of the head-stall, and buckled under the cheeks; the reins, or long thongs of leather that come from the rings of the bit, and, being cast over the horse's head, the rider holds in his hand.

BRIDLE-HAND is the horseman's left

hand; the right being called the spear or sword hand; and that in which the whip is held.

BRIDON. A sort of snaffle, with a very slender mouth-bit, without any branches. They are much used in England. It is sometimes written *bridoon*.

BRILLS. In horsemanship, a vulgar name for the hair growing on the horse's eye-lids.

BRIM. A term applied to a sow when she goes to the boar, which is called going to brim. It is sometimes written *brimme*.

BRINING OF GRAIN is the practice of steeping it in pickle, in order to prevent smut or other diseases. The steep is made with common salt and water, of sufficient strength to float an egg; or of sea-water, with salt added to it till it is of the requisite strength. The seed is then put into it, and well stirred about: the light grains rise to the surface, and are skimmed off; the rest is put upon a sieve to drain, and new-slaked lime sifted upon it: after being carefully mixed, and when a little dried, it is put into the earth. Urine, when kept stale, is used in the same manner; and, if the seed be sowed directly, with good effect. Brining the seed wheat is commonly believed by the farmers to be a prevention of smut, a disease which has been shown by Sir Joseph Banks to be a parasitical fungus. Recent experiments have suggested that it may even be of use, when employed in larger quantities, as a preventive of mildew—the most dreadful of the numerous diseases to which the cultivated grasses are exposed. The experiments of the late Rev. E. Cartwright strongly evidence, that when salt and water are sprinkled with a brush upon diseased plants, it is actually a complete cure, even in apparently the most desperate cases. The proportion, one pound to a gallon of water, laid on with a plasterer's brush, the operator making his casts as when sowing corn: it is instant death to the fungus, but it also destroys some plants. The time and expense are trifling. It appeared, in the course of some inquiries made by the Board of Agriculture, that a Cornish farmer, Mr. Sickler, and also the Rev. R. Hoblin, were accustomed to employ refuse salt as a manure, and that their crops were never infected with the rust or blight. The farmer may see most of the authorities collected together on this important fact in Johnson, *On Salt*, p. 50. If potatoes are immersed in a solution of ammoniacal water for four or five days (one ounce of the common liquor ammoniæ to a pint of water), they will have, according to Mr. Webster, their vegetative power completely checked or destroyed, and may be in this way preserved throughout the year, without the least injury to their general qualities—the same effect is produced by immersing them in a strong brine. This merely requires subsequent ablation, and repeated changes of water. (*Quart. Journ. of Agr.* vol. vii. p. 438.)

BRISTLES (Dut. *borstels*; Ger. *borsten*). The strong glossy hairs growing upon the back of the wild boar and the hog. Those for the use of brushmakers, saddlers, shoemakers, &c., are imported to a very considerable extent from Russia, those of the Ukraine being the

best. At an average of three years ending with 1831, says Mr. McCulloch, the entries for home consumption in England amounted to 1,789,801 lbs. annually. They contain a considerable quantity of gelatine, which may be separated from them by boiling water.

BRITTLE HOOF is an affection of the horse's hoof, very common, especially in summer, in England, from bad stable management. A mixture of one part of oil of tar and two of common fish oil, well rubbed into the crust and the hoof, will restore the natural pliancy and toughness of the horn, and very much contribute to the quickness of its growth. (Youatt, *On the Horse*, p. 282.)

BRIZA MEDIA. See Plate 6, n. Common quaking grass; ladies' tresses: a perennial grass, flowering in May and June. It is distinguished by the panicle of short spikelets, tinged with purplish brown. The spikelets are ovate, on very slender stems, which makes the panicle tremulous. This grass, says Sinclair, is best fitted for poor soils; its nutritive powers are considerable, compared with other grasses tenanted a similar soil. It is eaten by horses, cows, and sheep; and for poor sandy and tenacious soils, where improvements in other respects cannot be sufficiently effected, to fit them for the productions of the superior soils, the common quaking grass will be found of value.

BRIZE LANDS. A provincial term for lands which have remained long without tillage. *Brize* is also a name for the gad-fly, used commonly in the days of Shakspeare and Ben Jonson. (*Tr. and Cress.: Poetaster*, iii. 1.)

BROAD-CAST SOWING. The primitive, rapidly diminishing method of putting grain, turnip, pulse, clover, grasses, &c., into the soil, performed by means of the hand. This mode of sowing seems better adapted to the stony and more stiff kinds of land than that by machines; as in such grounds they are liable to be constantly put out of order, and to deposit the seed unequally. In this way, however, the seeds are scattered over the ground, and not confined in regular rows, as is the case with the drill husbandry, which is in several ways more advantageous to the farmer. This mode of sowing, perhaps from its being that made use of in the infancy of agriculture, has often been called the *old method*.

In this method of sowing, the usual practice, especially where the ridges are equal in breadth, and not of too great a width, as five or six yards, is that of dispersing the seed regularly over each land or ridge, in once walking over; the seedsman, by different casts of the hand, sowing one-half in going and the other in returning. In doing this, it is the custom of some seedsmen to fill the hand from the basket or hopper which they carry along with them, as they make one step forward, and disperse the seed in the time of performing the next; while others scatter the seed, or make their casts, as they are termed by farmers, in advancing each step. It is evident, therefore, that in accomplishing this business with regularity and exactness, upon which much of the success of the crop must depend, there is considerable difficulty, and the proper knowledge and habit

of which can only be acquired by experience. This, however, by long practice, is done with surprising regularity and precision. The broad-cast system not only requires more seed, but it renders the hoeing, so essential to the most profitable growth of grain, much more difficult. Machines have been invented for distributing the seed broad-cast, which they perform with perfect precision: these are more especially useful for the grass seeds, and are simple and economical; a plate of one may be seen in Professor Low's *Prac. Ag.* p. 108, and another in *British Husb.* vol. ii. p. 14. These, however, require some attention in their working, to prevent the clogging of the seed.

BROAD-WHEELED WAGON. A four-wheeled carriage, in which the parts of the wheels that act upon the road are of considerable breadth. By the acts 3 G. 4, c. 126, s. 12, and 4 & 5 W. 4, c. 81, wagons, wains, and other four-wheeled carriages, whether on springs or not, whose wheels have their fellies of not less than four and a half inches at the bottom or soles, are considered to be broad-wheeled.

BROCCOLI (*Brassica oleracea botrytis*). The varieties of this cabbage are now numerous, and are chiefly the fruits of the great attention which has been paid to its cultivation of late years. For an uninterrupted supply, scarce any of these varieties can be dispensed with; but the purple and white are those most generally cultivated. With respect to their quality, it has been remarked that they have less of the peculiar alkalies taste, and are more palatable, in proportion as they approach a pale or white colour. (*Transact. Hort. Soc. Lond.* vol. i. p. 116.)

1. Purple cape, or autumnal broccoli. 2. Green cape, or autumnal broccoli. 3. Grange's early cauliflower broccoli. 4. Green, close-headed winter broccoli. 5. Early purple broccoli. 6. Early white broccoli. 7. Dwarf brown close-headed broccoli. 8. Tall, large-headed purple broccoli. 9. Cream-coloured, or Portsmouth broccoli. 10. Sulphur-coloured broccoli. 11. Spring white, or cauliflower broccoli. 12. Late dwarf close-headed purple broccoli. 13. Latest green, Siberian, or Spanish broccoli.

Broccoli is propagated by seed. As all of the kinds are not generally at command, the following times and varieties are specified as being those employed in general practice, and by which a supply nearly unfailing is accomplished. A first sowing may be made under a frame at the close of January, and a second at the end of February, or early in March, on an eastern wall-border, of the purple cape and early cauliflower varieties, for production at the close of summer and during autumn; the seedlings from these sowings are respectively fit for pricking out, if that practice is followed, in March and early in April, and for final planting at the close of the latter month and May. In April, another crop of the same varieties may be sown, for pricking out in May and planting in June, to produce at the close of autumn and in early winter. During the middle of May, a fourth and larger crop than any of the preceding, of the early purple and white varieties, to be pricked out in June and planted

in July; and, finally, the last open-ground crop may be sown in June, to be pricked out in the succeeding month, and planted in August and September; the plants will follow from the others in succession throughout winter and spring. In a frame, however, they may be sown, like the cauliflower, in the last days of August, to remain until the following March, to be then planted out for production in early summer. By these repetitions, which, if for a family, should be small, an almost continued supply is afforded; but in general, for domestic use, especially if the establishment is small, three sowings of moderate extent will be sufficient; the first in the second week of April, the second in the third week in May, and the third in the middle of August, in a frame. Each variety should be sown separately, and the sowing performed thin; the beds not more than three or four feet wide, for the convenience of weeding, which must be performed as often as weeds appear, as they are very inimical to the growth of this vegetable. The seed must not be buried more than half an inch, and the beds be netted over to keep away the birds, which, especially in showery weather, are very destructive. The fitness of the plants for pricking out is intimated by their having five or six leaves, rather more than an inch in breadth; they are set four or five inches apart each way, and water given every night until they have taken root. They must have four or five weeks' growth before they are again moved; or not until they have leaves nearly three inches in breadth. When planted out, they must be set on an average two feet asunder each way, in summer a little wider, in winter rather closer. Water to be given at the time of planting, and occasionally afterwards, until they are established; during the droughts of summer it may be given plentifully with the greatest advantage. They must be hoed between frequently, and the mould drawn up about their stems. To force forward the winter standing varieties, it is a successful practice to take them up in November, and after trimming off the outer leaves, to lay them on their sides in a sloping position, in a bank or terrace of light earth, so much space being left between every two plants that their heads do not come in contact. To continue the supply uninterrupted, even in the mid-winter of the severest years, Mr. Maher recommends that when the crop sown about the third week in May has been planted out, the weaker plants which remain should be left eight or ten days to acquire strength, and then planted in pots (sixteens) filled with very rich compost; to be shaded, and watered until struck. These are to be plunged in the ground at similar distances as the main crops, and about three inches below the surface, so as to form a cup for retaining water round each; these cups are filled up by the necessary earthings, which must be pressed firmly down, to prevent the wind loosening them. A few of the plants generally flower early, and, to guard against the first frosts, must have the leaves broken over them: but on the approach of settled frost in December and January, the pots must be taken up and removed into a frame, shed, or any place

of shelter from the extreme severity of the weather; but to have air when mild. (*Tra. Hort. Soc. L.* vol. i. p. 118.)

To those crops which have to withstand the winter in the open ground, salt is beneficially applied, as it preserves them from being *frosted in the neck*, and also their roots from being worm-eaten; which may also be effected, Mr Mackay of Errol House, N. B., informs us, by pouring soap-suds between the rows, which application is also very beneficial to the plants. (*Mem. Caled. Hort. Soc.* vol. i. p. 275.)

To preserve the winter standing crops from destruction by severe weather, it is also a practice, early in November, to take them up, injuring the roots as little as possible, and to lay them in a sloping direction in the soil, with their heads to the north. A modification of this plan, adopted by the distinguished president of the Horticultural Society, is, however, much preferable, as it obviates the defect of few roots being produced, and consequently diminutive heads. A small trench is made in the first week of September, at the north end of each row, in which the adjoining plant is laid so low, that the centre of its stems at the top is put level with the surface of the ground, the root being scarcely disturbed; it is then immediately watered, and its roots covered with more mould. Thus every plant is in succession treated; and by the beginning of November, it is scarcely perceptible that they have been thus treated, though it certainly checks their growth. Before the arrival of snow, a small hillock must be raised round each plant, to support its leaves, and prevent their being broken. (*Trans. Hort. Soc. Lond.* vol. ii. p. 304.) If snow accompanies severe frost, advantage should be taken of it, and the plants be heaped over with it, which will afford them an effectual protection.

For the production of seed, such plants of each variety must be selected, in March or April, as most perfectly agree with their peculiar characteristics, and are not particularly forward in advancing for seed. As the stems run up, some gardeners recommend the leaves to be taken away; but this must be injurious. Mr. Wood of Queensferry, North Britain, is particularly careful that no foliage appears on the surface of the flower; he always lifts his plants, and plants them in another bed, watering abundantly; as this, from his long experience, he finds, prevents their degenerating, or producing *proud seed*; and when the head begins to open, he cuts out its centre, and leaves only four or five of the outside shoots for bearing. The sulphur-coloured he always finds the most difficult to obtain seed from. (*Mem. Caled. Hort. Soc.* vol. ii. p. 266.) As the branches spread, four or six stakes should be placed at equal distances round each plant, and hooped with string, to support them and prevent their breaking. When the pods begin to form, water should be given repeatedly, and occasionally some thrown over the whole plant, which tends to prevent mildew. Before the pods begin to change colour, those from the extremity of every shoot must be taken away; as these yield seed which produce plants very apt to run to seed without heading,

and by an early removal the others are benefited. The branches are to be gathered as soon as the pods upon them ripen. Varieties must never be planted near each other, or they will reciprocally be contaminated. The seed ripens in August or September; and it is often recommended to preserve it in the pod until wanted; but the general practice is to beat it out, and store it as soon as it is perfectly dry. The plants raised in frames are managed as directed for cauliflowers in the same situation. (*G. W. Johnson's Kitchen Garden.*)

BROKEN-KNEES, in horses. The best medical treatment, in slight cases, is to cleanse them from dirt and gravel by a sponge and warm water. In bad cases a veterinary surgeon is absolutely necessary, who will examine with his probe, and apply bandages, and even, in need, the hot iron.

BROKEN-WIND, in horses, is, says Professor Youatt, the rupture, dilatation, or running together of some of the air cells,—the inspiration by one effort, and the expiration by two; and is thus easily distinguishable from thick wind, in which the inspirations and the expirations are equal in amount. In healthy lungs, when the lungs are expanded, the air will rush in easily enough, and one effort of the muscles of expiration is sufficient for the purpose of expelling it; but when these cells have run into each other, the cavity is so irregular, and contains so many corners and blind pouches, that it is exceedingly difficult to force it out again, and two efforts are scarcely competent fully to effect it. A dry husky cough accompanies this disease, of a peculiar sound. Broken wind is usually caused by smart exercise on a full belly. We do not, therefore, find broken-winded horses on the race-course; for, although every exertion of speed is required from them, their food lies in a small compass; the stomach is not distended, and the lungs have room to play; and care is taken that their exertion shall be required when the stomach is nearly empty. Carriage and coach horses, from a similar cause, are not often broken-winded. The majority of broken-winded horses come from those for whose use these pages are principally designed; the farmer's horse is the broken-winded horse, from being fed on bulky food; and because, after many hours' fasting, the horses are often suffered to gorge themselves, and then, with the stomach pressing upon the lungs, and almost impeding ordinary respiration, they are put again to work, and sometimes to that which requires considerable exertion. But the pressure of the distended stomach upon the lungs is sufficient to do this, without exertion; many a horse goes to grass or the straw-yard sound, and returns broken-winded. The cure of a broken-winded horse no one has witnessed, yet much may be done in the way of palliation; the food should consist of much nutriment in little compass; the oats should be increased, and the hay diminished; occasional mashes will be found useful; water should be given sparingly except at night, and the horse should never be exercised on a full stomach. Carrots are excellent food for him. (*The Horse; Lib. of Useful Know.* p. 195.)

BROMUS. The brome grasses; a genus of which the chief species are as follow:—

Bromus arvensis, taper field brome grass, has a spreading, drooping, compound panicle, with lanceolate, sharp-pointed spikelets. Each spikelet consists of eight imbricated, smooth florets, with two close ribs at each side. The leaves are hairy, and the whole plant about three feet high. It is confined to rich pastures and meadows; while the next two, *Bromus multiflorus* and *Bromus mollis*, known by the leaves being soft and downy, abound most on poor or exhausted grass lands: they are all annuals. The farmer considers them to be bad grasses; the field brome grass, however, affords an early bite in the spring for sheep and lambs; it does not exhaust the soil; the roots do not extend to any depth; its seeds, which it sheds, readily and speedily take root and yield food; and it withstands the frost well: in England it flowers on the second week in August. At the time of flowering, the produce of its grass grown on a sandy loam per acre is 23,821 lbs.; of nutritive matter, 1488 lbs.

Bromus diandrus, upright annual orome grass.

Bromus erectus, upright perennial brome grass.

Bromus inermis, smooth awnless brome grass.

Bromus littoreus, sea-side brome grass.

Bromus mollis, soft brome grass.

Bromus multiflorus, many-flowered brome grass (named from the spikelets containing from ten to fifteen florets).

Bromus sterilis, barren brome grass. It grows principally under hedges in the shade; cattle refuse it.

Bromus tectorum, nodding-panicked brome grass.

These were all examined with much skill by Sinclair, but he had evidently a poor opinion of them as field grasses. (*Hort. Gram. Wob.*)

There are many other varieties of this family, the respective merits of which are pointed out by Sinclair in his *Hort. Gram. Wob.* That which is perhaps most interesting to the American farmer is the *Bromus secalinus*, commonly called cheat, so frequently found growing among the wheat or rye crops.

BRONCHITIS. A disease in horses. It is, says Professor Youatt, a catarrh extending beyond the entrance of the lungs. Symptoms, quicker and harder breathing than catarrh, peculiar wheezing, coughing up mucus. Treatment, moderate bleeding, chest blistering, digitalis. Neglected bronchitis often leads to thick wind. (*On the Horse*, p. 189.)

BROOD MARES. Mares generally commence breeding at three or four years of age. Some commence at two years, which is much too early. A mare will, if only moderately worked, continue to breed till nearly twenty. She is in heat in the early part of the spring; averages about eleven months in foal; but this varies considerably; some have been known to foal four or five weeks before this time, others five or six later. In race-horses, the colt's age is calculated the same, whether he is born in January or May. It is desirable that the mare should go to the horse as earl-

as possible. But in ordinary cases May is the best month; for then the mare foals at a period when there is an abundance of her natural food.

BROOKLIME (*Myositis palustris*). This herb loves shallow streams and wet ditches, like the water-cress, which it resembles in taste. It flowers and seeds in June, July, and August. Brooklime is known by its thick stalk, roundish leaves, and its spikes of small bright blue flowers. It grows about a foot in height, and it strikes root at the lower joints, and the roots are fibrous. The leaves are broad, oblong, slightly indented, round at their edges, and blunt at the point, to use an Irishism. The flowers stand singly upon short foot-stalks, one over another, forming a sort of loose spike. Brooklime possesses slight medicinal virtues; but it should be used fresh, as it loses its properties when dried. It is often eaten in salads, which is a pleasant mode of administering it; but its flavour is in any form warm and agreeable.

In many parts of the United States, the *M. palustris* is called Forget-me-not, Marsh scorpion grass. In French it is the *Oreille de souris*. In swampy places and spring heads, it remains vigorously green through the winter. It flowers from May to September. (*Flor. Cestric.*)

BROOM (the *Spartium scoparium* or *Cytiscus scoparius* of botanists). Pl. 9, d. An evergreen-branched shrub, native of sandy soils throughout Europe. The broom, with its gay yellow flowers, blooming from April to June, its tough stalks, and flat hairy pods, is well known on all barren and waste grounds, growing abundantly in dry gravelly thickets and fields, and is often admitted into shrubberies, for its delicate blooms and curious appearance. It is sown extensively in England as a shelter for game. Its branches, which are tough, are made up into brooms, to which they have given their name. The green stalks and tops of brooms are medicinally employed. They have a bitter nauseous taste, and a peculiar odour when green. The green twigs, when burned, yield a large quantity of carbonate of potash, and several other salts. Broom tops, administered in strong infusion, are emetic and purgative: in smaller doses they are diuretic; and as such have been long employed to excite the action of the kidneys in dropsy; but its efficacy depends on the nature of the dropsy, and its cause. When inflammation is present, broom tops do much harm; and, therefore, like other remedies, its use should not be intrusted to non-professional persons. It may be useful to know that its action is promoted by dilution.

BROOM-GRASS. The *Andropogon purpurascens*, *A. furcatus*, or forked spike-grass, and the *A. mutans*, or beard-grass, are all known in the Eastern States, where they flower in August.

BROOM-RAPE (*Orobancha major*). This is a parasitical plant which is found amongst the red clover; "meaning, perhaps," says Mr. Main, "a robber of broom, from its being frequently found on waste grounds growing on the roots of the common broom, and in fields on the roots of clover." In its first appearance

it resembles the roots of asparagus, just as they break through the ground; the stems rise from six to ten inches high, and without proper leaves, having what are called bractes instead. The flowers are arranged on the stem like those of a hyacinth, but not so showy, being of a dingy brown colour, succeeded by oblong capsules of seeds. A straggling individual plant is sometimes met with amongst ley-wheat feeding on a clover plant, which has escaped destruction by the plough and harrow at wheat sowing; but it never appears again until the field is sown with clover. From a note by Mr. Rham, quoting *Von Aelbrock's Agriculture of Flanders*, p. 283, it would seem that the minute seeds of the broom-rape, which can hardly be observed with the naked eye, exude a glutinous substance, by which they adhere to the seeds of the clover, and with which they are in consequence often sown. (*Journ. Roy. Eng. Ag. Soc.* vol. i. p. 175.) Orobanche is a powerful astringent, and might be advantageously used in chronic diarrhœas.

BROOM, SPANISH (*Spartium junceum*). Pl. 9, e. A handsome shrub, with fragrant yellow blossoms, which appear in July; Miller says, that in cool seasons it will keep blowing until September. It loves a sheltered situation. If raised by seed, sow it as soon as it is ripe, in a shady bed of common earth, kept free from weeds. Plant out the seedlings the following autumn. The white Spanish broom (*Spartium monospermum*) is more tender; therefore it should be sheltered during the winter. It grows well in shrubberies not exposed to a hot sun. Raised from seed. Phillips recommends the Spanish broom for shrubberies, from its long continuance in bloom, from July to October; and he adds, the common broom (*S. scoparium*) may as judiciously be placed at the foot of towering trees, where it will shine as gay in the gloom as a cypress fire in a forest. (*Shrubbery*, vol. i. p. 151.)

BRYONY, BLACK (*Tamus communis*, Gr. *Ἐβρα*, I grow rapidly). This is a wild native plant, and climbs like the white bryony; but it wreathes its stalk around the bushes, having no tendrils. The stalk also runs fifteen feet in length. The leaves are broad, shaped like a triangle, smooth, polished, and of a black green colour. The flowers and berries resemble the white bryony.

BRYONY, WHITE (*Bryonia dioica*). This plant, with its tendrils and leaves, somewhat resembles the vine, and clings like it around the trees and bushes in its progress. It grows in many parts of England under hedges and thickets. The leaves are hairy and broad. The flowers small, and of a greenish white colour, blowing from May till August. The berries are red, and full of seeds. The root is large, rough, and white, and the stalks from ten to twelve feet in length. The root contains a peculiar bitter principle, which has been termed *bryonin*. The root is poisonous, being both violently emetic and purgative, producing symptoms resembling those of cholera. It is sold by herbalists under the name of *Manāra* root. Many ignorant persons have been destroyed by the employment of bryony root, in diseases in which it is said to be useful in old

herbals. Decoctions made with one pound of the fresh root are purgatives for cattle. This is a powerful medicine, and should be given cautiously in small doses, even to cattle.

BUCK. The male of the deer, hare, rabbit, &c.

BUCK-BEAN (*Menyanthes trifoliata*). This is a beautiful wild flower, and deserving of cultivation. It naturally inhabits turbaries, and marshy places. In a garden it will live for many years, if planted in a pot filled with peat earth mixed with sphagnum or bog moss, and plunged in a pan of water; or better still, if planted out in rich soil, where it can be supplied with water from a pond or tank. It is not only a beautiful, but a valuable gift of Providence,—for it possesses powerful effects as a remedy against the fevers prevalent in marshy districts. (*Gardener's Chronicle*.) Withering, in speaking of this plant, says it is possessed of powerful medicinal properties; an infusion of the leaves is extremely bitter, and is prescribed in rheumatism and dropsies; it may be used as a substitute for hops in making beer, and is employed as a purgative for calves. It is easily recognised, possessing a very singular appearance. It grows a foot high; the leaf-stalks rise from the roots, and upon each stalk stand three large oblong leaves, somewhat resembling the garden bean leaves. The stalks themselves are round, thick, and smooth. The flowers are small, white, with a delicate tinge of purple, and hairy inside. They grow together, forming a short, thick spike, and stand upon thick, round, whitish, and naked stalks. The root is long, thick, and of a whitish colour. Buck-bean leaves should be gathered before the flower-stalks appear, and dried. Their powder, taken in tea, or any liquid, is considered excellent for rheumatism and ague.

BUCKEYE. Under this name, Michaux describes two species of trees in the United States, viz. the large buckeye or yellow pavia, (*Pavia lutea*); and the Ohio buckeye or Ohio horse-chestnut (*Pavia ohioensis*).

The *yellow pavia*, or large American buckeye, is first observed on the Alleghany Mountains in Virginia, near the 39th degree of latitude. It becomes more frequent in following the chain towards the southwest, and is most profusely multiplied in the mountainous districts of the Carolinas and Georgia. It abounds, also, upon the rivers that rise beyond the mountains and flow through the western part of Virginia, and the states of Kentucky and Tennessee, to meet the Ohio. It is much less common along the streams which have their sources east of the Alleghanies, and may therefore be considered as a stranger to the Atlantic states, with the exception of a tract thirty or forty miles wide in the Southern States, as it were beneath the shadow of the mountains. It is here called **big buckeye**, to distinguish it from the *Pavia rubra*, which does not exceed eight or ten feet in height, and which is called **small buckeye**.

Michaux states, that he had seen no situation which appeared more favourable to the development of the big buckeye, than the declivities of the lofty mountains in North Carolina, and particularly of the Great Father Mountain,

the Iron Mountain, and the Black Mountain, where the soil is generally loose, deep, and fertile. The coolness and humidity which reign in these elevated regions, appear likewise to be necessary to its utmost expansion; it here towers to the height of sixty or seventy feet, with a diameter of three or four feet, and is considered a certain proof of the richness of the land.

The flowers of this tree are of a light, agreeable yellow, and the numerous bunches, contrasted with the fine dense foliage, lend it a highly ornamental appearance. The fruit is contained in a fleshy, oval capsule, the surface of which, unlike that of the horse-chestnut of Asia and Ohio, is smooth. Each capsule contains two seeds or chestnuts, of unequal size, flat upon one side and convex on the other. They are larger and lighter-coloured than those of the common horse-chestnut, and, like them, are not eatable.

Of American trees, the large buckeye is one of the earliest to cast its leaves, which begin to fall near Philadelphia about the 15th of August, and whilst the other horse-chestnuts are still clothed with their finest verdure. Its foliage and flowering are also tardy, which is deemed an essential defect in a tree, the greatest merit of which is its beauty. The wood, from its softness and want of durability, cannot be made to subserve any useful purpose. In beauty, this species is reckoned inferior to that magnificent tree, the

Ohio buckeye, or common American horse-chestnut, which is not a native of any of the Atlantic states, where, however, it is a favourite ornamental tree. The ordinary stature of the American horse-chestnut is ten or twelve feet, but it sometimes equals thirty or thirty-five feet in height, and twelve or fifteen inches in diameter.

The foliage of this tree appears very early in spring, being very quickly followed by its flowers, which almost cover the tree in white bunches, making a very brilliant appearance. The fruit is of the same colour with that of the foreign horse-chestnut and of the large buckeye, and of about half the size: it is contained in fleshy, prickly capsules, and is ripe the beginning of autumn. Horse-chestnuts are said to injure swine and other stock which eat them.

The bark of the larger trees is blackish, and endowed with a disagreeable odour and highly acrimonious properties. The wood is white, soft, and wholly useless. The value of the Ohio buckeye or American horse-chestnut consists mainly in the beauty of its abundant, precocious, and beautiful foliage and flowers, qualities which bring it into great request as an ornamental tree. (*North Amer. Sylva*.)

For some notice of the European or Asiatic horse-chestnut, see **CHESTNUT**, **HORSE**.

BUCK-HEADING and **BUCK-STALLING**. Provincialisms applied to the cutting hedge-fences off, fence-height.

BUCKHORN. See **PLANTAIN**, **STAR OF THE EARTH**.

BUCK HUNTING. "In common parlance," says Mr. Blaine, "the hunting of a fallow deer, whether male or female, is said to be

buck hunting." This, according to Mr. Chaffin, in the reign of James II., was formerly practised after dinner; it was so fashionable, and so generally delighted in at that period, that even the judges on the circuit were accustomed to partake in it. (*Scott's Field Sports*, p. 435.)

BUCKLE-HORNS. A provincial name for short crooked horns turning inward in a horizontal manner.

BUCKTHORN, COMMON (*Rhamnus catharticus*). A hardy indigenous prickly shrub, common in hedge rows in England; flowering in May, and ripening its fruit in September. The leaves have strong lateral nerves, are ovate, toothed, with linear stipules; the flowers are yellowish-green, and are succeeded by a black berry, which is glossy, and the size of a large pepper-corn, containing three or four seeds, and a violet-red pulp. The bark is glossy and dark-coloured. This shrub likes a sheltered situation, and succeeds in any soil. It is propagated by seed, layers, and grafts. The juice of the unripe berries is a deep green dye, if boiled with a little alum. The juice contains a purgative principle, which enables it to operate as a powerful cathartic; but its action is accompanied with much griping and thirst. It was formerly often used as a domestic purgative; but the frequent violence of its action has caused its disuse.

The *Rhamnus* or buckthorn genus of plants is very numerous, ten species being found in the United States, chiefly in the warmer parts. The leaves of a species found in China, the *Rhamnus theeans*, resemble those of the tea-plant, and pass as a substitute for tea among the indigent population of that country. The buckthorn family of plants are all either very small trees or shrubs with the smaller branches often terminating in spines or thorns, qualities which fit them for hedges, for which purpose the common buckthorn (*Rhamnus catharticus*) is a favourite about Boston and other parts of New England, where the English and Virginia thorns will not stand the climate. The buckthorn, on the contrary, will grow in almost any climate and upon every variety of soil.

A species of *rhamnus*, called the *broadleaved alaternus*, a native of the south of Europe, is an ornamental evergreen, the blossoms of which are greatly frequented by the honey-bee. It is a rapid growing shrub, and useful for thickening screens, clothing walls, &c.

The *sea* or common sallow thorn, the *Hippophae rhamnoides* of Linnæus, is a very important shrub, growing wild on sandy shores, in various parts of the British coast, where it sometimes attains the height of eight or ten feet. Its bark is light brown, the wood white, the small leaves of a sea-green colour, but silvery white below. The leaves appear early in spring; the yellow flowers in June and July; the fine red berries late in autumn.

In situations contiguous to the sea-shore, or the banks of rivulets, this shrub eminently deserves to be cultivated, as it is well calculated to bind a sandy soil, and to prevent the water from penetrating through banks and fences. It may be raised from seeds, but more expeditiously by planting layers, or propagating it from the very abundant spreading roots.

On account of its 'horny points, it affords excellent hedges, even on a sandy soil.

Although cows refuse the leaves of the sea-buckthorn, yet they are browsed upon by goats, sheep, and horses. The berries are strongly acid, with an austere vinous flavour: in Lapland they are pickled and used as spice, but the fishermen of the Gulph of Bothnia prepare from them a rob, which, added to fresh fish, imparts a very grateful flavour.

From the leaves of this shrub, M. Suckow obtained an agreeable dark-brown dye for wool and silk, first treated with vitriol of iron (*copperas*): Dambourney succeeded in producing a similar colour on cloth that had been previously steeped in a solution of bismuth.

BUCKWHEAT (Germ. *buchweizen*). The name of a particular species of grain, of which, for the sake of their seeds, there are two species cultivated in Europe:—1. The common buckwheat (*Polygonum fagopyrum*), Pl. 3, g; 2. The Tartarian buckwheat (*P. tataricum*), h; and another in China and Tartary (*P. emarginatum*), i. A new kind of buckwheat, known to the peasants of Germany by the name of *Wild Italian buckwheat*, they prefer to the common buckwheat, because it is more productive, hardier, and has whiter and more savoury meal. This is described in the *Eull. des Scien. Agr.*, April, 1831. (*Quart. Journ. Agr.* vol. iii. p. 368.) Its flower is said to be deeper-coloured, and smaller.

Buckwheat is a plant known in almost every part of the world. It has been supposed to have been first known in Europe after the time of the Crusades. The French, in fact, call it *blé Sarrazin*. In China, Japan, and Russia, it forms a very considerable portion of the food of the inhabitants; it is likewise generally eaten in Switzerland and the southern parts of France, and in Flanders it is a considerable branch of husbandry. Gerard speaks of it as cultivated in England about the year 1597, particularly in the counties of Lancashire and Cheshire. It appears, however, to have made small progress in this kingdom, and has received less attention than it deserves. It thrives well in almost any dry soil, even those of the poorest kinds: and in most of the arable districts it is sown on the inferior sorts of land; as, when cultivated on the richer kinds of soil, it is found to run too much to straw. It is well adapted to light sandy lands. The quantity of seed sown varies from five to eight pecks per acre. Buckwheat is an annual. It has a strong, cylindrical, reddish, branching stem, about two feet in height, with alternate ivy-shaped leaves; the flowers, which are white, tinged with red, are in bunches at the end of the branches, and are succeeded by black angular seeds. Its flowers are very attractive to bees. It begins flowering in July, and is generally fit to mow about the beginning of October. If put together, says Mr. Main, a little green or damp, it does not much signify; for, although ever so mouldy, the grain is never damaged, and the more mouldy it is, the earlier it can be thrashed. It is the easiest of all barn-work for the thrasher. (*Quart. Journ. Agr.* vol. vii. p. 180.)

In England, the proper time for sowing

buckwheat is in May, when there is no longer any danger to be apprehended from the frosts; for so tender is this vegetable at its first appearance, as to be unable at an earlier period to withstand the vernal cold. The slightest frost in their infant state would infallibly cut off the young shoots; and as, from this circumstance, it must be sown at a season when dry weather may be expected, the crop, on that account, not unfrequently fails. The produce, which varies with the seasons (and this is rather an uncertain crop), ranges from two to four quarters per acre. It is commonly grown in England in preserves, as food for pheasants and partridges. It is an excellent food for poultry; pigs thrive upon and are fond of it (it is commonly given to them mixed with potatoes); and when bruised, it is good food for horses, two bushels being equal, for this purpose, it is said, to three of oats (a bushel weighs about forty-six pounds). Cows, when fed with it, yield a large increase of milk. Sheep, when fed upon the plant when in blossom, stagger and tumble about as if drunk. It is sometimes made into hay, which is nutritive, but tedious to make, and should be consumed before the winter. It is often grown on poor exhausted soils, and ploughed in when in bloom; in this way it increases very materially the fertility of the soil, and is a mode often practised in Essex, Suffolk, Norfolk, and in Scotland. Mr. Ballingal has given an account of his experiments with it upon a clay loam recently limed; from the result of which he warns his brother farmers that it is "needless to attempt to grow it upon damp soils, or to expect full crops upon lands exhausted by over-cropping." (*Trans. High. Soc.* vol. ii. p. 125.)

In reaping buckwheat, many farmers prefer pulling it, as less likely to shed the seed. The morning, or late in the evening, should be chosen for this purpose, when the dew is upon the plant. M. Vauquelin found 100 parts of its straw to contain 29.5 of carbonate of potash, 3.8 of sulphate of potash, 17.5 carbonate of lime, 13.5 carbonate of magnesia, 16.2 of silica, 10.5 earth of alum, and 9 of water.

Vast quantities of this grain, says Mr. Main, are annually imported into England from Holland and other northern countries, for the use of the gin-distilleries, who also consume considerable quantities of British growth, which, not being kiln-dried, as most of the Dutch grain is found to be, is more valued. The average quantity of buckwheat imported into England is about 10,000 quarters annually. It pays the same duty as barley. (*McCulloch's Com. Dict.*) For illustrations of the varieties of buckwheat, see Pl. 3.

Buckwheat is extensively cultivated in the United States, the species usually sown being the *Polygonum fagopyrum* of botanists. The grain affords a favourite article of food. It is generally thought to be a severe crop upon land, and for this reason is seldom sown on highly improved ground. Rough and hilly districts are considered peculiarly favourable to the culture of buckwheat, which is admirably adapted to subdue new or wild lands. Besides the Climbing Buckwheat (*Polygonum*

scandens), found in the Middle States and elsewhere, twining round bushes in moist thickets, &c., eight or ten additional varieties are enumerated in the United States. (*Flora Cestrica.*)

Buckwheat comes to maturity so quickly, that it is usual to sow it upon the same ground from which wheat or other grain crops have been taken. It flourishes best in a mellow, dry, loose, sandy soil, but even on the poorest land, so that it be not moist, it will produce a tolerable crop in from three to four months after sowing. When intended for seed, it is best to put in the crop early enough to allow the grain to become perfectly matured before frost. For this purpose June or the first of July is soon enough in the Middle States. In the state of New York, buckwheat is frequently sown in August along with winter wheat, affording a ripe crop in the fall, without injury to the wheat, which grows along with and succeeds it. When sown broad-cast, the usual manner, a bushel of buckwheat is generally put upon the acre. Half the quantity is said to answer when put in with a proper drill machine. When harvested, it is usual to mow it with the scythe, and allow it to remain some time before it is taken from the field. Being very liable to heat, it is advisable to put it into small stacks of about four to six loads each. Larger stacks, or close housing, would subject it to spoiling. The quantity of produce varies greatly, according to circumstances of soil and season. In the northern part of Pennsylvania and still farther north, it is so often nipped before maturity by autumnal frosts, as to be a precarious crop. From thirty to forty-five bushels per acre may be considered an average yield in a favourable season, but sixty or eighty bushels are not unfrequently produced. Its flowers bloom and fade successively for a long time. It is thought that the crop would be much more productive, if the same uniformity in blowing and ripening existed that is observed with other grains. The buckwheat flour most preferred in the southern cities, where it commands a higher price, is that which comes from New Jersey and Pennsylvania. It is common, especially in New Jersey, to grind up with the buckwheat a fifth or sixth part of Indian corn, a peculiar kind of which, being very soft and white, is raised for the purpose. The form in which it is brought to the table is almost universally that of flat cakes, made of batter raised by means of yeast, or, what is still preferable, and requires but a few minutes in the preparation, adding a seidlitz powder to the mixture of flour and water, which causes the batter to rise at once, from the carbonic acid gas disengaged. These cakes are soft and spongy, and absorb a large quantity of butter, which is always put on while they are very warm. Considering the large amount of butter used, they cannot be regarded as economical food, except where butter is very cheap. Persons troubled with feeble digestion should never eat buckwheat prepared in this way. In Tuscany, buckwheat is mixed with barley, ground, and the flour made into bread, which possesses the property of retaining its moisture much longer than that of pure wheat; and, though of a darker colour, it is thought to be equally nou-

rishing. In Germany, a very palatable grit, or coarse-grained meal, is made of it, which serves as an ingredient in pottage, puddings, &c. In Brandenburg, not only ale and beer are brewed from buckwheat mixed with malt, but likewise a very excellent spirit, of a bluish shade, is obtained by distillation, in flavour resembling French brandy.

The seeds of buckwheat afford excellent food for cattle, and are very fattening to poultry and hogs, though it is said to make them liable to a scabby eruption. When cut in proper season, that is to say, about the time of flowering, when the stems and leaves are succulent and tender, it affords an excellent provender for cattle, especially for milch cows, which are very fond of it. Some intelligent farmers have thought it, for the last purpose, superior to timothy hay.

One of the purposes to which buckwheat has been applied,—and for which it appears, from the rapidity and exuberance of its growth, peculiarly adapted,—is the ploughing down to add fertility to the land. This can be done when the soil is too far exhausted to produce clover for a similar purpose. "We cannot," says the editor of the Theatre of Agriculture, "too much recommend, after our old and constant practice, the employment of this precious plant as a manure. It is certainly the most economical and convenient the farmer can employ. A small quantity of seed, costing a mere trifle, sows a large surface and gives a great crop. When in flower, first roll, and plough it in, and it is soon converted into manure." This crop is recommended by Mr. Taylor, in the Maine Farmer, as an effectual destroyer of that frequent pest of the field called *couch-grass*, *quick-grass*, &c. For this purpose it must be sown as early in the season as frost will permit, and as soon as it gets into flower, rolled down and turned under with the plough. Another crop is then sown on top of the first, and harrowed in; and, if the season be not unfavourable, it will ripen and afford a harvest before frost sets in.

The fresh blossoms and succulent stems of buckwheat have been applied in Europe to the purposes of dyeing wool, &c. The infusion, by the addition of preparations of bismuth and tin, produces a beautiful brown colour. From the dried flower-bundles different shades of green are obtained. The Siberian species of buckwheat, in particular, yields a fine yellow, which, upon boiling the wool still longer in the dye, changes into a golden tint, and at length becomes a beautiful yellow.

BUD (Fr. *bouton*). The germ or first fruit of a plant, which is the organized rudiment of a branch or flower. Buds proceed from the extremities of the young shoots, and also along the branches, sometimes single, sometimes two and two, either opposite or alternate, and sometimes collected in greater numbers. In general, we may distinguish three kinds of buds; the *leaf-bud*, the *flower-bud*, and *mixed buds* which contain both in one covering. The first species (*foliferous buds*) contains the rudiments of several leaves, which are variously folded over each other, and surrounded by scales. The second species, or *flower-bud* (*floriferous buds*),

contains the rudiments of one or several flowers, folded and covered in a similar manner. The third sort, which is the most common of any, produces both flowers and leaves. A leaf-bud is constructed thus:—in its centre it consists of a minute conical portion of soft, succulent cellular tissue (the plumule or rudiment of the new twig), and over this are arranged rudimentary leaves, in the form of scales. These scales are closely applied to each other; those on the outside are the largest and thickest, and those in the interior are smaller and more delicate. In cold countries, the external scales are often covered with hair, or a resinous varnish, or some other contrivance, which enables them to prevent the access of frost to the young and tender centre which they protect, for they are strictly hybernacula; but in warm countries, where such a provision is not required, they are green and smooth, and much less numerous. The cellular centre of a bud is the seat of its vitality; the scales that cover it are the parts towards the development of which its vital energies are first directed. (*Penny Cyclopædia*, vol. v. p. 524.)

BUD. A term made use of in some districts for a weaned calf of the first year; probably from the horns then beginning to bud or shoot forth.

BUDDING, or grafting by germs, says Mr. Loudon (*Encyc. of Gard.* p. 2050), consists, in ligneous plants, in taking an eye or bud attached to a portion of the bark of different sizes and forms, and generally called a shield, and transporting it to a place in another or a different ligneous vegetable. In herbaceous vegetables the same operation may be performed, but with less success. It may also be performed with buds of two or three years' standing, and on trees of considerable size, but not generally so. The object in view in budding is almost always that of grafting, and depends on the same principle, all the difference between a bud and a scion being, that a bud is a shoot or scion in embryo; in other respects, budding is conducted on the same principles as grafting. In every case, the bud and the stock must be botanically related. An apple may be budded on a pear or thorn, but not upon a plum or peach. Common budding is performed from the beginning of July to the middle of August.

It is indispensable that the bud to be inserted should be fully formed, or ripe. After the incision of the stock, great care must be taken in raising the bark that the *cambium* be not scraped or injured. The *cambium* is that soft portion between the wood and the bark destined to give support to the descending fibres of the buds, which fibres subsequently become embedded in it. In budding, therefore, the bark must be very carefully lifted up, and not forced from the wood with a bone or metal blade as is too often done.

For propagating choice fruit, the operation of budding possesses several advantages over that of grafting. "It is," says Buel, "more readily performed, with fewer implements, less preparation, and with greater success; it does not injure the stock if unsuccessful, and the operation may be twice or thrice repeated

the same year, as the season for its performance is protracted, for some one or other of the varieties, for some three months. Although July and August constitute the ordinary season for budding, the plum and the cherry may often be budded in the latter part of June, and the peach, apricot, and nectarine as late as the middle of September. Youth may readily acquire the art, by little practice, under the directions we are about to give; and we know a young lady who is an adept in it, and who practises it annually as a pleasant recreation, as well as a useful labour. We have often been treated with delicious peaches produced by the buds which she has inserted.

The first consideration is to provide stalks, if this provision has not already been made. Seeds may be collected the coming season in almost every family. Those of stone fruit may be mixed with earth, or deposited in a hole in the garden, and in the autumn buried superficially in the earth, to expose them to the expanding influence of the frost; and in the spring those of the peach and plum that have not burst the shell should be cracked, and the whole sown in a well-prepared seed-bed. The cherries may be sown immediately after they are taken from the fruit, and the apple, pear, and quince either in autumn or spring. All the kinds will generally grow the first season. The same rule applies to plants as to animals: the better condition they are kept in while young, the more profitable they will become at maturity. Thus two or three roods of ground will suffice a farmer for a nursery of choice fruit, from which he may replenish his orchard and his garden at pleasure, and readily appropriate to his use every new variety which comes under his observation. No one will regret the trifling labour and attention which he has bestowed on a little plantation of this kind, after he has begun to realize the fruits of it. Ornamental shrubs and trees, to embellish the grounds about his buildings, may be added without cost and with trifling labour.

A bud is an organized plant in embryo, with roots, branches, and foliage, and, like a seed, possesses individual vitality capable of development and the reproduction of its species. The process of budding is the transferring this embryo plant from its parent tree to another tree, which must at least be of the same genus, if not of the same species. The apricot and nectarine may be, and generally are, budded upon the peach; the plum and the peach are budded on each other, and the pear and apple may be worked on the wild crab and hawthorn; and the former is put on the quince to produce dwarf trees. To render the transfer or budding successful, three things are requisite: 1. That the bud be in a proper condition to transfer; 2. That the stalk be in condition to receive and nourish it; and, 3. That the transfer be skilfully made. The bud ought to be matured, i. e., of full growth, and yet not so hard and firm as to cause injury in separating it from its parent. The stock must peel freely, as this is necessary for the insertion of the bud, and indicates the presence of what is termed the cambium, which is the soft

partially-formed woody matter underlying the bark, and which ripens into indurated wood. It is the source of nourishment to the bud, and the bond of union between it and the stock. The operator must therefore use caution that he injures neither the bud, the bark, nor the cambium, as these all exercise important offices in effecting the union; and he must withal take care to apply his ligatures properly. It will be seen, from these remarks, that both the stock and the graft should be in a state of active growth, and the more vigorous the better, when the budding process is performed. It is also preferable to bud when the weather is cloudy, but not wet. Twigs for budding may be preserved for many days with care. They should be immediately divested of their leaves, but not wholly of their leaf-stalks or petioles, to prevent the exhaustion of moisture, and may then be wrapped in fresh grass, wet cloths, or with their butt ends preserved in moisture.

Fig. 2.

The only implement necessary is a budding-knife (fig. 2), and the only preparation some bass matting, or the inner bark of the bass-wood or linden. Filaments torn from the husk of Indian corn are also recommended.

Professor Thouin enumerates twenty species or varieties of grafting, most of which are only practised by amateurs and professional gardeners. We shall describe only the common mode, which is in general practice in nurseries. We take it from the Encyclopedia of Gardening.

Shield-budding, or T budding, is thus performed: Fix on a smooth part of the side of the stock, rather from than towards the sun, and of a height depending, as in grafting, on whether dwarf, half, or whole standard trees are desired; then, with the budding-knife, make a horizontal cut across the rind, quite through to the firm wood; from the middle of this transverse cut make a slit downward, perpendicularly, an inch or more long, going also quite through to the wood. This done, proceed with all expedition to take off a bud; holding the cutting or scion in one hand, with the thickest end outward, and, with the knife in the other hand, enter it about half an inch or more below a bud, cutting nearly halfway into the wood of the shoot, continuing it with one clear slanting cut about half an inch or more above the bud, so deep as to take a part of the bud along with it, the whole about an inch and a half long (*a*, fig. 1); then directly with the thumb and finger, or point of the knife, clip off the woody part remaining to the bud; which done, observe whether the eye or germ of the bud remain perfect; if not, and a little hole appears in that part, it is improper, or, as gardeners express it, the bud has lost its root, and another must be prepared. This done, placing the back part of the bud or shield between your lips, expeditiously with the flat haft of the knife separate the back of the stock on each side of the perpendicular cut clear to the wood (*c*), for the admission of the bud, which directly slip down, close between

the wood and bark, to the bottom of the slit (*d*). The next operation is to cut off the top part of the shield (*b*) even with the horizontal first-made cut, in order to let it completely into its place, and to join exactly the upper edge of the shield with the transverse cut, that the descending sap may immediately enter the back of the shield, and protrude granulated matter between it and the wood, so as to effect a living union. The parts are now to be immediately bound round with a ligament of fresh bass (*e*), or other suitable substance, previously soaked in water to render it pliable and

Fig. 1.

tough, beginning a little below the bottom of the perpendicular slit, proceeding upward closely round every part, except just round the eye of the bud, and continue it a little above the horizontal cut, not too tight, but just sufficient to keep the whole close, and exclude the air, sun, and wet.

Future Treatment.—In a fortnight, at farthest, after budding, such as have adhered may be known by their fresh appearance at the eye; and in three weeks all those which have succeeded well will be firmly united with the stocks, and the parts being somewhat swelled in some species, the bandage must be loosened, and a week or two afterward finally removed. The shield and bud now swell in common with the other parts or the stock, and nothing more requires to be done till spring, when, just before the rising of the sap, they are to be headed down close to the bud, by an oblique cut, terminating about an eighth or quarter of an inch above the shield. In some cases, however, as in grafting, a few inches of the stalk is left for the first season, and the young shoot tied to it for protection from the winds."

BUFFALO (from the Italian; Lat. *bubalis*). A term originally applied to a species of antelope; but afterwards transferred, in the age of Martial, to different species of the ox. In modern zoology, the buffaloes, or the "bubaline group" of the genus *Bos*, include those species which have the bony core of the horn excavated with large cells or sinuses, communicating with the cavity of the nose; the horns are flattened, and bend laterally with a backward direction, and are consequently less applicable for goring than in the bisons or taurine group of oxen. The buffaloes are of large size, but low in proportion to their bulk; they have no hunch on the back, and only a small dewlap on the breast; the hide is generally black, the tail long and slender. The buffaloes occupy the warm and tropical regions of the earth; they avoid hills, and prefer the coarse vegetation of the forest and swampy regions to those of open plains; they love to wallow and lie for hours sunk deep in water; they swim well,

and cross the broadest rivers without hesitation. Their gait is heavy, and they run almost always with the nose horizontal, being principally guided by the sense of smelling. They herd together in small flocks, or live in pairs, but are never strictly gregarious in a wild state. The females bear calves two years following, but remain sterile the third; they propagate at four and a half years old, and discontinue after twelve. "The common buffalo (says Professor Low) has come to us, beyond a question, from Eastern Asia. He seems to have been introduced into Italy about the sixth century, and is now an important animal in the rural economy of that country. He is used by the Italians as food and as the beast of labour, and may be said to form the riches of the inhabitants in many parts of the country. He is cultivated, too, in Greece and Hungary. The milk of the female is good, but the flesh is held in less esteem than that of the common ox. The pace of the animal is sluggish; but from the low manner in which he carries his head, throwing the weight of his great body forward when pulling, he is well suited for heavy draught. But this is not a property sufficiently important to cause the introduction of the buffalo into the agriculture of northern Europe, and he is not likely, therefore, to be carried beyond the countries where he is now reared." Buffalo hunting on elephants is one of the field sports of the East; and this animal is also hunted on foot with avidity by the Caffres at the Cape of Good Hope, as well to get rid of a dangerous foe as to furnish themselves with food from his flesh and leather from his hide. (*Brande's Dict. of Science; Blaine's Encyc. of Rural Sports; Elements of Practical Agriculture.*) For American Buffalo, see **Bison**.

BUFFALO BERRY TREE (*Shepardia magnoides*). Silver-leaved Sheperdia. A very beautiful tree, discovered by Mr. Nuttall in Missouri. The tree is of upright growth and thorny, the leaves small and of a delicate and silvery appearance. The fertile and barren flowers are produced on different trees. The fruit consists of berries about the size and appearance of large currants, of a fine scarlet colour, and very beautiful, enveloping the branches in profuse clusters. It has a rich taste, and is considered valuable for making into tarts and preserves.

BUGLE, COMMON (*Ajuga reptans*). This very pretty wild plant grows in woods, copses, moist pastures, and shady places, flowering in April, May, and June. It is a perennial; has blue flowers, upright leafy stalks, and glossy leaves, of a deep purplish-green colour, oblong, broad, blunt at the point, and slightly indented round the edges, some growing immediately from the root. The flower-stalks rise eight or ten inches high, of a pale green—often purplish—and have two leaves at each joint, which joints are far apart from each other. The joint leaves are as large as those growing from the root. The scentless flowers are blue and white, sometimes entirely white, growing round the upper part of its stalk, forming a kind of loose spike. The cups remain, when the flower has fallen off, to hold its seeds: This plant is often denominated *sicklewort*, and

herb carpenter. The roots (says Smith) are slightly astringent; but the herb has little taste or smell, and still less of any healing or vulnerary property. The white variety abounds in the Isle of Wight; and a flesh-coloured one has sometimes been observed. In dry mountainous situations the plant acquires a considerable degree of hairiness. The French, who are great herbalists, affirm, that "with bugle and sanicle, no one needs a surgeon."

Besides the common bugle, Smith, in his *English Flora*, (vol. iii. p. 65—67), enumerates three other species, the alpine bugle, pyramidal bugle, and ground pine or yellow bugle (*Ajuga chamapitys*).

BUGLE-HORN (from *bucula*, a heifer). A wind-instrument, much more commonly employed in the sports of the field formerly than at present. It has been, however, in our days, much improved for musical purposes by the introduction of keys.

BUGLE-WEED (*Virginian lycopus*), a creeping perennial found in the Middle States, frequenting swamps and moist woodlands, producing minute white flowers in June and July. It constitutes a prominent article in the materia medica of certain German empirics, in the city of Lancaster, and other parts of Pennsylvania,—who prescribe an infusion as a certain remedy for a "dry liver," an infirmity which, they allege, afflicts a large proportion of those credulous persons who consult them. (See *Flor. Cestricea*.)

BULB (Lat. *bulbus*; Gr. *βυλλος*). A bud usually formed under ground, having very fleshy scales, and capable of separating from its parent plant. Occasionally it is produced upon the stem, as in some lilies. It contains the rudiments of the future plant, and partakes of the character of the bud (which see). In bulbous plants, as the tulip, onion, or lily, what we generally call the *root* is in fact a bulb or hybernaculum, or winter case, which incloses and secures the embryo or future shoot. At the lower part of this bulb may be observed a fleshy disk, knob, or tubercle, whence proceed a number of fibres or threads. This knob, with the fibres attached to and hanging from it, is, properly speaking, the true root; the upper part being only the cradle or nursery of the future stem, which, being replaced a certain number of times, the bulb perishes; but not till it has produced at its sides a number of smaller bulbs or cloves for perpetuating the species. In bulbous plants, where the stalk and former leaves of the plant are sunk below, into the *bulb*, the radicles or small fibres that hang from the bulb are to be considered as the root; that is, the part which furnishes nourishment to the plant: the several rinds and shells whereof the bulb chiefly consists successively perish, and shrink up into so many dry skins, betwixt which, and in their centre, are formed other leaves and shells, and thus the bulb is perpetuated. There are several kinds of bulbs; namely, 1. The tunicated bulb (*Bulbus tunicatus*), formed of thin membranous layers, as, for example, the *onion*; 2. The scaly bulb (*B. squamosus*), formed of fleshy abortive leaves, not in layers, as in the *lily*. The cloves, which are produced between the scales of

bulbs, are often, as it were, starved, when the bulb throws up a vigorous flowering stem; thence, in order to propagate bulbs, the flowering stem should be destroyed as soon as it appears.

BULLACE TREE, WILD (*Prunus insititia*). A small tree, chiefly growing in hedges and plantations, with irregularly-spreading round branches, for the most part tipped with a sharp straight thorn. There are several varieties of the black kind, differing in size and flavour, some good even in a fresh state, and of more or less excellence when dressed. (*Smith's Eng. Flor.* vol. ii. p. 356).

BULLEN. A provincial name applied to the hempstalk when the bark is stripped from it.

BULRUSH (*Scirpus lacustris*). A perennial found commonly in clear ditches, ponds, and the borders of lakes and rivers; flowers in July and August. (*Smith's Flora*, vol. i. p. 56.) From this plant the bottoms of chairs, mats, &c. are made. The common bulrushes of the English marshes, which bear masses of brown flowers, are the *Typha latifolia* and *angustifolia*. See *Rusu*.

BUNIAS. The oriental bunias (*Bunias orientalis*, Pl. 9, *k*) is a perennial plant, with leaves, branches, and its general habit of herbage, not unlike the wild chiccory. It is a native of the Levant or eastern shores of the Mediterranean, and has been cultivated by way of experiment in the grass garden at Woburn. It is less productive than chiccory, bears mowing well, and affords the same nutriment, in proportion to its bulk, as red clover. (*Loudon's Ency. of Agr.*)

BUR. The rough head of the burdock, &c.

BURDOCK (*Arctium*). There are two species, the *A. lappa*, common burdock or clotbur, and the *A. lardana*, woolly-headed burdock. This very cumbrous weed is removed the first year of its growth by stubbing, like other things comprehended by farmers under the name of docks, and paid for accordingly to the weeder. It is also very commonly found in waste ground, by waysides, and among rubbish. (*Smith's Eng. Flora*, vol. iii. p. 379.) It grows a yard high, with large leaves of a triangular shape, and of a whitish green colour. The stalks are round, solid, and tough. The florets are small and red, and they grow among the prickles of those heads called burs, which stick to the clothes of passers-by. The root is long and thick, brown outside, and whitish within. The plant is a biennial, and flowers in July and August. The root in decoction is a diuretic and sudorific; but it is of little value, except as a vehicle for more important medicines in some affections of the skin. This is a great remedy among village doctresses, who sometimes apply the bruised leaves to the soles of the feet in hysterics. Either the root or seeds decocted, or infused, are equally useful with the leaves. The root of the *lesser burdock*, or *xanthium* (*Bardana minor*), has a bitter and acrid flavour, and is useful in scrofulous disorders. A decoction of the root should be persevered in for a considerable length of time.

BURGLARY. The breaking into a dwelling-house in the night with a felonious intent.

The 7 W. 4, & 1 Vict. c. 86, s. 2, enact, that whosoever shall burglariously break and enter into any dwelling-house, and shall assault with intent to murder any person being therein, or shall stab, cut, wound, beat, or strike any such person, shall be guilty of felony, and being convicted thereof shall suffer death. S. 3 enacts, that whosoever shall be convicted of the crime of burglary shall be liable, at the discretion of the court, to be transported beyond the seas for the term of the natural life of such offender, or for any term not less than ten years, or to be imprisoned for any term not exceeding three years. S. 4 enacts, that, so far as the same is essential to the offence of burglary, the night shall be considered to commence at nine of the clock in the evening of each day, and to conclude at six of the clock in the morning of the next succeeding day. (*Archbold's Crim. Law.*)

BURGOT. A provincial word applied to yeast. It is sometimes pronounced *burgood*.

BUR-MARIGOLD (*Bidens*). This is an herbaceous, mostly annual, genus of plants, flowering in August and September. It is met with very frequently in watery places, and about the sides of ditches and ponds. There are two species, with one or two varieties in each. In the three-lobed bur-marigold (*B. tripartita*), the root is tapering with many fibres; stem two or three feet high, erect, solid, smooth, leafy, with opposite axillary branches. Leaves dark green, strongly serrated, in three deep segments, sometimes five. Flower, terminal, solitary, of a brownish-yellow, somewhat drooping, devoid of beauty and of fragrance. Seeds with two or three prickly angles, and as many erect bristles; likewise prickly with reflexed hooks, by which they stick like burs to any rough surface, and are said sometimes to injure fish by getting into their gills. The herb of this species gives a yellow colour to woollen or linen. The nodding bur-marigold (*B. cernua*) has a root with many stout fibres, herb more erect and taller, with less extended branches than the foregoing species. Leaves undivided, pointed, and less deeply serrated. Flowers drooping, though their stalks are quite straight to the very summit; larger and handsomer than the last. (*Smith's Eng. Flora*, vol. iii. p. 398.)

Among the species of bidens or bur-marigold, found in the United States, are the following: the chrysanthemum-like bidens, commonly called beggar-ticks, an annual; and the bipinnate bidens, popularly called Spanish needles. These and the other American species of bidens or burweed are noted for mature akenes adhering, by their barbed awns, to the clothing of those who go among them in autumn. They are rather troublesome weeds along fence-rows, &c., and bloom and ripen their seeds late in the season.

BURNET, COMMON (*Pimpinella saxifraga*). There are three species of burnet; namely, *burnet saxifrage*, *dwarf burnet*, and the *greater burnet*. The common burnet plant (Plate 9, a) was, a quarter of a century since, much cultivated as a green crop, from its being able to thrive on very poor, thin, and sandy soils, but it has been gradually super-

seeded by better grasses. Its growth is rather slow. Cattle prefer it to clover and rye-grass, but sheep do not. (*Ann. of Agr.* vol. i. p. 394.) It is sown in spring-time, the same as other grass seeds, and withstands severe weather. It should be fed off when young (*Ibid.* vol. ii. p. 176); and then, says Arthur Young, "it is one of the best grasses for sheep" (*Ibid.* p. 369), who are at that stage of its growth exceedingly fond of it. About 7 lbs. of seed suffice for an acre (*Ibid.* vol. xvi. p. 355); and the produce is six or seven bushels per acre, on moderate land. (*Ibid.* vol. xx. p. 237.)

BURNET, SALAD, SMALL or UPLAND (*Poterium sanguisorba*, from the Greek *πρωτρηρα*, a cup, used in cool tankards). The stem, which is angular, smooth, and leafy, rises one to two feet high, furnished with glaucous-green, smooth, pinnated leaves, with sharply cut stipules, in pairs at the base of the footstalk. The flowers are fertile and barren; the latter with crimson stamens resembling elegant silk tassels. (*Smith.*) It delights in a dry, poor soil, abounding in calcareous matter; any light compartment that has an open exposure, therefore may be allotted to it, the only beneficial addition that can be applied being bricklayers' rubbish or fragments of chalk. A small bed will be sufficient for the supply of a family. It may be propagated either by seed, or by slips and partings, or offsets of the roots. The seed may be sown towards the close of February, in open weather, and thence until the close of May; but the best time is in autumn, as soon as it is ripe; for if kept until the spring, it will often fail entirely, or lie in the ground until the same season of the following year, without vegetating. It may be inserted in drills, six inches apart, or broadcast; in either mode, thin, and not buried more than half an inch. The plants must be kept thoroughly clear of weeds throughout their growth. When two or three inches high, they may be thinned to six inches apart, and those removed placed in rows at the same distance, in a poor, shady border, water being given occasionally until they have taken root, after which they will require no further attention until the autumn, when they must be removed to their final station, in rows a foot apart. When of established growth, the only attention requisite is to cut down their stems occasionally in summer, to promote the production of young shoots, and in autumn to have the decayed stems and shoots cleared away. If propagated by partings, &c. of the roots, the best time for practising it is in September and October. As it grows freely from seed, this is not usually practised. They are planted at once where they are to remain, and only require occasional watering until established. The other parts of their cultivation are as for those raised from seed. For the production of seed, some of the plants must be left ungathered from, and allowed to shoot up early in the summer; they flower in July, and ripen abundance of seed in the autumn. The leaves taste and smell like cucumbers, thence the plant is used to flavour salads. (*G. W. Johnson's Kitchen Garden.*)

BURNING. See **ARSON**.

BURNING OF LIME. See **LIME**.

BURNS, in live stock, are best treated by a lotion composed of lime-water and linseed-oil, equal parts, applying it frequently; this allays the inflammation very rapidly.

BURNT CLAY. See **ASHES**.

BUR-REED (*Sparganium*). Smith (*Eng. Flora*, vol. iv. p. 73) enumerates three species: 1. The branched bur-reed (*S. ramosum*); 2. The unbranched upright bur-reed (*S. simplex*); 3. The floating bur-reed (*S. natans*). They are all creeping-rooted, aquatic, juicy, smooth, upright, or floating herbs, and found in pools and ditches, and the margins of ponds and rivers: common: the last named principally in muddy fens, or slow rivers. The bur-reed is a perennial, flowering in July and August; the stems of some of the species attain to the height of three or four feet. The herbage of the branched bur-reed serves for package along with similar coarse grassy plants, and is softer and more pliant than most of them, not cutting the hand by any sharp edges, like *carices* or ferns. The unripe burs are very astringent. A strong decoction of the burs makes a wash for old ulcers. Dr. Darlington describes an American species of bur-reed, frequent in ditches, sluggish streams, &c., in the Middle States. (*Flor. Ces.*)

BURROW (Teut. *bergen*, to cover). A provincial word, signifying a heap or hillock, hence stone-burrows, peat-burrows, &c.

BUR-WEED (*Xanthium strumarium*). The broad-leaved bur-weed is an annual plant, flowering in August and September, found in rich moist ground, or about dunghills in the south of England; but rare. It is herbaceous or somewhat shrubby, rather downy, of a coarse habit, root fibrous; stem solitary, erect, branched, leafy, two feet high, solid; leaves on long stalks, heart-shaped, two or three inches wide; clusters of four or five fertile green flowers, and one or two barren ones, making no show. Old tradition reports that the xanthium is good for scrofulous disorders, as the specific name seems to indicate; but it is now out of use. The generic appellation alludes to a quality of dyeing yellow, which Dioscorides mentions. (*Smith's Eng. Flora*, vol. iv. p. 136.)

The scrofulous xanthium, clot-weed, or cockle-bur is an obnoxious weed, found in the United States about farm-yards, road-sides, &c. It is an annual not much inclined to spread, and therefore, by a little attention, could generally be easily got rid off. The burs are a great annoyance in the fleeces of sheep. (*Flor. Cestr.*)

BUSH (Teut. *busch*; Dan. *busk*). A thick shrub, or a collection of shrubs or plants, growing close together, so as to form a sort of clump. It is also a provincial word, signifying the box of the nave of a wheel.

BUSH-DRAINING. A term applied to a kind of draining, which is done by putting in, or filling the drains with bushes. See **DRAINING**.

BUSHEL (Old Fr. *buschel*; low Lat. *bussellus*). A measure of capacity for dry goods, as grain, fruit, pulse, and many other articles, containing 4 pecks, 8 gallons, or 32 quarts, and is

the eighth of the English quarter. The name seems to be derived from an old English word, *buss*, signifying a box or vessel.

The bushel, by a statute made in the twelfth year of Henry the Seventh, is to contain 2150·42 cubic inches, or 8 gallons of wheat; the gallon of wheat to weigh 8 lbs. troy-weight; the pound, 12 oz. troy-weight; the ounce, 20 sterlings; and the sterling, 32 grains. By 5 Geo. 4, c. 74, the imperial gallon is declared the standard measure of capacity, and is directed to be made such as to contain 10 lbs. avoirdupois of distilled water, weighed in air at the temperature of 62° of Fahrenheit's thermometer, the barometer standing at 30 inches, or to contain 277 cubic inches, and 274 thousandth parts of a cubic inch; consequently, the imperial bushel contains 80 lbs. of distilled water, or 2218·192 cubic inches. By the same act (§ 7), the bushel is declared the standard measure of capacity for coals, culm, lime, fish, potatoes, or fruit, and all other goods or things commonly sold by heaped measure, and is prescribed to contain 2815 cubic inches, to be made round with a plain and even bottom, and being 18½ inches in the interior diameter by 8 in depth, and 19½ inches from outside to outside; the goods to be heaped up in the form of cone, to a height above the rim of the measure of at least three-fourths of its depth.

Besides the standard or legal bushel, there are in England several local bushels, of different dimensions in different places. At Abingdon and Andover, a bushel contains 9 gallons: at Appleby and Penrith, a bushel of peas, rye, and wheat, contains 16 gallons; of barley, big malt, mixed malt, and oats, 20 gallons. A bushel contains, at Carlisle, 24 gallons: at Chester, a bushel of wheat, rye, &c., contains 32 gallons, and of oats 40; at Dorchester, a bushel of malt and oats contains 10 gallons; at Falmouth, the bushel of stricken coals is 16 gallons; of other things 20, and usually 21 gallons: at Kingston-upon-Thames, the bushel contains 8½; at Newbury, 9; at Wycomb and Reading, 8¾; at Stamford 16 gallons. The contents of the bushel seems to have been gradually increasing; the Winchester bushel, used in England from the time of Henry VII. to 1826, contained 2150·42 cubic inches. The imperial bushel is therefore to the Winchester bushel as 2218·192 to 2150·42, or as 1 to ·969447. Hence to convert Winchester bushels into imperial, multiply by ·969447. To convert prices per Winchester bushel into prices per imperial bushel, multiply by 1·0315157.

The heaped bushel was abolished by 4 & 5 Will. 4, c. 49, an act which took effect from the first of January, 1835. (*Brand's Dict. Science*; *Penny Cyclopædia*; *M'Culloch's Com. Dic.*)

BUSH-HARROW. An implement constituted of any sort of bushy branches, interwoven in a kind of frame, consisting of three or more cross-bars, fixed into two end pieces in such a manner as to be very rough and brushy underneath. To the extremities of the frame before are generally attached two wheels, about twelve inches in diameter, upon which

it moves; sometimes, however, wheels are not employed, but the whole rough surface is applied to, and dragged on, the ground. See HARROW.

BUSH-HARROWING. The operation of harrowing with an instrument of the kind just described. It is chiefly necessary on grasslands, or such as have been long in pasture, for the purpose of breaking down and reducing the lumps and clods of the earth or manures that may have been applied, and thereby rendering them more capable of being washed into the ground, or for removing the worm-casts and mossy matter that may have formed on the surface.

BUSH-VETCH (*Vicia sepium*). A plant of the vetch kind, which may probably be cultivated to advantage by the farmer, where lucerne and other plants of a similar nature cannot be grown. Its root is perennial, fibrous, and branching; the stalks many, some of them shooting immediately upwards, others creeping just under the surface of the ground, and emerging, some near to, and others at a considerable distance from, the parent-stock. The small oval leaves are connected together by a mid-rib, with a tendril at the extremity; the flowers are in shape like those of the common vetch, of a reddish-purple colour; the first that blossom usually come in pairs, afterwards to the number of four at a joint; the pods are much shorter than those of the common vetch, larger in proportion to their length, and flatter, and are of a black colour when ripe; the seeds are smaller than those of the cultivated species, some speckled, others of a clay colour. It yields, from a brown sandy loam, 17,696 lbs. per acre of grass, and of nutritive matter 976 lbs. It flowers in the middle of May, and maintains its place when once in possession of the soil, but appears unfit for clayey soils. The seeds are sown in April or the beginning of May. (*Hort. Gram. Wob.* p. 210.) Being a perennial plant, Mr. Swayne deems it to be a proper kind to intermix with grass seeds for laying down lands intended for pasture; and that it is as justly entitled to this epithet as any herbaceous plant whatever, having observed a patch of it growing in one particular spot of his orchard for fourteen or fifteen years past. It is not only a perennial, but an evergreen: it shoots the earliest in the spring of any plant eaten by cattle with which he is acquainted; vegetates late in autumn, and continues green through the winter, though the weather be very severe: add to this, that cattle are remarkably fond of it. The chief reason that has hitherto prevented its cultivation has been the very great difficulty of procuring good seed in any quantity. The pods, he finds, do not ripen altogether; but as soon almost as they are ripe, they burst with great elasticity, and scatter the seed around; and after the seeds have been procured, scarce one-third part of them will vegetate, owing, as he supposes, to an internal defect, occasioned by certain insects making them the nests and food for their young. It seems, also, that a crop of this kind of vetch may be cut three or four times, and in some cases even so early as the beginning of March—a circumstance of much

importance to farmers who have a large stock of cattle. (*Trans. Bath and West of England Society*, vol. iii.)

BUTT. A provincial term applied to such ridges or portions of arable land as run out short at the sides or other parts of fields; also to a vessel holding 126 gallons of wine, 108 of beer; and to a measure of from 15 to 22 cwts. of currants. *To butt*, from Dutch *botten*, to strike. *Butt-land* is the place where, in days of archery, the butts for practice were placed. It is also applied provincially to a close-bodied cart: hence a *dung-butt*, or wheel-cart, *gurry-butt*, or sledge-cart, *ox-butt*, *horse-butt*, &c.

BUTTER (Ger. *butter*; Dut. *boter*). A well-known article of domestic consumption, commonly procured by churning the milk of the cow. It was not an article employed by the early Greeks and Romans. "The ancient Romans," says Mr. Aiton (*Quart. Journ. Agr.* vol. v. p. 357), "knew nothing of making butter until they were taught by the Germans how to make it, and it was not used by them as food, but merely as oil." Herodotus says, that the Scythians formed butter by agitating mare's milk; and the poet Anaxandrides says, that the Thracians ate butter, at which the Grecians were surprised. When Julius Cæsar invaded England, he found that the inhabitants had abundance of milk, from which they made butter, but could not make cheese till they were taught that art by their invaders. The Arabs, it seems (*Burckhardt's Travels in Nubia*, p. 441), are very large consumers of fresh butter, and they are in the habit of drinking every morning a cupful of melted butter, or *ghee*, as it is called in the East. In India, *ghee* is made from the milk of the buffalo, and a very considerable traffic is carried on with it. It is usually conveyed in leather bottles or dippers, holding from ten to forty gallons; some are made of hide. The colour of butter is yellow; it possesses the property of an oil, and mixes readily with other oily bodies; it melts and becomes transparent at 96° Fahrenheit, and if it is kept in this state for some time, it assumes exactly the appearance of oil, loses its peculiar flavour, and some curds and whey separate from it. Milk, in fact, is composed of cream, curd, and whey. The cream and the milk are merely united mechanically, and when, therefore, the new milk is allowed to rest, the cream, being the lighter of the two, rises gradually to the top; the curd separates from the milk, too, with the assistance of a very slight degree of acidity. Butter may be made by the agitation of either cream or new milk: fresh cream is not commonly used, because it requires four times the churning that stale cream does. (Fourcroy, *Ann. de Chém.* tom. vii. p. 169.) The contact of the atmospheric air is not absolutely essential to the production of butter from cream, although the oxygen of the air is usually absorbed in churning: according to Dr. Young, there is an increase in the temperature during the operation of four degrees. Buttermilk is merely milk deprived of its cream, in which it rapidly becomes sour, and the curdy or *cheesy part* is separated from the whey or *serum*. Cream of

the specific gravity 1.0244 was found by Berzelius to contain—

	Parts
Butter - - - - -	4.5
Cheese - - - - -	3.5
Whey - - - - -	92.0

Curd, which is easily separated from creamed milk by rennet, has many of the properties of coagulated albumen: it is composed, according to the analysis of MM. Gay Lussac and Thenard, of

	Parts.
Carbon - - - - -	59.751
Oxygen - - - - -	11.409
Hydrogen - - - - -	7.429
Azote - - - - -	21.381
	100.

Curd, adds Dr. Thomson (*System of Chem.* vol. iv. p. 499), as is well known, is used in making cheese, and the cheese is the better, the more it contains of cream, or of that oily matter which constitutes cream. It is well known to cheese-makers, that the goodness of it depends in a great measure on the manner of separating the whey from the curd. If the milk be much heated, the coagulum broken in pieces, and the whey forcibly separated, as is the practice in many parts of Scotland, the cheese is scarcely good for any thing; but the whey is delicious, especially the last squeezed out whey; and butter may be obtained from it in considerable quantities. But if the whey is not too much heated (100° is sufficient), if the coagulum be allowed to remain unbroken, and the whey be separated by very slow and gentle pressure, the cheese is excellent, but the whey is almost transparent and nearly colourless. (*Journal de Phys.*)

When milk is deprived of its cream, it is composed, according to M. Berzelius, of

	Parts.
Water - - - - -	928.75
Curd with a little cream - - - - -	28.
Sugar of milk - - - - -	35.
Muriate of potash (chloride of potassium) - - - - -	1.70
Phosphate of potash - - - - -	.25
Lactic acid and acetate of potash - - - - -	6.
Earthy phosphates - - - - -	30.
	1000.

(*Thomson*, vol. iv. p. 501.)

From some valuable experiments on the temperature at which butter may be best procured from cream, by Dr. John Barclay and Mr. Allen, it appeared "that cream should not be kept at a high temperature in the process of churning. In the experiment when the temperature was lowest, the quantity of butter obtained was in the greatest proportion to the quantity of cream used; and as the temperature was raised, the proportional quantity of butter diminished; while, in the last experiment, when the mean temperature of the cream had been raised to 70°, not only was the quantity of butter diminished, but in quality it was found to be very inferior, both with regard to taste and appearance. That the lowest possible temperature should be sought in churning, appears likewise from another result of these experiments, the specific gravity of the churned milk having been found to diminish as the temperature of the cream was increased; thus showing, that at the lower temperature, the butter, which is composed of the lighter parts

of the cream, is more completely collected than at the higher temperature, in which the churned milk is of greater specific gravity." The conclusion to which they came therefore was, that the most proper temperature at which to commence the operation of churning butter is from 50° to 55°, and that at no time of the operation ought it to exceed 65°; while, on the contrary, if at any time the cream should be under 50° in temperature, the labour will be much increased, without any proportional advantage being obtained; and a temperature of a higher degree than 65° will be injurious as well to the quality as the quantity of the butter. (*Trans. High. Soc.* vol. i. p. 194.) One of these experiments it may be well to abridge:—15 gallons of cream at the temperature of 50° were churned; each gallon (equal to holding 8 lbs. 4 oz. of water) weighed 8 lbs. 4 oz.; by churning for two hours, the temperature of the cream rose to 56°; at the end of the churning it was 60°. The butter obtained weighed 29½ lbs. avoirdupois, or nearly 2 lbs. for each gallon of cream: the butter was firm, rich, and pleasant. A gallon of the churned milk weighed 8 lbs. 9 oz.

Mr. J. Ballantyne found that the greatest quantity of butter from a given quantity of cream is obtained at 60°, and the best quality at 55° in the churn just before the butter came; when the heat exceeded 65°, no washing could detach the milk from the butter without the aid of salt; but when a quantity of salt was wrought well into it, and the mass allowed to stand for twenty-four hours, and then well washed, the milk was separated. (*Trans. High. Soc.* vol. i. p. 198.)

The method of making the best butter all over the dairy district of Scotland, is thus described by Mr. Aiton (*Quart. Journ. Agr.* vol. v. p. 351): The milk, when drawn from the cow, is placed from six to twelve hours in coolers, the same as when set aside to cast up its cream; but this is merely to let the milk cool; and whenever it is divested of its natural heat, the whole meal of milk is emptied from the coolers into a stand vat or tub sufficient to contain the whole. If the vat is large, and a second meal of milk has become cold before the former meal of milk has begun to acidify, the second may be turned into the first. It is then placed in a vat, covered over, and allowed to remain undisturbed, till the milk has not only acidified, but until it has been formed into a coagulum (or *lapper*, in dairy language). It is now ready to be churned; and, provided the lapper is not broken (which makes it ferment), it may remain, without injury, unchurned for some days.

Milk prepared in this way is churned in upright or plunge churns, of a size to suit the magnitude of the dairy. Where only a few cows are kept, the churns will hold about 100 quarts, from 200 to 240 quarts, and some still more. These large churns are on some large farms moved by machinery of various constructions, but in most dairy farms, churns of 200 quarts are wrought by hand-labour only. After the clotted milk is put into the churn, as much hot water is poured amongst the milk as to raise the temperature from 50° or 55°, which

is about the ordinary temperature of a good spring or milk-house. Experiments instituted for the purpose have determined this as the best temperature at which to commence the operation of churning, and that at no time during the operation ought it to exceed 65°. If the temperature be higher, it will be attended with injury to the quality and quantity of the butter. If lower than 50°, the butter will not "come." After the butter has formed, warm water may be gradually added, so as to raise the temperature to 70° or 75°, one person agitating while another throws in the water. The temperature must be raised to or above 70° before the butter can be separated from the milk; and this cannot be accomplished in any way so well as by pouring in boiling water after it has begun to be churned. If the milk is too cold, when churning it swells, has a pale white colour, throws upon the surface many air-bubbles, and emits a rattling noise; the time of churning is from 2¼ to 2¾ hours; the milk being of ordinary quality, 24 pints imperial yield 24 ounces of butter.

In the making of butter, care and cleanliness are requisite. The cows should be milked in the cool of the morning and evening; they should be driven very gently, and if brought to the milking-place some little time previously, it will be all the better. In some countries they milk them in their pastures, a practice commonly followed in mountainous districts, and where they are distant from the dairy. The teats of the cow should be washed often with water, and the dairy floors (which are best of brick) and all the dairy utensils cannot be too frequently washed, not only because dirt is exceedingly noxious to the production of good butter, but from the coolness which it produces in the dairy.

When the milk is brought into the dairy, it is strained through a sieve, to remove any mechanically diffused matters, and then placed in shallow pans and coolers, or leaden troughs. Some are made of iron tinned, others of brass. There is, however, an objection to leaden troughs, for at the point of contact between the air and the cream, the latter aids the oxidization of the lead; and carbonic acid being attracted, a carbonate of lead (*white lead*) is formed, and communicates a poisonous property to the cream. Painters' colic has been thus sometimes communicated to dairymaids. Zinc, or iron tinned, is preferable to lead for dairy vessels. The same objection applies to brass as to lead. Metal ones are regarded as the best, from their rapidity of cooling in summer, and from their being more easily warmed in the winter; they are besides (and the same remark applies to the milk pails, &c.) more readily and completely cleaned than those of wood or earthenware. The dairy should be well ventilated by wire-gauze windows, and protected by either trees or buildings from the heat of the sun. In twelve hours the finest portion of the cream has risen to the surface, which, if then separated from the milk and churned, produces a very delicate butter. It is commonly left, however, for twenty-four hours, and then skimmed off and deposited in an earthen vessel. In the dairies of the usual

size, the cream collected is churned every two days, and the formation of the butter is found to be materially accelerated by the cream acquiring a slight acidity; indeed, it has been sometimes contended that, without the presence of an acid, butter cannot be made. Lactic acid indeed is always present in buttermilk; an acid quality is even, in some cases, imparted to it by the dairywomen, who add a small quantity of vinegar or lemon-juice; this, however, does not improve the flavour of the butter, and it injures it considerably for salting. To effect the separation of the butter from the cream, a considerable degree of agitation is necessary, varying with the electrical state of the atmosphere, and other circumstances. Of the influence of electricity no one will doubt who has witnessed the effect of a thunder-storm on a dairy of milk. The agitation or churning is produced by various-sized churns, the most common shaped of which is the upright wooden churn, with an upright plunger; others are made of barrels, turning on an axle by means of a common winch; some are made like cradles, and rock much in the same manner: these are worked chiefly by hand. But it is sometimes done by horse power, and very commonly now in Cheshire by small portable high-pressure steam-engines: these last might easily be made to cut chaff, bruise corn for stock, crush bones, and a variety of other useful purposes.

In the course of a period varying from one hour to several hours, according to circumstances, the butter begins to make its appearance in small lumps or kernels, which are gradually increased in number as the churning proceeds; these are collected and placed in a shallow wooden vessel, or washing-tub, and when all the butter is "come" or extracted, little else remains but the buttermilk. The butter placed in the washing-tub is worked by the hand into a mass, the buttermilk squeezed out, and the butter washed in water, an operation which, when it is intended for keeping, cannot be too carefully performed; and if the person who works it has not a very cool hand, it should be kept as cool as possible by frequent ablutions in cold water. A large portion of the butter made at a distance from large towns is salted and put into casks or firkins, which weigh about 56 lbs.; about 3 or 4 lbs. of salt are required for this purpose, which should be of the finest and purest description, totally free from the bitter deliquescent salts which commonly abound in that made by artificial heat from sea water. The casks also should be made of clean wood, and before the butter is placed in them they should be well washed with hot brine. "If," says a writer in the *Penny Cyclopædia*, "there is not a sufficient quantity to fill the cask at once, the surface is made smooth, some salt is put over it, and a cloth is pressed close upon it to exclude the air. When the remainder is added at the next churning, the cloth is taken off, and the salt which had been put on the surface is carefully removed with a spoon. The surface is then made rough with a small wooden spade and left so, and the newly salted butter is added, and incorporated completely. This

prevents a streak which would otherwise appear at the place where the two portions joined. When the cask is full, some salt is put over it, and the head is put on. If the butter is well freed from all the buttermilk, and the salt mixed with it quite dry, it will not shrink in the cask, and it will keep its flavour for a long time." Dr. Anderson recommended for preserving butter a composition of salt 2 parts, saltpetre 1 part, sugar 1 part; 1 oz. of this mixture to 16 oz. of butter. It seems that butter thus treated will keep sweet for a lengthened period; but that for the first fortnight it does not taste well:

In Devonshire the method of making butter is peculiar to the county. The milk is placed in tin or earthen pans, and twelve hours after milking, these pans (each holding about eleven or twelve quarts) are placed on an iron plate, over a small furnace. The milk is not boiled, but heated until a thick scum arises to the surface; if when a small portion of this is removed bubbles appear, the milk is removed, and suffered to cool. The thick part is then taken off the surface, and this is the *clouted cream* of Devonshire, which is known all over England. By a gentle agitation this clouted cream is speedily converted into butter.

In Holland they churn the cream and milk together, after it has been kept sufficiently long for a slight acidity to appear. They churn, it seems, sometimes with a horse, sometimes by a dog, or turnspit, working on a wheel; a plan which I think might be well adopted, in many cases, in England, to the saving of the labour of many a poor dairy-maid. In the large dairies, however, about Dixmunde and Furnes, the cream only is churned three times a week. (*Flemish Husb.* p. 61.)

On an average, four gallons of milk produces a pound of butter, and a good cow should produce six pounds of butter per week in summer, and three pounds in winter. Of English butter, that of Cambridge and Epping is the most celebrated. But the consumption in England is much greater than the farmers can supply: very large quantities are in consequence annually imported into England; thus, in 1825, the import from Ireland amounted to 422,883 cwts., and from foreign countries 159,332 cwts.; this last in 1835 was 134,346 cwts., of which 106,776 cwts. came from Holland. (*McCulloch's Com. Dict.; Trans. High. Soc.; Quart. Journ. Agr.*)

To prepare Butter for a warm climate.—When butter is to be exposed to the heat of a warm climate, it should be purified by melting before it is salted and packed up. For this purpose let it be put into a proper vessel, and this immersed into another vessel containing water. Let the water be heated until the butter is thoroughly melted. Let it continue in this state for some time, when the impure parts will subside, leaving at the top a perfectly pure transparent oil. This, when it cools, will become opaque, and assume colour nearly resembling that of the original butter, being only somewhat paler, and of a firmer consistence. When this refined butter is become a little stiff, but while it is still somewhat soft, the pure part must be separated from the dregs, and be salted

and packed up in the same manner as other butter; it will continue sweet much longer in hot climates, as it retains the salt better than in its original state. It may also be preserved sweet, without salt, by adding to it a certain portion of fine honey, perhaps one ounce to a pound of butter, and mixing them together thoroughly, so that they may be perfectly incorporated. A mixture of this sort has a sweet pleasant taste, and will keep for years without becoming rancid: there is no doubt, therefore, but that butter might thus be preserved in long voyages without spoiling.

As butter made in winter and even at other times is mostly pale or white, and at the same time of a poorer quality than that made during the summer months under the most favourable circumstances, various articles have been mixed with it in order to produce the rich yellow colour associated with excellence. Those most commonly used are the juice of the carrot, or flowers of the marygold, carefully expressed and strained through a linen cloth, or a small portion of arnotta. When the juices of the carrot and marygold are used, a small quantity (to be determined by experience) is to be diluted with a little cream, and this mixture is added to the rest of the cream when put into the churn. The quantity of colouring matter required is so small as not to impart any particular taste to the butter. When arnotta is used instead of these vegetable juices a portion about the size of a pea is sufficient to colour sufficiently 25 lbs. of butter. It must be first mixed with a little water and put into the cream at the commencement of churning. The best Spanish arnotta should be used.

The butter most esteemed in London is that of Epping and Cambridge; the cows which produce the former feed during summer in the shrubby pastures of Epping forest, and the leaves of the trees and numerous wild plants which there abound are supposed to improve the flavour of the butter. It is brought to market in rolls from one to two feet long, weighing a pound each. The Cambridgeshire butter is produced from the milk of cows that feed one part of the year on chalky uplands, and the other in rich meadows or fens; it is made up into long rolls like the Epping butter, and generally salted, not cured, before brought to market. By washing it, and working the salt out of it, the London cheesemongers often sell it at a high price for fresh Epping butter.

The butter of the mountains of Wales and Scotland, and the moors, commons, and heath of England, is of excellent quality, when it is properly managed; and though not equal in quantity, it often is confessedly superior to that produced from the richest meadows. Bad butter is more frequently the result of mismanagement, want of cleanliness, and inattention, than of any other cause. Ireland would produce the finest butter in the empire, were it not for the intolerably filthy state of their cows, and the want of cleanliness in their dairies.

In packing fresh butter, prepared for immediate use or sale, the leaves of cabbage, white beet, or of the garden orache, are preferred in England. The bottom of the basket should be bedded with a thick cloth, folded two or three

times; then a thin gauze dipped in cold water, spread over it, on which the prints or rolls of butter are to be placed, each with one or more leaves beneath, and smaller ones over it. The lowermost layer being adjusted, fold half of the gauze cloth over it, put in another layer in the same way, and then cover with the remainder of the gauze. The butter should be put into and taken from the basket without being touched.

Whey butter, as its name implies, is butter made from the whey which is taken from the curd, after the milk is coagulated for the manufacture of cheese. It is chiefly made in those counties where cheese is manufactured, and where it forms no inconsiderable part of the profits of the dairy. In Derbyshire more butter is said to be made from whey than from the cream of milk, or from milk churned altogether.

Under the head of *Anthoxanthum Odorum*, reasons are given for ascribing to its presence in pastures, a certain rich flavour for which the butter made in some districts is celebrated, such as the "May butter" of Philadelphia, and the Epping and Cambridge butter of London. The sweet-scented vernal grass owes its aromatic qualities chiefly to the presence of benzoic acid or flowers of benzoin, and this when administered to cows mixed with their food has been found to communicate the peculiarly pleasant flavour common to Philadelphia "May butter," not met with at present in the butter of any other part of the United States, and so highly prized by epicures that when good fresh butter sells in the Philadelphia market for 20 and 25 cents, the high-flavoured spring grass butter will bring 40 or 50 cents per pound. Very agreeable flavours may be given to butter by adding to cream, before churning, certain agents, as flowers of benzoin, vanilla, etc. See ANTHOXANTHUM ODORATUM, DAIRY, WHEY.

BUTTER-CUP, butter-flower, or upright meadow crow's foot (*Ranunculus bulbosus*, Smith). (Pl. 10, t.) A common perennial weed, abounding in meadows and pastures, and blooming in May. The whole plant is extremely acrid, so as often to be employed by country people to raise a blister. Bees are, however, very fond of it; it is eaten by sheep and goats; but horses, cows, and swine refuse it; drying destroys its acrimony. The roots are perennial, and bulbous; the stem rises a foot high, and bears its yellow flowers on the ends of its branches.

Dr. Darlington says that some fifteen or twenty species of ranunculus have been enumerated in the United States. (*Flor. Cestricea.*)

BUTTERFLY. The common English name, says Brande (*Dict. of Science*), of an extensive group of insects, as they appear in their last and fully developed state, when they constitute the most beautiful and elegant examples of their class. These insects belong to the order *Lepidoptera*, and to the section *Diurna* of Latreille, or the genus *Papilio* of Linnæus. The eggs of the butterfly are deposited on such plants as afford the nutriment most appropriate to the caterpillars, that are to be excluded from them; thus, the common white butterfly (*Pieris brassicæ*) and other species, oviposit upon cabbages, and hence have been termed *brassicariæ*; the gaudy peacock butterfly lays

her eggs upon the nettle. The eggs are coated with a glutinous secretion as they are excluded from the parent, and thus they are provided with the means of adhesion to the leaves or stems of the plants selected. See CATERPILLARS.

BUTTERNUT (*Juglans cathartica* vel *Cinerea*). A species of walnut growing in the United States, in different parts of which it is known by different names. In the New England States it generally takes the name of oil-nut; in some of the Middle States it is called white walnut; but from New York to the Carolinas, and from Pennsylvania to Ohio, the most common name is butternut. The region of this tree is very extensive, as it is found from Upper and even Lower Canada to the Floridas, and from the Atlantic to the Missouri. Even in Vermont and other cold regions its growth is so luxuriant that it attains a circumference of eight or ten feet. Michaux measured some in New Jersey nearly opposite New York, growing on the steep and elevated banks of the Hudson, where the soil was cold and unproductive, and found them, five feet from the ground, ten or twelve feet in circumference, and fifty feet high, with roots running along the surface of the ground in a serpentine direction, and with little variation in size, to the distance of forty feet. The limbs generally branch off at a small height above the base, and spread themselves widely, which gives the tree a striking appearance.

In the spring its vegetation is forward, and its leaves unfold a fortnight earlier than those of the hickory. The black walnut and butternut, when young, resemble each other, in their foliage, and in the rapidity of their growth; but when arrived at maturity, their forms are so different as to be distinguishable at first sight. Remarkable peculiarities are also found, on examining their wood, especially when seasoned. The black walnut is heavy, strong, and of a dark-brown colour; while the butternut is light, of little strength, and of a reddish hue. But they possess in common the great advantage of lasting long, and of being secure from the annoyance of worms. The wood of the butternut is used for the sleepers and posts of frame houses and barns, for post and rail fences, troughs for cattle, &c. For corn-shovels and wooden dishes, it is preferred to the red-flowering maples, because it is lighter and less liable to split; consequently hollow ware and other articles made of it sell at higher prices. In Vermont the wood is used for the panels of coaches and chaises, being well adapted for this purpose, not only from its lightness, but because it is not liable to split. It receives paint in a superior manner, its pores being very open, more so than those of poplar and bass-wood.

The bark of the butternut possesses medicinal properties of a cathartic nature which have been highly recommended both by the testimony of the regular faculty and popular practice. An extract prepared from the bark is prescribed by American physicians in doses of from half a drachm to a drachm to adults. In the revolutionary war when supplies of foreign medicines were cut off, the extract of

butternut was considered an admirable substitute for jalap. At present it is but little resorted to except in domestic practice in the country, where many of the farmer's wives make a preparation in the spring for the use of themselves and their neighbours. They usually boil the bark entire in water, till the liquid is reduced, by evaporation, to a thick, viscid substance, which is almost black. This is a faulty process; the exterior bark should first be removed, for by continuing the boiling, it soaks up nearly four-fifths of the liquid, already charged with rich extractive matter. In the country the bark is sometimes employed for dyeing wool of a dark-brown colour; but the bark of the black walnut is preferable for this purpose.

If the trunk of the butternut is pierced in the month which precedes the unfolding of the leaves, a pretty copious discharge ensues of a slightly sugary sap, from which, by evaporation, sugar is obtained of a quality inferior to that of the sugar maple. (*Michaux's American Sylva.*)

BUTTERWORT (*Pinguicula vulgaris*). A perennial weed growing in moist soils, as bogs and wet heaths. The viscid exudation of the leaves, which are thick and glutinous, says Smith (*Eng. Flor.* vol. i. p. 29), is reputed to be good for the sore teats of cows, whence the Yorkshire name of this plant, sanicle. The country people make it into a syrup as a purgative, and boil it with their garden herbs in broth as a remedy in colds. An ointment made from butterwort is also used for chapped hands, and to rub upon animals when bitten by an adder or slow-worm.

Mr. Nuttall enumerates four species of this plant found in the United States, all of which, he says, grow nearly on a level with the ocean, in moist pine-barrens. (*Genera of North Am. Plants.*)

BUTTONWOOD, or SYCAMORE, the *Platanus occidentalis*, or western plane tree, of naturalists.

Among trees with deciduous leaves, none in the temperate zones, either on the old or new continent, equals the dimensions of the planes. The species which grows in the Western World is not less remarkable for its amplitude and for its magnificent appearance than the plane of Asia, whose majestic form and extraordinary size was so much celebrated by the ancients.

In the Atlantic States this tree is commonly known by the name of buttonwood, and sometimes, in Virginia, by that of water-beech. On the banks of the Ohio, and in the states of Kentucky and Tennessee, it is most frequently called sycamore, and by some persons plane-tree. The French of Canada and of Upper Louisiana give it the name of cotton tree.

The buttonwood is abundant and very vigorous along the great rivers of Pennsylvania and of Virginia; though in the more fertile valleys of the West, its vegetation is perhaps still more luxuriant, especially on the banks of the Ohio and rivers emptying into it. The bottoms watered by these rivers are covered with dark forests, composed of trees of extraordinary size. The soil is very deep, loose, of a brown

colour, and unctuous to the touch, formed apparently of the slime deposited in the course of ages by the annual overflowing of the rivers. The fertility derived from this source is increased by accumulations of decayed vegetable matter furnished by leaves and the trees themselves. A degree of fertility is thus attained by the vegetable mould without example in Europe, and which is manifested by prodigies of vegetation. In such situations the buttonwood is found to be the largest tree in the United States, although in point of loftiness it is exceeded by the tulip poplar, and still more the white pine. Often, with a trunk of several feet in diameter, the plane tree begins to branch out at the height of sixty or seventy feet, near the summits of surrounding trees; and often the base divides itself into several trunks equally vigorous and superior in diameter to all other trees in the vicinity. "On a little island in the Ohio, fifteen miles above the mouth of the Muskingum, my father," says Michaux, "measured a buttonwood which, at five feet from the ground, was forty feet and four inches in circumference, and consequently more than thirteen feet in diameter. Twenty years before, General Washington had measured the same tree, and found it to be of nearly the same size." The same distinguished naturalist mentions another tree which he and his travelling companion had measured, and found, at the height of four feet above the ground, forty-seven feet in circumference. This tree, which grew on the right bank of the Ohio, about thirty-six miles from Marietta, still exhibited the appearance of vigorous vegetation, and began to shoot out its limbs twenty-feet above the ground. A buttonwood of equal size is mentioned, as existing in Tennessee. "The extraordinary dimensions of these trees recalls," says Michaux, "the famous plane tree of Lycia, spoken of by Pliny, the trunk of which, hollowed by time, afforded a retreat for the night to the Roman Consul Licinius Mutianus, with eighteen of his followers. The interior of this grotto was represented to be seventy feet in circumference, and the summit of the tree resembled a small forest."

The most striking resemblance, in the majesty of their form and in the enormous size of their trunk, thus appears to exist between the only two species of plane that have been discovered. It is difficult to mark any difference in the colour and organization of their wood. The American species is generally thought, in Europe, to possess a richer foliage and to afford a deeper shade than the Asiatic plane. Its leaves are of a beautiful green, alternate, from five to ten inches broad, less deeply lobed, and formed with more open angles than those of the plane of the Eastern continent. In some places where this tree is very abundant, it has been a source of alarm to the neighbouring inhabitants, who believe that the fine down from the leaves, floating in the air, produces an irritation of the lungs and predisposes to consumption. There appears to be little if any foundation for such an apprehension.

According to Michaux's observations, the buttonwood does not venture towards the north-

east, beyond Portland, in the latitude of $40^{\circ} 30'$; but farther west, in 73° of longitude, it is found two degrees farther north, at the extremity of Lake Champlain and at Montreal. Proceeding from Boston and the shores of Lake Champlain towards the west and the southwest, the buttonwood is continually met with over a vast tract, comprising the Atlantic and Western States, and extending beyond the Mississippi.

The wood of the plane tree speedily decays when exposed to the atmosphere. Hence it is only adapted for work that is sheltered from the weather, and when thoroughly seasoned, it may be usefully employed in the interior of houses for joists, &c. Though never used in the construction of large vessels, it has been hollowed out into canoes, one of which, formerly on the river Wabash, made of a single tree, was sixty-five feet long, and carried nine thousand pounds. (*Michaux's Am. Sylva.*)

BUXUS. The boxwood, of which botanists commonly enumerate three species: 1. The *arborescens*, with oval leaves. 2. The *angustifolia*, with narrow leaves. 3. The *suffruticosa*, the species usually employed in the bordering of flower-beds. The first two, when allowed to grow in a natural manner, are deciduous shrubs of fine appearance. All the species are easily cultivated. The wood is extremely hard and capable of being wrought with great neatness by the turner. It is also used by the engravers on wood to cut figures upon.

BYRE. A term made use of in some places to signify a cow-house. It is commonly employed in the northern parts of England, and in Scotland; and they are differently denominated, according to the uses to which they are applied: thus, there are feeding-byres, turnip-byres, &c.

BYSLINS. A provincial word signifying the first milk of a new-calved cow.

C.

CABBAGE (Fr. *cabus*; probably from *cab*, old Fr. for head, top, or extremity. Ital. *cabuccio*; Dutch, *kabuys*. "But the form of the cabbage, resembling a head, shows *caput* to be the original."—*Todd's Johnson*. Lat. *brassica*; from *πρῶσιχον*, a garden herb; or perhaps from *brachia*, from its numerous sprouts). A biennial genus of plants, of which there are a large number of species and innumerable varieties. Many are extensively cultivated in the vicinity of London; and several kinds are also grown by the farmer for the purpose of feeding his cattle and sheep. Our field and garden cabbages, with their varieties, have originated from the *Brassica oleracea*, or culinary cabbage, an indigenous sort of colewort growing principally on cliffs near the sea-coast. It is found abundantly at Dover. (*Smith's English Flora*, vol. iii. p. 220.) The cabbage, says Mr. Amos (*Comm. to Board of Agriculture*, vol. iv. p. 178), is a most invaluable plant, very productive, accessible at all times, and is an infallible supply for sheep-feeding during the spring months, especially for ewes in lamb. Beasts and sheep are

all exceedingly fond of cabbages. It may be of some importance to the farmer to be informed that among all the plants of the natural order to which the cabbage belongs, not one perhaps is possessed of any really deleterious property. Among nearly one thousand species (as Dr. Lindley observes), scattered over the face of the world, all are harmless, and many highly useful. The innumerable varieties arise from difference of soil and cultivation; and as all the cabbage tribe form hybrids, new varieties are continually produced. This is effected by the bees, when different sorts are in flower. Hence, only one variety should be in flower at the same time in any garden or field, when we wish to keep the sort unadulterated, particularly if some sorts have expanded leaves, and others close heads. It is thus only that the excellent small miniature cabbage, which grows on the stem of the Brussels sprout, can be kept in perfection. The different sorts of cabbage most prized for the garden are chiefly divided into the close-hearting and the spreading. Of the first, the York and the savoys are the most common; of the latter, the coleworts and Scotch kale. (*Penny Cyclo.* vol. vi. p. 92.) Of the genus *brassica*, or cabbage, the species chiefly interesting to the farmer, and the objects of cultivation, are, 1. Common turnip (*B. Rapa*); 2. Wild navew (*B. campestris*); 3. Rape or cole (*B. Napus*); 4. Early cole (*B. præcox*); 5. Cabbage (*B. oleracea*). These species may be cultivated nearly in the same manner, but they may produce small fusiform roots when they are cultivated for their leaves, or for their seeds, which yield oils; or they may produce large esculent roots when they are cultivated chiefly for their roots. (*Low's Elem. of Prac. Agric.* p. 290.) The different kinds of cabbage in cultivation may, adds Professor Low (p. 307), be arranged in different classes, according to their general aspect and more popular characters:—1. Those which bear their leaves or stalks without their being formed into a head. Some of these have crisped leaves, and are a class of hardy potherbs everywhere familiar in the culture of the garden; others have smoothish leaves, with long branched stems. These comprehend the largest and most productive of all the cabbages,—the Jersey cole, the thousand-headed cabbage, and others. 2. Those whose leaves are formed into a large head. These comprehend the larger cabbages cultivated in the fields. The savoys of our gardens are allied to this class. 3. Those whose roots become napiform, as the *kohl-rabe*. 4. Those in which the stem divides, and forms a corymbose head, as in the cauliflower and broccoli.

The cabbages of the first class, with crisped leaves, frequently termed greens, are very hardy. They are cultivated pretty extensively in some parts of the north of Europe; but in others they are chiefly regarded as potherbs, and confined to the garden. The branched kinds with smoothish leaves are the most productive; but at the same time they demand a good soil and favourable climate. Their leaves are stripped off as they are required for use; and as these are constantly supplied by fresh leaves, the plants yield a succession of forage

throughout a great part of the season, and they remain growing for several years.

There are different varieties of these larger cabbages, which are more or less valued in the places where they are cultivated. The thousand-headed cabbage, *chou à mille têtes*, is remarked as possessing a greater number of shoots; the cow cabbage, *Cesarian cole* or tree cabbage, as growing more to one stem, and producing cream-coloured flowers; the Jersey cole, as being similar in its growth, and producing yellow flowers. In the Netherlands, and the Channel Islands, where the cultivation of these plants is well understood, they are sown in beds in autumn, and planted out in succession from November till February. About the month of April the farmers begin with the first sown, to strip off their under leaves for use. They give them to their cows, hogs, geese, and other stock, cutting them in small pieces, and mixing them with bran and other farinaceous substances. During the summer they continue this process of stripping off the leaves, the plant in the meantime rising to the height of several feet. (*Gard. Mag.* vol. v.) This plant requires a good soil and plentiful manure, and is regarded as a great exhauster of the soil. It perhaps yields a larger proportion of nutriment within the same period than any other forage plant. It may be presumed that it is not well fitted for general cultivation, and in England will only succeed in favourable situations, as the south of England and Ireland, and the beautiful little islands where it is now cultivated. When fed to milch cows, the decayed leaves should be carefully removed, as when eaten they impart an unpleasant taste to the milk.

The next class (continues Professor Low) consists of those in which the root becomes napiform. The principal variety is the kohlrabe or purple turnip cabbage (*Brassica oleracea* var. *caulo-rapa*). This plant is cultivated in Germany and the north of Europe. It is valued as a resource for cattle in winter. While it produces a root like a turnip, it at the same time sends forth stems bearing leaves like a cabbage. It is not only hardy, but keeps better in store than any plant of the cabbage kind. It may be cultivated in the same manner as the Swedish and yellow turnips; but the experiments that have been made with it in this country lead to the inference that it is not equal to those turnips for the purpose of feeding. The cabbages of the last-mentioned class, as the cauliflower and the broccoli, are entirely limited to the garden. The kinds of the cabbage which are best suited for field-crops and the support of cattle, are the York, or large Scotch, the ox-head, the drum-head, the red-veined, and the American, which commonly produce heads of 10 to 20 lbs., and not unfrequently arrive to upwards of 30 lbs. weight. The above and other names, however, are frequently applied where there is no real distinction. The most productive of these are the drum-headed and American; but the red-veined and Scotch stand the winter best. They are all known by their large leaves, which, as the plant advances, collapse and form a dense head. The large field cabbages are those

which are generally considered as the best suited to farm culture, and are therefore those most commonly planted; but the species known as the sugar-loaf cabbage, and so called from its pointed form, though rarely exceeding from 5 to 7 lbs., may yet be in many cases found more advantageous, for it can be grown on land of more ordinary quality than the other kinds; it is hardier in constitution, more solid and nutritive, and the inferiority of its weight may be in a great degree made up by the smallness of its size allowing of the plants being set closer together. (*Brit. Husb.* vol. ii. p. 255.) Of the different kinds, therefore, it appears that the large field cabbage, whatever name it may receive, is that which is best suited for common field culture. This plant impoverishes the soil very much. In collecting the produce for consumption, the plants (says the late Mr. Sinclair) should be drawn up by the roots, and not merely cut over, as is often practised to the detriment of the soil. The different varieties above enumerated afford about equal quantities of nutritive matter. The nutritive matter of the cabbage is wholly soluble in water; that of the potato only partially so, for a great proportion of the potato consists of starch. According to Mr. Sinclair's experiments—

	Nutr. Matter, grs.	Woody Fibre, grs.	The remainder water.
7000 grs. or 1 lb. of the drum-head cabbage (<i>B. oleracea capitata</i>) contains	430	280	
7000 grs. Early York cabbage (<i>B. oler.</i> , var.) - - - - -	430	312	
7000 grs. Woburn perennial kale (<i>B. oler. fimbriata perennis</i>) - - - - -	438	932	
7000 grs. Green curled kale (<i>B. oler. viridis</i>) - - - - -	440	880	
Purple borecole, or kale (<i>B. oler. laciniata</i>) - - - - -	448	1120	
7000 grs. bulb of turnip-rooted cabbage (<i>B. rapa</i> , var.) - - - - -	400	320	
7000 grs. leaves or tops of ditto - - - - -	252	360	

And upon an analysis of the respective average nutritive qualities of each species of root, cabbages were generally found superior to common turnips, in the proportion of 107½ to 80, and inferior to Swedes in that of 107½ to 110. Carrots are more nutritive than cabbages, in the proportion of 187 to 107½. (*Hort. Gram. Wob.* p. 407, 408.) It is, however, the opinion of an experienced farmer (Mr. Brown of Markle), that the culture of cabbage, taking into consideration the greater consumption of manure, and the superior nature of the requisite soil, does not afford advantages to be compared with the scourge it occasions to the land. (*Brit. Husb.* vol. ii. p. 258.)

It is no uncommon thing to raise single cabbages that weigh 40 lbs.: calculating the roots upon an acre to average each 20 lbs., and one to be planted on every square yard, the produce would yield 43 tons. Although it frequently averages 30 tons, few crops, except under very favourable circumstances, would reach to that extent. Cabbages are greatly esteemed by those farmers who have land capable of growing them, from their forming a substitute for turnips during frosty weather, and also affording an admirable change of food for cattle, by whom they are much relished; and they are also found to be very nutritious for stall-feeding, or for the dairy, when used with the addition of sound hay. Hogs prefer them to turnips,

and they are excellent for rearing calves and toothless crones. An acre of good cabbages is therefore considered by many as worth two of turnips, and is certainly equal to one and a half.

Woburn perennial kale is a valuable variety of the open-growing cabbage, which has been recently introduced, and appears far superior in amount of produce to either the green, purple, or borecole, and requires less manure. It has also this advantage, that it continues highly productive for many years, without further trouble or expense. Propagated by planting, in beginning of April, cuttings taken from the stems and branches of old plants. The seed is apt to produce spurious plants. For the table it is not inferior to the best kinds of greens or kale; and for the farm and cottage garden, its highly productive powers and cheapness of culture promise to render this plant highly valuable. Its perennial habit places it out of the reach of the yearly accidents of weather, bad seed, and depredations of insects, to which all other varieties sown annually are subject. (*Trans. Hort. Soc. Lond.* vol. v. art. 40.)

The *turnip-rooted* or bulb-stalked cabbage (*B. oleracea*, var.) is distinguished by its irregularly-shaped root, and the swelling of the stalk in upper part, which forms a kind of round fleshy head at the end of the stem on which the leaves are produced. It is a native of Germany, and was first introduced from thence by Sir Thomas Tyrwhitt, under the name of *kohl-rabe*. (*Decandolle*, in *Trans. Hort. Soc.* vol. v. art. 1.) The produce is nearly the same as that of Swedish turnips, and the soil that suits the one is equally good for the other. Two pounds of the seed will produce a sufficiency of plants for one acre: 64 drs. of the bulb of *kohl-rabe* afford 105 grs. of nutritive matter. (*Hort. Gram. Wob.* p. 411.)

The turnip-rooted cabbage is a hybrid production between the cabbage and turnip, which both belong to the same genus; and the various kinds which have become disseminated throughout Europe are so confused in nomenclature, that it has become difficult to state their properties with any great degree of precision, or to draw any certain inferences to guide us in their use. (*Brit. Husb.* vol. ii. p. 259.)

These species of brassica are but little cultivated, and at most a very small quantity of each is in request. The bulbs, for which they are cultivated, must have their thick outer skin removed, and in other respects treated as turnips in preparing them for use. Of the turnip cabbage, which is so named on account of the round fleshy protuberance that is formed at the upper end of the stem, there are four varieties: 1. White turnip cabbage; 2. Purple turnip cabbage; 3. Fringed turnip cabbage; 4. Dwarf early turnip cabbage.

Of the turnip-rooted cabbage, which is distinguished from the above by its root having the protuberance near the origin of the stem, there are two varieties, the white and the red. (*Trans. Hort. Soc. Lond.* vol. v. p. 18—24.) They are propagated by seed, which may be sown broadcast or in drills, at monthly intervals, in small quantities, from the commencement of

April until the end of June. The best mode is to sow thin, in drills two feet and a half apart, and allow the plants to remain where sown, the plants being thinned to a similar distance apart; or, if sown broadcast, to allow them to remain in the seed-bed until of sufficient size to be removed into rows at similar distances for production, rather than, as is the practice of some gardeners, to transplant them, when an inch or two in height, into a shady border, in rows three inches apart each way, to be thence removed as above stated.

Water must be given every night after a removal, until the plants are again established; and afterwards in dry weather occasionally, as may appear necessary.

Earth may be drawn up to the stem of the turnip cabbage, as to other species of brassica; but the bulb of the turnip-rooted must not be covered with the mould.

For directions to obtain seed, &c., see *Broccoli, Turnip, &c.* (*G. W. Johnson.*)

The red cabbage differs from the common cabbage in nothing but its colour, which is a purplish or brownish red. The varieties are three in number; the large, the dwarf, and the Aberdeen red. It is chiefly used for pickling, and the dwarf red is considered the best sort. Cultivated precisely similar to the white cabbage. The cabbage is not nearly so extensively cultivated in this country as it ought to be. It is not only a valuable food for live stock, rarely misses plant, and is come-at-able in all weathers; but it is exceedingly useful to fill up the spaces on the ridges where the Swedes and common turnips have missed plant. 1000 parts of cabbage contain 73 parts of nutritive matters. (*Brit. Husb.* vol. ii.; *Baxter's Agr. Lib.*; *Sinclair's Hort. Gram. Wob.*; *Low's El. Agr.*; *Com. Board of Agr.*, vol. iv.; *Quart. J. Agr.*, vol. vii. p. 76.)

The cauliflower is considered the easiest to be digested of all the various species of cabbage. It is not destitute of utility in a medicinal way; a decoction of red cabbage being supposed capable of relieving acrimonious humours in some disorders of the breast, and also in hoarseness. (*Willich's Dom. Encyc.*) A cabbage leaf placed on any fleshy part acts in keeping open a blister; but it should be frequently changed, as it speedily becomes corrupt. The seed, bruised and boiled, is good in broth.

Garden Cabbages.—For the seed-bed the soil should be moist, mouldy, and not rich; but for final production it should be a fresh, moderately rich, clayey loam, though very far removed from heavy, as they delight in one that is free and mouldy. Such crops as have to withstand the winter may have a lighter compartment allotted to them; the savoy, in particular, requires this, though it may be as rich as for the other crops, without any detriment: an extreme of richness is, however, for all the crops to be avoided. The ground is advantageously dug two spades deep, and should be well pulverized by the operation. Stable manure is usually employed in preparing the ground for this genus; but Mr. Wood, of Queensferry, N. B., who has for the greater part of his life paid particular attention to the cultivation of broc-

coli, recommends the following compositions in preference for that vegetable, and we are justified in concluding that they would be equally beneficial to all the other species. The manure collected from the public roads, used alone, causes the plants to grow strong, but with small heads. A mixture of road-rakings, sea-weed, and horse-dung is better. A manuring of the compartment on which they were intended to be planted with sea-weed in autumn, digging it up rough, repeating the application in spring, and pointing the ground before planting, produced the finest heads he had ever seen; but the compost of all others most suitable to them is one composed of the cleanings of old ditches, tree leaves, and dung. (*Mem. Caled. Hort. Soc.* vol. ii. p. 265.) The situation must in every instance be free and open, though, for the summer crops, it is advantageous to have them shaded from the meridian sun. They must never, however, be under the drip of trees, or in confined situations; for in such they, and especially savoys, are most subject to be infested with caterpillars, and to grow weak and spindling. In planting cabbage, it should be observed whether the roots of the plants are knotted or clubbed, as such should be rejected, or the excrescence entirely removed.

The numerous varieties of the cabbage, adds Mr. G. W. Johnson, may be divided into three classes, as most appropriate for sowing at an equal number of periods of the year. It may be here remarked, that, for family use, but few should be planted of the early varieties, as they soon cabbage, harden, and burst; on the contrary, the large York, and others that are mentioned in the middle class, though not far behind the others in quick cabbaging, never become hard, and continue long in a state fit for the table.

For First Crops.—Early dwarf; York; early dwarf sugar-loaf; early Battersea; early imperial; East Ham.

Midsummer Crops.—Large early York; large sugar-loaf; early Battersea; early imperial: these mentioned again as being valuable for successional crops also. Penton, this is valuable in late summer, when other varieties are strongly tasted. Antwerp, Russian; to have this in perfection, the seed must be had from abroad, as it soon degenerates in this country. Early London hollow. Musk is excellent at any period, but is apt to perish in frosty weather.

For Autumn, &c.—Large hollow sugar-loaf; large oblong hollow; long-sided hollow, and any of the preceding; red Dutch for pickling.

The cabbage is propagated by seed, the sowing of which commences with the year. Towards the end of January, on a warm border, or under a frame, a small portion of the early and red cabbages may be sown, to come first in succession after those which were sown in the August of the preceding year. A sowing may be repeated after intervals of a month during February, and until the close of July of the second or larger class, and from May to July of the third class of varieties. In August a full and last crop must be sown of the first class, as well as of the second, both to plant

out in October, November, and December, as to remain in the seed-beds for final removal in the February and two succeeding months of the next year: this sowing is best performed during the first or second week of the month; if sown earlier, they are apt to run in the spring; and if later, will not attain sufficient strength to survive the winter. By these various sowings, which, of course, must be small ones for a private family, a constant supply is afforded throughout the year. The seed is inserted broadcast rather thin, and raked in evenly about a quarter of an inch deep. The bed is advantageously shaded with mats, and occasionally watered until the plants are well above ground; and the waterings may afterwards be beneficially repeated two or three times a week until they are ready for removal, if dry hot weather continues. The seedlings arising from these various sowings, when of about a month's growth, or when they have got four or five leaves an inch or so in breadth, are, by those who are advocates for transplanting, pricked out in rows four or five inches asunder each way; they must be shaded and watered until completely established: those of the August sowing that are pricked out are to remain until the next spring, and those which are left in the seed-bed are employed for planting in October and two following months.

When of six or eight weeks' growth, they are of sufficient size for planting, which they are to be in rows from one and a half to two and a half feet asunder each way; the smaller early kinds being planted the closest. The red cabbage, the principal plantation of which should be made in March for pickling in September, is benefited by having the distances enlarged to three feet. They must be well watered at the time of removal, and frequently afterwards, until fully established, in proportion as dry weather occurs. They must be frequently hoed to keep under the weeds, as perhaps no plant is more injured by them than the cabbage; and as soon as their growth permits it, the earth should be drawn round the stems of the plants. To promote the cabbaging of the plants, when requisite, it is useful to draw the leaves together with a shred of bass-mat, which forwards it about a fortnight. If any plants advance to seed whilst very young, the deficiencies should be immediately filled up. The stems of the summer and autumn crops, if left after the main head has been cut, will produce numerous sprouts during those seasons, and continue to do so throughout the winter. For the production of seed in October, which is the preferable season, and from thence until the close of February, some of the finest and best cabbage plants must be selected; or in default of these, though not by any means to be recommended, such of their stalks as have the strongest sprouts. They must have the large outer leaves removed, and then be inserted up to their heads, in rows three feet asunder each way. Each variety must be planted as far from any other as possible, as indeed from every other species of brassica; and this precaution applies equally to those which will be subsequently dwelt upon. The red cabbage especially must be

kept distinct. Some plants of the early varieties should be planted in sheltered situations, as in severe winters they are apt to run prematurely.

Frame Seedlings.—The first sowing of the year in a hotbed must be carefully attended to. The heat must never exceed 55°, nor sink more than two or three degrees beneath 50°, which is the most favourable minimum; otherwise the plants will be weak and tender, or checked and stunted. Air should be admitted freely in the day, and the glasses covered, as necessity requires, at night with matting; the other offices of cultivation are the same as for plants raised in the open ground.

Coleworts.—One of the Latin names for cabbage is *caulis*, and from this is derived cale or cole and colewort. Coleworts now merely signify cabbages cut young, or previously to their hearts becoming firm, the genuine colewort or Dorsetshire cale being nearly extinct. The varieties of cabbage principally employed for the raising coleworts are the large York and sugar-loaf, as they afford the sweetest; but the early York and East Ham are also employed, as also occasionally the Battersea, imperial, Antwerp, and early London hollow. When large coleworts are in request, the great spreading varieties should never be employed.

Sowings may be performed during the middle of June and July, to be repeated at the end of the latter month, for transplanting in August, September, and October, for a continual supply in September until the close of March. A fourth must be made the first week in August, for succeeding the others in spring; but, if of sufficient extent, these various plantations may be made from the seed-beds of the cabbage crops made at these several periods, as directed under that head; as the chief object in growing coleworts is to have a supply of greens sooner than can be obtained from the plantations of cabbages if left to form hearts.

The observations upon transplanting, and the directions for cultivating cabbages, apply without any modification to coleworts; but the distance at which the plants may be set is much less: if the rows are a foot apart, and the plants seven or eight inches distant from each other, an abundant space is allowed. As mentioned for cabbages, the heading is greatly forwarded by their leaves being drawn together so as to enclose the centre. They may be cut when the leaves are five or six inches in breadth. The most preferable mode of taking them is to pull up or cut every other one; these openings are beneficial to the remaining plants; and some, especially of the August-raised plants, may be left, if required, for cabbaging.

Colewort, or Dorsetshire cale, is now nearly superseded by the new cabbages of modern times. The wild coleworts grow in ditches and moist places.

Savoy—(*Brassica oleracea sabauda*).—The savoy, which is one of the best and chief of our vegetable supplies during the winter, derives its name either from being an introduction from that part of Europe with which it bears a similar name, or, otherwise, is a corruption from the French *savourer*. All its

varieties may be denominated hardy, being generally rendered more sweet and tender by frost, though not all equally capable of withstanding the rigour of winter. There are three varieties of savoy,—the yellow, the dwarf, and the green: and of each of these there are likewise two sub-varieties, the round and the oval-headed, the first of which is the most permanent. Each variety has been described by Mr. Morgan, gardener to H. Brown, Esq., of North Mimms. Like the other members of this tribe, it is propagated by seeds; the first sowing to take place at the close of February, the plants of which are ready for pricking out in April, if that practice is adopted, and for final planting at the end of May for use in early autumn; this to be repeated about the middle of March, the plants to be pricked out in May for planting in June, to supply the table in autumn and early winter; lastly, the main crops must be sown in April and early May, to prick out and plant after similar intervals for production in winter and spring. The seed is sown broadcast thinly, and raked in as mentioned for other species of brassica. The plants are fit for pricking out when they have four or five leaves about an inch in breadth; they must be set three or four inches asunder each way, being both here and in the seed-bed kept well cleared of weeds. When finally removed, the plants of the first crops should be set out two feet apart each way from one another; but the winter standing crops are better at two feet by eighteen inches. Both before and after every removal they should be watered abundantly, if the weather is at all dry; and this application to be continued until the plants are well established. The only after-culture required is the keeping them clear of weeds by frequent broad-hoeing and the earth drawn up two or three times about their stems. For the production of seed, such plants must be selected of the several varieties as are most true to their particular characteristics, and as are not the first to run. These, in open weather, from early in November to the close of February, (the earlier, however, the better,) may be taken up with as little injury as possible to the roots, and the large under leaves being removed, planted entirely up to the head in rows two feet and a half each way, each variety as far from the other as possible. They flower in May or June, and ripen their seed in July and August. (*G. W. Johnson's Kitchen Garden.*)

CABBAGE CATERPILLAR. This belongs to a genus of butterflies called the potherb pontia (*Pontia oleracea*). See **CATERPILLAR**.

CABBAGE-CUTWORM. See **CUTWORM**.

CABBAGE-LICE. See **APHIS**.

CABBAGE TREE (*Chamaeops palmetto*). See **PALMETTO**.

CAG, or KEG. A vessel of the barrel kind, containing four or five gallons.

CAIRN (Welsh *carn*). A heap of stones.

CAKE. See **OAT CAKE** and **RAPE CAKE**.

CALAMINT, COMMON (*Thymus calamintha*, Smith). This is a wild plant, growing in England in hedges and dry places, flowering from June till autumn. It is eight or ten inches high; has roundish dark-green leaves, and

whitish flowers standing in whorls or little clusters surrounding the stalks, which are square and very much branched. Calamint should be gathered and dried just as it is coming into flower. This herb is grown in almost every garden; it is strong-scented, and of an agreeable odour. Coles says it preserves meat from taint.

Pennyroyal calamint (*Mentha pulegium*, Eng. Flor. vol. iii. p. 87) is a medicinal herb, and should be planted in every herbalist's garden. It grows a foot high, with firm stalks, small leaves of a light green colour, and hairy, and small white purplish flowers. The pennyroyal calamint is more erect than its elder sister, and has a stronger but less pleasant smell. It must be dried with care, and given in infusion. It is a popular remedy for hysterics, and in deficiency of the periodical change in females; but the plant and its infusion is rarely ordered by professional men. A water arising from the distillation of the plant, to produce its volatile oil, is used as a vehicle for more important drugs; and the oil dropped on sugar and rubbed up with water as an oleosaccharum is sometimes employed as a carminative and an antispasmodic, in doses of two to five drops. There is, also, an officinal spirit of pennyroyal, which is used for the same purposes as the oil. This aromatic plant must not be confounded with the common pennyroyal of the United States. See PENNYROYAL.

CALANDRE. A name given by French writers to an insect of the *scarabæus* or beetle tribe, which frequently does great injury in granaries. It has two antennæ or horns, formed of a great number of round joints, and covered with a soft and short down; from the anterior part of the head there is thrust out a trunk, which is so formed at the end that the creature easily makes way with it through the coat or skin that covers the grain, and gets at the meal or farina on which it feeds; the inside of the grain is also the place where the female deposits her eggs. See CORNWEEVIL.

CALCAREOUS MARL. A mineral fertilizer, extensively used in many parts of Europe and the United States. See MARL.

CALCAREOUS SOILS (from the Latin *calx*) are soils which contain carbonate of lime (chalk of limestone) in such a proportion as to give it a determinate character. Calcareous sand is merely chalk or limestone divided into pieces of the size of sand. This variety abounds on the seashore in some parts of the east of England, and is employed in Devonshire and Cornwall to a very large extent as a manure, especially about Padstow Harbour, from which bay many thousand tons are annually carted by the Cornish farmers, which they take free of toll, under a grant from Richard Duke of Cornwall, another of the 45th of Henry III., A. D. 1261. (*Johnson on Fertilizers*, p 17) See CHALK; EARTHS, *their Uses to Vegetation*; and SOILS.

CALF, DISEASES OF (Sax. *cealp*, *calp*; Dutch, *kalf*). See CATTLE. The most common diseases of calves are—

1. *Navel Ill.*—The best treatment for this dangerous disease is, 1st, to administer two or three doses (each about a wine-glassful) of

castor oil (linseed oil does just as well, and is much cheaper); and, 2dly, cordials, which may be made of 2 drachms of caraway-seeds, 2 do. of coriander-seeds, 2 do. powdered gentian; bruise the seeds, and simmer them in beer or gruel for a quarter of an hour; give these once or twice a day.

2. *Constipation of the Bowels.*—For this doses of castor oil (or linseed oil), of 2 or 3 oz., are the best remedy.

3. *Diarrhœa*, or *Scouring.*—The farmer may rely on the following mixture. Let him keep it always by him; it will do for all sucking animals:—

Prepared chalk	-	-	-	-	4 ounces
Canella bark, powdered	-	-	-	-	1 —
Laudanum	-	-	-	-	1 —
Water	-	-	-	-	1 pint.

Give two or three table-spoonfuls, according to the size of the animal, two or three times a day. A table-spoonful or two of powdered chalk may be given daily or every other day, to calves whilst sucking, mixed in a little warm milk. It prevents the milk from turning acid, and thus checks the tendency to diarrhœa or looseness.

4. *Hoese*, or *Catarrh.*—Good nursing, bleeding, and then a dose of Epsom salts, with half an ounce of ginger in it. (*Youatt on Cattle*, p. 557.)

CALKERS. A name given to the prominent or elevated part of the extremities of the shoes of horses, which are forged thin, and turned downwards for the purpose of preventing their slipping. It is sometimes written *calkins* or *cawkins*.

CALLUNA VULGARIS. The common heath or ling. It abounds in peaty soils. (See PEAT SOILS.) Its uses are considerable in some districts for litter, and, when young, sheep eat it. It is also shelter for grouse, and food for bees. See LING.

CALVING OF COWS. The treatment before calving is to keep the cow moderately well, neither too fat nor too lean; remember that she commonly has the double duty of giving milk and nourishing the fœtus; dry her some weeks before calving; let her bowels be kept moderately open; put her in a warm sheltered place, or house her; rather reduce her food; do not disturb her when in labour, but be ready to assist her in case of need; let her have warm gruel; avoid cold drinks. A pint of sound good ale in a little gruel is an excellent cordial drink.

CALYCANTHUS FLORIDUS, the sweet-scented shrub, or, as it is also sometimes called, Carolina allspice. See SWEET-SCENTED SHRUB.

CAM. A provincial term for a mound of made earth.

CAMELLIA JAPONICA. A beautiful ever-green greenhouse shrub; but if carefully attended to it will blow in the open air. It bears single, double, and semi-double flowers, in February and March; and they are red, white, blush-coloured, and various other tints. Plant it under a south wall, in good rich garden mould mixed with sand; and shelter it during winter with mats, or keep it in a large pot. It cannot endure the broiling mid-day sun. Propagate by cuttings, layers, and grafts;

and water the plants plentifully when in flower.

CAMLET (Fr. *camelot*; Ital. *ciambelotto*; Span. *camlote*; from the Gr. *καμηλωτή*). A stuff or cloth made of wool, silk, and sometimes of hair combined, especially that of goats and camels. The real oriental camlet is made from that of the Angola goat. No camlets are made in Europe of goat's hair alone. France, Holland, Flanders, and England are the chief places where this manufacture is carried on. The best are made in England, and those of Brussels stand next in repute. It has been occasionally written *camelot* and *camblet*.

CAMMAS. A new species of plant found in the valley of the Columbia river. It has a truncated root in the form of an onion, and grows in moist rich land. It is prepared for eating by first roasting, then pounding, after which it is made into loaves like bread. It has a liquorice taste, and is a food of great importance among the Indians.

CAMMOCK (Sax). The name of a weed infesting arable, especially chalky soils, generally known by the name of rest-harrow. See **REST-HARROW**.

CAMOMILE, CHAMOMILE, COMMON or SWEET (*Anthemis nobilis*. From *ἀνθεον*, on account of its abundance of flowers, or luxuriance of growth. Fr. *camomille*; Lat. *chamomilla*). A hardy perennial, growing on open gravelly pastures or commons, in England, flowering from June to September, and well known for its use in medicine. Cattle do not appear to touch any part of this plant. Most of what is brought to the London market is cultivated about Mitcham, in Surrey. Every part of the plant is intensely bitter, and gratefully aromatic, especially the flowers, whose stomachic and tonic powers are justly celebrated. (*Eng. Flora*, vol. iii. p. 546.) In gardens there are two varieties,—the common single and the double-flowering. They require a poor dry soil, otherwise they grow very luxuriant, and become not only less capable of withstanding severe winters, but also less powerful in their medicinal qualities. They will grow in any situation almost, but the more open the better. They are generally propagated by parting the roots, and by offsets, which may be planted from the close of February until the end of May; the earlier, however, it is performed the better: this is the most favourable season, but it may be practised in the autumn. They are also raised from seed, the proper time of sowing which is in any of the early spring months; but as the former mode is so easily practised and with much less trouble, it is generally pursued; though it is advisable after a lapse of several years to raise fresh plants, the old ones often declining in production after such lapse of time. Being shrubby, with extending lateral branches, they should not be planted nearer to each other than eighteen inches, as that also gives an opportunity to employ the hoe. Water must be given moderately at the time of planting, if dry weather, otherwise it is not at all required. If raised from seed, they require no further cultivation than to be kept free of

weeds in the seed-bed; and when three or four inches high, to be thinned to about six inches apart; after which, they may remain thus until the following spring, then be thinned and remain, or be removed to the above-mentioned distance apart. A very small bed will supply the largest family. In July the flowers are generally in perfection for gathering; the period for performing it, however, must be governed by the aspect of the flowers themselves, as the best time is when they are just opened. Particular care must be taken to dry them thoroughly before they are stored; otherwise they will not keep. If seed is required, the only attention necessary is to leave some of the first opening flowers ungathered; the seed will ripen early in September, when the plant may be cut, and the seed dried, and rubbed out. (*G. W. Johnson's Kitchen Garden*.)

Camomile flowers, fresh or dried, are tonic. They contain *volatile oil*, *bitter extractive*, *tannic acid*, and *piperina*, a resinoid which was discovered in them by Dr. A. T. Thomson, and which, in conjunction with the volatile oil, explains their power of curing agues. The leaves and flowers dried are also anodyne applied to the bowels outwardly in fomentations. Camomile tea if strong promotes vomiting. The flowers of camomile distilled yield a fine blue oil, like that from yarrow, which becomes yellow by time. It is used for cramps, &c. The double flowers have not the same virtue which the single ones possess. The infusion is a useful stomachic in weakened states of the stomach, and as a general tonic. The strong warm infusion is a useful emetic in low states of the habit, and to promote the action of other emetics. Combined with any astringent, camomile is an antiperiodic and cures ague.

Smith (*Engl. Flor.* vol. iii. p. 457) enumerates four other species. The sea camomile (*A. maritima*); annual, met with on the sea-coast, but rare; flowers smell like tansy, the leaves like mugwort. Corn camomile (*A. arvensis*); annual or biennial, in cultivated fields, as well as waste ground, chiefly on a gravelly soil. The herbage has little or no smell, but the flowers are pleasantly scented. The stinking mayweed, or camomile (*A. stula*); an annual, found in the same situation as the last. Every part of the plant is fetid and acrid, blistering the skin when much handled, which Dr. Hooker justly attributes to the minute resinous dots sprinkled over its surface. And the ox-eye camomile (*A. tinctoria*), found sometimes in stony mountainous places, growing on a bushy stem eighteen inches high. The flowers afford a fine yellow dye, for which, Linnæus says, they are much used in Sweden. There are several handsome exotic species nearly akin to this.

CAMOMILE, WILD, or FEVER FEW (*Matricaria camomilla*, Pl. 10, w w). Found in cultivated and waste ground, on dunghills, and by roadsides; very common about London. Root annual, rather large and woody; flowering from May till August; stem a foot high; flowers numerous, about the size of the common sweet camomile, and with some portion of the same scent, of which the herbage, though faintly, partakes. The greatest part of the oil

of camomile found in the shops is procured from this plant.

CAMPHOR TREE (*Laurus camphora*). Among the vegetable productions of the Old Continent which possess a high degree of interest for the United States, the camphor tree holds an eminent place. It especially deserves attention from the inhabitants of the Floridas, of the lower part of the Carolinas, and of lower Louisiana. Its multiplication in these climates would be so easy, that after a few years it might be abandoned to nature.

The camphor tree belongs to the same family as the common sassafras of the United States, though in its general character it is most nearly related to the red bay, so common throughout the southern regions just referred to, both being evergreens of similar height, and at a small distance looking so much alike as to be easily mistaken for each other.

The camphor tree is a native of China, Japan, and some other parts of the East Indies, where it often attains forty or fifty feet in height, with a proportional diameter. The leaves are two or three inches long, pointed at their extremities, about an inch broad, with long petioles or stems. The young branches are green. The flowers are small and whitish. The leaves, bark, wood, and roots are all strongly impregnated with the odour of camphor. The roots especially yield this substance in greatest quantity. They are cut to pieces, boiled in water in large iron retorts, &c. (See *Michaux's Sylva*.)

Camphor may likewise be obtained from certain plants or herbs of the class of *labiæ*, such as lavender and mint, but not in sufficient quantities to form an article of commerce.

CANADA ONION. See **ONION**.

CANADA THISTLE (*Carduus arvensis*). This plant is widely spread in the northern part of the state of New York, and has been introduced into Pennsylvania and many other parts of the Middle States, the seeds having been sometimes mixed in timothy seed, and sometimes entangled in the fleeces of sheep driven from the North. The root of the Canada thistle is perennial, creeping and exceedingly tenacious of life, which, with its prolific character, for it springs up from the filaments of the roots as well as from seed, makes it the vilest pest in the form of a weed that has ever invaded American farms. It is a foreigner. The utmost vigilance will be required to prevent its spread wherever it may be discovered.

A great many devices have been resorted to for the eradication and destruction of the Canada thistle. Some aim at the entire removal of the root by means of extirpating machines, contrived to cut off and harrow up the roots. Others rely upon mowing down the thistles when they are in full bloom, as a most certain method. Not content with simply cutting down, some apply common salt to the stems or crowns of the roots which makes the destruction more sure. It is an admitted fact that the life of trees and plants, when these are not in the torpid state in which they are enabled to exist in winter, depends upon a function performed by their leaves. These are in

fact their lungs, deprived of the use of which for a given time, during the season of their growth, trees and plants inevitably die. Low and frequent cutting down in summer about the blooming period, will doubtless destroy plants however tenacious of life they may be, since the roots are as much indebted for life to their leaves or lungs as the leaves are to the roots. Neither can subsist long without the aid of the other important members of the system. The most usual methods, resorted to in England, for the eradication of thistles, couchgrass, and other weeds with creeping and tenacious roots, will be found mentioned under the head of **THISTLES**. A highly interesting article upon this subject, originally published in that valuable agricultural periodical, *The Genessee Farmer*, and republished in *Ruffin's Farm. Reg.* vol. ii. p. 29, contains a great deal of information relative to the extermination of this pest of our plough fields.

CANARY-GRASS, CAT'S TAIL. See **CAT'S TAIL**.

CANARY-GRASS (*Phalaris canariensis*—Pl. 4, a) is cultivated in a few parts of the south of England, and chiefly in the Isle of Thanet. The plant (says Prof. Low) is easily raised, but it is of little economical importance; it is a native of the Canary Islands, but is found frequently wild in cultivated and waste ground, and has probably become naturalized. It is an annual, with a stem from a foot to eighteen inches high, and lively green leaves about half an inch in width. In England it flowers from June to August, and ripens its seed from September to October. The seeds are sown in February, in rows about a foot apart, four or five gallons per acre. The reaping commences in September. The common yield is from thirty to thirty-four bushels per acre. The chaff is superior to that of every other culmiferous plant for horse food, and the straw, though short, is also very nutritive. From Mr. Sinclair's experiments, it appears, that at the time of flowering, the produce of this grass per acre, from a rich clayey loam, on a tenacious subsoil, was 54,450 lbs.; which yielded in dry produce 17,696 lbs. 4 oz., nutritive matter 1,876 lbs. 2 oz. The herbage is but little nutritive, and the plant cannot be recommended for cultivation, but for the seeds only, which are principally in demand in the neighbourhood of large towns, as food for small singing-birds, particularly canaries, whence it derives its name. The produce is generally from three to five quarters an acre, and the actual price is from 40s. to 42s. per quarter. The straw or haulm is a most excellent fodder for horses. (*Hort. Gram. Wob.* p. 399; *Low's El. Prac. Ag.* p. 266; *Brit. Husb.* vol. ii. p. 329.)

The reed canary-grass (*Ph. arundinacea*, *Smith's Engl. Flora*, vol. i. p. 74) is very common in ditches, pools, and the margins of rivers. At the time of flowering, the produce from a black sandy loam incumbent on clay was,—

	lbs.	oz.
Green produce per acre	27,225	0
Dry produce	12,251	4
Nutritive matter	1,701	9

On a strong tenacious clay, the produce was,—

	lb.	oz.
Green produce per acre	34,031	0
Dry produce	17,015	8
Nutritive matter	2,126	15

From this, it appears to be much more productive on a tenacious clay soil than on a rich sandy loam; the superior nutritive powers which this grass possesses recommend it therefore to the notice of occupiers of such soils. The foliage cannot be considered coarse, when compared with other grasses which afford a produce equal in quantity. Dry straw is a much coarser food than the hay made from this grass, and the objection may be met by reducing this hay to chaff. The striped reed canary-grass has not yet been found in a wild state; it is cultivated in gardens for the beauty of its striped leaves:—the common wild variety wants this distinguishing feature, it grows to a greater height than the striped-leaved variety, does not appear to be eaten by cattle, but birds are fond of the seeds. It comes into flower about the first and second weeks of July, and ripens about the middle of August. (*Hort. Gram. Wob.* p. 359.)

CANCER, IN CATTLE (Lat.; Sax. *cancep.*) A virulent swelling or sore. Cancer of the eye, or a perfect change of its mechanism into a fleshy half-decomposed substance, that ulcerates and wastes away, or from which fungous growths spring that can never be checked, is a disease of occasional occurrence in cattle. The remedy should be extirpation of the eye; if it were deemed worth while to attempt it. (*Lib. of Usef. Know., Cattle*, p. 293.)

CANDLE (Lat. *candela*; Sax. *candol*; Ital. *candelle*; Fr. *chandelle*; Welsh, *canwyll*). A taper or cylinder of tallow, wax, or spermaceti, the wick of which is commonly of several threads of cotton spun and twisted together. Candles in England were subject for a lengthened period to an excise duty of 3½d. per lb., but this was repealed in 1831. Good tallow candles ought to be made with equal parts of sheep and ox tallow; care being taken to avoid any mixture of hog's lard, which occasions a thick, black smoke, attended with a disagreeable smell, and also causes the candle to run.

The farmer, if far from any town, may make his own candles. The cotton for making the wicks is sold, ready prepared, in balls. When it is intended to be used for candles, a certain number of pieces of it of equal length are to be cut, and stripped through the hand to remove any knots or inequalities. They are next to be affixed by one end to a rod about three feet long, leaving about two inches between each wick. The whole is then to be dipped into a vessel, large enough, and filled with fluid tallow; and this is to be repeated three times for the first layer or coat. They are then to be suspended in a rack over the vessel to drain and solidify; after which they are to be dipped twice, and again hung up to drain; and so on, successively, until they acquire the desired degree of thickness.

The first part of the process is the sorting of the tallow. Mutton suet with a proportion of ox-tallow is selected for mould candles, because it gives them gloss and consistence. Coarser tallow is reserved for the dipped can-

dles. After being sorted, it is cut into small pieces, preparatory to its being melted or rendered; and the sooner this is done after the fat is taken from the carcase the better, because the fibrous and fleshy matters mixed with it promote its putrefaction. Tallow is too commonly melted by a naked fire applied to the bottom of the vessel, whereas it should be done either in a cold set pan, where the flame plays only round the sides a little way above the bottom, or in a steam-cased pan. After being fused a considerable time, the membranous matters collect at the surface, constituting the *cracklings* used sometimes for feeding dogs, after the fat has been squeezed out of it by a press. The liquid tallow is strained through a sieve into another copper, where it is treated with water at a boiling temperature in order to wash it. After a while, when the foul water has settled to the bottom, the purified tallow is lifted out, by means of tinned iron buckets, into tubs of a moderate size, where it concretes, and is ready for use.

Wax Candles.—Next to tallow, the substance most employed in the manufacture of candles is wax. Wax candles are made either by the hand or with a ladle. In the former case, the wax, being kept soft in hot water, is applied bit by bit to the wick, which is hung from a hook in the wall; in the latter, the wicks are hung round an iron circle, placed immediately over a large copper-tinned basin full of melted wax, which is poured upon their tops, one after another, by means of a large ladle. When the candles have by either process acquired the proper size, they are taken from the hooks, and rolled upon a table, usually of walnut tree, with a long square instrument of box, smooth at the bottom.

In June, 1825, M. Gay Lussac obtained a patent in Eng'and for making candles from *margaric and stearic acids*, improperly called *stearine*, by converting tallow into the above fat acids by the following process:—Tallow consists, by Chevreul's researches, of stearine, a solid fat, and elaine, a liquid fat; the former being in much the larger proportion. When tallow is treated with an alkaline body, such as potash, soda, or lime, it is saponified: that is, its stearine and elaine become respectively stearic and elaic acids, and, as such, form compounds with these bases. When by the action of an acid, such as the sulphuric or muriatic, these combinations are decomposed, the fats reappear in the altered form of stearic and elaic acids; the former body being harder than tallow, and of a texture somewhat like spermaceti, the latter body being fluid, like oil. "The decomposition of the soap should be made," says the patentee, "in a large quantity of water, kept well stirred during the operation, and warmed by steam introduced in any convenient way. When the mixture has been allowed to stand, the acid of the tallow or fat will rise to the surface, and the water being drawn off will carry the alkaline or saline matters with it; but if the acids of the tallow should retain any portion of the salts, fresh water may be thrown upon it, and the whole well agitated, until the acids have become perfectly free from the alkaline mat-

ers; and when allowed to cool, the acids will be formed into a solid mass. This mass is now to be submitted to considerable pressure in such an apparatus as is employed in expressing oil from seeds; when the liquid acid will run off in the form of a substance resembling oil, leaving a solid matter, similar, in every respect, to spermaceti, which is fit for making candles.

The wick to be used in the manufacture of these improved candles, and which forms one of the features of this invention, is to be made of cotton yarn, twisted rather hard, and laid in the same manner as wire is sometimes coiled round the bass strings of musical instruments. For this purpose, straight rods or wires are to be procured, of suitable lengths and diameters, according to the intended size of the candles about to be made; and these wires, having been covered with cotton coiled round them as described, are to be inserted in the candle-moulds as the common wicks are; and when the candle is made, and perfectly hard, the wire is to be withdrawn, leaving a hollow cylindrical aperture entirely through the middle of the candle. See STEARINE.

For the process of making mould candles, which is even more simple than that for dipping, see *Ure's Dictionary of Arts, &c.*, art. CANDLE: where also may be found a drawing and description of an ingenious machine for making dipped candles, much used in Edinburgh.

Candles ought never to be used until several weeks have elapsed after they are made; otherwise they are apt to gutter and run. (*McCulloch's Com. Dic.: Willich's Dom. Encyc.*)

CANDLE-BERRY MYRTLE (*Myrica gale*). A hardy shrub, native of Britain, which grows to four feet high, and bears a small red blossom in May and June. It loves heath mould, and is propagated by seed, or by dividing the roots.

The species called candle-berry myrtle in the United States, is the *myrica cerifera* of botanists. It grows on the lands bordering on the sea and bays of the Atlantic States, where the wax which surrounds the clusters of berries is often collected by the poor either for their own use in mixing with tallow to make candles, or to sell. The berries when gathered are put into hot water, which melts the wax by which each is enveloped, and which, rising to the top, is skimmed off. It is of an olive-green colour and fragrant odour. As a popular remedy in dysentery it has acquired considerable reputation.

Almost every region of the United States produces varieties of the wax myrtle. Michaux considers them all as belonging to one species, a conclusion which is warranted by the great number of intermediate sizes and forms of leaf, which may be observed between the different extremes. Pursh, however, has chosen to distinguish three species which bear wax, and which he names *cerifera* after Linnaeus, *Carolinensis* from Willdenow, and *Pennsylvanica* from Lamarck. The wax myrtle or bayberry, as it is often called, which is common in New England, varies in height from one to seven or eight feet. It is found in every

kind of soil from the borders of swamps to the tops of barren hills, and is very much influenced in its size and appearance, by the place in which it happens to grow.

The wax myrtle is found bearing fruit at every size, from the height of one foot, to six or eight. In Louisiana, it is said, to grow to twelve feet. The top is much branched, and covered with a grayish bark. Every young part of the wax myrtle has a fragrant, balsamic smell, which it communicates to the fingers when rubbed by them.

Dr. J. F. Dana has published, in Silliman's Journal, an account of some experiments made to ascertain the proportion of wax, and of the other parts which compose the entire berry. He found the wax to constitute nearly a third of the whole, or thirty-two per cent; the kernels 47.00, the black powder 15.00, with about 5.00 of a resino-extractive matter.

The myrtle wax is useful for many of the purposes for which bees wax and tallow are employed, particularly for candles. It burns with a clear flame, though less vivid than that of common oil, and emits a considerable fragrance. It was formerly much in demand as an ingredient in a species of blacking ball, to which it communicated a temporary lustre and power of repelling water. It has occasionally been used in pharmacy in various compositions intended for external use, and is mild or stimulating according as it is more or less pure and freed from the colouring matter.

In some parts of Europe plantations of this shrub have been raised with a view to the profit to be derived from the wax. In this country, where the shrub abounds, the berries are often neglected, their collection and the separation of the wax being deemed too laborious to compensate the trouble. The bark of the wax myrtle considered medicinally is an acrid stimulant and astringent. (*Dr. Bigelow's Am. Med. Botany.*)

CANE. A provincial term used to signify a hollow place, where water stands. It also implies a wood of alder, or other aquatic trees, in a moist boggy situation.

In the South-western States of America there are extensive and almost impenetrable cane-brakes, consisting of a rank growth of a sub-aquatic species of cane or reed (*Arundo prugmites?*). These cane-brakes resemble in many respects the jungles of the East Indies.

CANINE MADNESS. See HYDROPHOBIA.

CANKER, OR ULCER (Lat. *canker*; Sax. *cancere*, or *cancpe*). In the vegetable creation, a disease to which our apple, pear, elm, and other trees are subject.

"This disease," says Mr. G. W. Johnson, "is accompanied by different symptoms, according to the species of the tree which it infects. In some of those whose true sap contains a considerable quantity of free acid, as in the genus *Pyrus*, it is rarely accompanied by any discharge. To this dry form of the disease, it would be well to confine the term canker, and to give it the scientific name of *Gangrana sicca*, or dry gangrene. In other trees, whose sap is characterized by abounding in astringent or mucilaginous constituents, it is usually attended by a sanious discharge. In

such instances, it might be strictly designated *ulcer*, or *Gangræna saniosa*. This disease has a considerable resemblance to the tendency to ossification, which appears in aged animals, arising from their marked appetency to secrete the calcareous saline compounds that chiefly constitute their skeletons. The consequence is an enlargement of the joints, and ossification of the circulating vessels, and other parts; phenomena very analogous to those attending the cankering of trees. As in animals, this tendency is general throughout their system; but, as is observed by Mr. Knight, 'like the mortifications in the limbs of elderly people,' it may be determined, as to its point of attack, by the irritability of that part of the system. This disease commences with an enlargement of the vessels of the bark of a branch, or of the stem. This swelling invariably attends the disease when it attacks the apple tree. In the pear, the enlargement is less, yet is always present. In the elm and oak sometimes no swelling occurs, and in the peach I do not remember to have seen any; I have never observed the disease in the cherry tree, nor any of the pine tribe. The swelling is soon communicated to the wood; which, if laid open to view, on its first appearance, by the removal of the bark, exhibits no marks of disease beyond the mere unnatural enlargement. In the course of a few years, less in number in proportion to the advanced age of the tree, and the unfavourable circumstances under which it is vegetating, the swelling is greatly increased in size, and the alburnum has become extensively dead: the superincumbent bark cracks, rises in discoloured scales, and decays even more rapidly than the wood beneath. If the canker is upon a moderately sized branch, the decay soon completely encircles it, extending through the whole arburnum and bark. The circulation of the sap being thus entirely prevented, all the parts above the disease of necessity perish. In the apple and pear, the disease is accompanied by scarcely any discharge; but in the elm this is very abundant. The only chemists who have examined these morbid products are Sir H. Davy and Vauquelin; the former's observations being confined to the fact, that he often found carbonate of lime on the edges of the canker in apple trees. (*Elem. of Agr. Chemistry*, 2d edit. p. 264.)

Vauquelin has examined the sanies discharged from the canker of an elm with much more precision. He found this liquor nearly as transparent as water, sometimes slightly coloured, at other times a blackish-brown, but always tasting acrid and saline. From it a soft matter, insoluble in water, is deposited upon the sides of the ulcer. The bark over which the transparent sanies flows attains the appearance of chalk, becoming white, friable, crystalline, alkaline, and effervescent with acids. A magnifier exhibits the crystals in the forms of rhomboids and four-sided prisms: when the liquid is dark-coloured, the bark appears blackish, and seems as if coated with a varnish. It sometimes is discharged in such quantities as to hang from the bark like stactites. The matter of which these are composed is alkaline, soluble in water, and with

acids effervesces. The analysis of this dark slimy matter shows it to be compounded of carbonate of potassa and ulmin, a product peculiar to the elm. The white matter deposited round the canker was composed of—

	Parts.
Vegetable matter - - - -	60 5
Carbonate of potassa - - - -	34 2
Carbonate of lime - - - -	5
Carbonate of magnesia - - - -	0 3

Although young trees are liable to this disease, yet their old age is the period of existence most obnoxious to its attacks. It must be remembered, that that is not consequently a young tree which is lately grafted. If the tree from which the scion was taken is an old variety, it is only a multiplication of an aged individual. The scion may for a few years exhibit signs of increased vigour, owing to the extra stimulus of the more abundant supply of healthy sap supplied by the stock; but the vessels of the scion will, after the lapse of that period, gradually become as decrepid as the parent tree. The unanimous experience of naturalists agrees in testifying that every organized creature has its limit of existence. In plants it varies from the scanty period of a few months to the long expanse of as many centuries: but of all, the days are numbered; and though the gardener's, like the physician's skill, may retard the onward pace of death, he will not be permanently delayed. In the last periods of life they show every symptom that accompanies organization in its old age—not only a cessation of growth, but a decay of former developements, a languid circulation, and diseased organs.

The canker, as already observed, attends especially the old age of some fruit trees, and of these, the apple is most remarkably a sufferer. "I do not mean," says Mr. Knight, "to assert that there ever was a time when an apple tree did not canker on unfavourable soils, or that highly cultivated varieties were not more generally subject to the disease than others, where the soil did not suit them; but I assert, from my own experience and observation within the last twenty years, that this disease becomes progressively more fatal to each variety, as the age of that variety beyond a certain period increases; that all the varieties of the apple which I have found in the catalogues of the middle of the seventeenth century, are unproductive of fruit, and in a state of debility and decay." (*Some Doubts relative to the Efficacy of Mr. Forsyth's Plaster*, by T. A. Knight, Esq. 1802.)

Among the individuals particularly liable to be infected, are those which have been marked by an excessively vigorous growth in their early years. I have in my garden a maiden standard peach, which is now about sixteen years old. The size and abundance of its annual shoots, until within the last quarter of its existence, were unnaturally large. It is now grievously affected by canker. Trees injudiciously pruned, or growing upon an ungenial soil, are more frequently attacked than those advancing under contrary circumstances. The oldest trees are always the first attacked.

f those similarly cultivated. The golden pippin, the oldest existing variety of the apple, is more frequently and seriously attacked than any other. The soil has a very considerable influence in inducing the disease. If the subsoil is a ferruginous gravel, or if it is not well drained; if the soil is aluminous, and effective means are not adopted to free it of superabundant moisture,—the canker, under any one of these circumstances, is almost certain to make its appearance among the trees they sustain. If an old worn-out orchard is replanted with fruit trees, the canker is almost certain to appear among them, however young and vigorous they were when first planted. How inductive of this disease is a wet, retentive subsoil, if the roots penetrate it, appears from the statement of Mr. Watts, gardener to R. G. Russell, Esq., of Chequer's Court, in Buckinghamshire. A border beneath a south wall had a soil three feet and a half in depth, apparently of the most fertile staple; twice remade under the direction of the late Mr. Lee, of the Vineyard, Hammer-smith. In this the trees, peaches and nectarines, flourish for the next three or four years after they are planted, but then are rapidly destroyed by the canker and gum. The subsoil is a stiff sour clay, nearly approaching to a brick earth; and the disease occurs as soon as it is reached by the roots of the trees. (*Gardener's Magazine*, vol. vi. p. 617.) Pruning has a powerful influence in preventing the occurrence of canker. I remember a standard russet apple tree, of not more than twenty years' growth, with a redundancy of ill-arranged branches, that was excessively attacked by this disease. I had two of its three main branches removed, and the laterals of that remaining thinned carefully, all the infected parts, at the same time, being removed. The result was a total cure. The branches were annually regulated, and for six years the disease never reappeared. At the end of that time the tree had to be removed, as the ground it stood upon was required for another purpose. John Williams, Esq., of Pitmaston, from long experience concludes that the golden pippin, and other apples, may be preserved from this disease by pruning away, every year, that part of each shoot which is not perfectly ripened. By pursuing this method for six years, he brought a dwarf golden pippin tree to be as vigorous and free from canker as any new variety. (*Trans. London Hort. Soc.* vol. vi. art. 64.)

All these facts unite in assuring us that the canker arises from the tree's weakness; from a deficiency in its vital energy, and consequent inability to imbibe and elaborate the nourishment necessary to sustain its frame in vigour, and much less to supply the healthy development of new parts. It matters not whether its energy is broken down by an unnatural rapidity of growth, by a disproportioned excess of branches over the mass of roots, by old age, or by the disorganization of roots in an ungenial soil; they render the tree incapable of extracting sufficient nourishment from the soil, consequently incapable of developing sufficient foliage, and therefore unable to digest and elaborate even the scanty sap that is supplied to them

The reason of the sap becoming unnaturally saline appears to be, that in proportion as the vigour of any vegetable declines, it loses the power of selecting by its roots the nourishment congenial to its nature. M. Saussure found in his experiments that the roots of plants growing in saline solutions absorbed the most of those salts that were injurious to them, evidently because the declining plant lost the sensitiveness and energy necessary to select and to reject. Thus, when plants of *Polygonum Persicaria* and of *Bidens cannabina* were grown in a solution containing sulphate of soda (Glauber salt), acetate of lime, and chloride of sodium (common salt), they altogether rejected the acetate of lime; but when grown in a solution of sulphate of copper and acetate of lime, they imbibed the latter abundantly. Now, sulphate of copper M. Saussure found to be the most deleterious to the plants of all the salts, in a solution of which he plunged their roots. Supposing the portion originally in solution to be 100, the proportions of each absorbed were as follows:—

	Pa.
{ Chloride of sodium - - -	10
{ Sulphate of soda - - -	6
{ Acetate of lime - - -	0
{ Sulphate of copper - - -	34
{ Acetate of lime - - -	31

M. Saussure also found, that if the extremities of the roots were removed, the plants absorbed all solutions indiscriminately. (*Saussure's Recherches Chimiques sur la Vegetation*, 260.) An ungenial soil would have a debilitating influence upon the roots in a proportionate, though less violent degree than the sulphate of copper; and these, consequently, would absorb soluble bodies more freely, and without that discrimination so absolutely necessary for a healthy vegetation; so the other most essential organs of nutrition, the leaves of the weakened plant, would promote and accelerate the disease. These, reduced in number and size, do not properly elaborate the sap; and I have always found that, under such circumstances, these stunted organs exhale the aqueous particles of the sap very abundantly, whilst their power of absorption is greatly reduced. The sap, thus deficient in quantity and increased in acidity, seems to corrode and affect the vascular system of the tree in the manner already described. These facts afford us most important guides in attaining the desired objects, the prevention and cure of the disease. If superluxuriance threatens its introduction, the best remedy is for the cultivator to remove one of the main roots of the tree, and for him to be particularly careful not to add any fertile addition to the soil within their range. On the contrary, it will be well, if the exuberant growth shows its necessity, for the soil to be reduced in fertility by the admixture of one less fertile, or even of drift sand. If there is an excess of branches, the saw and the pruning-knife must be gradually applied. It must be only trees of weak vital powers, such as the golden pippin, that will bear the general cutting of the annual shoots, as pursued by Mr. Williams. A new vigorous variety would exhibit itself in the following year in the production of new wood.

Having completely headed down, if the can-

ker is generally prevalent, or duly thinned the branches, entirely removed every small one that is in the least degree diseased, and cut away the decayed parts of the larger, so as not to leave a single speck of the decayed wood, I cover over the surface of each wound with a mixture, whilst in a melted state, of equal parts of tar and rosin, applying with a brush immediately after the amputations have been performed, taking care to select a fine dry day. I prefer this to any composition with a basis of cow-dung and clay, because the latter is always more or less absorbent of moisture, and is liable to injury by rain and frost, causing alternations of moisture and dryness to the wounds, that promote decay rather than their healing, by the formation of new wood and oak. The resinous plaster seldom or never requires renewal. Mr. Forsyth, the arch-advocate of alkaline plasters, finding they promoted decay, if applied to the wounds of autumn-pruned trees, recommends this important act of cultivation to be postponed to the spring. Such a procrastination, however, is always liable to defer the pruning till bleeding is the consequence. If a resinous plaster is employed, it excludes the wet, and obviates the objection to autumnal pruning. Mr. Forsyth's treatment of the trunks and branches of the trees, namely, scraping from them all the scaly, dry exuviae of the bark, is to be adopted in every instance: he recommends them to be then brushed over with a thin liquid compound of fresh cow-dung, soapsuds, and urine. But I very much prefer a brine of common salt: each acts as a gentle stimulus, which is their chief source of benefit, and the latter is more efficacious in destroying insects, and does not, like the other, obstruct the perspiratory vessels of the tree. The brine is advantageously rubbed in with a scrubbing or large painter's brush. Some persons recommend a liquid wash, containing, as prominent ingredients, quicklime and wood-ashes; which, as the disease arises from an over-alkalescent state of the sap, cannot but prove injurious and aggravate the disease. Mr. Forsyth's composition, used as a plaster for the wounds made when cankered matter had been extracted, was—

1 bushel of fresh cow-dung,
 $\frac{1}{2}$ bushel of lime rubbish,
 $\frac{1}{2}$ bushel of wood ashes,
 $\frac{1}{8}$ bushel of finely-sifted sand.

Mr. Knight well observed of this quackery (for which Forsyth was rewarded with a grant of money), that "it afforded a much better proof that he was paid for a discovery than that he made one." (*G. W. Johnson; Quar. Journ. of Agr.* vol. viii. p. 470; J. Pearson, *ibid.* vol. ii. p. 379; A. Drummond, *On the Canker in the Larch*, *ibid.* p. 231.)

Canker in horses is a separation of the horn from the sensible part of the foot, and the sprouting of fungous matter instead of it, and occupying a portion of, or even the whole of the sole and frog. (*The Horse*, p. 308, *Lib. of Useful Knowledge*.) The whole secret of the treatment of canker consists in the use of superficial caustics or stimulants,—pressure as

firmly and as equably as it can be made, and the careful avoidance of all greasy applications, and all moisture, either applied immediately to the foot, or suffered to penetrate to it through the dressing. (*Cluter's Farriery*, p. 324.)

CANKERED. A word sometimes used to signify mildewed or blighted.

CANKERS. A local name in some parts of England for caterpillars.

CANKER-WORM. The insects, called in the Eastern States canker-worms, are caterpillars with ten legs, the larvæ of a natural group of moths called *hybernians*. They belong to the tribe of *geometers*, commonly called earth-measurers, span-worms, and loopers. See **SPAN-WORMS**.

CANTER. (Said to be an abbreviation of Canterbury gallop, and derived from the pilgrims riding to Canterbury on easy ambling horses.—*Todd's Johnson*.) A well-known pace of the horse, which is not, generally, a natural pace. When the horse is excited to move his station from one place to another, he performs it with a velocity proportionate to the exciting cause. Thus, he changes from the walk to the trot, and from the trot to the gallop, according to his inclination. In each of these changes he acquires an addition of speed; but, as the trot is equal in speed to the canter, he seldom adopts the canter, but changes to the gallop, when he wishes to accelerate his motion. The horse is taught to perform the canter by shortening the gallop. The canter is to the gallop very much what the walk is to the trot, though probably a more artificial pace. The exertion is much less, the spring less distant, and the feet come to the ground in more regular succession: it is a pace of ease, quite inconsistent with any exertion of draught. (*Lib. Use. Know., The Horse*, p. 413.) Some persons, and among them Nimrod, do not consider this pace injurious to horses. "A canter," he observes, "is much more easy, as well as safer to the rider, than a trot; the horse having his haunches more under him in the canter than when he trots, is hereby more likely to recover himself in case of making a mistake, which the best is sometimes subject to. Fast trotting also distresses a horse more than cantering, because, in the one, he is going at the top of his speed, and in the other much below it." (*Blaine's Ency. of Rural Sports*, p. 297.)

CAPERS. The caper is a small prickly shrub, cultivated in Spain, Italy, and the southern provinces of France. The flowers are large roses of a pretty appearance, but the flower-buds alone are the objects of this cultivation.

They are plucked before they open, and thrown into strong vinegar slightly salted, where they are pickled. The crop of each day is added to the same vinegar tub, so that, in the course of the six months during which the caper shrub flowers, the vessel gets filled, and is sold to persons who sort the capers (the smallest being most valued) by means of copper sieves. This metal is attacked by the acid, wherefrom the fruit acquires a green colour, much admired by *ignorant connoisseurs*.

The capers, as found in the French market, are distinguished into five sorts; the *nonpareille*, the *capucine*, the *capote*, the *second*, and the *third*; this being the decreasing order of their quality, which depends upon the strength of the vinegar used in pickling them, as also the size and colour of the buds.

The caper shrub grows in the driest situations, even upon walls, and does not disdain any soil; but it loves a hot and sheltered exposure. It is multiplied by grafts made in autumn, as also by slips of the roots taken off in spring.

CAPEs, or CAPPs, provincial words, applied to the ears of corn broken off, either wholly or in part, in thrashing; as well as to the grain to which the chaff adheres.

CAPITAL (Lat. *capitalis*). The capital required by a farmer, to a great extent, varies with the soil and country in which he is placed; all practical observations in this place, therefore, can only be of a general nature. The first and best direction, however, to a farmer must be, "do not take more land than your capital will enable you to farm well." For this purpose, the observations of the author of the *British Husbandry*, vol. i. p. 41, may very well be introduced in this place. "Most farmers are anxious for large occupations, and many are thus betrayed into the error of renting a greater quantity of ground than they have the means of managing to advantage; some, in the delusive hope of acquiring those means by future savings; others, from the vanity of holding more land than their neighbours: hence arises deficiency of stock, imperfect tillage, and scanty crops; with all the consequent train of rent in arrear, wages ill-paid, and debts unsatisfied—distress, duns, and final ruin. Whereas, he who is prudently content to commence with only such a number of acres as he has the power of cultivating with proper effect, is certain of obtaining the full return from the soil; while, not being burdened with more land than he can profitably employ, his engagements are within his means, and thus, while enjoying present ease of mind, he lays the surest foundation for his future prosperity." And, as it is well observed (*Quart. Journ. of Agr.* vol. iii. p. 452), "Or if, to save appearances, he borrows money to complete his necessary arrangements, his condition is not improved; because the interest he will have to pay for the borrowed money will operate as an additional yearly rent, and thus take from him all the advantages which he was led to expect he would enjoy under a moderate one." Under the head APPRAISEMENT will be found the amount of the valuation of the crops, and other things commonly paid by the incoming to the outgoing tenant on a farm of 309 acres, amounting to 1702*l.* This, however, varies considerably according to the CUSTOM OF COUNTIES, which see. To this must be added the expenses incurred of stocking the farm for the first year. Wages, seed, keep of family, rent, taxes, rates, &c. On a farm of 500 acres, Professor Low (*Prac. Agr.* p. 674) estimates the capital required for the first year to be (in Scotland)—

	£	s.	d.
1. Implements - - - - -	470	4	4
2. Live stock - - - - -	1423	15	0
3. Seed - - - - -	273	0	0
4. Manure - - - - -	516	10	0
5. Labour, &c. - - - - -	528	17	6
6. Maintenance of horses - - - - -	343	7	11
7. Burdens - - - - -	31	15	9
	3488	8	6
Furniture of house - - - - -	200	0	0
Family expenses, 1½ years - - - - -	150	0	0
	3838	8	6
From this he deducts for produce sold in this time - - - - -	995	17	9
Required net capital - - - - -	2842	10	9

or 5*l.* 13*s.* 8½*d.* per acre. In this calculation, he supposes that no rent is paid till the crop is reaped. The estimate for the capital required for a Scotch farm of 500 acres (allowing nothing for payments to outgoing tenant) is, according to a statement in the *Quart. Journ. of Agr.* vol. iii. p. 475, as follows:—

	£	s.	d.
Value of implements for farm work - - - - -	228	2	2
— do. live stock - - - - -	43	19	4
— do. barn work - - - - -	17	14	4
— Thrashing machine - - - - -	170	0	0
— Horses - - - - -	450	0	0
— Cattle - - - - -	511	0	0
— Sheep - - - - -	420	0	0
— Other live stock - - - - -	7	0	0
— Grass seeds - - - - -	87	10	0
— Tares - - - - -	6	8	0
— Peas - - - - -	4	0	0
— Turnips - - - - -	12	15	0
— Potatoes - - - - -	2	16	0
— Corn - - - - -	215	6	3
— Labour - - - - -	565	6	10
	3041	17	11
Rent 500 acres, at 40 <i>s.</i> - - - - -	1000	0	0
	4041	17	11

From which, however, deduct the value of the following articles, derived from the farm before the period of paying the second half year's rent, viz.

Profit on 20 fat cattle, 5 <i>l.</i> each - - - - -	£100
Wintering 20 kyloes for 24 weeks, at 2 <i>s.</i> 6 <i>d.</i> per week - - - - -	30
Sold 30 dinmots and gewmers at 25 <i>s.</i> each, and 20 draft ewes at 30 <i>s.</i> each - - - - -	130
Profit on turning 120 hogs 24 weeks, at 3 <i>d.</i> per head per week - - - - -	36
Sold 14 pigs - - - - -	14
Produce of 4 cows over what required by family - - - - -	10
Wool sold - - - - -	152
	472 0 0
	3569 17 11

At p. 658, of *Low's Prac. Agr.* will be found a catalogue of the various implements of a farm of 500 acres, from a thrashing machine worth 100*l.* to a grease pot valued at 1*s.* 6*d.*, amounting altogether to 474*l.* 4*s.* 4*d.* And this includes hardly a single article that the young farmer can well do without. As a general rule on the chalks of Hampshire, they deem 5*l.* per acre to be a sufficient capital; but on some of the rich highly cultivated soils of Surrey, Kent, and Essex, 10*l.* per arable acre is not too much. Grazing farms require less in proportion than arable lands.

CAPON (Sax. *capun*; Fr. *chapon*; Lat. *capo*). If cocks, when young, are emasculated, it has a prodigious effect upon their condition, and a similar effect may be produced upon young hens by the abstraction of their egg-bags. These operations have been practised upon

poultry from the earliest antiquity, for the purpose of improving the flesh. In England, it is chiefly practised in the great poultry-breeding counties of Sussex, Essex, and Berks, but is little known anywhere else. There are, indeed, persons who make a trade of it, and it is best to employ one of those when they can be had; but it is not uncommon for the poultry-farmers' wives and daughters to acquire dexterity in performing the operation. This, indeed, seems to be no new thing, for Mascall, in his minute but very quaint directions, uses the feminine gender throughout. "To cut young cockrels," he says, "to make them capons, the time thereof best to cut and carve them is soone after their dam has left them, or when they cry or pule no more after her, as when they begin to crowe and waxe hote to tread the pullets. The common way of cutting or carving is not to be disprayed, and is most knowne as this waye: they take them in the morning, commonly in the wane of the moone, and laye the cocke in her lappe, upon his back, trussing up his legges by his sides. Then the carver pluckes first awaye the feathers above the vent, and takes up the upper skin on the point of a needle, and slits it over-thwart an inche long, and then takes up the under thin skinne nexte the guts, and slits that likewise. Then the carver annoyntes her fore finger of her right hande with oyle or butter, and puts it gently to the raines of the cock, on the left side, and with her finger bringes forthe the stone. Then she annoyntes the fore finger of her left hande, and puts it into the stone on the right side of the cocke, and with her finger bringes it forthe. So done, she placeth the guts, and sows the skinne up again with a threade, and then annoyntes that place with some fresh butter, and lets him go."

The art of caponing fowls forms a part of rural economy, and as the mode of operating is very little understood in the United States, we propose giving such ample and minute instructions upon the subject, as, with the aid of original drawings, will enable any one to succeed who possesses common dexterity.

The chickens intended for capons should be of the largest breed that can be obtained, and in the United States there is not perhaps one better suited in this respect than the celebrated large *Buck's county breed*, well known in the Philadelphia market, where capons made from these fowls have been sold weighing 25 lbs. the pair. As in breeding with a special view to making capons, male chickens alone are required, those eggs should be selected to set under hens which produce males, namely, such as have the sharpest points. The alteration of the chicken into a capon will, in about a twelvemonth, nearly double the size of the bird. Persons wishing to become expert in the operation of making capons would do well to imitate surgeons, who always try their hand upon dead subjects before performing on the living. It is, however, quite simple, and in France and Italy is often allotted to mere children.

The Chinese mode of operating we think preferable not only to the old one described by Mascall, but to any other of which we have ever heard.

Chickens intended for capons may be operated upon at any age, though when between two and three months old is considered much the best time. Old fowls seldom survive the operation. Previous to cutting, the chickens must be kept entirely from food, and even water, for about thirty-six hours, as experiments have determined this time to insure the best chance of success by causing the bowels to be empty and lessening the tendency to bleeding. The fowl may be secured either in the Chinese mode,—that is to say, lying on its left side with its wings folded back till they meet, and pressed under the foot of the operator, whose other foot is placed upon the legs;—or, it may be held by an assistant in a similar position; or, what adds greatly to the convenience of the operator, especially in relieving him from the necessity of stooping low, the fowl may be confined by straps, &c. to a table one of which, of a highly ingenious construction, has been invented by a Philadelphian, and will be subsequently described and delineated. (See Figs. 2 and 3.)

The chicken being secured with its left side downwards, wings clasped behind its back, legs extended backwards, the upper one being drawn the furthest back (see fig. 3), the head and neck left perfectly free, the feathers are next to be plucked from its right side near the hip joint, in a line between that and the shoulder joint; the space uncovered (*a*, fig. 3) may be a little over an inch square. Having first drawn the skin of the part backward, so that when left to itself after the operation, it will cover the wound in the flesh, make an incision with the bevel-edged knife, (fig. 1. *a*.) between the last two ribs, commencing about an inch from the backbone, and extending obliquely downwards about an inch or inch and a half, just going deep enough to separate the ribs, and taking good care not to wound the intestines. A pair of broad blunt hooks (fig. 1, *c*, *c*) attached to a piece of elastic whalebone or ratan (*b*) about six inches long are then applied, one hook to each side of the cut, and these being stretched apart by the spring bow, keep the wound open wide enough to give room for the operation. Then carefully cut open the skin covering the intestines, which last, if not sufficiently drawn up in consequence of the previous fasting, may be pushed forwards or towards the breastbone, by means of a flat instrument contrived for the purpose, or, what answers equally well, the handle of a teaspoon. When the testicles are exposed to view, they will be found to be connected with the back and sides by means of a thin skin which passes over them. This tender covering must be seized with the pincers *a*, *a*, and torn open with the assistance of the sharp-edged hook *h*; after this, with the left hand, introduce the curved spoon under the lower or left testicle (which is generally a little nearer the rump than the right one): then take the tube *i*, and with the right hand pass the loop *n*, over the small hooked end of the spoon *h*, running it down under the spoon and included testicle, so as to bring the loop to act upon the part which fastens the testicle to the back. Then by drawing the ends of the hair-loop

backwards and forwards, and at the same time pushing the lower end of the tube towards the rump of the chicken, the cord or fastening of the testicle is sawn off. The same process is to be followed with the uppermost or right testicle, after which the separated testicles, together with any blood in the bottom of the wound are to be scooped out with the crooked spoon. When performed properly, little or no blood of consequence is observed, neither does the fowl seem to experience any pain, after the first incision, but will eat if food be given to it. To enable the operator to produce the sawing movement, the hair or other ligature used may be tied in a knot so as to allow the index or fore finger of the operator's right hand to pass through it. This finger being then turned or rolled repeatedly from side to side, communicates to the loop below the sawing motion which contributes to cut off the testicle. The reason for cutting off the lowermost testicle first, is to prevent the blood which may issue, from covering the remaining one, and rendering it difficult to be seen. After this operation which, if skilfully performed, occupies very few minutes, the hooks are to be taken out, the skin drawn over the wound, and this covered with the feathers plucked off at the commencement of the operation. The chicken is then released, and as soon as let go will take grain or other food eagerly, and in a day or two be restored to its usual health. A person well skilled may operate on fifty chickens without killing more than one or two.

In some fowls the fore part of the thigh covers the last two ribs; in which case care must be taken to draw the fleshy part of the thigh well back, to prevent its being cut, as this might lame the fowl or even cause its death.

For ligatures nothing answers so well as that commonly employed by the Chinese, namely, the fibre of the cocoanut husk. This is rough, and makes a loop which saws off and separates the testicle very readily. The next best substance for this purpose is horse-hair. Experiments with fine wire, silk, silk-gut, &c. show that these are all inferior to cocoanut fibre and horse-hair.

Sometimes a portion of the testicle adheres and is left behind, in which case the fowls will not prove capons, as will soon be evident, and may be killed for use as soon as the head begins to grow large and get red, and they show a disposition to chase the hens. The real capon will make itself known by the head remaining small, the comb and gills losing their bright redness and appearing withered; the feathers of the neck and tail will also grow longer. They should be kept to the age of fifteen or eighteen months, which will bring them in the spring and summer, when poultry is scarce and bears a high price. But they should not be killed near moulting time, as all poultry then is very inferior. The operation fails principally in consequence of the bursting of the skin which encloses the soft matter of the testicle, some of which remains in the bird.

Fowls of five or six months are less liable to have the testicles burst in the operation than

younger ones, but they are also more apt to bleed to death than those of from two to four months old. As the large vessel that supplies the entrails with blood passes in the neighbourhood of the testicles; there is danger that a young beginner may pierce this with the pointed instrument in taking off the skin of the lower testicle, in which case the chicken would die instantly. There are one or two smaller vessels to be avoided, which is very easy, as they are not difficult to be seen. If properly managed, no blood ever appears until a testicle is taken off: so that should any appear before that, the operator will know that he has done something wrong.

If a chicken die during the operation by bleeding, it is of course as proper for use as if bled to death by having its throat cut. They very seldom die after the operation unless they have received some internal injury, or the flesh of the thigh has been cut through, from not being drawn back from off the last two ribs, where the incision is made; all of which accidents may be liable to occur with young practitioners.

Where the testicles are found very large, the silver tube may be too small for the operation; in this case a larger one made of small bamboo or elder, about $\frac{3}{4}$ ths of an inch in diameter, may be substituted, with a strong cocoanut string or ligature. But for chickens of small and medium sizes, the silver tube, with a horse-hair in it, will answer perfectly well.

When a chicken has been cut, it is necessary, before letting it run, to put a permanent mark upon it; otherwise it would be impossible to distinguish it at first from others not operated on. Cutting off the outside or the inside toe of the left foot, will enable one to distinguish them at a distance. Another mode is to cut off the comb, then shave off the spurs close to the leg, and stick them upon the bleeding head, where they will grow and become ornamental in the shape of a pair of horns. This last mode is perhaps the best, but it is not so simple and ready as the first. Whichever plan is adopted, the fowl should be marked before performing the operation.

It is very common, after the operation, and whilst the wound is healing, for the side to puff out with a windy swelling. This may be relieved by making a small incision or puncture in the skin, which will let the wind escape.

Those fowls make the finest capons which are hatched early in the spring; as they can be cut before the hot weather comes, which is a great advantage.

The operator should not be discouraged with the first difficulties; for with practice they will disappear; every year's experience will render one more expert, until the cutting of a dozen fowls before breakfast will be a small matter.

It may be well to give a warning against becoming dissatisfied with the instruments. A raw hand, when he meets with difficulties, is apt to think the tools are in fault, and sets about to improve them and invent others; but it may be only himself that lacks skill, which practice alone can give. Those who have devoted much time and attention to the subject say

that they have found the old Chinese instruments, a drawing of which is given in fig. 1, preferable to all others.

In addition to these instruments, a regular Chinese set contains a flat kind of spatula something like the upper part of a spoon handle. This is about four inches long and half an inch wide, and slightly curved at each

end in opposite directions. It is for the purpose of pushing the intestines out of the way, an office very well performed by the handle of a teaspoon.

Fig. 1 represents the instruments used in making capons, according to the Chinese method, reduced only about one-fourth their actual sizes.

Fig. 1

a, a knife, the edge of which resembles that of a chisel with a bevel or slanting edge, half an inch in the greatest width; the other end or handle consists of two forcep blades terminating at *a, a*, in slender points, and forming spring forceps. The whole length from the cutting edge to the end of the pliers is about six inches.

c, c, two broad blunt hooks of silver or other metal, each half an inch in width and one and a half in length.

b, an elastic bow, six inches long, made of whalebone or ratan, about the thickness of a large quill, and split horizontally into two pieces. To the ends of this bow the broad hooks are attached by strong cords about half an inch long. At the end *d*, the cord embraces only the lower half of the split bow, whilst both pieces are included in the string, at the end *e*.

f, is a small ring which encircles both portions of the bow. When the hooks are first put in and only half the strength of the bow is required to act upon them, this ring is slipped to the end *e*. But if the whole strength of the bow is needed to force the hooks apart and stretch the wound open, the ring is passed towards the end *d*. Thus, by means of the split bow and sliding ring, the strain upon the hooks can be increased or slackened at pleasure.

i, a tube of silver or other metal three or four inches long, made square at the upper, and flattened at the lower end *k*, to the width of three-tenths of an inch; this tube is for the purpose of passing the fibre or hair ligature *m*, forming the loop *n*.

g, a narrow curved spoon, the slender handle of which tapers off and has a steel point fitted into it, furnished at the extremity with a very small hook, *h*; the inner edge of this hook is sometimes sharpened.

The operating table contrived in Philadelphia, and before referred to, is represented in the following cut, fig. 2.

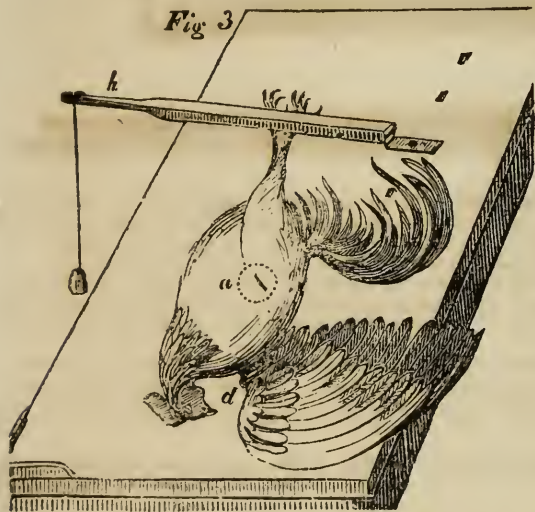

Fig. 2

This table may be about $2\frac{1}{2}$ feet long by $1\frac{1}{2}$ feet wide, and $2\frac{1}{2}$ feet high. At two of its corners it can have a raised moulding about $\frac{1}{2}$ an inch high, extending along the sides six or nine inches, for the purpose of placing the instruments at one corner and at the other some of the feathers under a stone, to keep them from being blown away. On one side there is a slit *c* passing through the table, about $1\frac{1}{4}$ inch long by $\frac{1}{2}$ an inch wide, running diagonally; being about three inches from the end and $6\frac{1}{2}$ from the side. Through this slit the padded band or soft list, *d, d*, for confining the wings, passes below to be attached to the lever *e*. This lever has a 4 or 5 lb. weight hung to it, and works on a screw or pin, by which it is attached to the leg. When not in use the lever rests on a pin or ledge in the other leg. On being led down, the attached band clasps the wings of the chicken lying on the table, with greater or less force as the weight is drawn to or from the end of the lever. The next thing to be described is the lever, *h*, upon the table,

the object of which is to hold down the legs as these are extended backwards. This lever is padded beneath, and is furnished with a hinge at *i*, which admits of being raised at the end *k*; it projects beyond the edge of the table, and has also a 5 lb. weight suspended by the string *l*, which increases or diminishes the pressure by being moved to or from the table. Through one portion of the hinge an iron screw, *m*, passes beneath the table where the end is secured by a nut. This screw or pin allows the lever to move sidewise, whilst the hinge admits of its being raised or let down. A range of holes, about $\frac{1}{2}$ of an inch wide, are made through the table to receive the pin of the lever, as this has to be placed nearer to or further from the slit *c*, according to the size of the chicken. The first hole is about eleven inches from the nearest end; the second, fourteen inches; the third, seventeen inches. The last is adapted to very large cocks or even turkeys.

In fig 3, the position of the fowl when secured, lying upon its left side upon the table, is represented, *d* being the wing-band, *h* the lever placed over the legs, and *a* the place where the incision is made.

The table is a refinement in the art of caponing which we believe is altogether new, notwithstanding the thousands of years which have elapsed since the operation has been habitually practised. The difficulty of making a subject, apparently simple, well understood by persons to whom it is entirely new, is, we think, a sufficient apology for the length of the details given.

In France and other countries, besides furnishing a luxurious food, capons are made useful in taking care of broods of young chickens, ducklings, turkeys, and pheasants, which they are said to do much better than hens, owing to their larger size and thicker coats of feathers. The moment the chickens are hatched they are taken from the hens and given to a capon, who rears them with all the care of a parent, often having a small bell attached to his neck, the tinkling of which serves the purpose of keeping the brood about him, similar to the clucking and maternal sounds of the mother. Should he show a disposition to treat the young chickens roughly

at first, he may be confined alone for a day or two in a dark place, after which if they be put with him he will be pleased with their company and continue to take care of them. The hen is cooped, and well fed until she regains the flesh and strength lost whilst setting, and then turned out to lay again. In this way the poulterer is enabled to raise a large number of chickens from a few hens. The capon generally brings double or treble the price of common poultry.

CAPILLARY VESSELS OF VEGETABLES. The fine hair-like vessels that assist in the absorption and circulation of the juices of plants.

CAPSICUM. (Supposed either from *καπτα*, *mordeo*, to bite; or from *capsa*, a chest.) *Capsicum annuum*. Of this there are five varieties. 1. Long-podded. 2. Heart-shaped. 3. Short-podded. 4. Angular-podded. 5. Round short-podded. Of the *Capsicum cerasiforme* there are three varieties. 1. Cherry-shaped. 2. Bell-shaped, or Ox-heart. 3. Yellow-podded. The soil best suited for them is a rich, moist, mouldy loam, rather inclining to lightness than tenacity. When completely ripe, the pods are cut and hung up in the sun, or in a warm room, until completely dry, in which state they are kept until the seed is wanted for sowing. (*G. W. Johnson's Kitchen Garden.*)

The capsicum loses some of its aromatic odour by drying, its taste, both recent and dry, is hot and acrid, depending on a fixed acrid oil, not volatile and distinct from that oil which gives the odour to the fresh pod. Capsicum is used as a condiment in cookery; it is more excitant than pepper; but its effects are less permanent.

CARAWAY, or CARRAWAY (*Fr. and It. carvi*; *Lat. carum carui*). A naturalized biennial plant, with a taper root like a parsnip, but much smaller; stem about two feet high, growing wild in meadows and pastures. This plant is extensively cultivated in several parts of Essex and some other counties, for the sake of its seeds, which are in daily use as a grateful and wholesome aromatic, and are largely consumed in confectionary and medicinal preparations; but its root was formerly much esteemed when boiled, and it is not easy to account for its falling into disuse. The seeds, which are grayish-brown, and ribbed, are too well known to need description. They should be chosen large, new, of a good colour, not dusty, and of a strong agreeable smell. Caraway is sometimes sowed with coriander and teasel, and harvested the second year. The produce of this seed has often been very great; even as much as 20 cwt. per acre, which always finds a market in London. On account of their aromatic smell and warm pungent taste, the seeds of caraway may be classed among the first stomachics and carminatives of our climate. To persons afflicted with flatulency, and liable to colic, if administered in proper quantities, they generally afford considerable relief. Their virtue depends on a volatile oil, which is procured in a separate state, by distillation with water. The water retains some of the oil, and is used as a vehicle for other medicines.

Caraway delights in a deep, rich, moist loam. The ground for this, as well as other deep-rooting plants, is advantageously dug two spades deep. An open situation is most suitable to it; but in extensive orchards, where the trees are far apart, it may be grown with success. It is propagated by seed, which may be sown in March or April, either broadcast and raked in, or in drills six inches apart; in either case being performed thin, and buried about half an inch deep. When well distinguishable, the plants must be thinned to six inches apart, and carefully hoed. The hoeing must be several times repeated in the early stages of their growth, to extirpate the weeds, which at a later period cannot be conveniently got at. The plants flower in June, and ripen their seed at the close of summer. (*G. W. Johnson's Kitch. Gard.*; *English Flora*, vol. ii. p. 86; *M'Culloch's Com. Dict.*; *Willich's Dom. Encyc.*; *Brande's Dict. Science.*)

CARBON (Fr. *carbone*; Lat. *carbo*). A hitherto undecomposed combustible body, which enters into the composition, in some form or other, of all vegetable substances. In a perfectly pure state, carbon constitutes diamond. Carbonaceous substances are usually more or less compounded, containing hydrogen, or sometimes oxygen, and azote, along with earthy and metallic matters. Carbon, tolerably pure, abounds in the mineral kingdom; and, in a combined state, it forms a main constituent of vegetable and animal bodies. Anthracite is a mineral charcoal, differing from common pit-coal in containing no bitumen, and therefore burning without flame or smoke. *Coke* is the carbonaceous mass which remains after pit-coal has been exposed to ignition for some time out of contact of air; its volatile parts having been dissipated by the heat. It is a spongy substance, of an iron-black colour, a somewhat metallic lustre, and does not easily burn unless several pieces are kindled together. With a good draught, however, it produces a most intense heat. It is readily obtained in the form of *charcoal* by heating wood (and any kind of wood will answer the purpose) red-hot, covered with sand, in a crucible. The covering with sand is added to prevent the wood undergoing combustion by coming in contact with the atmosphere. In this state when reduced to powder, charcoal constitutes an excellent manure for most soils, either when applied by itself, or mixed with decomposing animal and vegetable substances. In such cases it absorbs a considerable volume of the gases which such substances constantly emit. Thus, reckoning the bulk of the charcoal to be 1, it absorbs of

	Volumes.
Ammoniacal gas - - - -	90
Sulphuretted hydrogen - - - -	55
Carbonic acid gas - - - -	35

When burnt, charcoal unites with the oxygen of the atmosphere, and forms, in the state of carbonic acid gas, a very important portion of the gases required by all plants for their healthy vegetation. (See **GASES, THEIR USE TO VEGETATION.**) Carbon constitutes about 42.47 per cent. in sugar, 41.906 per cent. in gum, 43.55 per cent. in wheat starch, 52.58 per cent. in the wood of the oak, and 51.45 in that

of the beech; 46.83 in pure acetic acid or vinegar, 36.167 in tartaric acid, and 41.369 in the citric. In the state of carbonic acid gas, and in various organic matters, it is found in all cultivated soils, in all waters, and in the atmosphere; and in each situation, as will be more particularly described under the head **GASES**, it is absorbed by and becomes the food of plants.

CARBONATES. A peculiar class of salts formed by the combination of carbonic acid gas with various earths, alkalies, and metallic oxides. The composition of those most commonly met with by the farmer is as follows:—

	Acid.	Base.
Carbonate of lime, <i>chalk, limestone, &c.</i> - - - -	66.2	33.8
Carbonate of magnesia - - - -	68.75	31.25
Bicarbonate of potash - - - -	46.19	53.81
Carbonate of soda - - - -	40.14	59.86
Carbonate of ammonia - - - -	56.41	43.59

CARBONIC ACID GAS. A peculiar gas, the same as that emitted by fermenting beer, or other liquors; it is inhaled by, and its carbon is the food of plants. It is composed of carbon 72.73, oxygen 27.27. See **GASES, THEIR USE TO VEGETATION**,

It is important to know, that carbonic acid gas is poisonous, if breathed. If, for example, a person descends into a tun where fermented liquor occupies the bottom, and an atmosphere of carbonic acid gas floating over it; as soon as his mouth is immersed in it, he is suffocated in the same manner as if his mouth and nostrils were closed. He dies from the defect of atmospheric air in the lungs, and the circulation of black blood through the brain. This is the manner also in which death occurs when persons descend into old wells and cellars that have been long closed. When the gas is diluted with air, as for instance, when a person dies by burning charcoal in a chafing-dish in a bed-room, he is not suffocated; but he dies from the sedative influence of the diluted carbonic acid, which is breathed, on the nervous system. When such accidents happen, persons should not venture to bring out the bodies, until a quantity of pure lime mixed with water to the thickness of milk, has been thrown into the tun, well, or cellar; or in the event of death from burning charcoal, until a current of air has been sent through the apartment. The bodies should be laid on their backs, with the heads moderately elevated; cold water dashed on the chest, and frictions employed over the whole body; and the aid of a medical practitioner quickly procured.

This is the heaviest of all gases, its weight, compared with the common air of the atmosphere, being about one-half greater. This is the reason why it always subsides to the bottom of apartments, wells, sinks, &c., where it may have been formed, or gained access. Its weight even admits of its being poured from one vessel to another. Hence it was at first called *aërial acid*. From its existing copiously, in a solid state, in limestones and the mild alkalies, it was styled *fixed air* by its proper discoverer, Dr. Black. About one volume of it exists in one thousand volumes of common atmospheric air, which may be made manifest by the crust of

carbonate it occasions upon the surface of lime-water. Carbonic acid gas is found accumulated in many caverns of volcanic districts, and particularly in the *grotto del cani* at Paulsippo, near Puzzuoli; being disengaged in such circumstances by the action of subterranean fire, and, possibly, of certain acids, upon the limestone strata. It often issues from fountains in copious currents, as at Franzensbrunn, near Eger, in Polterbrunnen; near Trier; and Byrreshorn. This acid gas occurs also frequently in mines and wells, being called *choke damp*, from its suffocating quality. Its presence may, at all times, be detected, by letting down a lighted candle, suspended from a string, into the places suspected of containing this mephitic air. It exists, in considerable quantities, in the water of every pumpwell, and gives it a fresh and pleasant taste. Water, exposed some time to the air, loses these aerial particles, and becomes vapid. Many springs are highly impregnated with carbonic acid gas, and form a sparkling beverage; such as the *Selterswasser*, from Selters, upon the Lahn, in the grand duchy of Nassau; of which no less than two millions and a half of bottles are sold every year. The amount in Saratoga water is very great. A prodigious quantity of a similar water is also artificially prepared under the name of aerated or soda water.

Carbonic acid occurs in nature, combined with many salifiable bases; as in the carbonates of soda, baryta, strontia, magnesia; the oxides of iron, manganese, zinc, copper, lead, &c. From these substances it may be separated, generally speaking, by strong ignition, or more readily, by the superior affinity of muriatic, sulphuric, or nitric acid, for the earth or metallic oxyde. It is formed whenever vegetable or animal substances are burned with free access of air, from the union of their carbonaceous principle with atmospheric oxygen. It is also formed in all cases of the spontaneous decomposition of organic substances, particularly in the process of fermentation; and constitutes the pungent, noxious, heavy gas thrown off, in vast volumes, from beer vats. See DISTILLATION and FERMENTATION. Carbonic acid is also generated in the breathing of animals; from 4 to 5 per cent., in volume, of the inhaled oxygen being converted, at each expiration, into this gas, which contaminates the air of crowded apartments, and renders ventilation essential to health, and even to life; witness the horrible catastrophe of the Black-hole at Calcutta.

Carbonic acid gas is destitute of colour, has a sourish, suffocating smell, an acidulous pungent taste, imparts to moist, but not dry, litmus paper, a transient reddish tint, and weighs per 100 cubic inches, 46½ grains; and per cubic foot, 803½ grains; a little more than 3½ oz., avoirdupois. A cubic foot of air weighs about two-thirds of that quantity, or 527 grains. It may be condensed into the liquid state by a pressure of 40 atmospheres, and this liquid may be then solidified by its own sudden spontaneous evaporation. If the air contain more than 15 per cent. in bulk of this gas, it becomes unfit for respiration and combustion,

animal life and candles being speedily extinguished by it.

Before a person ventures into a deep well, or vault containing fermenting materials, he should introduce a lighted candle into the space, and observe how it burns. Carbonic acid being so much denser than common air, may be drawn out of cellars or fermenting tubs, by a pump furnished with a leather hose, which reaches to the bottom. Quicklime, mixed with water, may be used also to purify the air of a sunk apartment, by its affinity for, or power of, absorbing this aerial acid. (*Ure's Dict. of Arts, &c.*)

CARBURETTED HYDROGEN. A compound of carbon and hydrogen gases, of which there are several species; such as *oil gas, coal gas, olefiant gas, oil of lemons, otto of roses, oil or spirits of turpentine, petroleum, naphtha, naphthaline, oil of wine, caoutchoucine, and caoutchouc or Indian rubber.* (*Ure's Dict. of Arts, &c.*)

CARDINAL, SCARLET (*Lobelia cardinalis*). An herbaceous hardy plant, a native of Virginia. It blows its scarlet flowers in July, and again in October. It loves bog earth and shade, and the root should be parted every spring. Ripen the flower intended for seed under a glass hung over it, for it rarely ripens in this climate without assistance. This superb wild flower is worth a place in every garden. It continues blooming a long time. Five or six species are known in the United States.

CARDOON, or CHARDON (Span. *cardo*, an artichoke; Lat. *Cynara cardunculus*). A kind of wild artichoke, which is principally confined to garden culture, as it has not yet been employed as an article of food for any sort of live stock.

The stalks of the inner leaves, when rendered tender by blanching, are used in stews, soups, and salads. A light rich soil is most suitable to this vegetable, dug deep and well pulverized. The situation must be open, and free from trees, for, like the artichoke, it is impatient of confinement. It is propagated by seed, which may be sown at the close of March; but, for the main crop, not until the early part of April; those plants raised from earlier sowings being apt to run at the close of autumn: for a late crop, a sowing may be performed in June. The best practice is to sow in patches of three or four rows, four feet apart each way, to be thinned finally to one in each place, the weakest being removed. The seedlings are nearly a month in appearing. If, however, they are raised in a seed-bed, they will be ready for transplanting in about eight or ten weeks from the time of sowing, and must be set at similar distances as are specified above. The plants of the first sowing are generally three weeks before they make their appearance; those from the later ones, about two. If, after a lapse of these times, they do not appear, it should be ascertained if the seed is decayed, and in that case the sowing may be renewed. The seed must be sown rather thin, and covered with about half an inch depth of mould. When about a month old, the seedlings, if too crowded, must be thinned to four inches apart; and those removed may

be placed out at a similar distance, if there is any deficiency of plants. When of the age sufficient for their removal, they must be taken up carefully, and the long straggling leaves removed. The bed for their reception must be dug well and laid out in trenches as for celery, or a hollow sunk for each plant; but as they are liable to suffer from excessive wet, the best mode is to plant on the surface, and form the necessary earthing in the form of a tumulus. Water must be applied abundantly at the time of planting as well as subsequently, until they are established; and also in August, if dry weather occurs, regularly every other night, as this is found to prevent their running to seed. The only other necessary point to be attended to is, that they may be kept free from weeds during every stage of their growth. When advanced to about eighteen inches in height, which, according to the time of sowing, will be in August, and thence to October, the leaves must be closed together by encircling them with a hay-band, and earth placed round each plant, a dry day being selected for performing it. As they continue to grow, fresh bands and earth must be constantly applied, until they are blanched to the height of two feet, or about two-thirds of their stems. They will be fit for use in eight or ten weeks after the earthing first commences. Care must be had in earthing them up, to prevent the earth falling in between the leaves, which is liable to induce decay. The surface of the soil should likewise be beaten smooth, to throw off the rain. In severe weather their tops should be covered with litter, it being removed as invariably in mild weather: by this treatment, they may be preserved in a serviceable state throughout the winter. For the production of seed, which in England seldom comes to maturity except in dry seasons, a few plants should be set in a sheltered situation, of the April sowing; of course not earthed up, but allowed the shelter of mats or litter in frosty weather. In the spring, the ground may be dug round them to destroy weeds, as well as to encourage the growth of the roots. The flowers make their appearance about the beginning of July, and the seed is ripe in September. (*G. W. Johnson's Kitchen Garden.*)

CAREX. A vast genus of grasses comprehending more than two hundred species, nearly all of which are indigenous to America. It includes sedges, and a vast variety of grasses found in salt-water marshes. See **SEdge**.

CARLICK. A provincial term applied in some places to charlock.

CARNATION, or CLOVE PINK (Lat. *carnes*; *Dianthus caryophyllus*). A beautiful and odoriferous perennial, blowing in July and August, and cultivated in beds or in pots. The wild *D. caryophyllus* is the origin of our fine garden carnations. (*Smith's Eng. Flor.* vol. ii. p. 287.) There are three distinct varieties; the flake, the bizarre, and the picotée. The flake has two colours only, with large stripes; the bizarre is variegated with irregular stripes and spots, of not less than three colours; and the picotée has a white ground, spotted with every variety of scarlet, red, purple, and pink. They love a light, rich earth mixed with sea-

sand, and never bloom very handsomely without a proportion of the latter. Carnations are propagated by layers, pipings, and from seed, which produce new sorts. There is an immense collection of fine prize carnations, well known to the public, too lengthy to insert here; but they are easily procured at a reasonable price. If you raise flowers from seed, sow it in pots of light earth in April; cover the seed very lightly with mould filtered through the fingers; shade the seedlings from the sun, and prick them out when each seedling has six leaves. Pot or plant for blowing in autumn. They will not blow well if moved in the spring. Carnations must be sheltered from excessive rains and hard frosts, and they should be placed in warm sunny borders.

CARNATION GRASS. In agriculture, a term applied to some grasses, as the hair grass (*Aira*), probably from their having this kind of colour in their flowers. Any coarse species of carex is so named in the north of England and Scotland.

CAROB (*Ceratoria caroubier*). A tree cultivated extensively in the south of Europe, the pods produced by which contain a sweet, eatable fæcula. The tree attains a medium size, and the flowers, which are of a deep purple colour, are disposed in clusters. The fruit-pods are a foot long, contain a reddish pulp, of an agreeable sweet taste when dry; and are supposed to be "the husks (*κεράτια*) that the swine did eat," (Luke xv. 16). They are used as food for man and horse. The carob tree is raised from seeds.

CARPET (Dutch, *karpēt*; Ital. *carpetta*). A covering for floors, &c., manufactured of wool, or other materials, worked with the needle or by the loom. Carpets are generally composed of linen and worsted, but the Kidderminster or Scotch carpets are entirely fabricated of wool. Persian and Turkish carpets are the most esteemed. In England carpets are principally manufactured at Kidderminster, Wilton, Cirencester, Worcester, Axminster, &c.; and in Scotland at Kilmarnock. Those made at Axminster are believed to be very little, if any thing, inferior to those of Persia and Turkey. (*McCulloch's Com. Dict.*; *Willich's Dom. Encyc.*; *Brand's Dict. of Science.*)

CARRIAGE (Fr. *cariage*). A general name applied to carts, wagons, and other vehicles, employed in conveying passengers, goods, merchandise, &c., from one place to another, and which are usually constructed with two or four wheels. Wheel-carriages first came into use about 1381; they were called *whirlcotes*, and were little better than litters or cots (*cotes*) placed upon wheels.

Carriage, in irrigation, is a conduit made of timber or brick: if the latter, an arch is turned over the stream that runs under it, and the sides bricked up; if the former, which it commonly is, it is constructed with a bottom and two sides, as wide and as high as the main it lies in. It must be made very strong, close, and well-jointed. Its use is to convey the water in one main over another which runs at right angles with it; its depth and breadth are of the same dimensions with the main it belongs to; its length is in proportion to the

breadth of the main it crosses. It is the most expensive conveyance belonging to the irrigating of land.

CARRIAGE DRAIN. See **DRAINS.**

CARROT (Fr. *carote*). A well-known annual or biennial root, common alike to the field and the garden. The wild carrot, from whence all those now commonly cultivated came, is a native of England, found chiefly on chalky hills. The kinds now preferred for field culture are the long red, the Altringham, and the orange. It is a crop which, for the heavier description of soils, is becoming more and more cultivated in this country; for its produce is not only large, but it can be grown on lands not suited to turnip culture; for although the soils best adapted to it are deep sandy loams, yet it can be grown successfully on sands and peats. The carrot delights, however, in a deep soil, and thus land intended for it can hardly be ploughed too deep. It is usual to trench plough or subsoil for it; and in Holland they are even at the pains to deepen with the spade the furrows made by the plough. It may be sown, like the turnip, on ridges, by the drill or otherwise, or broadcast. The seed should be of the previous season's growth; if mixed a fortnight before sowing with two bushels of sand or mould, kept wetted and turned over once or twice, they will grow all the better (*Com. to Board of Agr.* vol. vii. p. 70—299); and it keeps the seed from clinging together. (*Jour. of Roy. Agr. Soc. of Eng.* p. 40.) The quantity proper to be sown per acre (April is the best period) is two pounds by the drill, and about five when sown broadcast. The plants should be hoed out like turnips, and dug up in October for storing; but they may be left in the ground if preferred, and dug up as they are wanted. They may be stored either in a building covered with straw or haulm, or in pits piled in heaps four feet deep. (*Brit. Husb.* vol. ii. p. 287.) The common produce is from 280 to 450 bushels per acre—9000 lbs. (*Com. Board of Agr.* vol. vi. p. 141.) It is admirable food for all kinds of stock. (*Low. Agr.* p. 326.) Either the tops mown off green, which is said not to injure the roots (*Com. Board of Agr.* vol. v. p. 211), or the roots, for horses, half a bushel a day, sliced in chaff, is admirable food. (*Youatt on the Horse*, p. 358, 392, 213; *Brit. Husb.* vol. i. p. 125.) 1000 parts of the carrot contain 98 of nutritive matter. (*Davy's Lect.*) It should be well manured with either farm-yard dung (20 cubic yards per acre); or pigeons' dung is excellent (*Quar. Jour. of Agr.* vol. v. p. 144); or a mixture of salt, 6½ bushels, and soot 6½, trenched in (*Sinclair; Johnson on Salt*, 31, 146; *Rev. E. Cartwright, Com. Board of Agr.* vol. iv. p. 376); or sea-weed trenched in fresh as collected from the shore (*Quar. Jour. of Agr.* vol. vii. p. 268); or turf trenched in deep (*Com. Board of Agr.* vol. iv. p. 191); or street sweepings, mixed with one-third of pigs' dung and 20 hogshead of liquid manure. (*Flem. Husb.* 40.) The white or Belgian carrot has been recently tried as a field crop with considerable success; Sir C. Burrell having grown of this variety in 1840, "on a very indifferent field," 1000 bushels per acre (*Brit. Farm. Mag.* vol. iv. p. 464); Lord Ducie, 26 tons 3 cwt.;

and from 20 to 32 tons by Mr. Harris; and in Jersey 38 tons per acre. It is described in the *Report of the Yoxford Farmers' Club* as well adapted for strong or mixed soil lands, as keeping well, and as excellent food for horses. (*Journ. of Royal Agr. Soc.* vol. ii. p. 42.)

CARROT, THE GARDEN (*Daucus carota*; as some imagine from *δαιον*, though its taste is far from being pungent. Perhaps from *δαουρ*, on account of the thickness of its root). There are a considerable number of varieties of the carrot, which are divided by horticulturists into two families: those with a regular fusiform root, which are named *long carrots*; and those having one that is nearly cylindrical, abruptly terminating, but continuing with a long slender tap-root, which are denominated *horn carrots*. The first are employed for the main crops; the second, on account of their superior delicate flavour, and are advantageously grown for early use. They are likewise commonly recommended for shallow soils. Horn carrots,—early red horn, common early horn, long horn: this last is the best for the summer crop. Long carrots,—white, yellow, long yellow, long red, Chertsey or Surrey, superb green-topped or Altringham: the last two are the best for main crops. Carrots should have a warm, light, sandy, fertile soil, dug full two spades deep, as they require to be deeper than any other culinary vegetable. With the bottom spit it is a good practice to turn in a little well-decayed manure; but no general application of it to the surface should be allowed in the year they are sown. A spot should be allotted them which has been made rich for the growth of crops in the previous year, or else purposely prepared by manuring and trenching in the preceding autumn. The fresh application of manure is liable to cause their growing forked, and to expend themselves in fibres, as well as to be worm-eaten. If, however, the want of manure must be obviated at the time of sowing, it should be used in a highly putrescent state, and but in small quantities, finely divided and well mixed with the soil. If the soil is at all binding, it should be well pulverized by digging very small pits at a time, &c. Mr. Smith of Keith Hall, N. B., recommends pigeons' dung as the best manure for this crop: it not only prevents the maggot, but causes them to grow finer. He applies it in the same proportion as is usually done of stable manure. (*Mem. Caled. Hort. Soc.* vol. i. p. 129.) Carrots are propagated by seed. The first sowing for the production of plants to draw whilst young should take place in a moderate hotbed during January, and in a warm border at the conclusion of February or early in March. At the close of the last month, or more preferably in the early part of April, the main crop must be inserted; though, to avoid the maggot, it is even recommended not to do so until its close. In May and July the sowing may be repeated for production in autumn; and lastly, in August, to stand through the winter, and produce in early spring. For sowing, a calm day should be taken advantage of; and, previous to commencing, the seeds should be separated by rubbing them between the hands, with the admixture of a little sand;

otherwise, by reason of their adhering by the hairs that surround their edges, they are clotted together, and cannot be sown regular. The surface of the bed should likewise be laid smooth; otherwise, in raking it, the seed will be drawn together in similar heaps. To avoid this, before raking, it may be gently trod in. The seed should be sown thin, and the beds not more than four feet wide, for the convenience of after-cultivation. The larger weeds must be continually removed by hand; and when the plants are seven or eight weeks old, or when they have got four leaves two or three inches long, they should be thinned; those intended for drawing young to four or five inches apart, and those to attain their full growth to eight or ten; at the same time, the ground must be small-hoed, which operation should be regularly performed every three or four weeks, until the growth of the plants becomes an effectual hinderance to the growth of the weeds. The crop to stand through the winter should, in a frosty weather, be sheltered with a covering of litter, as, if frost occurs with much severity, it often destroys them. The hotbed for the first sowing of the year must be moderate, and earthed about sixteen inches deep; two or three linings of hot dung, as the heat decreases, will be sufficient to bring them to a state fit for use. These are the first in production, but are closely followed by those that have withstood the winter. The temperature must never exceed 70°, or fall lower than 65°: if it rises higher, it is a certain cause of weakness; if lower, it checks the advance of the root. They need not be thinned to more than three inches apart.

At the close of October, or early in November, as soon as the leaves change colour, the main crop may be dug up, and laid in alternate layers, with sand, in a dry outhouse; previous to doing which, the tops, and any adhering earth, must be removed. A dry day should always be chosen for taking them up.

For the production of seed, it is by much the best practice to leave some where raised. If, however, this is impracticable, some of the finest and most perfect roots should be selected, and their tops not cut so close as those for storing; these likewise must be placed in sand until February or March, though some gardeners recommended October or November, then to be planted out two feet asunder in a stiff loamy soil. Those left where grown, or those planted at the close of autumn, must, during frosts, have the protection of litter; it being invariably removed, however, during mild weather. As the seed ripens in August, which is known by its turning brown, about the end of August each umbel should be cut; for if it is waited for until the whole plant decays, much of the seed is often lost during stormy weather. It must be thoroughly dried by exposure to the sun and air, before it is rubbed out for storing. For sowing, the seed should always be of the previous year's growth; if it is more than two years old, it will not vegetate at all. (*G. W. Johnson's Kitchen Garden.*) The boiled carrot forms a good poultice in foul and cancerous ulcers.

Carrots, are much cultivated in many parts of the United States, where many farmers prefer them over every other vegetable for fattening swine, cattle, and even as feed for horses. To fatten swine they should be given boiled, to store-hogs, raw.

The following remarks upon the culture and use of carrots in New England, are extracted from Mr. Colman's Second Report on the Agriculture of Massachusetts.

"Jno. Merrill, of South Lee, has been a very successful cultivator of carrots. He states the yield on two acres at 600 bushels to the acre; and the cost of cultivation, exclusive of manure and rent of land, at twenty-five dollars per acre; or a little more than four cents per bushel. For feeding horses, he says, he should prefer one hundred bushels of carrots and one hundred bushels of oats to two hundred bushels of oats. He applied them in a raw state to the feeding of his team horses, and horses in preparation for market; and they were kept by them in high health and spirits. Oats followed his carrot crop on the same ground with great success. The experience of J. C. Curwen, Eng., in the use of carrots for horses, corresponds with that of Mr. Merrill. The authority of Curwen is unquestionable; and he was in the habit of employing constantly as many as eighty horses on his farm and in his extensive coal mines.

"I cannot omit," he says, "stating the great profit of carrots. I have found by the experience of the last two years, that where eight pounds of oat-feeding was allowed to draft horses, four pounds might be taken away and supplied by an equal weight of carrots; and the health, spirit, and ability of the horses to do their work be perfectly as good as with the whole quantity of oats. With the drill husbandry and proper attention, very good crops of carrots may be obtained upon soils not generally supposed suitable to their growth."

"He adds in another place. 'The profits and advantages of carrots are in my opinion greater than any other crop. This admirable root has, upon repeated and very extensive trials for the last three years, been found to answer most perfectly as a part substitute for oats. Where ten pounds of oats are given per day, four pounds may be taken away; and their place supplied by five pounds of carrots. This has been practised in the feeding of eighty horses for the last three years, with the most complete success, and the health and condition of the horses allowed to be improved by the exchange. An acre of carrots supplies a quantity of food for working horses equal to sixteen or twenty acres of oats.'

"My own experience of the value of carrots, which has not been small, fully confirms these statements. I have obtained at the rate of more than a thousand bushels to the acre on three quarters of an acre; but on several acres my crop has usually averaged 600 bushels to the acre.

— Smith of Middlefield, Hampshire county, from three-fourths of an acre obtained 900 bushels.

"Charles Knowlton of Ashfield, Franklin

county this year obtained 90 bushels on twelve rods of ground. This was at the rate of 1200 bushels to the acre.

"D. Moore, of Concord, Middlesex county, from six rods of land, obtained this year 56 bushels; or at the rate of 1493 bushels to the acre.

"According to Josiah Quincy's experience in Quincy, Plymouth county, charging labour at one dollar per day his carrots cost him eleven cents per bushel. David and Stephen Little, in Newbury, Essex county, in 1813, obtained, 961 bushels to the acre, at an expense of \$79.50 every expense included, excepting rent of land. This was at a rate less than nine cents to a bushel."

Mr. Colman subjoins, in an Appendix, an account of an experiment made in feeding swine, illustrating the value of this vegetable, upon the authority of Arthur Young.

"The great objection to the cultivation of carrots lies in the difficulty of keeping them while growing free from weeds. If sown without any preparation, the seed is a long time in germinating; and a plentiful crop of weeds is liable to get possession of the land before the carrots make their appearance. There is another difficulty. The carrot seed from its minuteness is liable to be sown too thickly. To obviate in a degree these objections, let the ground be ploughed deeply, well manured, and put in fine tilth; and let the first and perhaps the second crop of weeds be ploughed in. After this let the land be thrown into ridges two feet apart, and the seed sown on top of the ridges either in a single line, or the ridges be made so wide as to receive two rows of carrots, eight inches or one foot apart. In the mean time the seed should be freely mixed with fine sand; and the sand kept so moist that the seed shall germinate. As soon as it is sprouted it should be sown. This may be so arranged that the sowing shall take place about the first of June. They will then have the start of the weeds. The mixture with sand will prevent their being sown too thickly. After the first thinning and weeding is over, if done with care, the battle may be considered as won. Afterwards let them be cultivated with a plough or cultivator and kept clean. When the time of digging arrives, the work will be greatly facilitated by passing a plough directly along the side of the carrots; and they are easily thrown out by the hand."

CARROT, WILD (*Daucus carota*, Pl. 10, o). This common plant is abundant in pastures, and about hedges, in a gravelly soil. It is a biennial plant, flowering in June and July. Its root is small, slender, aromatic, and sweetish. It grows two feet high, branched, erect, leafy; the stalks are firm and striated; the leaves are divided into fine and numerous partitions, of a pale-green colour, being also hairy. The flowers are in large umbels, with large, pinnatifid involucre, and undivided involucre, small and white, except the central flower, which is red; and they are succeeded by rough seeds. This is one of those plants in which we are able to perceive design. The seeds require to be protected, to produce which all the flower-stalks become incurved, making

the umbel hollow, or giving it the aspect of a cup or nest. The seed is medicinally used; it is a powerful diuretic. An infusion of the seeds in white wine is very restorative in hysterical disorders.

The wild carrot is found in pastures, roadsides, &c. in Pennsylvania and the Middle States. Although much esteemed in Europe as a food for milch-cows, it is regarded as rather a nuisance by the farmers in the United States, and requires great exertion to destroy and keep under when once introduced into fields. (*Flor. Cest.*)

CARRUCAGE (from *caruca*, an old name for the plough). In husbandry, denotes the ploughing of ground, either ordinary, as for grain, hemp, flax; or, extraordinary, as for woad, dyer's weed, rapeseed, &c.

CARRUSATE. A term that anciently denoted the quantity of arable land capable of being tilled in one year with one plough.

CARRYING. A term used in horsemanship. A horse is said to carry low, when, having naturally an ill-shaped neck, he lowers his head too much. This fault may be remedied by a proper bridle. A horse is said to carry well, when his neck is raised or arched, and he holds his head high and firm, without constraint. *Carrying in the wind*, is applied to horses which frequently toss their noses as high as their ears, and do not carry their heads handsomely.

CARSE. A provincial term applied to such lands as lie in the hollows near large rivers or estuaries of the sea, and have a deep rich soil. The carse of Gowrie, in Scotland, yields the heaviest crops of grain north of the Tweed. Such lands are either of the deep clayey loamy kind, or alluvial soils in a state of aration.

CART. A vehicle constructed with two or more wheels, and drawn by one or more horses. Half a century since, Lord Robert Seymour advocated the cause of the single-horse cart: he observed, that the advantages of single-horse carts are universally admitted, wherever they have been attentively compared with carriages of any other description. By his own observation he was led to think that a horse when he acts singly, will do half as much more work as when he acts in conjunction with another; that is to say, that two horses will, separately, do as much work as three conjunctively: this arises, he believes, in the first place, from the single horse being so near the load he draws; and, in the next place, from the point or line of draught being so much below his breast—it being usual to make the wheels of single-horse carts very low. A horse harnessed singly has nothing but his load to contend with; whereas, when he draws in conjunction with another, he is generally embarrassed by some difference of rate, the horse behind or before him being quicker or slower than himself; he is likewise frequently inconvenienced by the greater or lesser height of his neighbour: these considerations gave, he conceived, a decided advantage to the sort of cart he recommended. If any other is wanted, that of the very great ease with which a low cart is filled may be added; as a man may load it with the help of a long-handled shovel or fork, by means

his hands only: whereas, in order to fill a
er cart, not only the man's back, but his
s and whole person must be exerted. To
use of single horses in draught he has
rd no objection, unless it be the supposed
essity of additional drivers created by it:
fact, however, is, that it has no such effect;
horses once in the habit of going singly,
follow each other as uniformly and as
dily as they do when harnessed together;
accordingly we see, says he, on the most
quented roads in Ireland, men conducting
e, four, or five single-horse carts each,
hout any inconvenience to the passengers:
h, likewise, is the case in England, in
ch lime and coal are generally carried.
Ann. of Agr. vol. xxvii. p. 337.) And
might likewise have added, the single-horse
ts in some of the northern counties, where
a man manages two or three, and sometimes
re.

The subject of carts has recently engaged
attention of the Royal Agricultural Society
England. Mr. Baker of Gloucestershire,
s, in their *Journ.* vol. i. p. 429, "My land is
a stiff clay; my carts are on six-inch wheels,
I made to hold half the quantity that my
ghbours carry in theirs. My land is hilly;
carts generally go with one horse; but up
, when loaded, another is put on before,
ich comes down the hill with the next re-
ning cart. Thus, on a level ground, with
o carts, and two or perhaps with three horses,
ake out the same quantity of dung that my
ghbours carry in their carts with never less
n three horses, and sometimes with four."
d in the *Journ. of the Roy. Agr. Soc. of Eng.*
. ii. p. 73, is a very good article by Mr. Han-
n of Burcott, illustrated by engravings of the
e-horse cart, and of a new one of his own
struction. "The counties of Cumberland
d Westmoreland," he observes, "have uni-
sally and immemorially used the one-horse-
t. They have no other carriage for any
d of agricultural produce, and never is the
dition of another horse on any occasion
en." The practice, apparently originating
economy, has long since spread into Dum-
esshire; and, according to Mr. Wilkie of
ddingston, it is all but universal at the present
ment throughout the west of Scotland.
y dung-carts," he adds, "are taken from the
proved Cumberland cart, which measures
nches long \times $47\frac{1}{2}$ inches wide \times 17 inches
ep = 1 cubic yard = 21 bushels; and it tilts
th a spring key-stick, which adjusts itself
the horse moves forward; the wheels are
out 4 feet 6 inches high, and are set so far
part as to conveniently span two 27-inch
dges; it weighs 8 cwt." There are a variety
carts peculiar to different counties, most of
hich are described, and drawings given, in
Brit. Husb. vol. i. p. 159; from the heavy one-
horse cart of the vicinity of London, to the
ght simple Irish or Yarmouth car, as well as
e improved car first introduced into Leices-
rshire by Bakewell.

The carts of Pennsylvania are perhaps un-
rpassed in the United States for neatness
d strength. Either one, two, or three horses
e used, as circumstances may require, and

broad or narrow wheels, but the former are
preferable for farmwork.

CARTER. An inferior sort of farm servant,
who has the care of driving and foddering the
team. He should always be chosen as steady,
regular, sober, and trustworthy as possible, and
be perfectly gentle and humane in his disposi-
tion. It is of great importance to the farmer
to have a carter with these qualifications; for
otherwise his horses may be ill-treated, neg-
lected, overworked, or overfed, and much
fodder wasted. (*Brit. Husb.* vol. i. p. 170.) Le-
onard Mascall, nearly two centuries since, told
the carter of his day to "have patience in mo-
derate using of his horses; and at all other
times he ought to bear a love alwayes to his
cattel, that his cattel may love him, not fearing
him too much; let him never use to beat them
with the stock of his whip, but whip them with
the lash, and use them to the sound thereof,
and yet not often for dulling of them."

CARTHAMUS, or SAFFLOWER (*Chartha-
mus tinctorius*), an annual plant cultivated in
Spain, Egypt, and the Levant, for its flower,
which is used in dyeing silks, &c., and in
making rouge. See **SAFFRON**.

CART LODGE. A small outhouse for
sheltering carts from the weather. Farmers
should be very careful to place their carts, &c.
under proper shelter, when out of use, as they
will last much longer by this means than if
left exposed in the yard to the effects of the
weather; for, as they are thus sometimes wet,
and sometimes dry, they soon rot, and become
unfit for use. The dust and dirt should also
be constantly washed off before they are laid
up. There are some excellent observations on
the necessity of care in the preservation of
agricultural implements by Mr. Crosskill of
Beverley. (*Journ. of Roy. Agr. Soc.* vol. ii. p.
150.) He advises that the implements should
all be placed under the care of one workman
on the farm, who should be encouraged to feel
a pride in showing his master's implements in
fine order.

CARY'S CATTLE GAUGE. An instru-
ment made in the form and on the principle of
a slider rule, for ascertaining the weight of
live cattle, which is indicated in stones of 8 lbs.
and 14 lbs. (See *Brit. Husb.* vol. ii. foot note
at p. 393.)

CASINGS. A provincial term, signifying
dried cow's dung, which is used in several
parts of England for fuel.

CASK. A vessel of capacity, for holding
different sorts of liquids, or other matters.
See **BARREL**.

CASSAVA. See **TAPIOCA**.

CAST. A term applied to a swarm or flight
of bees (see **BEES**); and to poultry when they
lose their feathers or moult. It is also used to
denote the changing of the hair and hoofs of
horses. Horses cast or shed their hair at least
once a year. Every spring they cast the win-
ter coat, and gain a summer one; and some-
times in the end of autumn they put on their
winter hair, in case they have been ill-fed,
carried, or clothed, or kept in a cold stable.
Occasionally they cast their hoofs: when this
happens, let them be turned out into a pa-
ture.

CASTING. The operation of throwing a horse down, which should be performed with great care on straw. Take a long rope, double it, and cast a knot a yard from the bow; put the bow about his neck, and the double rope betwixt his fore legs, about his hinder pasterns, and under his fetlocks: when you have done this, slip the ends of the rope underneath the bow of his neck, and draw them quick, and they will overthrow him; then make the ends fast, and hold down his head.

CASTING A COLT. A term which implies a mare's proving abortive.

CASTOR OIL. The well known medicinal oil obtained from the seeds or beans of the *Palma Christi*, a plant indigenous to the West Indies. The cultivation of the *Palma Christi* and the manufacture of castor oil is extensively carried on in some parts of the United States, and continues on the increase. A single firm at St. Louis has worked up 18,500 bushels of beans in four months, producing 17,750 gallons of oil, and it is stated that 800 barrels have been sold at \$50 the barrel. This oil may be prepared for burning, machinery, soap, &c., and is also convertible into stearin. It is more soluble in alcohol than lard-oil.

CASTRATION. In farriery, a term signifying, in regard to animals, the operation of gelding in males, and spaying in females. The operation may be performed at any age, but, in general, the earlier the better. For cattle, between two and eight months; for sheep, before they are twenty-one days old; in horses, between four and twelve months.

CAT (*Felis catus*, L.). A genus of animals comprising twenty-one species, and belonging to the same class as the lion and the tiger. Though originally a variety of the wild cat, one of the most ferocious brutes, this animal is now domesticated. The former inhabits hollow trees, especially the oaks of large forests, and in winter retreats to the deserted holes of foxes and badgers. Its skin is an excellent fur, but by no means compensates the damage done by wild cats to game and poultry.

The domestic cat, when suffered to retire to thickets, easily returns to a wild state. Its colour is uncommonly diversified; but the most beautiful varieties are the reddish Spanish cat, and that of Angora, with long silken hair. A tame cat generally attains the age of about twelve years; the female breeds in the first year, though it grows till eighteen months old; she usually produces from four to six blind kittens, after a gestation of fifty-five days; and carefully conceals them, apprehensive of the unnatural voracity of the male. It is further remarkable, that the female also has been observed to devour her offspring, when it happened to be deformed or monstrous.

The flesh of animals or fish is the most agreeable food to cats; for they partake of vegetable aliment only from necessity. As they chew with difficulty, frequent drink is indispensably requisite to the preservation of their health. There are, however, some plants of which they are excessively fond, and when indulged with them, present a variety of whimsical gesticulations; of this nature is the vale-

rian root, and the herb called nep, or catmint, the *Nepeta cataria*, L.; on the contrary, they shun other vegetables as their mortal enemies, for instance, the common rue, or *Ruta graveolens*, L. Any substance rubbed with the leaves of this plant is said to be perfectly secure from their depredations: for the communication of this useful fact in domestic life we are indebted to C. P. Funke, a German naturalist.

Cats enjoy a warm temperature and a soft couch; moisture and filth, as well as water and cold, are equally repugnant to their nature; hence they are continually cleaning themselves with their paws and tongue. Another peculiarity is the *purring* of these animals, when they are cajoled or flattered, by passing the hand over their backs; this singular noise is performed by means of two elastic membranes in the larynx, or the upper part of the wind-pipe. Their hair is so electric that the expanded skin of a cat makes an excellent cushion for the glass cylinder or globe of an electrifying machine.

The flesh of cats is eaten by several nations, but the substance of the brain is said to be poisonous. From the intestines of these animals are manufactured the celebrated Roman chords for covering the violin.

They are manufactured out of the guts of rabbits and sheep also; they are cleaned, soaked in water, stretched by a machine, and dried. The name catgut comes from the circumstance of cats being used as food in many parts of Italy, and their guts applied to the making of strings. (*Willich's Dom. Encyc.*)

Several species of the cat kind are found wild in America. Dr. Harlan, in his "Fauna Americana," describes the following:

1. The *Cougar* of Buffon, the *Pouma* of some travellers, vulgarly called the *American Lion*. This is of a deep yellow colour, without a mane or a tuft at the end of the tail. Its total length is about three feet six inches, including the tail, which is over two feet long. The body is long and slender, head small, legs strong and short, tail long and trailing, colour grayish about the eyes, hairs within the ears white slightly tinged with yellow. This animal inhabits both American continents, from Paraguay and Brazil to Canada. Dr. Harlan thinks the *Pennsylvania Cougar*, *Panther* or *Wild-cat* a variety of the *Pouma*. The ferocity of these animals is familiarly known, and the pioneers often suffer from their depredations upon pigs, sheep, calves, and even colts.

2. The *Jaguar*, or South American panther, is also met with in the southwestern portions of the United States, and has occasionally been found east of the Mississippi. It is much larger than the North American panther, being four and a half feet long, including the tail, the length of which is two feet two inches. Their proportions are thick and clumsy. The hairs are short, strong, compact, silky. The fur yellowish, and covered with spots either entirely black, or yellow encircled with black. Like all wild cats they rove by night, and retire into thick swamps by day.

3. The *Spotted Mountain Cat*, the *Felis pardalis* of Linnæus, and *Ocelet* of Buffon, inhabits

Mexico and the southwestern parts of the United States, though it has not been found east of the Mississippi. Its general colour is gray, marked with large fawn-coloured spots, bordered with black, forming oblique bands on the flanks. It is about two feet long from the end of the snout to the origin of the tail, which measures about two feet.

4. The *Canadian Lynx*, or *Felis Canadensis* of Buffon, inhabits the Canadas, Labrador, &c. Its tail is very short, and black on the posterior half. The ears are terminated by a small tuft of hairs. The colour of the body is grayish, with yellowish or pale brown points below, and some black lines on the head. Total length two feet three inches, the included tail being only three or four inches long.

5. Another species of wild cat, called by naturalists *Felis rufa*, or *Red Cat*, the *Chat-cervier* of furriers, is found in the forests of New York, Pennsylvania, and Ohio. This is rather smaller than the common lynx, the head and back being of a deep red, with small spots of blackish brown, throat whitish, breast and belly of a clear reddish white.

6. Another lynx of large size, found on the northwestern coast by Lewis and Clarke, has been called by naturalists *Felis fasciata*. This Dr. Harlan thinks is probably the same as that described by Mr. Nuttall in his *Travels in Arkansas*. Its tail is very short, white, with the point black. The ears are furnished with pencils of hair, and black externally. The furs very thick, of a brownish-red colour, with stripes and points above.

7. The common American *Mountain Cat* or *Catamount* (*Felis montana*), has been also named the *Mountain Lynx* and *Mississippi Lynx*. It is found in the Alleghany mountains, from New York to Florida. The tail is very short, and in colour gray. The ears are destitute of pencils of hair, and externally blackish, with whitish or yellow spots within. Length three or four feet including the tail.

8. Another species has been found on the borders of the Yellow Stone river, in size about one half larger than the domestic cat, the tail being only two inches long. It is the *Lynx aureus* or *Golden Lynx* of Rafinesque, so named from its clear, brilliant yellow colour. It is spotted with black and white. The ears are without pencils.

CATALPA (*Bignonia catalpa*). A shrub growing in England thirty or forty feet high; its beautiful pendulous flowers bloom in August. It has a peculiarly large bright green leaf; loves heat, and does not blow in wet summers. It is tolerably hardy; easily raised from layers or seed.

The catalpa is an American tree which Michaux says begins to be found in the Atlantic States, on the banks of the Savannah river, near Augusta, Georgia, and west of the Alleghanies, on the banks of the Cumberland, between the 35th and 36th degrees of latitude. Further south it becomes still more common, and abounds near the borders of all the rivers which empty into the Mississippi, or which water West Florida. Michaux expresses surprise that this tree should not have been naturally distributed in the lower part of the

Carolinas and Georgia, and in East Florida, which lie so near the country of its primitive growth. This is the more strange from the fact that the catalpa manifests a great tendency to spread itself abroad by means of its winged seeds, and has in so many instances left the vicinity of dwellings where it was planted as a shade tree and mixed with the natives of the forest. It may, for example, be seen along the banks of the Schuylkill, and many other places, growing wild.

In the South it frequently exceeds fifty feet in height, with a diameter of eighteen to twenty-four inches. Its ample heart-shaped leaves, clusters of rich and beautiful flowers, long bean-shaped seed-pods, and wide spreading summit, give a strong character to this tree, which differs from all others in the fewness of its branches.

That the catalpa is a tree of rapid growth is proved by the distance of the annual concentric circles. Its wood is of a grayish white colour, of a fine texture, very light, and very brilliant when polished. It resembles the butternut wood, with the exception that the butternut wood is of a reddish hue, and is less durable when exposed to the weather. Posts of the catalpa perfectly seasoned have been proved to be very lasting. In the spring, if a bit of the cellular integument of the bark be removed, a very offensive odour is exhaled. The honey collected from the flowers of this tree is somewhat poisonous, its effects, though less alarming, being similar to those produced by eating that collected by bees from the yellow jasmine (*Geselinum nitidum*).

In the Southern States the catalpa is called Catawba tree, after the name of the Indian tribe that formerly inhabited a large part of the country from which the tree was first procured. The French of Upper Louisiana call it *Bois Shavanon*, from the Shavanon or Shawnee nation which once existed in West Tennessee, watered by the Cumberland river. (*Michaux*.)

The rapid growth of the catalpa in almost every situation in which it can be placed in the Middle States, and the adaptation of its wood to posts and other useful purposes, make it deserving the attention of the farmer wherever other kinds of wood are scarce, especially the kinds suitable for fences.

CATARACT. In farriery, a disease in the eyes of horses, in which the crystalline humour is rendered opaque, and the vision impeded or destroyed. The only certain method of cure in these complaints is to remove the lens by means of extracting or couching. By the first mentioned operation, an incision is made into the eye, and the opaque lens taken out; by the second, it is depressed by the point of a couching needle thrust into the eye, and, being carried to the lower part of the chamber of the eye or vitreous humour, it is left there to be absorbed. The first operation is the more effective, but the more hazardous of the two, owing to the inflammation which succeeds. The second is tedious and sometimes fails, but it is free from the risk of inflammation.

CATCH-WEED, CLEAVERS, or GOOSE-GRASS (*Galium Aparine*, *Eng. Flor.* vol. i. p

21). Pl. 10, *h*. A weed growing in hedges and by roadsides. See HARRIFF.

CATCH-WORK. A term employed in irrigation for the works for throwing the water over such lands as lie on the declivities of hills.

CATCH-WORK MEADOW. That sort of meadow which is formed by turning the water of a spring or small rivulet along the side of a hill or declivity, so as to water the lands between the cut or *main carriage* and the original water-course, which in this case becomes the main drain. See IRRIGATION.

CATERPILLAR. The name given to the larva state of butterflies and moths.

The natural history of insects so universally destructive as caterpillars, which in voracity are only inferior to locusts, cannot fail to interest all, whether residents of town or country; and it is evident that persons acquainted with the precise nature and habits of destructive insects, their times and seasons of multiplication and transformation, must be enabled to devise the most effectual means of protection against their ravages. Thanks to the intelligent policy and liberal patronage of the Legislature of Massachusetts, the most exact and valuable information upon this branch of the history of destructive insects has been placed before the public, through the labours of the distinguished American entomologist, Doctor Harris.

Caterpillars are the larvæ or young of moths and butterflies, of which, Dr. Harris says, 500 species are already known to him as natives of Massachusetts; and he thinks there may be as many more yet undiscovered in the limits of that state. As each female usually lays from 200 to 500 eggs, 1000 different kinds of butterflies and moths will produce, on an average, 300,000 caterpillars. If one-half of this number, when arrived at maturity, are females, they will give 45,000,000 of caterpillars in the second, and 6,750,000,000 in the third generation. These data, whilst they suffice to show that the actual number of these insects existing at any one time is far beyond the limits of numerical calculation, explain their formidable capacity to destroy vegetation. Whilst most caterpillars feed upon the leaves of plants, some devour the solid wood of trees, some live only in the pith of plants, and some confine themselves to grains and seeds. Certain species attack wools, furs, and other animal substances; for even leather, meat, wax, flour, and lard afford nourishment to particular kinds of caterpillars. "Some species herd together in great numbers, and pass the early period of their existence in society; and of these there are kinds which unite in their labours, and construct tents serving as a common habitation, in which they live, or to which they retire occasionally for shelter. Others pass their lives in solitude, either exposed to the light and air, or sheltered in leaves folded over their bodies, or form for themselves silken sheaths, which are either fixed or portable. Some make their abodes in the stems of plants, or mine in the pulpy substances of leaves; and others conceal themselves in the ground, from which they issue only when in search of food.

"Caterpillars usually change their skins

about four times before they come to their growth. At length they leave off eating entirely, and prepare for their first transformation. Most of them, at this period, spin around their bodies a sort of shroud or cocoon, into which some interweave the hairs of their own bodies, and some employ, in the same way, leaves, bits of wood, or even grains of earth. Other caterpillars suspend themselves, in various ways, by silken threads, without enclosing their bodies in cocoons; and, again, there are others which merely enter the earth to undergo their transformations.

"When the caterpillar has thus prepared itself for the approaching change, by repeated exertions and struggles it bursts open the skin on the top of its back, withdraws the forepart of its body, and works the skin backwards till the hinder extremity is extricated. It then no longer appears in the caterpillar form, but has become a pupa or chrysalis, shorter than the caterpillar, and, at first sight, apparently without a head or limbs. On close examination, however, there may be found traces of a head, tongue, antennæ, wings, and legs, closely pressed to the body, to which these parts are cemented by a kind of varnish. Some chrysalids are angular, or furnished with little protuberances; but most of them are smooth, rounded at one end, and tapering at the other extremity. While in the pupa state, these insects take no food, and remain perfectly at rest, or only move the hinder extremity of the body when touched. After a while, however, the chrysalis begins to swell and contract, till the skin is rent over the back, and from the fissure there issues the head, antennæ, and body of a butterfly or moth. When it first emerges from its pupa skin, the insect is soft, moist, and weak, and its wings are small and shrivelled; soon, however, the wings stretch out to their full dimensions, the superfluous moisture of the body passes off, and the limbs acquire their proper firmness and elasticity.

"The conversion of a caterpillar to a moth or butterfly is a transformation of the most complete kind. The form of the body is altered, some of the legs disappear, the others and the antennæ become much longer than before, and four wings are acquired. Moreover, the mouth and digestive organs undergo a total change; for the insect, after its final transformation, is no longer fitted to subsist upon the same gross aliment as it did in the caterpillar state: its powerful jaws have disappeared, and instead thereof we find a slender tongue, by means of which liquid nourishment is conveyed to the mouth of the insect, and its stomach becomes capable of digesting only water and the honeyed juice of flowers.

"Ceasing to increase in size, and destined to live but a short time after their final transformation, butterflies and moths spend this brief period of their existence in flitting from flower to flower and regaling themselves with their sweets, or in slaking their thirst with dew or with the water left standing in puddles after showers, in pairing with their mates, and in laying their eggs; after which they die a natural death, or fall a prey to their numerous enemies.

"These insects belong to an order called *LEPIDOPTERA*, which means scaly wings; for the mealy powder with which their wings are covered, when seen under a powerful microscope, is found to consist of little scales, lapping over each other like the scales of fishes, and implanted into the skin of the wings by short stems. The body of these insects is also more or less covered with the same kind of scales, together with hair or down in some species. The tongue consists of two tubular threads placed side by side, and thus forming an instrument for suction, which, when not in use, is rolled up spirally beneath the head, and is more or less covered and concealed on each side by a little scaly or hairy jointed feeler. The shoulders or wing-joints of the fore-wings are covered on each side by a small triangular piece, forming a kind of epaulette, or shoulder-cover; and between the head and the thorax is a narrow piece, clothed with scales or hairs sloping backwards, which may be called the collar. The wings have a few branching veins, generally forming one or two large meshes on the middle. The legs are six in number, though only four are used in walking by some butterflies, in which the first pair are very short, and are folded like a tippet on the breast; and the feet are five-jointed, and are terminated, each, by a pair of claws.

"It would be difficult, and indeed impossible, to arrange the Lepidopterous insects according to their forms, appearance, and habits, in the caterpillar state, because the caterpillars of many of them are as yet unknown; and therefore it is found expedient to classify them mostly according to the characters furnished by them in the winged state.

"We may first divide the *Lepidoptera* into three great sections, called butterflies, hawk-moths, and moths, corresponding to the genera *Papilio*, *Sphinx*, and *Phalæna* of Linnæus.

"The butterflies (*Papiliones*) have threadlike antennæ, which are knobbed at the end; the fore-wings in some, and all the wings in the greater number, are elevated perpendicularly and turned back to back, when at rest; they have generally two little spurs on the hind-legs, and they fly by day only. Their caterpillars, when about to transform, suspend themselves by the tail, and are not enclosed in cocoons.

"The hawk-moths (*Sphinges*) generally have the antennæ thickened in the middle and tapering at each end, and most often hooked at the tip; the wings are narrow in proportion to their length, and are confined together by a bristle or bunch of stiff hairs on the shoulder of each hind-wing, which is retained by a corresponding hook on the under side of each fore-wing. All the wings, when at rest, are more or less inclined like a roof, the upper ones covering the lower wings: there are two pairs of spurs on the hind-legs. A few fly by day, but the greater number in the morning and evening twilight.

"In the moths (*Phalænæ*) the antennæ are neither knobbed at the end nor thickened in the middle, but taper from the base to the extremity, and are either naked, like a bristle, or are feathered on each side. The wings are confined together by bristles and hooks, the

first pair covering the hind-wings, and are more or less sloping when at rest; and there are two pairs of spurs to the hind-legs. These insects fly mostly by night."

Among American destructive caterpillars described by Dr. Harris, are the larvæ of those butterflies called *Asterias*, seen in great abundance upon certain flowers in the month of July—particularly on the sweet-scented phlox. These flies, which are of a black colour with a double row of yellow dots on the back, lay their eggs, in this and the following month, on various umbellate plants, placing them singly on the different parts of the leaves and stems. The fly is large, its wings expanding from three and a half to four inches. The hinder wings are tailed, and have seven blue spots, with an eye-like spot of an orange colour near their hinder angle. The caterpillars of this tribe, Dr. Harris has found on various garden vegetables and plants, such as the carrot, parsley, celery, anise, dill, caraway, and fennel; also upon nightshade, hemlock, and other plants of the same poisonous family, which, he observes, constituted the appropriate food for these insects, before the exotics just named became abundant and furnished them in greater variety and profusion.

"Their injury to these cultivated plants," says the doctor, "is by no means inconsiderable; they not only eat the leaves, but are particularly fond of the blossoms and young seeds. I have taken twenty caterpillars on one plant of parsley which was going to seed. The eggs, laid in July and August, are hatched soon afterwards, and the caterpillars come to their growth towards the end of September, or the beginning of October; they then suspend themselves, become chrysalids, in which state they remain during the winter, and are not transformed to butterflies till the last of May or the beginning of June in the following year."

"I know of no method so effectual for destroying these caterpillars as gathering them by hand and crushing them. An expert person will readily detect them by their ravages on the plants which they inhabit; and a few minutes devoted, every day or two, to a careful search in the garden, during the season of their depredations, will suffice to remove them entirely.

"In Europe there are several kinds of caterpillars which live exclusively on the cruciferous or oleraceous plants, such as the cabbage, broccoli, cauliflower, kale, radish, turnip, and mustard, and oftentimes do considerable injury to them. The prevailing colour of these caterpillars is green, and that of the butterflies produced from them, white. They belong to a genus called *Pontia*; in which the hind-wings are not scolloped nor tailed, but are rounded and entire on the edges, and are grooved on the inner edge to receive the abdomen."

In the northern and western portions of Massachusetts, there is a white butterfly, the wings of which expand about two inches. This in all its states agrees with the character of the European insect. It is the potherb *pontia* (*Pontia oleracea*), a white butterfly, described by Dr. Harris in the *New England Farmer* in

1829 (page 402). "About the last of May and beginning of June, it is" he says, "seen fluttering over cabbage, radish, and turnip beds, and patches of mustard, for the purpose of depositing its eggs. These are fastened to the undersides of the leaves, and but seldom more than three or four are left upon one leaf. The eggs are yellowish, nearly pear-shaped, longitudinally ribbed, and are one fifteenth of an inch in length. They are hatched in a week or ten days after they are laid, and the caterpillars produced from them attain their full size when three weeks old, and then measure about one inch and a half in length. Being of a pale green colour, they are not readily distinguished from the ribs of the leaves beneath which they live. They do not devour the leaf at its edge, but begin indiscriminately upon any part of its under-side, through which they eat irregular holes. When they have completed the feeding stage, they quit the plants, and retire beneath palings, or the edges of stones, or into the interstices of walls, where they spin a little tuft of silk, entangle the horns of their hindmost feet in it, and then proceed to form a loop to sustain the forepart of the body in a horizontal or vertical position."

The next day after attaching itself it casts off its caterpillar skin and becomes a chrysalis, sometimes of a pale green, and sometimes of a white colour, regularly and finely dotted with black. The chrysalis state lasts eleven days, at the expiration of which comes out the white-winged butterfly. The chrysalids produced from an autumnal brood of these insects survive the winter, and the butterflies from them make their appearance in May or June. "In gardens or fields infested by the caterpillars, boards, placed horizontally an inch or two above the surface of the soil, will be resorted to by them when they are about to change to chrysalids, and here it will be easy to find, collect, and destroy them, either in the caterpillar or chrysalis state. The butterflies also may easily be taken by a large and deep bag-net of muslin, attached to a handle of five or six feet in length; for they fly low and lazily, especially when busy in laying their eggs. In Europe the caterpillars of the white butterflies are eaten by the larger titmouse (*Parus major*), and probably our own titmouse or chickadee, with other insect-eating birds, will be found equally useful, if properly protected.

"We have several kinds of small six-footed butterflies, some of which are found, during the greater part of summer in the fields and around the edges of woods, flying low and frequently alighting, and oftentimes collected together in little swarms on the flowers of the clover, mint, and other sweet-scented plants."

The heads of the common hop are frequently eaten by the small green and downy caterpillars of a very pretty little dusky brown butterfly, which Dr. Harris has given the name of Hop-vine Thecla (*Thecla humili*).

The caterpillars of many of the four-footed butterflies are spiny, or have their backs armed with numerous projecting points, beset all around with small stiff hairs, and sometimes long, hard, and sharp prickles disposed in bunches.

The poplar, the willow, and the elm are infested with caterpillars in great numbers, produced by a butterfly called the Antiopa, the wings of which are purplish brown above, with a buff-yellow margin, near the inner side of which there is a row of pale blue spots. The wings of this Antiopa butterfly expand from three to three and a half inches. It comes out from its winter retreats with the first warmth of spring, and may be seen, even in Massachusetts, sporting in warm and sheltered spots at the beginning of March, at which time its wings look ragged and faded. Wilson, the ornithologist, in his beautiful lines upon the well known American harbinger of spring—the blue bird—alludes to its coming:

"When first the lone butterfly flits on the wing."

The caterpillars of the Antiopa butterfly are black, minutely dotted with white, with a row of eight dark, brick-red spots on the top of the back. When fully grown they measure an inch and three quarters in length, and appear very formidable with their thorny armature, doubtless intended to defend them from their enemies. It was formerly supposed that they were venomous, and capable of inflicting dangerous wounds, and poplar trees about dwellings have frequently been cut down from fear of these worms. "This alarm was unfounded; for although," says Dr. Harris, "there are some caterpillars that have the power of inflicting venomous wounds with their spines and hairs, this is not the case with those of the Antiopa butterfly. The only injury which can be laid to their charge, is that of despoiling of their foliage some of our most ornamental trees, and this is enough to induce us to take all proper measures for exterminating the insects, short of destroying the trees that they infest. I have sometimes seen them in such profusion on the willow and elm, that the limbs bent under their weight; and the long leafless branches which they had stripped and deserted gave sufficient proof of the voracity of these caterpillars. The chrysalis is of a dark brown colour, with large tawny spots around the tubercles on the back. The butterflies come forth in eleven or twelve days after the insects have entered upon the chrysalis state, and this occurs in the beginning of July. A second brood of caterpillars is produced in August, and they pass through all their changes before winter."

There is a species of caterpillar which comes from a butterfly called the Semicolon (*Vanessa interrogationis*). It lives on the American elm and lime trees, and also on the hop-vine; and on this last they sometimes so abound as to destroy its produce. In the latter part of August the hop-vine caterpillars attain their full growth, and suspend themselves beneath the leaves and stems of the plant, and change into chrysalids. "This fact," says Dr. Harris, "affords a favourable opportunity for destroying the insects in this their stationary and helpless stage, at some loss, however, of the produce of the vines, which, when the insects have become chrysalids, should be cut down, stripped of the fruit that is sufficiently ripened, and then burnt. There is probably an early brood of caterpillars in June or July

but I have not seen any on the hop-vine before August, the former are therefore confined to the elm and other plants in all probability. The caterpillar is brownish, variegated with pale yellow, or pale yellow variegated with brown, with a yellowish line on each side of the body; the head is rust-red, with two blackish branched spines on the top; and the spines of the body are pale yellow or brownish and tipped with black. The chrysalis is ashen brown, with the head deeply notched, and surmounted by two conical ears, a long and thin nose-like prominence on the thorax, and eight silvery spots on the back. The chrysalis state usually lasts from eleven to fourteen days; but the later broods are more tardy in their transformations, the butterfly sometimes not appearing in less than twenty-six days after the change to the chrysalis. Great numbers of the chrysalids are annually destroyed by little maggots within them, which, in due time are transformed to tiny four-winged flies (*Pteromalus vanesseæ*), which make their escape by eating little holes through the sides of the chrysalis. They are ever on the watch to lay their eggs on the caterpillars of this butterfly, and are so small as easily to avoid being wounded by the branching spines of their victims."

The semicolon butterfly which produces this caterpillar expands its wings from two and a half to two and three-quarter inches, and even more. The colour of the wings is orange-tawny on the upper sides, with black spots in the middle. The under sides of the wings in some are rust-red, in others reddish white, with a pale gold-coloured semicolon on the middle of the hinder part, which last gives its specific name.

Another species of caterpillar living upon the hop, also proceeds from a butterfly having wings of an orange-tawny colour on the upper side; the hinder wings having a silvery comma in the middle of the under side. The wings expand from $2\frac{1}{8}$ to $2\frac{3}{4}$ inches. This comma butterfly, as it is called (*Vanessa comma*), resembles the white comma of Europe, for which it has probably been mistaken. In habits, &c. the American comma resembles the preceding species.

Among American caterpillars, which attract the particular notice of the farmer, are several appertaining to the family of insects called hawk-moths, or *sphinxes*, the latter name having been applied by Linnæus, from a fancied resemblance that some of the caterpillars, when at rest, have to the Egyptian sphynx. The attitude of these caterpillars is indeed remarkable. Supporting themselves by their four or six hind legs, they elevate the fore part of the body, and remain immovably fixed in this posture for hours together. In the winged state, the true *sphinxes* are known by the name of humming-bird moths, from the sound they make in flying, and hawk-moths from their habit of hovering in the air while taking their food. They may be seen during the morning and evening twilight, flying with great swiftness from flower to flower. Their tongues, when uncoiled, are, for the most part, excessively long, and with them they extract the honey from the blossoms of the honeysuckle

and other tubular flowers, while on the wing. There are other sphinges which fly during the daytime only, and in the brightest sunshine. Then it is that the large clear-winged *sesia* make their appearance among the flowers, the fragrant phlox being their special favourite. From the size and form of these last, their fan-like tails, brilliant colours, and mode of taking their food whilst poised above the blossoms upon rapidly vibrating wings, they might readily be mistaken for humming-birds. (*Harris.*)

Among the caterpillars of the sphinges, is that commonly called the potato-worm, a large green caterpillar, with a kind of thorn upon the tail, and oblique whitish stripes on the sides of the body. "This insect, which devours the leaves of the potato, often to the great injury of the plant, grows to the thickness of the fore-finger, and the length of three inches or more. It attains its full size from the middle of August to the first of September, then crawls down the stem of the plant and buries itself in the ground. Here, in a few days, it throws off its caterpillar-skin, and becomes a chrysalis, of a bright brown colour, with a long and slender tongue-case, bent over from the head, so as to touch the breast only at the end, and somewhat resembling the handle of a pitcher. It remains in the ground through the winter, below the reach of frost, and in the following summer the chrysalis-skin bursts open, a large moth crawls out of it, comes to the surface of the ground, and mounting upon some neighbouring plant, waits till the approach of evening invites it to expand its untried wings and fly in search of food. This large insect has generally been confounded with the Carolina sphinx (*Sphinx Carolina* of Linnæus), which it closely resembles. It measures across the wings about five inches; is of a gray colour, variegated with blackish lines and bands; and on each side of the body there are five round, orange-coloured spots encircled with black. Hence it is called by English entomologists *Sphinx quinquemaculatus*, the five-spotted sphinx. Its tongue can be unrolled to the length of five or six inches, but, when not in use, is coiled like a watch-spring, and is almost entirely concealed, between two large and thick feelers, under the head.

"Among the numerous insects that infest our noble elms the largest is a kind of sphinx, which, from the four short horns on the forepart of the back, I have named *Ceratonia quadricornis*, or four-horned ceratonia. On some trees these sphinges exist in great numbers, and their ravages then become very obvious; while a few, though capable of doing considerable injury, may escape notice among the thick foliage which constitutes their food, or will only be betrayed by the copious and regularly formed pellets of excrement beneath the trees. They are very abundant during the months of July and August on the large elms which surround the northern and eastern sides of the common in Boston; and towards the end of August, when they descend from the trees for the purpose of going into the ground, they may often be seen crawling in the mall in considerable numbers. These caterpillars, at this period of their existence, are about three inches and

a half in length, are of a pale green colour, with seven oblique white lines on each side of the body, and a row of little notches, like saw-teeth, on the back." (Harris.)

The grape-vine suffers from the ravages of a sphinx caterpillar, which, not content with eating the leaves alone, in their progress from leaf to leaf, down the stem, stops at every cluster of food, nips off the stalks of the half-grown grapes, and allows these to fall to the ground untasted. I have, says Dr. Harris, gathered under a single vine above a quart of unripe grapes thus detached during one night by these caterpillars. They are naked and fleshy, and generally of a pale-green colour, (sometimes, however, brown), with a row of orange-coloured spots on the top of the back, six or seven oblique darker green or brown lines on each side, and a short spine or horn on the hinder extremity. It is found on the vine and also upon the creeper in July and August. When fully grown it descends to the ground, conceals itself under fallen leaves, which it draws together by a few threads so as to form a kind of cocoon, or covers itself with grains of earth and rubbish in the same way, and under this imperfect cover changes to a pupa or chrysalis, to reappear in the winged state in the month of July of the following year. See GRAPE-VINE CATERPILLAR.

Among this section of insects, naturalists have placed a group, many of which in the winged state bear a resemblance to bees, hornets, wasps, with their narrow wings. They fly only in the daytime, and frequently light to bask in the sunshine. Their habits, in the caterpillar state, are entirely different from those of the sphinges; the latter living exposed upon plants the leaves of which they devour, while the caterpillars of the *ægerians*, as they are called, conceal themselves within the stems or roots of plants, and derive their nourishment from the wood and pitch. (Harris.)

The ash tree suffers very much from the attacks of borers of this kind, which perforate the bark and sap-wood of the trunk from the roots upwards, and are also found in all the branches of any considerable size. The trees thus infested soon show symptoms of disease, in the death of the branches near the summit; and then the insects become numerous, the trees no longer increase in size and height, and premature decay and death ensue. These borers assume the chrysalis form in the month of June, and the chrysalids may be seen projecting half way from the round holes in the bark of the tree in this and the following month, during which time their final transformation is effected, and they burst open and escape from the shells of the chrysalis in the winged or moth state.

"During the month of August, the squash and other cucurbitaceous vines are frequently found to die suddenly down to the root. The cause of this premature death is a little borer, which begins its operations near the ground, perforates the stem, and devours the interior. It afterwards enters the soil, forms a cocoon of a gummy substance covered with particles of earth, changes to a chrysalis, and comes

forth the next summer a winged insect. This is conspicuous for its orange-coloured body, spotted with black, and its hind legs fringed with long orange-coloured and black hairs. The hind wings only are transparent, and the fore wings expand from one inch to one inch and a half. It deposits its eggs on the vines close to the roots, and may be seen flying about the plants from the tenth of July till the middle of August. This insect, which may be called the squash-vine *ægeria*, was first described by me in the year 1828, under the name of *Ægeria cucurbita*, the trivial name indicating the tribe of plants on which the caterpillar feeds. See *New England Farmer*, vol. viii. p. 33; Dr. Harris's *Discourse before the Massachusetts Horticultural Society*, in 1832, p. 26; and *Silliman's Journal*, vol. xxxvi. p. 310." (Harris.)

The pernicious borer, which, during many years past has proved so very destructive to the peach trees throughout the United States, belongs to this group of the sphinx family. See PEACH TREE WORM AND BORER.

In Europe there is a species of *ægeria* which has long been known to inhabit the stems of the currant-bush. There is an American insect, resembling this, found in the cultivated currant-bush, with which it may have been introduced from Europe. See CURRANT-BUSH BORER.

Several caterpillars belonging to the family of *tiger-moths* are very destructive to vegetation, as, for example, the *salt-marsh caterpillar*, the *yellow bear caterpillar* of our gardens, and the *fall web-caterpillar*. These well-known insects are covered with coarse hairs, spreading out on all sides like the bristles of a bottle-brush. They creep very fast, and when handled roll themselves almost into a ball. When about to transform, they creep into the chinks of walls and fences, or hide themselves under stones, logs, or fallen leaves, where they enclose themselves in rough oval cocoons, made of hairs, plucked from their own bodies, interwoven with a few silken threads.

The caterpillars of the *Arge*, a species of tiger-moth, sometimes make great devastation among the young Indian corn in the Southern and Middle States. Their ordinary food consists of the leaves of the plantain and other herbaceous plants. It appears in Massachusetts, sometimes in large swarms, in the month of October. When fully grown they measure about an inch and a half in length. Their colour is a dark greenish-gray, although they appear almost black from the multitude of black spots with which they are dotted. They have three longitudinal stripes of fleshy white on the back, and a row of kidney-shaped spots of the same colour on each side of the body. The warts are dark gray, each one producing a thin cluster of spreading blackish hairs. The moth into which this caterpillar is finally converted, has flesh-coloured wings which expand about from 1½ to 2 inches.

Of all the hairy caterpillars frequenting American gardens, there are none so common and troublesome as that which Dr. Harris calls the *Yellow Bear*. "Like most of its genus," he observes, "it is a very general feeder, devour-

ing almost all kinds of herbaceous plants, with equal relish, from the broad-leaved plantain at the door-side, the peas, beans, and even the flowers of the garden, and the corn and coarse grasses of the fields, to the leaves of the vine, the currant, and the gooseberry, which it does not refuse when pressed by hunger. This kind of caterpillar varies very much in its colours; it is perhaps most often of a pale yellow or straw colour, with a black line along each side of the body, and a transverse line of the same colour between each of the segments or rings, and is covered with long pale yellow hairs. Others are often seen of a rusty or brownish yellow colour, with the same black lines on the sides and between the rings, and they are clothed with foxy red or light brown hairs. The head and ends of the feet are ochre-yellow, and the under side of the body is blackish in all the varieties. They are to be found of different ages and sizes from the first of June till October. When fully grown they are about two inches long, and then creep into some convenient place of shelter, make their cocoons, in which they remain in the chrysalis state during the winter, and are changed to moths in the months of May or June following. Some of the first broods of these caterpillars appear to come to their growth early in summer, and are transformed to moths by the end of July or the beginning of August, at which time I have repeatedly taken them in the winged state; but the greater part pass through their last change in June. The moth is familiarly known by the name of the white miller, and is often seen about houses. Its scientific name is *Arctia Virginia*, and, as it nearly resembles the insects commonly called ermine-moths in England, we may give to it the name of the Virginia ermine-moth. It is white, with a black point on the middle of the fore-wings, and two black dots on the hind-wings, one on the middle and the other near the posterior angle, much more distinct on the under than on the upper side; there is a row of black dots on the top of the back, another on each side, and between these a longitudinal deep yellow stripe; the hips and thighs of the fore-legs are also ochre-yellow. It expands from one inch and a half to two inches. Having been much troubled with the voracious yellow bears in the little patch, (I cannot call it a garden,) where a few beans, and other vegetables, together with some flowers, were cultivated, I required my children to pick off the caterpillars from day to day and crush them, and taught them not to spare 'the pretty white millers,' which they frequently found on the fences, or on the plants, laying their golden yellow eggs, telling them that, with every female which they should kill, the eggs, from which hundreds of yellow bears would have hatched, would be destroyed. In some parts of France, and in Belgium, the people are required by law to *écheniller*, or un-caterpillar, their gardens and orchards, and are punished by fine if they neglect the duty. Although we have not yet become so prudent and public spirited as to enact similar regulations, we might find it for our advantage to offer a bounty for the destruction of caterpillars; and though we should pay for them by

the quart, as we do for berries, we should be gainers in the end; while the children, whose idle hours were occupied in the picking of them, would find this a profitable employment." (Harris.)

"The salt-marsh caterpillar, an insect by far too well known on our sea-board, and now getting to be common in the interior of the state, whither it has probably been introduced, while under the chrysalis form, with the salt hay annually carried from the coast by our inland farmers, closely resembles the yellow bear in some of its varieties. The history of this insect," says Dr. Harris, "forms the subject of a communication made by me to the 'Agricultural Society of Massachusetts,' in the year 1823, and printed in the seventh volume of the 'Massachusetts Agricultural Repository and Journal,' with figures representing the insect in its different stages. At various times and intervals since the beginning of the present century, and probably before it also, the salt marshes about Boston have been overrun and laid waste by swarms of caterpillars. These appear towards the end of June, and grow rapidly from that time till the first of August. During this month they come to their full size, and begin to run, as the phrase is, or retreat from the marshes, and disperse through the adjacent uplands, often committing very extensive ravages in their progress. Corn-fields, gardens, and even the rank weeds by the wayside afford them temporary nourishment while wandering in search of a place of security from the tide and weather. They conceal themselves in walls, under stones, in haystacks and mows, in wood-piles, and in any other places in their way, which will afford them the proper degree of shelter during the winter. Here they make their coarse hairy cocoons, and change to chrysalids, in which form they remain till the following summer, and are transformed to moths in the month of June. In those cases where, from any cause, the caterpillars, when arrived at maturity, have been unable to leave the marshes, they conceal themselves beneath the stubble, and there make their cocoons. Such, for the most part, is the course and duration of the lives of these insects in Massachusetts; but in the Middle and Southern States, two broods are brought to perfection annually; and even here some of them run through their course sooner, and produce a second brood of caterpillars in the same season; for I have obtained the moths between the 15th and 20th of May, and again between the 1st and the 10th of August. Those which were disclosed in May passed the winter in the chrysalis form, while the moths which appeared in August must have been produced from caterpillars that had come to their growth, and gone through all their transformations during the same summer. This, however, in Massachusetts, is not a common occurrence. For by far the greater part of these insects appear at one time, and require a year to complete their several changes. The full-grown caterpillar measures one inch and three-quarters or more in length. It is clothed with long hairs, which are sometimes black and sometimes brown on the back and forepart of the

body, and of a lighter brown colour on the sides. The hairs, like those of the other *Arctias*, grow in spreading clusters from warts, which are of a yellowish colour in this species. The body, when stripped of the hairs, is yellow, shaded at the sides with black, and there is a blackish line extending along the top of the back. The breathing-holes are white, and very distinct even through the hairs. These caterpillars, when feeding on the marshes, are sometimes overtaken by the tide, and when escape becomes impossible, they roll themselves up in a circular form, as is common with others of the tribe, and abandon themselves to their fate. The hairs on their bodies seem to have a repelling power, and prevent the water from wetting their skins, so that they float on the surface, and are often carried by the waves to distant places, where they are thrown on shore, and left in winrows with the wash of the sea. After a little time most of them recover from their half-drowned condition, and begin their depredations anew. In this way these insects seem to have spread from the places where they first appeared to others at a considerable distance. Although these insects do not seem ever entirely to have disappeared from places where they have once established themselves, they do not prevail every year in the same overwhelming swarms; but their numbers are increased or lessened at irregular periods, from causes which are not well understood. These caterpillars are produced from eggs, which are laid by the moths on the grass of the marshes about the middle of June, and are hatched in seven or eight days afterwards, and the number of eggs deposited by a single female is, on an average, about eight hundred. The moths themselves vary in colour. In the males, the thorax and upper side of the fore-wings are generally white, the latter spotted with black; the hind-wings and abdomen, except the tail, deep ochre-yellow, the former with a few black spots near the hind margin, and the abdomen with a row of six black spots on the top of the back, two rows on the sides, and one on the belly; the under-side of all the wings and the thighs are deep yellow. It expands from one inch and seven-eighths to two inches and a quarter. The female differs from the male either in having the hind wings white, instead of ochre-yellow, or in having all the wings ashen gray with the usual black spots. It expands two inches and three-eighths or more. Sometimes, though rarely, male moths occur with the fore-wings ash-coloured or dusky. Professor Peck called this moth *pseuderminea*, that is, false ermine, and this name was adopted by me in my communication to the 'Agricultural Society.' (Harris.)

In order to lessen the ravages of the salt-marsh caterpillars, and to secure a fair crop of hay when these insects abound, Dr. Harris recommends that "the marshes should be mowed early in July, at which time the caterpillars are small and feeble, and being unable to wander far, will die before the crop is gathered in. In defence of early mowing, it may be said that it is the only way by which the grass may be saved in those meadows where

the caterpillars have multiplied to any extent; and, if the practice is followed generally, and continued during several years in succession, it will do much towards exterminating these destructive insects. By the practice of late mowing, where the caterpillars abound, a great loss in the crop will be sustained, immense numbers of caterpillars and grasshoppers will be left to grow to maturity and disperse upon the uplands, by which means the evil will go on increasing from year to year; or they will be brought in with the hay to perish in our barns and stacks, where there dead bodies will prove offensive to the cattle, and occasion a waste of fodder. To get rid of 'the old fog' or stubble, which becomes much thicker and longer in consequence of early mowing, the marshes should be burnt over in March. The roots of the grass will not be injured by burning the stubble, on the contrary, they will be fertilized by the ashes; while great numbers of young grasshoppers, cocoons of caterpillars, and various kinds of destructive insects, with their eggs, concealed in the stubble, will be destroyed by the fire. In the province of New Brunswick, the benefit arising from burning the stubble has long been proved; and this practice is getting into favour in New England.

"The caterpillars of all the foregoing *Arctias* (or harnessed moths) live almost entirely upon herbaceous plants; those which follow (with one exception only), devour the leaves of trees. Of the latter, the most common and destructive are the little caterpillars known by the name of fall web-worms, whose large webs, sometimes extending over entire branches with their leaves, may be seen on our native elms, and also on apple and other fruit trees, in the latter part of summer. The eggs, from which these caterpillars proceed, are laid by the parent moth in a cluster upon a leaf near the extremity of a branch; they are hatched from the last of June till the middle of August, some broods being early and others late, and the young caterpillars immediately begin to provide a shelter for themselves, by covering the upper side of the leaf with a web, which is the result of the united labours of the whole brood. They feed in company beneath this web, devouring only the upper skin and pulpy portion of the leaf, leaving the veins and lower skin of the leaf untouched. As they increase in size, they enlarge their web, carrying it over the next lower leaves, all the upper and pulpy parts of which are eaten in the same way, and thus they continue to work downwards, till finally the web covers a large portion of the branch, with its dry, brown, and filmy foliage, reduced to this unseemly condition by these little spoilers. These caterpillars, when fully grown, measure rather more than one inch in length; their bodies are more slender than those of the other *Arctias*, and are very thinly clothed with hairs of a grayish colour, intermingled with a few which are black. The general colour of the body is greenish yellow dotted with black; there is a broad blackish stripe along the top of the back, and a bright yellow stripe on each side. The warts, from which the thin bundles of

spreading, silky hairs proceed, are black on the back, and rust-yellow or orange on the sides. The head and feet are black. I have not observed the exact length of time required by these insects to come to maturity; but towards the end of August and during the month of September they leave the trees, disperse, and wander about, eating such plants as happen to lie in their course, till they have found suitable places of shelter and concealment, where they make their thin and almost transparent cocoons, composed of a slight web of silk intermingled with a few hairs. They remain in the cocoons in the chrysalis state through the winter, and are transformed to moths in the months of June and July. These moths are white, and without spots; the fore-thighs are tawny-yellow, and the feet blackish. Their wings expand from one inch and a quarter to one inch and three-eighths.

“During the months of July and August, there may be found on apple trees and rose-bushes, and sometimes on other trees and shrubs, little slender caterpillars of a bright yellow colour, sparingly clothed with long and fine yellow hairs on the sides of the body, and having four short and thick brush-like yellowish tufts on the back, that is on the fourth and three following rings, two long black plumes or pencils extending forwards from the first ring, and a single plume on the top of the eleventh ring. The head, and the two little retractile warts on the ninth and tenth rings are coral red; there is a narrow black or brownish stripe along the top of the back, and a wider dusky stripe on each side of the body. These pretty caterpillars do not ordinarily herd together, but sometimes our apple trees are

infested by them, as was the case in the summer of 1828. When they have done eating, they spin their cocoons on the leaves, or on the branches or trunks of the trees, or on fences in the vicinity. The chrysalis is not only beset with little hairs or down, but has three oval clusters of branny scales on the back. In about eleven days after the change to the chrysalis is effected, the last transformation follows, and the insects come forth in the adult state, the females wingless, and the males with large ashen-gray wings, crossed by wavy darker bands on the upper pair, on which, moreover, is a small black spot near the tip, and a minute white crescent near the outer hind angle. The body of the male is small and slender, with a row of little tufts along the back, and the wings expand one inch and three-eighths. The females are of a lighter gray colour than the males, their bodies are very thick, and of an oblong oval shape, and, though seemingly wingless, upon close examination two little scales, or stunted winglets, can be discovered on each shoulder. These females lay their eggs upon the top of their cocoons, and cover them with a large quantity of frothy matter, which on drying becomes white and brittle. Different broods of these insects appear at various times in the course of the summer, but the greater number come to maturity and lay their eggs in the latter part of August, and the beginning of September; and these eggs are not hatched till

the following summer. The name of this moth is *Orgyia* leucostigma*, the white-marked *Orgyia* or tussock-moth. It is to the eggs of this insect that the late Mr. B. H. Ives, of Salem, alludes, in an article on ‘insects which infest trees and plants,’ published in Hovey’s ‘Gardener’s Magazine.’ Mr. Ives states, that on passing through an apple orchard in February, he ‘perceived nearly all the trees speckled with occasional dead leaves, adhering so firmly to the branches as to require considerable force to dislodge them. Each leaf covered a small patch of from one to two hundred eggs, united together, as well as to the leaf, by a gummy and silken fibre, peculiar to the moth.’ In March, he ‘visited the same orchard, and, as an experiment, cleared three trees, from which he took twenty-one bunches of eggs. The remainder of the trees he left untouched until the tenth of May, when he found the caterpillars were hatched from the egg, and had commenced their slow but sure ravages. He watched them from time to time, until many branches had been spoiled of their leaves, and in the autumn were entirely destitute of fruit; while the three trees, which had been stripped of the eggs, were flush with foliage, each limb without exception ripening its fruit.’ These pertinent remarks point out the nature and extent of the evil, and suggest the proper remedy to be used against the ravages of these insects.”

In the New England States there is found a tussock or vaperer moth, seemingly the same as the *Orgyia antiqua*, the antique or rusty vaperer-moth of Europe, from whence, possibly its eggs may have been brought with imported fruit trees, for a description of which, and other tussock moths, see Dr. Harris’s treatise, and also Mr. Abbott’s work on the insects of Georgia. Also communications by Miss Dix to Silliman’s Journal, vol. xix. p. 62.

“To this group of hairy caterpillars belong those which swarm in the unpruned nurseries and neglected orchards of the slovenly and improvident husbandman, and hang their many-coated webs upon the wild cherry trees that are suffered to spring up unchecked by the way-side, and encroach upon the borders of our pastures and fields. The eggs from which they are hatched are placed around the ends of the branches, forming a wide kind of ring or bracelet, consisting of three or four hundred eggs, in the form of short cylinders, standing on their ends close together, and covered with a thick coat of brownish water-proof varnish. The caterpillars come forth with the unfolding of the leaves of the apple and cherry tree, during the latter part of April or the beginning of May. The first signs of their activity appear in the formation of a little angular web or tent, somewhat resembling a spider’s web, stretched between the forks of the branches a little be-

* This name is derived from a word which signifies to stretch out the hands, and it is applied to this kind of moth on account of its resting with the fore-legs extended. The Germans call these moths *streckfüssige Spinner*, the French *pattes étendues*, and the English vaperer-moths, the latter probably because the males are seen flying about ostentatiously, or vapering, by day when most other moths keep concealed.

low the cluster of eggs. Under the shelter of these tents, in making which they all work together, the caterpillars remain concealed at all times when not engaged in eating. In crawling from twig to twig and from leaf to leaf, they spin from their mouths a slender silken thread, which is a clue to conduct them back to their tents; and as they go forth and return in files, one after another, their pathways in time become well carpeted with silk, which serves to render their footing secure during their frequent and periodical journeys in various directions to and from their common habitation. As they increase in age and size they enlarge their tent, surrounding it from time to time with new layers or webs, till at length it acquires a diameter of eight or ten inches. They come out together at certain stated hours to eat, and all retire at once when their regular meals are finished; during bad weather, however, they fast, and do not venture from their shelter. These caterpillars are of a kind called *lackeys* in England, and *livrées* in France, from the party-coloured livery in which they appear. When fully grown they measure about two inches in length. Their heads are black; extending along the top of the back from one end to the other is a whitish line, on each side of which, on a yellow ground, are numerous short and fine crinkled black lines, that lower down become mingled together, and form a broad longitudinal black stripe, or rather a row of long black spots, one on each ring, in the middle of each of which is a small blue spot; below this is a narrow wavy yellow line, and lower still the sides are variegated with fine intermingled black and yellow lines, which are lost at last in the general dusky colour of the under side of the body; on the top of the eleventh ring is a small blackish and hairy wart, and the whole body is very sparingly clothed with short and soft hairs, rather thicker and longer upon the sides than elsewhere. The foregoing description will serve to show that these insects are not the same as either the *Neustria* or the *camp lackey* caterpillars of Europe, for which they have been mistaken. From the first to the middle of June they begin to leave the trees upon which they have hitherto lived in company, separate from each other, wander about a while, and finally get into some crevice or other place of shelter and make their cocoons. These are of a regular long oval form, composed of a thin and very loosely woven web of silk, the meshes of which are filled with a thin paste, that on drying is changed to a yellow powder, like flour of sulphur in appearance. Some of the caterpillars, either from weakness or some other cause, do not leave their nests with the rest of the swarm, but make their cocoons there, and when the webs are opened these cocoons may be seen intermixed with a mass of blackish grains, like gunpowder, excreted by the caterpillars during their stay. From fourteen to seventeen days after the insect has made its cocoon and changed to a chrysalis, it bursts its chrysalis skin, forces its way through the wet and softened end of its cocoon, and appears in the winged or *miller* form. Many of them, however, are unable to finish their transformations

by reason of weakness, especially those remaining in the webs. Most of these will be found to have been preyed upon by little maggots living upon the fat within their bodies, and finally changing to small four-winged ichneumon wasps, which in due time pierce a hole in the cocoons of their victims, and escape into the air.

"The moth of our American lackey-caterpillar is of a rusty or reddish brown colour, more or less mingled with gray on the middle and base of the fore-wings, which, besides, are crossed by two oblique, straight, dirty white lines. It expands from one inch and a quarter to one inch and a half or a little more.

"The moths appear in great numbers in July, flying about and often entering houses by night. At this time they lay their eggs, selecting the wild cherry in preference to all other trees for this purpose, and next to these apple trees, the extensive introduction and great increase of which in this country afford an abundant and tempting supply of food to the caterpillars in the place of the native cherry trees that formerly, it would seem, sufficed for their nourishment. These insects, because they are the most common and most abundant in all parts of our country, and have obtained such notoriety that in common language they are almost exclusively known among us by the name of *the caterpillars*, are the worst enemies of the orchard. Where proper attention has not been paid to the destruction of them, they prevail to such an extent as almost entirely to strip the apple and cherry trees of their foliage, by their attacks continued during the seven weeks of their life in the caterpillar form. The trees, in those orchards and gardens where they have been suffered to breed for a succession of years, become prematurely old in consequence of the efforts they are obliged to make to repair, at an unseasonable time, the loss of their foliage, and are rendered unfruitful, and consequently unprofitable. But this is not all; these pernicious insects spread in every direction from the trees of the careless and indolent to those of their more careful and industrious neighbours, whose labours are thereby greatly increased, and have to be followed up year after year without any prospect of permanent relief.

"Many methods and receipts for the destruction of these insects have been published and recommended, but have failed to exterminate them, and indeed have done but little to lessen their numbers. Mr. Lowel has justly said that 'the great difficulty is the neglect to do any thing, till after the caterpillars have covered the trees with their nests. Then the labours of the sluggard commence, and one tree, let his receipt be ever so perfect and powerful, will cost him as much time and labour as ten trees would have required three weeks sooner.' The means to be employed may be stated under three heads. The first is, the collection and destruction of the eggs. These should be sought for in the winter and early part of the spring, when there are no leaves on the trees. They are easily discovered at this time, and may be removed with the thumb-nail and fore-finger. Nurseries and the lower limbs of large trees may thus be entirely cleared of eggs dur-

ing a few visits made at the proper season. If a liberal bounty for the collection of the eggs were to be offered, and continued for the space of ten years, these destructive caterpillars would be nearly exterminated at the end of that time. Under the second head are to be mentioned the most approved plans for destroying the caterpillars after they are hatched, and have begun to make their nests or tents. It is well known that the caterpillars come out to feed twice during the day time, namely, in the forenoon and afternoon, and that they rarely leave their nests before nine in the morning, and return to them again at noon. During the early part of the season, while the nests are small, and the caterpillars young and tender, and at those hours when the insects are gathered together within their common habitation, they may be effectually destroyed by crushing them by hand in the nests. A brush, somewhat like a bottle-brush, fixed to a long handle, as recommended by the late Colonel Pickering, or, for the want thereof, a dried mullein head and its stalk fastened to a pole, will be useful to remove the nests, with the caterpillars contained therein, from those branches which are too high to be reached by hand. Instead of the brush, we may use, with nearly equal success, a small mop or sponge, dipped as often as necessary into a pailful of refuse soap-suds, ley, strong white-wash, or cheap oil. The mop should be thrust into the nest and turned round a little, so as to wet the caterpillars with the liquid, which will kill every one that it touches. These means, to be effectual, should be employed during the proper hours, that is, early in the morning, at mid-day, or at night, and as soon in the spring as the caterpillars begin to make their nests; and they should be repeated as often, at least, as once a week, till the insects leave the trees. Early attention and perseverance in the use of these remedies will, in time, save the farmer hundreds of dollars, and abundance of mortification and disappointment, besides rewarding him with the grateful sight of the verdant foliage, snowy blossoms, and rich fruits of his orchard in their proper seasons. Under the third head, I beg leave to urge the people of this commonwealth to declare war against these caterpillars, a war of extermination, to be waged annually during the month of May and the beginning of June. Let every able-bodied citizen, who is the owner of an apple or cherry tree, cultivated or wild, within our border, appear on duty, and open the campaign on the first washing-day in May, armed and equipped with brush and pail, as above directed, and give battle to the common enemy; and let every housewife be careful to reserve for use a plentiful supply of ammunition, strong waste soap-suds, after every weekly wash, till the liveried host shall have decamped from their quarters, and retreated for the season. If every man is prompt to his duty, I venture to predict that the enemy will be completely conquered in less time than it will take to exterminate the Indians in Florida.

“Another caterpillar, whose habits are similar to those of the preceding, is now and then met with, in Massachusetts, upon oak and walnut trees, and more rarely still upon apple trees.

According to Mr. Abbot, ‘it is sometimes so plentiful in Virginia as to strip the oak-trees bare.’ It may be called *Clisiocampa sylvatica*, the tent-caterpillar of the forest. With us it comes to its full size from the tenth to the twentieth of June, and then measures about two inches in length.” (Harris.)

Those who wish to become more intimately acquainted with the natural history of the caterpillar tribe against which such incessant war is waged both in country and town, wherever a tree or a plant is found, will meet with abundant information in Dr. Harris’s Treatise upon Insects destructive to vegetation.

Some others of the caterpillar tribe will be found noticed under the several heads of CASE-BEARERS, or BASKET-WORMS, CURRANT-BUSH BORER, CUTWORM CATERPILLAR, LEAF-ROLLERS, APPLE-TREE AND NURSERY CATERPILLARS, OAK AND WALNUT CATERPILLARS, HOP-VINE AND GRAPE-VINE CATERPILLARS, LOCUST TREE and other caterpillars infesting hickory and elm trees, &c., TURPENTINE MOTH, infesting the fir and pine, caterpillars living upon reeds, flags, and other aquatic plants, SPANWORMS, LOOPERS, or GEOMETERS, among which are the insects commonly called canker worms; GREASE-MOTH CATERPILLARS, &c.

CATKIN. A name given to such amentaceous flowers as consist of a great number of chaffy scales and flowers, dispersed along a slender thread-like axis or rachis, hanging downward, in the form of a rope or cat’s tail. It is the male flower of the trees which produce them, as the birch, beech, pine, fir, poplar, walnut, hazel, &c. They drop as soon as the pollen is shed.

CATMINT, or NEP (*Nepeta cataria*, Smith, vol. iii. p. 70). This is a common plant, growing in borders of fields and in moist places, flowering in June and July. It grows a yard high, with broad whitish leaves, and white flowers, not unlike mint. The plant has a strong and rather unsavoury smell. It is easily recognised by its hoary, square, and erect stalks; its leaves slightly indented on the edges, of a whitish-green on their outside, and almost perfect white underneath; and its flowers growing in spiked clusters around the stalk at certain distances. Cats are exceedingly fond of rolling upon this plant, and they chew it eagerly. This has obtained for it the familiar name of catmint.

CAT’S-FOOT. A term sometimes provincially applied to ground-ivy.

CAT’S-MILK. A common name for the plant wartwort, which see.

CAT’S-TAIL, or TIMOTHY GRASS (*Phleum pratense*, Pl. 5, *l*). This grass flourishes best in moist deep loams. Perennial, native of Britain. At the time of flowering, in the end of June, Sinclair found the produce per acre was, from a clayey loam, 40,837 lbs.; of nutritive matter 1595 lbs. This is a great American grass, and is called timothy from Mr. Timothy Hanson, who first introduced its seeds into Maryland. Seeds ripe in July. It produces an abundance of early feed, but its product of aftermath is poor. See GRASSES.

Timothy is undoubtedly one of the most valuable grasses known to American farmers

Mixed in the field with red clover, it affords excellent hay. The seed is usually sown in the autumn, among and immediately after wheat, and rye, though it succeeds very well when sown in the spring at the same time clover is sown. The clover dies out after the second year, leaving the ground in possession of the timothy, which requires a good soil and is considered an exhausting crop to land.

The smaller Meadow Cat's-tail (Phleum minus). Indigenous to England, on tenacious soils.

The Bulbous-jointed Cat's-tail Grass (Phleum nodosum). Perennial; native of Britain, but rare; found on a clayey soil at Woburn. Flowers in beginning of July. Seeds ripe at the end of the same month.

Purple-stalked Cat's-tail Grass (Phleum boehmeri). Indigenous and perennial; grows best on a sandy loam. Flowers in July.

In the New England States timothy, or *P. pratense*, is called *herd's grass*, a name applied in the Middle States exclusively to the *Agrostis vulgaris* or *red-top*, a kind of grass so very unpopular among Pennsylvania farmers, that in selecting clover and other grass seeds, they reject all samples containing herd's grass.

CATTLE. Under this head I propose to include the ox tribe, *Lovida*, of the class Mammalia, having teats or *mamma*; these are of the order *Ruminantia*, or ruminating, or cud-chewing animals. Of this tribe there are eight species:—1. *Bos urus* or *Auroch*, the ancient bison; 2. *B. bison*, the bison, or American buffalo; 3. *B. moschatus*, or musk ox; 4. *B. frontalis*, or gaur; 5. *B. grunniens*, or grunting ox; 6. *B. caffer*, or buffalo of southern Africa; 7. *B. bubalus*, or common buffalo; 8. *B. taurus*, or common domestic ox. That the ox has been domesticated, and in the service of man from a very remote period, is quite certain. We learn from *Gen.* (iv. 20.) that cattle were kept by the early descendants of Adam. Preserved by Noah from the flood waters, the original breed of our present oxen must have been in the neighbourhood of Mount Ararat; and from thence, dispersing over the face of the globe, altering by climate, by food, and by cultivation, originated the various breeds of modern ages. That the value of the ox tribe has been in all ages and climates highly appreciated, we have abundant evidence. The natives of Egypt, India, and of Hindostan seem alike to have placed the cow amongst their deities; and, judging by her usefulness to all classes, no animal could perhaps have been selected whose value to mankind is greater. Of the old race of British cattle, some remains of which are yet to be found in Chillingham Park, in Northumberland, in a state of tolerable purity, and in one or two other places in Great Britain, improved by judicious or accidental crossings, came most of our modern breeds. George Culy, in his valuable work on cattle, describes these aboriginals as being of a creamy white, with black muzzles, white horns with black tips bending upwards. The cows weighing from twenty-five to thirty-five stone. They hide for a week or ten days their calves, in some sequestered place; and these, when they are disturbed, put their heads to the ground, and lie close like a hare. Their wildness pre-

vents the introduction of them into any situation not surrounded by stone walls; and the mode in which they were wont to be killed by the keepers was by a rifle ball. See also two excellent papers by Dr. Knox on the wild ox of Scotland (*Quart. Journ. of Agr.* vol. ix. p. 367); and on the ox tribe, in connection with the white cattle of the Hamilton and Chillingham breeds, by the Rev. Dr. Patrick (*Ibid.* p. 514).

In nearly all parts of the earth cattle are employed for their labour, for their milk, and for food. In southern Africa they are as much the associates of the Caffres as the horse is of the Arab. They share his toils, and assist him in tending his herds; they are even trained to battle, in which they become fierce and courageous. In central Africa the proudest ebony beauties are to be seen on their backs. They have drawn the plough in all ages; in Spain they still trample out the corn; in India raise the water from the deepest wells to irrigate the thirsty soils of Bengal. When Cæsar invaded England they constituted the chief riches of its inhabitants (*Cæsar*, lib. v. c. 10); and they yet form no inconsiderable item in the estimate of that country's abounding riches. According to the estimate of Mr. Youatt, to whom in this and other articles on live stock I am so much indebted (*On Cattle*, p. 9), it would seem that 1,600,000 head of cattle are consigned to the butcher every year in the United Kingdom, and the value of the entire national stock of all kinds of cattle, sheep, and pigs, he is of opinion, amounts to nearly 120,000,000*l.* sterling. An excellent paper on the origin and natural history of the domestic ox and its allied species, by Professor Wilson (*Quart. Journ. of Agr.* vol. ii. p. 177), may be consulted with advantage by those who wish for more information on this head.

The breeds of cattle in England are remarkable for their numerous varieties, caused by the almost endless crossings of one breed with another, often producing varieties of the most mongrel description, and which are rather difficult to describe. I will in this place touch upon the principal varieties; and in these we should, in looking for the chief points of excellence, regard, as Mr. Youatt well observes, "wide and deep girth about the heart and lungs; and not only about these, but above the whole of the ribs must we have both depth and roundness; the *hooped* as well as the deep barrel is essential. The beast should also be ribbed home; there should be little space between the ribs and the hips. This is indispensable in the fattening ox, but a largeness and drooping of the belly is excusable in the cow. It leaves room for the udder, and if it is also accompanied by swelling milk-veins, it generally indicates her value in the dairy. This roundness and depth of the barrel, however, is most advantageous in proportion as it is found behind the point of the elbow, more than between the shoulders and legs; or low down between the legs, than upwards towards the withers; for it diminishes the heaviness before, and the comparative bulk of the coarser parts of the animal, which is always a very great consideration.

"The loins should be wide, for these are the prime parts; they should seem to extend far along the back; and although the belly should not hang down, the flanks should be round and deep, the hips large, without being ragged, round rather than wide, and present, when handled, plenty of muscle and fat; the thighs full and long, and, when viewed from behind, close together; the legs short, for there is almost an inseparable connection between length of leg and lightness of carcass, and shortness of leg and propensity to fatten. The bones of the legs and of the frame generally should be small, but not too small; small enough for the well-known accompaniment, a propensity to fatten; small enough to please the consumer, but not so small as to indicate delicacy of constitution and liability to disease. Finally, the hide, the most important thing of all, should be thin, but not so thin as to indicate that the animal can endure no hardships, movable, mellow, but not too loose, and particularly well covered with fine and soft hair."

On the points by which live stock are judged, some very excellent papers have appeared in the *Edin. Quart. Journ. of Agr.*, by Mr. James Dickson, cattle-dealer of Edinburgh. He very truly observes (vol. v. p. 159), that, "were an ox of fine symmetry and high condition placed before a person not a judge of live stock, his opinion of its excellences would be derived from a very limited view, and consequently from only a few of its qualities. He might observe and admire the beautiful outline of its figure, for that would strike the most casual observer. He might be pleased with the tint of its colours, the plumpness of its body, and the smoothness and glossiness of its skin. He might be even delighted with the gentle and complacent expression of its countenance;—all these properties he might judge of by the eye alone. On touching the animal with the hand, he could feel the softness of its body, occasioned by the fatness of the flesh. But no man not a judge could rightly criticise the properties of an ox farther. He could not possibly discover without tuition those properties which had chiefly conduced to produce the high condition in which he saw the ox. He would hardly believe that a judge can ascertain merely by the eye, from its general aspect, whether the ox were in good or bad health; from the colour of its skin, whether it were of a pure or cross breed; from the expression of its countenance, whether it were a quiet feeder; and from the nature of its flesh, whether it had arrived at maturity. The discoveries made by the hand of a judge might even stagger his belief. He could scarcely conceive that the hand can feel a hidden property. The touch, which of all tests is the most surely indicative of fine quality of flesh and of disposition to fatten, can find whether that flesh is of the most valuable kind; and it can foretell the probable abundance of fat in the interior of the carcass. In short, a judge alone can discriminate between the relative values of the different points, or appreciate the aggregate value of all the points of an ox. These 'points' are the parts of an ox by which it is judged." The first point to be ascertained in examining an ox, is the purity

of its breed, whatever that breed may be; for that will give the degree of the disposition to fatten of the individuals of that breed. The purity of the breed may be ascertained from several marks: the colour or colours of the skin of a pure breed of cattle, whatever those colours are, are always definite. The colour of the bald skin on the nose and round the eyes, in a pure breed, is always definite, and without spots. This last is an essential point. When horns exist, they should be smooth, small, tapering, and sharp-pointed, long or short, according to the breed, and of a white colour throughout in some breeds, and tipped with black in others. The shape of the horn is a less essential point than the colour. Applying these remarks on the different breeds in Scotland, as illustrations of the point which we have been considering, we have the definite colours of white and red in the short-horns. The colour is either entirely white or entirely red, or the one or the other predominates in their mixture. The skin on the nose and around the eyes is uniformly of a rich cream colour. The Ayrshire breed, in its purity, is also distinguished by the red and white colour of the skin, but always mixed, and the mixture consists of spots of greater or smaller size not blended together. The colour of the skin on the nose and around the eye is not definite, but generally black or cream-coloured. In other points, these two celebrated breeds differ from one another more than in the characters which I have just described. In the West Highland Angus, and Galloway breeds, the colour of the skin of the nose and around the eyes is indicative of the pure blood of black-coloured cattle, but a cream-coloured nose may frequently be observed amongst the other colours of skin. The characters above given will certainly apply to the purity of the blood in the short-horn and Ayrshire breeds, if not to the West Highlanders.

"The second point to be ascertained in an ox is the form of its carcass. It is found that the nearer the section of the carcass of a fat ox, taken longitudinally vertical, transversely vertical, and horizontally, approaches to the figure of a parallelogram, the greater quantity of flesh will it carry within the same measurement. That the carcass may fill up the parallelogram as well as its rounded form is capable of filling up a right-angled figure, it should possess the following configuration:—The back should be straight from the top of the shoulder to the tail. The tail should fall perpendicularly from the line of the back. The buttocks and twist should be well filled out. The brisket should project to a line dropped from the middle of the neck. The belly should be straight longitudinally, and round laterally, and filled at the flanks. The ribs should be round, and should project horizontally, and at right angles to the back. The hooks should be wide and flat; and the rump, from the tail to the hooks, should also be filled and well filled. The quarter from the itch-bone to the hook should be long. The loin bones should be long, broad, and flat, and well filled; but the space betwixt the hooks and the short ribs should be rather short and well arched over, with a thickness of beef between

the hooks. A long hollow from the hooks to the short ribs indicates a weak constitution and an indifferent thriver. From the loin to the shoulder-blade should be nearly of one breadth, and from thence it should taper a little to the front of the shoulder. The neck-vein should be well filled forward to complete the line from the neck to the brisket. The covering on the shoulder-blade should be as full out as the buttocks. The middle ribs should be well filled, to complete the line from the shoulders to the buttocks along the projection of the outside of the ribs; these constitute all the *points* which are essential to a *fat* ox.

“The first of the *points* in judging of a *lean* ox, is the nature of the *bone*. A round thick bone indicates both a slow feeder and an inferior description of flesh. A flat bone, when seen on a side view, and narrow when viewed either from behind or before the animal, indicates the opposite properties of a round bone. The whole bones in the carcass should bear a small proportion in bulk and weight to the flesh, the bones being only required as a support to the flesh. The texture of the bone should be small-grained and hard. The bones of the head should be fine and clean, and only covered with skin and muscle, and not with lumps of fat and flesh, which always give a heavy-headed, dull appearance to an ox. The fore-arm and hock should also be clean and full of muscle, to endure travelling. Large joints indicate bad feeders. The neck of an ox should be, contrary to that of the sheep, small from the back of the head to the middle of the neck. A full, clear, and prominent eye is another *point* to be considered, because it is a nice indication of good breeding. It is always attendant on fine bone: the expression of the eye is an excellent index of many properties in the ox. A dull, heavy eye clearly indicates a slow feeder. A rolling eye, showing much white, is expressive of a restless capricious disposition, which is incompatible with quiet feeding. A calm, complacent expression of eye and face is strongly indicative of a sweet and patient disposition, and of course kindly feeling. The eye is frequently a faithful index of the state of health. A cheerful clear eye accompanies good health: a constantly dull one proves the probable existence of some internal lingering disease; the dullness of eye, however, arising from internal disease is quite different in character from a natural or constitutional phlegmatic dullness.

“The state of the skin is the next *point* to be ascertained; the skin affords what is technically and emphatically called the *touch*—a criterion second to none in judging of the feeding properties of an ox. The touch may be good or bad, fine or harsh, or, as it is often termed, hard or mellow. A thick, firm skin, which is generally covered with a thick-set, hard, short hair, always touches hard, and indicates a bad feeder. A thin, meager, papery skin, covered with thin, silky hair, being the opposite of the one just described, does not, however, afford a good touch. Such skin is indicative of weakness of constitution, though of good feeding properties. A perfect touch will be found with a thick, loose skin, floating, as it were, on

a layer of soft fat, yielding to the least pressure, and springing back to the finger like a piece of soft, thick, chamois leather, and covered with thick, glossy, soft hair. It is not unlike a bed of fine soft moss, and hence such a skin is not unfrequently styled ‘mossy.’ A knowledge of touch can only be acquired by long practice; but after having acquired it, it is of itself a sufficient means of judging of the feeding quality of an ox, because, when present, the properties of symmetrical form, fine bone, sweet disposition, and purity of blood are the general accompaniments. These are the essential points in judging *lean* cattle, but there are other and important considerations in forming a thorough judgment of the ox. The head should be small, and set on the neck as if easily carried by the animal; this shows the animal to advantage in the market. The face long from the eyes to the point of the nose. The skull broad across the eyes, contracted a little above them, but tapering considerably below them to the nose. The muzzle fine and small; the nostrils capacious; the ears large, a little erect, and transparent; the neck short and light. A droop of the neck from the top of the shoulder to the head indicates a weakness of constitution, arising frequently from breeding too near akin. The legs below the knees should be rather short than long, and clean made; stand where they apparently bear the weight of the body most easily, and wide asunder. The tail rather thick than otherwise, as that indicates a strong spine, and a good weigher. It should be provided with a large tuft of long hair. The *position* of the *flesh* is important: that part called the spare rib in Edinburgh, and the fore and middle ribs in London, the loins and the rump, or hook-bone, are of the finest quality, and are generally used for roasts and steaks; consequently the ox which carries the largest quantity of beef on these *points* is the most valuable. Flesh of fine quality is actually of a finer texture than coarse flesh. The other desirable objects in a fat ox are a full twist, lining the division between the hams called ‘the closing’ with a thick layer of fat, a thick flank, and a full neck bend; these generally indicate internal tallow. The last points generally covered with fat are the point of the shoulder-joint and the top of the shoulder: if these parts are, therefore, felt to be well covered, the other and better parts of the animal may be considered ripe. It is proper, in judging of the weight of a fat ox, to view his gait while walking towards you, which will, if the ox has been well fed, be accompanied with a heavy rolling tread on the ground. In this way a judge can at once come very near to its weight.” (*Quart. Journ. of Agr.* vol. v. p. 167.) At the end of this paper will be found an account of the mode of ascertaining the weight of stock by admeasurement.

When we survey the frame of a short horn ox, adds Mr. Dickson (*Ibid.* vol. vi. p. 267), we have a straight, level back from behind the horns to the top of the tail, full buttocks, and a projecting brisket; we have, in short, the rectangular figure, as represented in a side view by fig. 1. We have also the level loin across the hook bones, and the level top of the

shoulder across the ox, and perpendicular lines down the hind and fore-legs on both sides, these constituting the square form when the ox is viewed before and behind, as represented in figures 2 and 3; and we have straight parallel lines from the sides of the shoulders, along the outmost points of the ribs, to the sides of the hind quarters; and we have these lines connected at their ends by others of shorter and equal length, across the end of the rump and the top of the shoulder, thus constituting the rectangular form of the ox when viewed from above down upon the back, as represented by fig. 4; the form of the short ox and heifer, in perfect accordance with the diagrams of the rule. Farther, I should be inclined to assert, though I have not directed my attention sufficiently to the fact to be able to prove the assertion from examples, that the carcass of a full fed, symmetrical, short-horn ox, included within the rectangle, is in length double its depth, and in depth equal to its breadth; hence figures 2 and 3 are squares, and figures 1 and 4 each two similar squares, placed in juxtaposition.

The cow goes with calf about forty weeks, and is often capable of breeding when only a year old; but she should not be allowed to do so until she is above two years old. When the calves are intended for veal, January, February, and March are the best months for calving. On the question of breeding live stock in general, and upon the difficult question of the comparative influence of the male and female parents in impressing their offspring, a theme propounded by the Highland Society, there are some excellent papers by Mr. Boswell, Mr. Christian, and Mr. Mill (*High. Soc. Trans.* vol. i. p. 17), by the Rev. Henry Berry (*Brit. Farm. Mag.* vol. i.), and by Mr. Knight (*Trans. Roy. Soc.* 1809), in which they all seem to uphold the superior influence of the male; and on the selection of the male animal in breeding there is a paper by Lord Spencer (*Journ. Roy. Agr. Soc.* vol. i. p. 22); another on the gestation of cows (*Ibid.* 165); and on the means of calculating the number of calves which will probably be produced by a herd of cows, by the same noble lord (*Ibid.* vol. ii. p. 112); and on the detection of pregnancy in the horse and cow by Professor Youatt (*Ibid.* p. 170); on a method of obtaining a greater number of one sex at the option of the owner in the breeding of livestock (*Quart. Journ. of Agr.* vol. i. p. 63); on the rearing of calves, in which the writer recommends that skimmed milk should have a piece of red-hot iron plunged into it, not only to warm it, but to give an astringent quality (*Com. Board of Agr.* vol. iv. p. 382); on the mode of fattening them in Strathaven there is an account by Mr. Aiton in the *Quart. Journ. of Agr.* p. 249; and of the mode of fattening them near London by Mr. Main (*Ibid.* vol. v. p. 608).

“Every cow is made to suckle her own calf three times a day for the first three or four days, and afterwards twice a day, and, in need, her bag is emptied by another calf. If a calf goes on thriving and well, it will be what is esteemed in England *prime veal* in about ten weeks, and weigh from 17 to 20 stones of 8 lbs. each.”

The North Devon.—Of this breed the bull should have yellow horns, placed neither too low nor too high, nor be too thick, but growing gradually less towards the points; the eye clear, prominent, and bright; the forehead small, flat, and indented; the muzzle fine; the cheek small; the nose of a clear yellow, the nostril high and open; the neck thick, and the hair about the head curled. The head of the ox is smaller, otherwise he does not differ materially from the shape of the bull; his action is free, and he is quicker in his movements than any of our oxen; but his legs are apparently placed too much under his chest for speed, yet he possesses this property in an eminent degree; his legs are straight; the forearm is large and strong; the bones of the leg, especially below the knee, very small; the tail is set on high, on a level with the back, rarely much elevated, never depressed, is long and

taper, with a bunch of hair at the end; the skin is very elastic, mellow, and rather thin; some have smooth hair, which should be fine and glossy; some curly, and these are rather the most hardy and fatten the best; red is the most favourite colour; many, however, are brown, and others are approaching to chestnut. Those of a yellow colour are reported to be subject to the *steat* (diarrhœa.) The drawing, Plate 12, fig. 3, is taken from Low's splendid work upon British animals. It represents a young Devon bull, two years and nine months old, of a deep red colour.

The Devon cow is much smaller than the bull; she has a full, round, clear eye, the countenance cheerful, the muzzle orange or yellow, the jaws free from thickness, and the throat from dewlap. On all soils, except the very heavy, the Devon ox is very superior at the plough, for its quickness of action, docility, good temper, stoutness, and honesty. It is always worked in yokes. Four Devon oxen are considered equal in their work to three horses: they are commonly worked from two years old until they are four, five, or six, and then in ten or twelve months, on grass and hay, they are fit for market; neither corn, cake, nor turnips are needed for them during the first winter. They fatten faster and with less food than most others; their flesh is excellent. Some comparative experiments between the Devon and other cattle were made by the Duke of Bedford, of which the following table gives the result: they were fed from November 16, 1797, until December 10, 1798.

	First Weight.	Gained.	Consumed		
			Oil Cake.	Turnips.	Hay.
			lbs.	lbs.	lbs.
1. Hereford	cwt. qrs. lbs 17 0 1	24 3	—	2700	457
2. —	18 1 0	41 5	423	2712	432
3. Devon	14 1 7	45 4	438	2668	295
4. —	14 2 4	64 6	442	2056	442
5. Sussex	16 2 0	45 4	432	2655	392
6. Leicester	15 2 14	40 2	434	2652	400

There is much difference of opinion with regard to the fitness of Devon cows for the dairy, it being pretty generally asserted that their acknowledged grazing qualities render them unfit for the dairy, that their milk is rich, but deficient in quantity; but there are many very superior judges who prefer them even for the dairy. Of the calves, those which are dropped about Michaelmas time are preferred to those which are calved in January or February. They allow the calf to suck three times a day for a week; then new warm milk is given it for three weeks longer; then it has warm scalded milk mixed with a small portion of finely divided linseed cake, and its meals are gradually lessened, and at four months old it is entirely weaned. (Youatt *On Cattle*, p. 7—25.)

The Hereford.—The oxen of Herefordshire are much larger than the Devon, and of a darker red, some are dark yellow, and a few brindled; they generally have white faces, bellies, and throats. They have thicker hides than those of Devonshire, and they are more hardy, and shorter in the carcase and leg; are

higher, heavier, and broader in the chine; have more fat, and are rounder and wider across the hips; the thigh is more muscular, the shoulders larger. (*Ibid.* p. 31.) Marshall long since described them pretty correctly as follows:—"The countenance pleasant, cheerful, open; the forehead broad; eye full and lively; horns bright, taper, and spreading; head small; chap lean; neck long and tapering; chest deep; bosom broad, and projecting forward; shoulder-bone thin, flat, no way protuberant in bone, but full and mellow in flesh; chest full; loin broad; hips standing wide, and level with the spine; quarters long and wide at the neck; rump even with the general level of the back, not drooping nor standing high and sharp above the quarters; tail slender, and neatly haired; barrel round and roomy, the carcase throughout deep and well spread; ribs broad, standing close and flat on the outer surface, forming a smooth even barrel, the hindmost large and of full length; round bone small, snug, not prominent; thigh clean, and regularly tapering; legs upright and short; bone below the knee and hough, small; feet of middle size; cod and twist round and full; flank large; flesh everywhere mellow, soft, yielding pleasantly to the touch, especially on the chine, the shoulder, and the ribs; hide mellow, supple, of a middle thickness, and loose; coat neatly haired, bright, and silky; colour of a middle red with a bald face, characteristic of the true Herefordshire breed."

"They fatten," says Mr. Youatt, "to a much greater weight than the Devons, and run from fifty to seventy score; a tolerable cow will average from thirty-five to fifty score; a cow belonging to the Duke of Bedford weighed more than seventy; an ox of Mr. Westcar's exceeded one hundred and ten score. The Hereford ox fattens speedily at an early age. They are not now much used for husbandry, although their form adapts them for the heavier work, and they have all the honesty and docility of the Devon ox, and greater strength, if not his activity.

"The Hereford cows are worse milkers than those of Devon, but then they will grow fat where a Devon would starve. The beef is sometimes objected to from the largeness of the bone, and the coarseness of some of the inferior pieces, but the best sorts are generally excellent. Mr. Youatt gives an account of an experiment in feeding, made in the winter of 1828-9, between the Herefords, and the improved short-horns, which, although by no means decisive of the merits of either breed, yet is worthy of notice by the grazier.

"Three Herefords and three short-horns were put together into a straw yard, December 2d, 1827, and each had, in the open yard, a bushel of turnips per day, besides straw, until May 2, 1828; they then were weighed, and sent to grass:—

No.	cwts. qrs. lbs.	No.	cwts. qrs. lbs.
1. Hereford	8 3 0	1. Short-horn	9 2 0
2. —	7 3 0	2. —	8 2 0
3. —	7 0 0	3. —	9 0 0

When taken from grass, November 3, they weighed—

No.	cwts.	qrs.	lbs.	No.	cwts.	qrs.	lbs.
1. Hereford	11	3	0	1. Short-horn	12	3	14
2. —	10	2	0	2. —	12	2	0
3. —	10	3	0	3. —	12	3	0

From this time till the 25th March, 1829, they consumed—

	Swedish Turnips.	Hay.
	lbs.	lbs.
The Herefords - - -	46,655	5,065
The Short-horns - - -	59,430	6,779

They then weighed—

No.	cwts.	qrs.	lbs.	No.	cwts.	qrs.	lbs.
1. Hereford	13	0	14	1. Short-horn	14	2	0
2. —	12	0	0	2. —	14	1	14
3. —	12	0	0	3. —	14	2	14

making a difference in favour of the short-horns of 3 cwts. 3 qrs. 14 lbs.; but then they consumed more turnips by 12,775 lbs., and more hay by 1,714 lbs. When they were sold at Smithfield on the 30th of March, the short-horns realized 97l., and the Herefords 96l." (*On Cattle*, p. 34.)

The Sussex.—One of the best descriptions, says Mr. Youatt, that we have of the Sussex ox is given by that excellent agriculturist, Mr. Ellman. He speaks of the Sussex ox as having a small and well-turned head; and so it has, compared with many other breeds, and even with the Hereford, but evidently coarser than that of the Devon, the horns pushing forwards a little, and then turning upwards, thin, tapering, and long, not so as to confound the breed with the *long-horns*, and yet in some cases a little approaching to them. The eye is full, large, and mild in the ox, but with some degree of unquietness in the cow. The throat clean; and the neck, compared with either the long or short-horns, long and thin, yet evidently coarser than that of the Devon. The shoulder is the principal defect. There is more wideness and roundness on the withers; it is a straighter line from the summit of the withers towards the back; there is no projecting point of the shoulder when the animal is looked at from behind, but the whole of the fore-quarter is thickly covered with flesh, giving too much weight to the coarser and less profitable parts; but then the fore-legs are wider apart, straighter, and more perpendicular than in the Devon, and are placed more under the body than seeming to be attached to the sides. The fore-arm is large and muscular; the legs, though coarser than those of the Devon, are small and fine downwards, particularly below the fetlock. The barrel is round and deep. In the back, no rising spinal processes are to be seen, but rather a central depression; and the line of the back, if broken, is only done so by a lump of fat rising between the hips; the belly and flank are capacious; there is room before for the heart and lungs, and there is room behind in the capacious belly for the full exercise of its functions; yet the beast is well ribbed home; the space between the last rib and the hip-bone is often very small, and there is no hanging heaviness of the belly or flank. The loins of the Sussex ox are wide; the hip-bone does not rise high, nor is it ragged externally; but it is large and spread out, and the space between the hips is well filled up. The tail fine, and thin, is set on lower than in the Devon, yet the rump is nearly as straight. The hind-quarters are cleanly made, and if the

thighs appear to be straight without, there is plenty of fulness within. The Sussex ox has all the activity of the Devon, and the strength of the Hereford, the propensity to fatten, and the beautiful fine-grained flesh of both. It possesses as many of the good qualities of both as can be combined in one frame. By crossing them with the Herefords, a heavier animal, but not fattening so profitably, or working so kindly, is produced. When the Sussex has been crossed with the Devon, a lighter breed has resulted, but not gaining in activity, while it is materially deteriorated in its grazing properties. The colour of the Sussex ox is a deep chestnut-red, or blood bay. The black, or black and white, generally indicate some strain in the breed, as a cross from the Welsh. The hide of the true Sussex ox is soft and mellow, the coat short and sleek. The Sussex ox does much of the farming labour of the Weald of Sussex. From ten to twelve of these are usually kept on a farm of 150 to 200 acres. These are fed with grass and straw till they begin to work, and then they have cut hay mixed with straw. There are, however, two breeds: the coarser Sussex is always slow; the lighter, or true Sussex is as light and fast as most cart-horses; of their speed proof was given by a Sussex ox which ran four miles against time, over the Lewes race-course, in sixteen minutes. Many farmers, if they have ten oxen at work, sell five or six every year, and break in an equal number to succeed them; the beasts will thus be broken in at three years old, and fatted at five or six. They are commonly taken from work when spring seed-time is over, and turned into the meadows, and thus prepared for winter stall-feeding. These are gradually accustomed to being constantly tied up. Some farmers, Mr. Ellman amongst the rest, are of opinion that there is a saving of one-fourth the food by stall-feeding, but many other farmers maintain that the cattle fatten faster when only confined to the yard. They average at Smithfield about one hundred and twenty stones; but they occasionally attain to much greater weights; one of Mr. Ellman's weighed two hundred and fourteen stones.

The Sussex cow is not a favourite with the generality of farmers. She does not answer for the dairy, for her milk, although of very good quality, is far inferior in quantity to either the Holderness or the Suffolk cow. They are, moreover, what their countenance indicates, of an unquiet temper, and are commonly restless and dissatisfied, especially if not bred on the farm on which they are kept. They are, therefore, chiefly kept as breeders; are generally in fair condition, even while milking; and no cows, except the Devon or Hereford, will thrive so fast after being dried; they fatten even faster than the ox. Nearly all the calves are reared, adds Mr. Youatt—the males for work, and the females for breeding or early fattening. By the best breeders, the bull is changed every two years. (*On Cattle*, p. 40.) The Hereford and Sussex cattle have so many points in common that in Loudon's *Encyclopædia of Agriculture*, both breeds are illustrated by one figure.

The Welch.—The cattle of Wales are principally of the middle-horns, and stunted in their growth from the poverty of their pastures. Of these there are several varieties. The Pembrokeshire are chiefly black, with white horns; are shorter legged than most other Welch cattle; are larger than those of Montgomery, and have round and deep carcasses; have a lively look and good eyes; though short and rough, not thick; have not large bones, and possess, perhaps, as much as possible, the opposite qualities of being very fair milkers, with a propensity to fatten. The meat is equal to the Scotch. They will thrive, says Mr. Youatt, where others starve, and they rapidly outstrip most others when they have plenty of good pasture. The Pembroke cow has been called the poor man's cow. The Pembroke ox is a speedy and an honest worker, and when taken from hard work fattens speedily. Many are brought to London, and rarely disappoint the butcher.

The Glamorganshire breed were patronised by George III., and were held in great estimation. They were, however, allowed to degenerate during the period of the late war, and have not since, in spite of the exertions of Mr. David of Radyr, been entirely restored. The counties of Carmarthen, Cardigan, Brecon, and especially Radnor, also produce many excellent black cattle, which have been materially improved of late by the introduction of other breeds, especially by crossing with the Herefords. Of North Wales, the cattle are rather more approaching to the long-horns than those of the south. In the counties of Anglesea, Carnarvon, and Merioneth, the chief attention of the farmer is directed to the rearing of stock. In Denbigh, Flint, and Montgomery, the dairy is chiefly regarded. The cattle of Anglesea, says Mr. Youatt, are small and black, with moderate bone, deep chest, rather heavy shoulders, enormous dewlap, round barrel, high and spreading haunches, flat face, horns long, almost invariably turning upwards; the hair coarse; the hide mellow; hardy, easy to rear, and well disposed to fatten when transplanted to better pastures than those of their native island. Attempts have been made, with little success, to improve the breed by crossing them with others; but it is difficult to find any other sufficiently hardy to withstand the climate and the privations of Mona. Many yearlings are brought from the island, and very few are kept in the island after they are three years old. They were formerly not castrated till they were a year old; this gave them a peculiar bull-like appearance. This operation, however, is now practised earlier. There is still with them, however, adds Mr. Youatt, a striking contrast with the mild intelligence of the Devon and the quiet submission of the Hereford. The Anglesea cows are not kept for the dairy to a greater extent than for home consumption. The cheese is negligently made, and, in consequence, poor and worthless. The cattle of the other Welch counties, bred amongst the rocks of Carnarvon, and the hills of Merioneth, Montgomery, and Denbigh, have little distinguishing features from other Welch cattle. They are small, hardy, and rapidly fatten, when

transferred to richer pastures. The beef they produce is excellent. (*Ibid.* p. 58.)

The Scotch.—Of this valuable and improving race of cattle there are several varieties, all of which are thus classed by Mr. Youatt, and are to be considered as belonging to the middle-horns. Of these the chief varieties are,

1. The West Highlanders, which, whether we regard those found in the Hebrides or in the county of Argyle, seem to retain most of the aboriginal character. They have remained unchanged, or improved only by selection, for many generations, or, indeed, from the earliest accounts that we possess of Scottish cattle.

2. The North Highlanders are a smaller, coarser, and in every way inferior race, and owe the greater part of what is valuable about them to crosses from the western breed.

3. The northeastern cattle were derived from, and bear a strong resemblance to the West Highlander, but are of considerably larger size.

4. The Fife breed are almost as valuable for the dairy as for the grazier, and yield to few in activity and docility.

5. The Ayrshire breed are second to none as milkers; many of the varied mingled breeds of the Lowlands are valuable.

6. The Galloways, which, scarcely a century ago were middle-horned, and with difficulty distinguished from the West Highlanders, are now a polled breed, increased in size, with more striking resemblance to their kindred the Devons; with all their aptitude to fatten, and with a hardness of constitution which those of Devon never possessed.

The West Highlanders, or kyloes, as they are called (supposed to be from a corruption of a Gaelic word pronounced *kael*, signifying Highlands), are bred in great abundance in, and exported from, the Hebrides. The true bull of this breed is described by Mr. McNeil of Islay as black; the head not large, the ears thin, the muzzle fine, and rather turned up; broad in the face; eyes prominent; countenance calm and placid; the horns should taper to a point, neither drooping too much nor rising too high, of a waxy colour, widely set at the root; the neck fine, particularly where it joins the head, and rising with a gentle curve from the shoulder; the breast wide, and projecting well before the legs; the shoulders broad at the top, and the chine so full as to leave but little hollow behind them; the girth behind the shoulder deep; the back straight, wide, and flat; the ribs broad, the space between them and the ribs small; the belly not sinking low in the middle, yet, in the whole, not forming the round and barrel-like carcass which some have described; the thigh tapering to the hock-joint; the bones larger in proportion to the size than in the breeds of the southern districts; the tail set on a level with the back; the legs short and straight; the whole carcass covered with a long thick coat of hair, and plenty of hair also about the face and horns, and that hair not curly. They are hardy, easily fed; the proportion of their offal is not greater than in the most approved larger breeds; they lay their fat and flesh equally on

SHORT HORNED CATTLE.

the best parts, and when fat, the beef is fine in the grain, and so well mixed or marbled that it commands a superior price in every market. About 30,000 of these are annually sent from the Hebrides to the main land. (*On Cattle*, p. 67.)

In the Hebrides, the dairy is only attended to so far as to serve the family with milk, butter, and cheese. The milk of the Western Highland cow is small in quantity, but excellent in quality; she does not yield, however, more than one-third of that of the Ayrshire. The oxen of the Hebrides are never worked. (*Ibid.* p. 71.)

The Argyleshire breed are larger than those of the Hebrides, and are bred according to what the soil and the food will best support. The Highlander, however (says the gentleman whom I have in this article quoted so often), "must be reared for the grazier alone; every attention to increase his weight, in order to make him capable of agricultural labour, every effort to qualify him for the dairy, will not only lessen his hardiness of constitution and propensity to fatten, but will fail in rendering him valuable for the purpose at which the farmer aims. The character of the Highlander must still be, that he will pay better for a quantity of food than any other breed, and will fatten where any other breed will scarcely live." (*Ibid.* p. 79.)

Of the North Highland cattle, those of the Shetland islands are the smallest; dwarfish, ill-shaped, and covered with hair; they sometimes are not more than 35 or 40 lbs. to the quarter. When they are taken to the north of Scotland, they thrive and fatten on very poor food with great rapidity; but when brought further to the south, the change is too great for them; they languish and sicken. The Shetland calf suffers privations from her birth; it is, in fact, killed often as soon as it is born. It is never allowed to suck its mother, but, if reared, is fed at first with milk, and afterwards with *bland*, a wretched kind of buttermilk; and when it grows up it has nothing to subsist upon but moss, heath, and sea-weed. The cows are housed at night, and, in the absence of straw, are littered with heath and the dust of peat. Their milk, which is exceedingly rich, is very small in quantity.

In the northerly counties of Scotland, there is nothing very peculiar in the breed of their cattle. The introduction of sheep, and of better modes of cultivating the soil, have gone far to diminish the stocks of poor, ill-fed, and worse managed breeding herds of this once desolate extremity of the island. These improvements, however, were long opposed by the husbandmen and the tenders of cattle as bold innovations, which were, at all events, to be opposed. Mobs, therefore, collected; the sheep were driven away; fences destroyed; the new farmers intimidated: the laws alone supported these national improvements to a successful issue.

The county of Aberdeen breeds more cattle than any other in Scotland. Its stock has been estimated at 112,000, and its annual sale of both fat and lean cattle is equal to more than 20,000. These vary in character with the soil and elevation: amongst the hills, they are

chiefly of the Highland breed; in the plains, a better description has been produced, by breeding from these by bulls from Fifeshire. The horns of these, says Mr. Youatt, do not taper so finely, nor stand so much upwards, as in the West Highlanders; and they are also whiter; the hair is shorter and thinner; the ribs cannot be said to be flat, but the chest is deeper in proportion to the circumference, and the buttocks and thighs are likewise thinner. The colour is usually black, but sometimes brindled; they are heavier in carcass; they give a larger quantity of milk, but they do not attain maturity so early as the West Highlanders, nor is their flesh quite so beautifully marbled; yet, at a proper age, they fatten as readily as the others, not only on good pasture, but on that which is somewhat inferior. They are rarely used for husbandry work, or, at most, for only one year. They are sent to grass at four years old for six months, after which they will weigh from 5 to 6 cwt. "The breed," adds Mr. Youatt, "has progressively improved, and this by judicious selections from the native stock: it has increased in size, and become nearly double its weight, without losing its propensity to fatten, and without growing above its keep." There is also in this great agricultural county an excellent breed of poll cattle; they are not so handsome, yet larger than the horned cattle; the quality of their meat is also said not to be so good. The calves are reared in Aberdeenshire much in the ordinary way. They are commonly fed with milk warm from the cow, and they are even sometimes reared partly on oil-cakes.

In Fifeshire the breed of cattle are of a very superior description. "They are generally," says Dr. Thompson, "of a black colour; the horns small and white, generally pretty erect, or, at least, turned up at the points, and bending rather forward; the bone small in proportion to the carcass; the limbs clean but short, and the skin soft; wide between the extreme points of the hock-bones; the ribs narrow and wide set, having a greater curvature than in other kinds, which gives the body a thick round form; they fatten quickly, and fill up well at all the choice points; are hardy, fleet, and travel well; are docile, and excellent for work." Whatever may be the explanation of the fact, it is certain that, at the present day, the Fifeshire breed of cattle is peculiarly her own. That they were centuries since improved by a cross with the then small cattle of England, is pretty certain; but whether English cattle formed part of the dowry of Margaret, the daughter of Henry VII. of England, when she married James IV. of Scotland, or whether English cattle were sent as a present to Scotland by James II. of England, is almost mere matter of conjecture; but, be that as it may, "the Fifeshire farmers," says Mr. Youatt, in his valuable work on cattle, "are convinced that their cattle cannot be further improved as a whole by any foreign cross, and they confine themselves to a judicious selection from their own." The pure Durhams have been established in some parts of Fife, but not always without difficulty.

Ayrshire has a peculiarly fine breed of dair-

cattle, which is thus described by Mr. Aiton, in his excellent treatise (p. 26) on the dairy breed of cows:—"The most approved shapes in the dairy breed are, small head, rather long, and narrow at the muzzle; eye small, but smart and lively; the horns small, clear, crooked, and their roots at considerable distance from each other; neck long and slender, tapering towards the head, with no loose skin below; shoulders thin; fore-quarters light; hind-quarters large; back straight, broad behind; the joints rather loose and open; carcass deep, and pelvis capacious and wide over the hips, with round fleshy buttocks; tail long and small; legs small and short, with firm joints; udder capacious, broad, and square, stretching forward, and neither fleshy, low hung, nor loose; the milk-veins are large and prominent; teats short, all pointing outwards, and at considerable distance from each other, skin thin and loose; hair soft and woolly; the head, bones, horns, and all parts of least value, small; and the general figure compact and well proportioned. See Pl. 12, fig. 2. (Youatt, *On Cattle*, p. 127.)

"The qualities of a cow," adds Mr. Aiton in another place, "are of great importance. Tameness and docility of temper greatly enhance the value of a milch cow. Some degree of hardiness, a sound constitution, health, and a moderate degree of spirits, are qualities to be wished for in a dairy cow, and what those of Ayrshire generally possess. The most valuable qualities which a dairy cow can possess are that she yields much milk, and that of an oily, butyraceous and caseous nature; and that after she has yielded very large quantities of milk for several years, she shall be as valuable for beef as any other breed of cows known; her fat shall be much more mixed through the whole flesh, and she shall fatten faster than any other." And again, "the best Scotch dairy cows yield 1000 gallons of milk in one year; and in general, from $3\frac{3}{4}$ to 4 gallons of their milk will yield $1\frac{1}{2}$ lbs. of butter, and about $27\frac{1}{2}$ gallons will produce $1\frac{1}{2}$ stone imperial of full milk cheese."

Lanarkshire is noted for its calves, whose veal is highly esteemed in the markets of Glasgow and Edinburgh. These, according to Mr. Aiton (*Survey of Ayrshire*, p. 441), are fed on milk from a dish, not suckled. This is often given to them sparingly at first, to improve their appetite and relish for their food; but it is gradually increased till the calf has a full supply. Other farmers allow them as much as they please from the first. For the first week or two a calf consumes about half a good cow's milk; at a month old the whole of a cow's milk; and at two months old the greater part of that of two cows. Those which are reared for stock have commonly the first drawn milk; those which are fattening, the last drawn from two or three cows. When the calves are costive, they have a little bacon or mutton broth given them; if they purge, a little rennet in their milk cures the complaint. They are used to have, also, a lump of chalk in their cribs.

The Galloway polled cattle are a peculiarly fine and valuable breed. They are described by Mr. Youatt, on the authority of the author

of the *Survey of Galloway*, as straight and broad in the back, and nearly level from the head to the tail—round in the ribs, and also between the shoulders and the ribs, and the ribs and the loins—broad in the loins, without any large projecting hook-bones—long in the quarters and deep in the chest, but not broad in the ribs, and twist. There is much less space between the hook or hip-bones and the ribs than in most other breeds. They are short in the leg and moderately fine in the shank-bone. The happy medium seems to be preserved in the leg, securing hardihood and a disposition to fatten. With the same cleanness and shortness of shank, there is no breed so large and muscular above the knee, while there is more room for the deep, broad, and capacious chest. They are clean, not fine and slender, but well proportioned in the neck and chaps; a thin and delicate neck would not correspond with the broad shoulders, deep chest, and close, compact form of the breed. The neck of the Galloway bull is thick even to a fault. The Galloway has a loose, mellow skin, of medium thickness, with long, soft, silky hair. The skin, which is thinner than the Leicester, is not so fine as the improved Durham: it handles soft and kindly. Their colour is commonly black, but there are several varieties; the dark-coloured are preferred, from their being considered to indicate hardness of constitution. 30,000 of these are estimated to be sent yearly out of Galloway to the south. (Youatt, *On Cattle*, p. 158.) The Galloway breeders prefer allowing the calves to suck the cow; they consider they thrive materially better than those fed from the pail, and that fewer die of stomach complaints. Another valuable breed of polled cows is bred in Angus, which much resemble in appearance those of Galloway; they are, however, rather larger and longer in the leg, flatter sided, and with thinner shoulders.

In Norfolk and Suffolk a polled breed of cows prevails, which are almost all descended from the Galloway cattle, "whose general form," says Mr. Youatt (p. 172), "they retain, with some of, but not all their excellences; they have been enlarged, but not improved, by a better climate and soil. They are commonly of a red or black colour, with a peculiar golden circle around the eye. They are taller than the Galloways, but thinner in the chine, flatter in the ribs, and longer in the legs; rather better milkers; of greater weight when fattened; though not fattening so kindly, and the meat is not quite equal in quality."

The Suffolk dun cow, which is also of Galloway descent, is celebrated as a milker, and, there is little doubt, is not inferior to any other breed in the quantity of milk which she yields; this is from six to eight gallons per day. The butter produced, however, is not in proportion to the milk. It is calculated that a Suffolk cow produces annually about $1\frac{1}{2}$ cwt. of butter.

The Suffolk duns derive the last part of their name from their usual pale yellow colour. Many, however, are red, or red and white. They are invariably without horns, and small in size, seldom weighing over 700 lbs. when fattened. The male and female are nearly of the same height, and seldom exceed $4\frac{1}{4}$ to $4\frac{1}{2}$ feet

They are rather rough about the head, with large ears. Their bodies are long and legs short, hip-bones high, and generally deficient in the points of the finer breeds. Still many of the cows fatten well, and produce beef of superior quality. In proportion to their size, the Suffolk dun cows yield a great abundance of milk; and as a dairy stock, there are very few breeds that are preferable.

Irish Cattle.—Of the Irish cattle there are two breeds, the middle and the long-horns. The middle-horns are the original breed, and tenant the forests and most mountainous districts. "They are," says Mr. Youatt, "small, light, active, and wild; the head commonly small; the horns short but fine, rather upright, and frequently, after projecting forward, turning backward; somewhat deficient in hind-quarters; high-boned, and wide over the hips, yet the bone not commonly heavy; the hair coarse and long, black or brindled, with white faces. Some are finer in the bone and in the neck, with a good eye and sharp muzzle, and great activity; are hardy, live upon very scanty fare, and fatten with great rapidity when removed to a better soil: they are good milkers. The Kerry cows are excellent in this respect. These last, however, are wild and remarkable leapers. They live, however, upon very little food, and have often been denominated the poor man's cow."

The other breed is of a larger size. It has much of the blood of the old Lancashire or Craven breed, or true long-horn. Their horns first turn outwards, then curve, and turn inwards. Of each of these kinds, an immense number of both lean and fat stock are annually exported to England; in 1825 it amounted to 63,524.

The long-horns.—The long-horns of England came originally from Craven in Yorkshire, and derived their name from a length of horn, which often extended to an unbecoming degree. Bakewell, Culley, and other great breeders improved upon, and have long since destroyed, the chief traces of the old, long-bodied, coarse, large boned breed. It is needless, therefore, to follow this breed through the various counties in which it once predominated, for it has long been rapidly disappearing, and has almost everywhere given place to better kinds.

The improved breed of Leicestershire, is said to have been formed by Webster of Cauley, near Coventry, in Warwickshire. Bakewell, of Dishley, in Leicestershire, afterwards got the lead as a breeder, by selecting from Cauley's stock; and the stocks of several other eminent breeders have been traced to the same source.

The Lancashire breed of long-horned cattle may be distinguished from other cattle by the thickness and firm texture of their hides, the length and closeness of their hair, the large size of their hoofs, and their coarse, leathery, thick necks. They are likewise deeper in their fore quarters, and lighter in their hind quarters than most other breeds; narrower in their shape, less in point of weight than the short-horns, though better weighers in proportion to their size; and though they give considerably less milk, it is said to yield more cream in pro-

portion to its quantity. They are more varied in colour than any other breeds; but, whatever the colour may be, they have in general a white streak along their back, which the breeders term *finched*, and mostly a white spot on the inside of the hough. (Culley, p. 53.) "In a general view," says Loudon, "this race, notwithstanding the singular efforts that have been made towards its improvement, remains with little alteration; for, except in Leicestershire, none of the subvarieties (which differ a little in almost every one of those counties where the long-horns prevail) have undergone any radical change or any obvious improvement." (Loudon's *Encyc. of Agr.* p. 1015.)

The short-horns.—Of this noble breed of cattle, which seems to be annually increasing in favour with the dairyman and the grazier, we are mainly indebted to the description of the late Rev. Henry Berry. Durham and Yorkshire have for ages been celebrated for a breed of these possessing extraordinary value as milkers, "in which quality," says Mr. Youatt, "taken as a breed, they have never been equalled. The cattle so distinguished were always, as now, very different from the improved race. They were generally of large size, thin skinned, sleek haired, bad handlers, rather delicate in constitution, coarse in the offal, and strikingly defective in the substance of girth in the fore-quarters. As milkers they were most excellent, but when put to fatten, as the foregoing description will indicate, were found slow feeders, producing an inferior quality of meat, not marbled or mixed as to fat and lean; the latter sometimes of a very dark hue. Such, too, are the *unimproved* short-horns of the present day."

About the year 1750, in the valley of the Tees, commenced that spirit of improvement in the breeders of the old short-horns, which has ended in the improved modern breed. These efforts, begun by Sir William Quintin, and carried on by Mr. Milbank of Birmingham, were nearly completed by Mr. Charles Colling. The success of this gentleman was, from the first, considerable. He produced, by judicious selections and crossings, the celebrated bull Hubbuck, from whom are descended the best short-horns of our day. Of this breed was the celebrated Durham ox, which was long shown in a travelling van at country fairs, and which, when slaughtered in April, 1807, at eleven years of age, weighed 187 stone; and the Spottiswoode ox, probably the largest ever exhibited. In June, 1802, he measured—height of shoulder, 6 feet 10 inches; girth behind the shoulder, 10 feet 2 inches; breadth across the hooks, 3 feet 1 inch; computed weight, 320 stones of 14 lbs. (*Quart. Journ. of Agr.* vol. vi. p. 271.)

Besides Mr. Colling, his brother Mr. Robert Colling, Mr. Charge, and Mr. Mason were hardly second to him in skill and success as breeders of the short-horns.

With the pure improved short-horns, crossed with a red polled Galloway cow, was produced a variety of this breed, which was long named "the alloy," but for which at Mr. C. Collings's sale, October 11, 1810, some most extraordinary prices were obtained: thus a cow called

	Guineas.
Lady, 14 years old, sold for	206
Countess, her daughter, 9 years	400
Laura, ditto 4 years	210
Major, her son, 3 years	200
George, ditto, a calf	130

In short, at this sale, forty-eight lots produced 7115l. 17s., Comet, a six year old bull, selling for 1000 guineas. (See COLLING, ROBERT AND CHARLES.)

The colours of the improved short-horns are red or white, or a mixture of both; "no pure improved short-horns," adds Mr. Youatt, "are found of any other colour but those above named." That the matured short-horns are an admirable grazier's breed of cattle is undoubted: they are not, however, to be disregarded as milkers; but they are inferior, from their fattening qualities, to many others as workers.

"In its points," says Mr. James Dickson (*Quart. Journ. of Agr.* vol. vi. p. 269), for quantity and well laid on beef, the short-horn ox is quite full in every valuable part; such as along the back, including the fore-ribs, the sirloin and rump, in the runners, flanks, buttocks, and twist, and in the neck and brisket as inferior parts. In regard to quality of beef, the fat bears a due and even preponderating proportion to the lean, the fibres of which are fine and well mixed, and even marbled with fat, and abundantly juicy. The fine, thin, clear bone of the legs and head, with the soft mellow touch of the skin, and the benign aspect of the eye, indicate, in a remarkable degree, the disposition to fatten; while the uniform colours of the skin, red or white, or both, commixed in various degrees, bare, cream-coloured skin on the nose and around the eyes, and fine, tapering, white, or light-coloured horns mark distinctly the purity of the blood; these points apply equally to the bull, the cow, and the heifer. The external appearance of the short-horned breed," adds Mr. Dickson, "is irresistibly attractive. The exquisitely symmetrical form of the body in every position, bedecked with a skin of the richest hues of red, and the richest white approaching to cream, or both colours, so arranged or commixed as to form a beautiful fleck or delicate roan, and possessed of the mellowest touch; supported on clean small limbs, showing, like those of the race-horse and the greyhound, the union of strength with fineness; and ornamented with a small, lengthy, tapering head, neatly set on a broad, firm, deep neck, and furnished with a small muzzle, wide nostrils, prominent, 'mildly beaming' eyes, thin, large biny ears set near the crown of the head and protected in front with semicircularly bent, white, or brownish coloured, short (hence the name), smooth pointed horns; all these parts combine to form a symmetrical harmony, which has never been surpassed in beauty and sweetness by any other species of the domesticated ox."

An excellent paper by Mr. Dickson on crossing the short-horns with other cattle, may be consulted with advantage by the breeder in the *Edin. Quart. Journ. of Agr.* vol. vii. p. 495, and on crossing in general, *Ibid.* p. 247.

In the first plate a representation is given of short-horned cows; in Plate 12, fig. 1, is a drawing of a short-horned bull, which may re-

present the breeds variously termed, Dutch, Holderness, Teeswater, Yorkshire, Durham, Northumberland, &c. The Teeswater breed, a variety of short-horns established on the banks of the Tees, at the head of the vale of York, is at present in the highest estimation, and is alleged to be the true Yorkshire short-horned breed. Bulls and cows from this stock, purchased at most extraordinary prices, are spread over all the north of England and the border counties of Scotland. The bone, head, and neck of these cattle are fine; the hide is very thin; the chine full; the line broad; the carcass throughout large and well fashioned; and the flesh and fattening quality equal, or perhaps superior, to those of any other large breed. The short-horns give a greater quantity of milk than any other cattle; a cow usually yielded 24 quarts of milk per day, making 3 firkins of butter during the grass season. (*Culley*, p. 48.)

The Yorkshire cow.—With Mr. Youatt's account of the Yorkshire cow (and this article is, in fact, hardly any thing else but an abridgment of his excellent work "On Cattle" in the *Library of Useful Knowledge*) we shall conclude. The Yorkshire cow is that generally found in the great dairies in the vicinity of London, and in these the character of the Holderness and the Durham unite. "A milch cow good for the pail as long as she is wanted, and then quickly got into marketable condition, should have a long and rather small head; a large-headed cow will seldom fatten or yield much milk. The eye should be bright, yet with a peculiar placidness and quietness of expression; the chops thin, and the horns small. The neck may be thin towards the head; but it must soon begin to thicken, and especially when it approaches the shoulder. The dewlap should be small; the breast, if not so wide as in some that have an unusual disposition to fatten, yet should be very far from being narrow, and it should project before the legs; the chine to a certain degree fleshy, and even inclining to fulness; the girth behind the shoulder should be deeper than is usually found in the short-horn; the ribs should be spread out wide, so as to give as globular a form as possible to the carcass, and each should project farther than the preceding one, to the very loins. She should be well formed across the hips, and on the rump, and with greater length there than the milker generally possesses, or if a little too short not heavy. If she stands a little long on the legs, it must not be too long. The thighs somewhat thin, with a slight tendency to crookedness or being sickle-hammed behind; the tail thick at the upper part, but tapering below; and she should have a mellow hide, and but little coarse hair. Common consent has given to her large milk-veins. A large milk-vein certainly indicates a strongly developed vascular system, one favourable to secretion generally, and to that of the milk amongst the rest. The udder should rather incline to be large in proportion to the size of the animal, but not too large; its skin thin and free from lumps in every part of it; the teats of a moderate size. The quantity of milk given by some of these cows is very great; it is by no means uncom-

CATTLE.

mon for them in the beginning of the summer to yield thirty quarts a day. There are rare instances of the cow yielding thirty-six quarts; the average is about twenty-two to twenty-four quarts. The milk, however, is not so rich in its produce of butter as that of the long-horns, the Scotch, or the Devons." (For the Alderney cow, see ALDERNEY.)

The quantity of cattle annually sold in Smithfield is very great: it was (according to *M'Culloch's Dict. of Commerce*) in—

Year.	Catt'e.	Sheep.
1732	76,210	511,700
1742	79,601	503,260
1752	73,703	642,100
1762	102,831	772,160
1772	89,503	609,540
1782	101,176	723,970
1792	107,348	760,859
1802	126,389	743,470
1812	133,854	953,630

1832	166,224	1,364,160

Fatted calves—

1822	21,255
1832	19,522

The quantity of cattle in various European countries has been estimated to be as follows:

	Cattle.
Great Britain	5,100,000
Russia	19,000,000
Netherlands	2,500,000
Denmark	1,607,000
Austria	9,912,500
France	6,681,900
Spain	2,500,000
Portugal	650,000
Italy	3,500,000
United States of America in 1810	14,971,566

Live and dead weight of cattle.—Salesmen commonly calculate that the dead weight is one-half of what the animal weighs when alive; but the butcher knows that the produce is greater: it often approaches to three-fifths; and by an extensive stock bailiff of the late Mr. Curwen, it was found that the dead weight amounted to fifty-five per cent. of the live. But the amount differs strangely, as may be seen by the following statement of Mr. Ferguson of Woodhill. (*Brit. Husb.* vol. ii. p. 392.)

	Live Weight.	Dead Weight.	Tallow.
	st. lbs.	st. lbs.	st. lbs.
An Aberdeenshire ox	132 11	84 6	16 5
A short-horned ox	132 0	90 1	14 0
A short-horned heifer	120 4	77 9	15 8
A short-horned steer	120 5	67 7	14 12

In ascertaining the weight by admeasurement, the girth is taken by passing a cord just behind the shoulder-blade and under the fore-legs: this gives the circumference, and the length is taken along the back from the fore-

CATTLE.

most corner of the blade-bone of the shoulder, in a straight line to the hindmost point of the rump. (See engraving below.)

Table for Admeasurement of Cattle.

(*M'Derment's Farmer's Assistant.*)

The breeds of cattle which stock the farms of the United States are all derived from Europe, and, with few exceptions, from Great Britain. The highest breeds at the present day are comparatively of recent origin, since the great improvements commenced by Bakewell only date about the period of the American Revolution. The old importations made by the primitive settlers must consequently have been from comparatively inferior grades. In some sections of the Union, and more particularly in New England, the primitive stock is thought to have undergone considerable improvement, whilst in many parts of the Middle, and especially of the Southern States, a greater or less depreciation has ensued. The prevailing stock in the Eastern States is believed to be derived from the North Devons, most of the excellent marks and qualities of which they possess. Hence they are very highly esteemed, and have been frequently called the "American Devons." The most valuable working oxen are chiefly of this breed, which also contributes so largely to the best displays of beef found in the markets of Boston, New York, and Philadelphia. The prevailing colour of the New England cattle is a deep red. Sometimes, however, they are dark-brown, or brindle, or nearly black. Their horns are moderately long, smooth, and slender. The oxen are remarkable for their docility, strength, quickness, and powers of endurance. The cows are fair milkers, and both kinds are hardy and fatten readily. By means of this fine domestic stock, and the importations still so extensively made of selections from the short-horned, and other of the finest European breeds, the cattle, not only of New England, but of other sections, are rapidly improving, especially in the Middle and Western States.

The graziers of Kentucky and other parts of the West have heretofore generally shown the greatest preference to the short-horned breed, which, with various crosses, is now perhaps the predominant stock of the country. Since Durhams have become so common, the extravagantly high prices they once brought are no longer maintained; and, indeed, the farmers now not only think of changing the breed, but have actually commenced doing so. They have been led to this chiefly for the reason, that the short-horned cattle, which take on fat so readily when well fed, and become so heavy, are unable to retain their fat and flesh on being driven some 1000 or 1200 miles to the Eastern markets, where they generally arrive in such a meager condition as to bring only the price of lean stock. The Western graziers, therefore, wish to adopt some breed which will be able to *carry their beef along with them*. The English Herefords have been sought after, and as much as \$500 paid for an imported cow. Captain Barclay, a gentleman owning a large estate in Scotland, called Ury, and who has recently made a tour through the United States, says that he thinks our Western farmers will find themselves mistaken in this selection from the British breeds, and that they would derive more advantage by importing Angus or Aberdeenshire *Doddies*, which are kindred breeds of well-formed, moderate-sized,

active animals; or, perhaps still better, the small and peculiarly symmetrical West Highland cow; and to cross them with a short-horn or Durham bull. The West Highlander, he says, possesses all the points of a good feeder; and being hardy, and active as a deer, would suffer little from being driven even 1000 miles. In its native glens it may feed to 20 or 25 stones, Amsterdam;* but the heifers, on being transplanted to a rich and sheltered pasture, attain to nearly double that weight. This he says he has demonstrated by introducing a herd of forty West Highland heifers on his farm at Ury, where they were crossed with short-horned bulls, and the experiment, on repeated trials, has been attended with great success; for while the mothers, by removal to better pasture, have greatly increased in size, the cross has produced strong and handsome animals, kindly feeders, rising to a great weight, and bringing high prices. It is a great desideratum for the graziers of Kentucky and other parts of the West, where pastures of the richest kind abound, could they find some active breed which would be able to perform the long journeys to the Eastern markets, and carry their beef with them.

A very general impression now exists in the United States in favour of breeding a cross from the best short-horned bulls with the finest native cows.

Mr. Colman, in his Reports upon the agricultural interests of Massachusetts, recently made to the legislature of that state, has collected a fund of valuable information in relation to American neat cattle, showing their distinguishing characteristics for dairy and other purposes, together with the improvements made and still making by the introduction of select cattle from Europe, and the results of feeding in various ways. Several books and periodicals published in the United States, and devoted to agriculture, are rich in details relating to American and European neat stock. But, instead of culling from these, we prefer drawing upon Mr. Colman's Report to the Legislature of Massachusetts, as we regard it a high source of authentic information, and calculated to be the more highly useful from the exactness of the details. We regret that our limits will not admit of some particular notice of numerous mammoth beasts which have been raised and fattened in Pennsylvania, New Jersey, and elsewhere. Particular accounts of these, with the modes of management and feeding, are duly recorded in more or less of the periodicals.

Stall-fed animals.—It appears that the stall-feeders in Massachusetts usually select cattle brought from Vermont, New Hampshire, and New York, choosing such as are small-boned, neat, and thrifty. Rather than keep these on hand a long time, they generally find it most advantageous to "turn them soon," and after thus disposing of their fat stock early in the season, many purchase an additional supply pretty far advanced for the market, and finish these so as to be ready to send them off in the spring. In the hilly districts, where Indian

* The Amsterdam stone is only about 10 lbs. of English troy weight.

corn is not raised to any considerable extent, the cattle are generally fed upon hay and potatoes, whilst in the river valleys Indian meal is generally and most advantageously substituted for potatoes. When potatoes are chiefly depended upon in stall-feeding, a bushel of these well washed, are usually given in a day to each head, at two or more times, along with as much good hay as the animal can consume, but no water is allowed. Many farmers think that a yoke of oxen put up in good condition, may be well fattened or finished off for market with one hundred bushels of potatoes, in addition to the hay they will consume. Cattle fed upon potatoes will, it is said, in general prove as well, that is, have as much tallow, as those fed in any way, and the beef of such cattle is thought by many to have a peculiar juiciness or sweetness. In driving to market, however, the cattle fed upon potatoes will fall away more than those fed upon hay and corn; and when they come into market by no means appear as well. Several farmers are in the practice of boiling or steaming the potatoes which they give to their cattle, and profess to find a great advantage in it. The experiments which have come within my own knowledge have not yet satisfied me that the advantages are a compensation for the labour and expense incurred by such operation.

"The articles usually employed in fattening cattle are hay and Indian meal, or corn and rye meal mixed, or pease and oats, or oats and corn ground together. Besides this, many farmers are in the practice of giving their stall-fed cattle occasionally certain quantities of potatoes. An excellent farmer, of fifty years experience in the fattening of cattle, is of opinion that potatoes are good feed for fattening cattle in the fall and spring, when the weather is warm; but that they do no good in cold weather unless they are cooked. I rely much upon his judgment and experience. The value of potatoes is differently estimated by different individuals; some considering five bushels, others rating four bushels, as equivalent to one bushel of corn.

"In the feeding of cattle for market a great deal of practical skill is required, and constant observation of their condition, otherwise they may be surfeited and their appetite destroyed; or their digestive powers be overtaken and the feed fail of its object.

"A farmer in Charlemont, of large experience in the fattening of stock, considers the common English or flat turnip of little value for fattening stock. The cattle fed upon them appear healthy and in fine condition, but yield very little tallow. A pair of cattle fattened by him and much admired by the butchers, which weighed eighteen hundred pounds when dressed, had only thirty pounds tallow each.

"I presume the experiment has never been fairly tried, of the value of turnips for fattening stock. This is likely to have been only a solitary instance; besides this, we want to know in the case, how many turnips, were given; under what circumstances they were given; and with what other feed accompanied.

"The same farmer is of opinion, that oil-meal

for fattening cattle is of great value. He is quite content to pay twenty to twenty-three dollars per ton, the current price for it in his town. A farmer in Conway concurs in this opinion; and believes that for a beneficial change a farmer can well afford to buy oil-meal with corn at bushel for bushel. The price here rises sometimes to thirty dollars per ton. The weight of oil-meal is about forty-five pounds to the bushel."

In England and Scotland, turnips are freely given to growing and fattening cattle, though more sparingly to milch cows, in consequence of the flavour they impart to milk and butter.*

Mr. Colman furnishes the results of experience gained by many persons who have been long in the practice of stall-feeding. A few of these we shall notice.

"A. R. has twenty head of cattle in the stall. They are of good size and calculated to average over eleven hundred pounds each, when dressed in Brighton.

"He has tried a variety and a mixture of feed, such as oats, broom-corn seed, &c., but he prefers Indian meal to every other feed. He disapproves of excessive feeding; and thinks it a great error to give too much. He deems four quarts with hay ordinarily enough; and ten quarts a day sufficient for any animal. He feeds twice a day with great regularity. His present cattle have never received over eight quarts per day each; and at first putting up a much less quantity. He deems it best to reduce their feed of provender a few days before starting for market. He buys his cattle for feeding in the fall; and his present stock averaged in the cost seventy-five dollars per pair.

"S. W. is of opinion that one bushel of corn one year old for feeding any kind of stock, is equal to one bushel and one peck of new corn, or corn before it becomes perfectly sound and dry.

"T. C. has in stall, 27th February, five pairs of oxen, which were purchased in Brighton, in June last. When purchased, they were thin in flesh and were immediately put into good pasture. The cost was as follows:

Two pairs cost 60 dollars per yoke	-	120 00
One pair cost 46 50 " "	-	46 50
" " 47 00 " "	-	47 00
" " 45 00 " "	-	45 00

"These cattle were put into a good pasture until the 20th of November, when they were brought to the stall. From that time until the 20th December, they were fed with hay only. From that time until the first of January, they received six quarts of provender each, daily. From the first of January, they received each

* Turnips, though used extensively as an auxiliary in feeding cattle and other stock in Europe, and especially in Great Britain, do not seem to answer so well in the United States, unless perhaps it may be in some portions of New England. The general complaint against them in the Middle States, is that they do not appear to possess sufficient nourishing and fattening qualities. Hence the sugar beet, ruta бага, mangel-wurtzel, and carrot are greatly preferred, all of which roots may be given with very great advantage to stock, as auxiliaries. Testimonials of their value when thus employed are numerous and conclusive. For information relative to the feeding of cattle on turnips, see Stephens's "*Book of the Farm.*"

eight quarts daily. This provender consists of one-half oil-meal, one quarter oats and one quarter corn; the two last ground together and the whole intermixed when given to the cattle.

"The oil-meal in this case cost forty dollars per ton. It weighs about forty-five pounds to a bushel. If ground very fine, it will not weigh more than thirty-eight or forty pounds to the bushel. It is best, therefore, to buy it by weight. This farmer is of opinion that his oxen, if now killed, would return him one thousand pounds of beef each.

"Meal made from the seed of broom-corn," Mr. Colman says, "is occasionally used, mixed with other provender, but for neat cattle it is not approved by the best farmers. Flaxseed jelly, that is, half a pint or a pint of flaxseed formed into a jelly by boiling, as an allowance for a stall-fed animal per day, has been used for fattening cattle by some farmers with remarkable success. It does not supersede the use of meal, but is best mixed with it. It is believed that no article, according to cost, can be used with more advantage than this for this object; and that none is known, which is more nutritious. This jelly, which I have myself used with great advantage, is prepared as follows: 'to seven parts of water let one part of linseed be put for forty-eight hours; then boil it slowly for two hours, gently stirring the whole lest it should burn. Afterwards it ought to be cooled in tubs; and mixed with meal, bran, or cut chaff, in the proportion of one bushel of hay to the jelly produced by one quart of linseed well mashed together. This quantity given daily with other food will forward cattle rapidly, but it must be increased when they are intended to be completely fattened.'"

The quantity of Indian corn meal required to fatten cattle, usually varies a little. One experienced feeder gives it as the result of his observation that a yoke of good cattle, to be well stall-fed, will take from twenty to twenty-five bushels of meal, besides the usual allowance of hay.

Some farmers have ground their corn for fattening cattle on the cob. In such cases it is suggested that the miller has it in his power to take advantage by drawing his measure of toll from the lowermost portion of the grist to which the corn usually settles. There can be little doubt that corn cobs will serve the purpose of coarse hay for distension, etc., since cattle are often quickly fattened upon nubbins or the smaller ears of corn. They will thus often be found a useful auxiliary.

The Massachusetts stall-feeders consulted by Mr. Colman are almost universally agreed upon one point—namely, that a mixture of provender is best. While Indian meal is to be considered as the basis, certain proportions of rye, or oats, or pease and oats, are always deemed best to be mixed with it. An excellent farmer, whose fat cattle do him much credit, is of opinion that the meal given should always be scalded. Oxen from four to six years old are generally selected for fattening, though some prefer young stock of from three to five years old. With regard to the particular breeds preferred, Mr. Colman says that the

small-boned, medium-sized animals, of good length, strongly marked with the Devon blood, are those which are chosen. In considering the capacities of cattle for fattening, a wide chest has been regarded as an unerring sign of a good and quick feeder. Bearing upon this point, Dr. Jenner, the great benefactor of mankind, made an observation, the truth of which appears to have been fully confirmed by further examination—namely, that no animal whose chest was narrow could easily be made fat. This observation applies not only to neat cattle, but to sheep, goats, and hares. It even holds good in the human species. The experienced farmer is seldom at a loss to distinguish the most thrifty cattle, in respect to which there are great differences among individuals of the same breed. To the assistance of the eye is added the sense of touch by the operation technically called handling, the mode of conducting which, according to the most approved English authorities, has been already detailed. In reference to the several breeds of cattle and their distinguishing qualities, Mr. Colman makes the following remarks as the result of his observations and inquiries:—

"The pastures in New England are short, and the winters long and severe, and therefore ill-adapted to a race of large size, of tender habits, and requiring extraordinary keeping and the most particular care to maintain their condition. The most celebrated breeds in England are the improved Durham short-horn, the Hereford, the Ayrshire, and the North Devon. Of these different races, highly improved animals of each sex, for the purposes of breeding, have been introduced into the country and into the state; and each race has found strong advocates, who have preferred it to every other. For dairy purposes, as far as my own limited experience and observation go, I have no doubt that the Ayrshire, or a first cross with the improved Durham and the Devon, are to be preferred. For early maturity and size as beef animals, the improved Durham short-horn appears to me to take the lead. But they are tender, and require extraordinary keeping and care to maintain their good qualities. They seem better adapted to the rich prairies and feeding grounds of the Western States than to our scanty pastures. The Hereford, of which some remarkably beautiful animals have been imported into Albany, have warm advocates both here and abroad, and come in strong competition with the improved Durhams. Those of the Herefords, which I have had the pleasure of seeing, seemed to me considerably larger than the Devons, but smaller than the Durhams. These were choice specimens, and were remarkably thrifty and beautiful animals, clean about the limbs, not so straight on the back and square behind as the Durhams, but exhibiting upon the whole admirable constitution and symmetry. Having had no farther personal observation or experience with this breed of animals, I will not venture to speak of them with any confidence. Of their particular qualifications for the dairy I know nothing. For our purposes as working oxen and for stall-feeding, the North Devon cattle are most generally approved. This undoubtedly is the prevalent

1. Short Horned Bull. 2. Ayrshire Cow. — 3. Devon Bull, 2 Years old.

stock of the country, though diversified and contaminated by various mixtures. No pains have been taken, by systematic efforts, by judicious selection, and by perseverance in endeavours to combine the best qualities and to eradicate or remedy defects, in order to form, from what we call our native stock, a distinct and valuable breed. Indeed, where the improved blood has been introduced, it has been suffered, after a short time, to run out through neglect, or to become degenerate by poor keeping."

As regards the capacity for thrift in the different breeds, Mr. Colman thinks that the perfection of any animal depends essentially upon his good keeping from his birth; and that severity or hard fare, or negligence while in a growing state, do an injury to the constitution, and so stint the growth, that no after keeping can ever repair it. The animal constitution always suffers essentially by reverses. It is said that a sheep is never fat but once. Perhaps this assertion is to be received with some qualification, but still it must be admitted as a difficult task to raise an animal from a low condition. "The farmers prejudice very greatly their own interest in suffering their milch cows to come out in the spring in low condition. During the time they are dry, they think it enough to give them the coarsest fodder, and that in limited quantities; this, too, at a time of pregnancy, when they require the kindest treatment and the most nourishing food. The calf itself under this treatment of the cow is small and feeble. He finds comparatively insufficient support from his exhausted dam; and the return which the cow makes in milk during the summer is much less than it would be, if she came into the spring in good health and flesh. It requires the whole summer to recover what she has lost. The animal constitution cannot be trifled with in this way.

"It is so with all live-stock, and especially with young animals at the period of their most rapid growth. They should not be prematurely forced; but, on the other hand, they should not be stinted or checked. It is a very important question, whether it is more profitable to fatten young animals than older ones. I have given the different opinions of different farmers on this subject. In England, it seems an almost universal opinion, that the sooner an animal can be made fit for the market the better, and their fatted animals, especially of the improved breeds, are slaughtered at two and three years old. They are often brought to market at even an earlier age than this; but it is considered, and with reason, that the meat of such animals is not so good as when they have attained a full growth. It is natural to suppose that the animal can only be in perfection when he has ceased to grow, and if killed before that period, there would seem to be a loss of that enlargement of size and weight, separate from an increase of fatness, to which he might attain. While an animal is growing and well fed at the same time, there is evidently a double gain; and if he increases one pound a day by his extra feed, he may be supposed to increase another pound by his ordinary growth. After this period, however, it may be advisable

to send him to market as soon as he can be put into condition. Farmers often make great mistakes in keeping their cattle too long. There is a reasonable calculation to be made in respect to the markets, which are generally higher in the spring than in the autumn; but the advance in price does not always meet the increased expense of keeping. It is important, as a general rule, that the animal should go to market as soon as the gain which he makes ceases to pay the expense of his keeping.

"It has been made a question, whether heifers are not more profitable than steers. They are as thrifty, and, in general, pay as well for their keeping. It is the practice of some farmers, to allow them to come in with calves at two years old; if at that time they promise well as cows, a good market can almost always be found for them; but, if otherwise, after suckling the calf three months or more, they are turned out to be fatted for beef, and are either sold immediately at the close of the pasturing season, or otherwise, after being stalled for a short time. Their meat, if well fed, is always highly esteemed. This proves, in general, a good operation. In England, heifers designed for the stall are very frequently *spayed*, by which their thrift is greatly assisted.

"This is often done in Kentucky and some other of the Western States; but I have never known more than one instance of its being practised in New England. I do not feel authorized, therefore, to pronounce upon its advantages.

"It is sometimes asked, whether oxen are injured in their growth from being worked. If their strength is prematurely and too severely taxed, or if they are subjected to severe usage, undoubtedly it must prove injurious; but, if otherwise, if reasonably worked and carefully and kindly attended, there is no doubt that their health and growth are promoted by it. It is often matter of inquiry, whether fattening cattle should be kept in close stalls, or be suffered to lie out-doors. The experience of all the farmers whom I have consulted, who have made any trial, is conclusive in this case, in favour of the superior thrift of animals kept constantly in the barn, or turned out only for watering and immediately put up again, over those which are kept in open sheds, or tied up for feeding only, and at other times allowed to lie in the yard. No exact experiments have been made in this country in relation to this subject; but experiments made abroad lead to the conclusion, that cattle thrive best in a high and equable temperature, so warm as to keep them constantly in a state of active perspiration, and that their thrift is much hindered by an exposure to severe alternations of heat and cold. It is certain, that in order to thrive, cattle cannot be made too comfortable; their mangers should be kept clean; their stalls be well littered; and the cattle protected from currents of air blowing through crevices or holes in the floors or the sides of the stables, which prove often much more uncomfortable than an open exposure."

As at present conducted in Massachusetts, and at the present prices of provender and beef, Mr. Colman thinks the business of fat-

tening cattle for market any thing but profitable, and that if extensively and exclusively carried on by individuals, the result must generally be embarrassment and ruin. "From the best observation which I have been able to make, I have," he says, "found very few instances in which a pair of cattle or a single ox kept for any length of time in the stall have ever made compensation for the produce which they or he consume, even at prices considerably below the current prices in the market. There are occasional and accidental exceptions, but they are very seldom to be met with." In the estimates presented to Mr. Colman, Indian corn-meal is reckoned at from 60 to 75 cts. per bushel, potatoes 25 cts. per bushel, a mixture of peas and oats at 50 cts. per bushel, and hay at \$10 per ton.

"It has been supposed that farmers by going extensively into the cultivation of esculent roots, such as carrots, ruta-baga, parsnips, or mangel-wurtzel, could fatten cattle to much more advantage, or rather at much less expense than on hay or corn. This deserves great consideration. On this subject we want light, and that which springs from actual and intelligent experience. My belief is, that for the fattening of cattle, where the coarse fodder is well saved, few crops are more profitable to the farmer than a crop of Indian corn at the rate of seventy bushels to the acre. Next to corn, potatoes at the rate of four hundred bushels to the acre would be a profitable crop. In number of bushels to the acre, there is no doubt that more can be produced and at a less expense of cultivation and harvesting of common turnips, of ruta-baga, and of mangel-wurtzel, than of potatoes. But it is believed that more nutritive matter can be obtained from one hundred bushels of potatoes than from two hundred of common turnips. Ruta-baga and mangel-wurtzel have undoubtedly a great superiority over the common white turnip, but these are much inferior to the best and most farinaceous potatoes. Hay is without question one of the best articles which can be given to fattening animals; but where an abundance of meal or of esculent vegetables is given, the nature of the long feed to be given them seems of much less importance. Rye, wheat, or oat straw, in such case, is found to be given with an almost equal advantage as the best hay. Many of the best beasts in England are fattened upon straw and turnips. In England, it is considered as doing well, if an acre of turnips will fatten an ox for market. An experienced farmer here is of opinion, that one hundred bushels of potatoes with a small amount of hay will fatten an ox. Another says, that he allows twenty-five bushels of corn to fatten an ox, and but little hay will be required.

"It is curious to compare the gain of fattening cattle with the actual cost of keeping. Two pounds live weight per day in an ox are considered a large gain. The largest gain mentioned in this report is a little more than three pounds per day. At seven dollars per hundred, this would be equal to twenty-seven cents. To make this, we suppose the animal to receive one peck of Indian meal, which, at 66 $\frac{2}{3}$ cents

per bushel, would be 16 $\frac{2}{3}$ cents, and 28 lbs. of hay, which, at 8 dollars per 2000 lbs., would be 11 cents and 2 mills, or both about 28 cents. Or suppose him to gain only 2 lbs. per day, which would be 14 cents; and his daily allowance of meal be reduced to 4 quarts, and hay the same as before, the daily cost of keeping would be about 20 cents; in which case, if we place the manure as an offset for the attendance, interest, and commissions on sale, &c., there will be a loss of about six cents per day. I believe the result is often much worse than this; and it is much to be regretted that farmers are not willing to look these facts in the face. I do not mean to deny that there are instances of success in this department of husbandry, instances in which the farmer is well paid for his trouble and attendance, and receives a full compensation for the feed supplied to them; but these instances are comparatively rare, and so much matter of contingency, that even the most skilful farmers cannot always rely upon their best judgment. The farmer always feels satisfied, if he can, as he terms it, double his money; that is, if he receives for his cattle in the market twice as much as they cost him when he first put them into the stall. This is sometimes done. It is seldom exceeded; and fatteners often fall short of it."

At Mr. Colman's request, a careful farmer made experiments for the purpose of ascertaining the actual quantity of hay ordinarily consumed by a fattening ox. In conducting these, the hay was first weighed, and then the weight of the leavings deducted. Five oxen consumed 150 lbs. hay per day. Two of these oxen had at the same time 20 quarts of provender—half Indian corn and half broom-seed meal; two of them 24 quarts of the same provender per day; and one of them eight quarts per day. Upon a second experiment with the same cattle, fed as just stated, the consumption of hay by each ox averaged 25 lbs. per day.

It is stated in the Complete Grazier, that an unworked ox for several days together consumed 33 lbs. of hay per day. In the New York Memoirs of Agriculture, it is stated that an ox will eat every twenty-four hours 14 lbs. of hay, half a bushel of potatoes, and 8 quarts of Indian meal. It hence appears that the capacities of cattle for the consumption of food vary according to circumstances of size, age, condition, &c. Many farmers who engage in fattening cattle only expect to get paid in the operation for their grain, without taking into account the hay consumed. They, however, derive the great advantage of consuming their crops upon the ground, and reserving the manure to keep up the productiveness of the soil. The farmer who annually sells off the produce of his land in the form of grain, hay, &c., soon finds the necessity of making a considerable outlay for manure, to compensate for certain and often rapid deterioration. It is freely admitted that with respect to hay, straw, and all kinds of what is called "long feed," it is always better to consume the produce on the farm, even at a nominal loss of twenty-five per cent., than to carry it off any distance to market; that is to say, a farmer had best feed his hay

at home, although it may net him only \$6 per ton in fattening his cattle, than carry it even a short distance to market and obtain \$8 for it. Such estimates would seem to indicate that the value of articles consumed in fattening stock ought not to be valued so high as the current market prices.

If the hay consumed on the farm nets the farmer \$5 per ton, and the average product is two tons, it will pay a remunerating profit, allowing the land to be valued at \$75 and even much higher, per acre.

Gain of stall-fed cattle.—Colman gives some interesting estimates showing the actual gain per day in stall-fed cattle, a matter generally left to conjecture.

Example 1.—A pair of cattle owned by S. C. weighed

Oct. 16, 2305 lbs. and 2110 lbs., together -	-	4415 lbs.
Jan. 17, 2435 " 2185 "	-	4620 "
The gain, therefore, in 3 months and 1 day, was	205 "	

"The same cattle weighed on the following March 11th,

One 2590 and one 2345 lbs., together -	-	4935 lbs.
The gain, then, in this 1 month and 22 days,		315 "
was		315 "
The whole gain in 4 mos. 23 days, being	-	520 "

The gain during 146 days was at the rate of 3.56 lbs. per day.

"These cattle had, besides hay, a small allowance of meal, and ran in a good pasture through the summer. They were put up to be stall-fed early in the autumn, and were soon brought to receive together one bushel of meal per day, even measure; one-third pease and oats, two-thirds corn, with a liberal allowance of hay.

Example 2.—A pair of oxen belonging to R. D. weighed

Nov. 8, 1995 lbs. and 1985 lbs., together -	-	3980 lbs.
Mar. 12, ensuing, 2250 lbs. and 2255 lbs., together -	-	4505 "

"The whole gain in 124 days, was 525 lbs. or at the rate of 4.33 lbs. per day.

Example 3.—One pair of cattle fed by R. D. weighed in the first part of Nov. 3765 lbs. Dec. 15, 4220 lbs. Jan. 15, 4410 lbs. The gain in one month was 190 lbs. March 7, weighed 4730 lbs. The gain from the commencement was 965 lbs.; from Dec. 15 to March 7, was 510 lbs.

"The average gain of the above, from Dec. 15 to March 7, 81 days, being 510 lbs. is 6.29 lbs. per day. The gain from Dec. 15 to Jan. 15, 30 days, being 190 lbs. is 6.33 lbs. per day.

"These cattle were old, and at the time of being purchased appeared to have been hardly driven and poorly fed."

Loss of weight in driving.—The loss of cattle in driving to market is generally estimated at from 50 to 100 lbs. dead weight, in a distance of some seventy-five or eighty miles. Cattle fatted upon potatoes lose more than others during the journey, which is ascribed to the difficulty of getting them to eat upon the road. The drover usually receives from the farmer a commission of two dollars a head for driving and selling the cattle, with no allowance for feeding. He is therefore but little interested

in the fare or treatment they are to receive on the way.

The respectable and responsible officer employed to take an account of all the cattle and other stock brought to the Brighton market, note the average prices, and report weekly these and other interesting particulars, states that the ordinary allowance for shrinkage, in cattle driven to market, is from thirty to thirty-five per cent. Some which have come a long distance, or are very fat or hollow from want of food, will not shrink more than twenty-five per cent.; while others thin of flesh, or full of food, will shrink forty per cent. In sheep, the wethers usually shrink fifty per cent. and sometimes more. It depends very much upon the state of the animal at the time of weighing. Oxen fresh from the pasture at night have frequently been weighed and reweighed on the following morning at nine o'clock, and found to have shrunk 80 or 100 lbs. each.

Live and dead weight of cattle.—In England, the difference between the dead and live weight is calculated at eleven-twentieths; this, however, only includes the four quarters; the fifth quarter, as it is there termed, being the hide, loose tallow, and offal, goes to the butcher as his perquisite. In New England, five quarters are also made, the hide and tallow being weighed, and the amount of it and the meat returned to the owner. That is to say, the cattle brought to market by the farmer or drover, being sold, the purchaser turns them over to a slaughtering establishment to be killed and dressed, for which he pays what amounts in money and perquisites to about two dollars per head. The meat is then sold to the retailing butchers. The heart and liver are valued at 50 cents, excepting in the barrelling season; the tongue is considered worth 2 cents; the tripe 50 cents; the head, which has on it a large piece of the neck, being of late years cut off at the second joint from the crown, furnishing some good meat for cooking, and when boiled given to swine with great advantage, and also the feet, from which oil and glue are obtained, valued at 40 cts., go among the offal, and of course are lost to the farmer or drover. Some cunning butchers are said to have a way by which, after cutting through the shoulders, in splitting down the chine they turn the edge of the axe outwards, thus leaving a large portion of the neck attached to the head, a perquisite of the slaughterer. With respect to the value of the hide at different seasons, a skilful farmer informed Mr. Colman that the hide of an ox, which, if the animal was killed in December, might weigh 100 lbs., would not weigh more than 85 lbs. if kept till June, such is the loss from shedding the hair, and perhaps from the thinning of the hide itself.

The offal or perquisites of the slaughterer consist of the entrails, feet, head, a strip from the foreskin, and the blood. The tongue, cheeks, and heart of the bullock go to the butcher. The slaughterer sells the feet and head to the tallow-chandler and soap-boiler, who extract the tallow and oil; the claws go to the comb-maker, the bones and pith of the horns to the bone-mill for manure or for the

purpose of making animal charcoal, and the blood to the sugar-refiners.

In New York only four quarters are made by the slaughterer, and the hide and tallow are not weighed or reckoned in the price: facts which are to be remembered in making comparisons of prices in the different markets.

The following are some examples of live and dead weights of New England cattle, killed at home and after having been driven from the Connecticut river to Brighton, the Boston beef market, a distance of 75 or 80 miles.

"*Example 1.*—One ox, live weight in market 2393 lbs.; quarters weighed 418 lbs., 415 lbs., 324 lbs., 331 lbs.; hide, 150 lbs.; tallow, 173 lbs.—1811. Difference 582 lbs.

"*Example 2.*—Two oxen of A. S., killed at home, weighed as follows:

Live—One	1979 lbs.	-	-	Killed—1400 lbs.
"	1910 "	-	-	" 1341 "

About 294 lbs. loss on a hundred of the live weight.

"*Example 3.*—An ox owned by A. S., conveyed to Brighton on a sled, weighed at home about 2630 lbs.; the precise number of pounds not recollected. On being slaughtered, his weight was as follows: quarters, 480 lbs., 479 lbs., 374 lbs., 383 lbs.; hide, 154 lbs.; tallow, 250 lbs. Total, 2120 lbs. Loss, 510 lbs.

"*Example 4.*—Ox belonging to R. D.; when he left Connecticut river weighed 2435 lbs. Weight at Brighton when dressed, 1588 lbs. Loss of weight, 867 lbs. This is a little more than one-third, and is a remarkable result.

"*Example 5.*—An ox weighing on Connecticut river 2250 lbs. weighed in market 1472 lbs. Loss, 778 lbs.

"*Example 6.*—An ox weighing as above 2255 lbs., weighed in market 1487 lbs. Loss 768 lbs.

"*Example 7.*—A fat bull of D. S., killed at home, weighed alive 1495 lbs.; dead 1051 lbs. Loss, 444 lbs.

"*Example 8.*—A fat heifer of E. W., killed at home, weighed alive 1120 lbs.; dead, 832 lbs. Loss, 288 lbs.

"*Example 9.*—An ox belonging to S. C. weighed on Connecticut river, alive, 2590 lbs.; at Brighton, dressed, as follows: quarters, 394 lbs., 350 lbs., 362 lbs., 358 lbs.; hide, 120 lbs.; tallow, 207 lbs. Total, 1791 lbs. Difference between live and dead weights, 799 lbs.

"*Example 10.*—An ox belonging to S. C. weighed as above 2345 lbs.; at Brighton, dressed, as follows: quarters, 352 lbs., 310 lbs., 364 lbs., 308 lbs.; hide, 115 lbs.; tallow, 217 lbs. Total, 1666 lbs. Difference between live and dead weights, 679 lbs."

Pasturage.—The cost of pasturage is difficult to estimate, since the qualities of soil and facilities afforded differ so much in different sections of country, and even in the same neighbourhood. In Conway, situated a little west of the Connecticut river, the pasturage is excellent; that is to say, 30 acres will keep twelve cattle, consisting of cows and oxen, the year round. Oxen from four to six years of age are taken to be pastured at from 50 to 67 cents per week; farrow cows at 25 cents per week; steers at two years old at 75 cents per

week each. Sheep are pastured at 3 cents each per week, and lambs at 1½ cents.

In Buckland, in the same county, cows are pastured at 25 cents per week, including salt. Pasturing of an average quality will feed eight cows upon 30 acres. A yoke of oxen require half as much again as two cows. In Hawly two acres of pasturage are considered sufficient for a cow.

In the fattening of cattle, universal experience, Mr. Colman remarks, shows the importance of a scrupulous punctuality as to the times of feeding. Under the influence of that mighty despot, habit, which reigns throughout the animal creation, these animals measure time with great exactness; and if at the customary hour the feed is not ready for them, they become restless, uneasy, and fretful, dispositions exceedingly unfriendly to all cases of thrift. During the time of feeding they should have little given to them at once, that their food may not become loathsome by being frequently tossed over and blown upon.

In regard to the native stock of New England, in which various bloods and breeds are intermingled, Mr. Colman remarks that "many of them are indeed miserable in appearance, in shape, in condition, and every other quality. This comes in general from neglect and indifference, because we kill or sell to the butcher our best calves, and commonly leave what we do attempt to raise 'to shift for themselves.' Yet at the same time without presumption, I think, New England may challenge the world to produce finer teams of oxen, by fifties and hundreds of pairs, than are to be found at our cattle-shows. Let any intelligent judge of stock go into Worcester county, Mass.; into New Haven and Hartford counties, in Connecticut; or especially to Saccarappa, in Maine, where ox teams are constantly employed in carting lumber to Portland, and if he will find any superior oxen for labour and condition than are to be found there, he would do a signal favour to the agricultural public in letting us know where we may look for them. I have seen none. I believe we should search the world over in vain to find any.

"Our native cows are of every variety, but there are several parts of the state where, though it cannot be said that any scientific or systematic improvement has been undertaken, yet by a long-continued selection from the best, whole families or breeds are to be found distinguished for their excellent properties as dairy stock. The list of native cows which I have given shows conclusively that we have those which, for the quantity of milk they give, are scarcely inferior to any, and for the amount of butter and cheese which they produce are surpassed by none. The numbers referred to prove that they are not rare.

"Whether any thing would be gained by substituting the improved short-horns for our present stock is, to say the least, questionable. The short-horns are great consumers. Though animals do not always consume in proportion to their size, yet this must be considered as a general rule. They require most particular attention and liberal feeding to bring them to

maturity, though we admit that they arrive at maturity early. Many of the short-horned premium young animals which have been exhibited at our cattle-shows have had the benefit of two wet-nurses for six months. Most of our native calves are put off with two teats, and at eight or ten weeks old are turned adrift into the pasture to live or die as they please. Our own stock has never had fair play; and if treated in the same manner as the best short-horned stock, they would not perhaps fall so far behind them as might be supposed. Our pastures are in general short, and our winters long. A smaller race of cattle, therefore, and a more hardy stock would seem better adapted to our condition.

"The London milk establishments are mainly supplied with the short-horns, because, it is said, they give more milk, and, after becoming dry, take on flesh sooner than other races, and are therefore more easily disposed of to the butcher. The size of these animals would naturally indicate a larger yield of milk, and, at the same time, a greater consumption of food. But the yield of milk is put down at an average of nine quarts daily. These are presumed to be wine quarts, and deducting one-fifth, it does not much exceed the yield of some milk establishments among us. Besides, in the London dairies, cows are not suffered to become with calf.

"One of the most extraordinary short-horn cows known in England, it is said, produced 373 pounds of butter in 32 weeks: 17 pounds being the largest quantity made in any one week. This is quoted as quite remarkable; but this, as far as it goes, does not equal the Oakes, the Nourse, the Adams, or the Springfield cow. One of the best-informed and most ardent advocates for the short-horns, the late Henry Berry, remarks:—"That their milk does not contain the same proportionate quantity of butter as that from the long-horns, the Scotch cattle, or the Devons, is probably true; but we have reason to believe that the difference has been much exaggerated, and is more than compensated by the additional quantity of milk."

"The quantity of cheese made in a year from a cow in the celebrated cheese district of Wiltshire, England, is thus stated:—"The quantity of cheese that is made from each cow in this district is greater than is common in any other cheese-making country, sometimes as much as 4½ cwt. or 5 cwt. per cow, seldom lower than 3 cwt. Perhaps 3½ cwt. is a fair average in a good cheese-making year on every cow that calves in proper time." In the famous district of Cheshire, in England, the average amount of cheese to a cow is stated at 2½ cwt. The old breed of Irish cattle, much valued for the dairy, will produce from 84 to 112 lbs. of butter per year; a very good cow will yield 1½ cwt., that is, 168 lbs. net. Of the Ayrshire cows, kept in the highest condition for giving milk, it is stated that the yearly average in milk may be 650 gallons or 2600 quarts, (wine measure, I presume, is intended), and 90 gallons will make 24 lbs. of butter, or 15 quarts (wine measure) to a pound. In another case it is said 'that a well-fed cow of a good breed will produce on an average 180 lbs. of butter

in the season, though the common calculation is 150 lbs. In the Epping district, where there is an indiscriminate mixture of Devon, Suffolk, Leicester, Holderness, and Scotch, the calculation in a well managed dairy amounts to 212 lbs. per year to a cow. In one case in Sussex, upon an actual trial, the cows produced only 136 lbs. per season."

"As far, then, as we can depend on these accounts, our own native cattle for dairy stock will not suffer by comparison with the best English stock of any of those races most distinguished for their milking properties. Our own Cheshire cheese dairies certainly yield the palm to none.

"The cross of the Durham short-horns with the Devon has produced in many cases an excellent stock. But, if of no other value to the country, their introduction will prove an immense benefit by showing our farmers what can be done in improving the size, form, and condition of their own stocks, by a most careful selection from the very best, by persevering attempts to amend defects and engraft good properties in the animal constitution, and by constant care and good keeping.

"It cannot be denied that a vast proportion of our cows are wretched in their form, health, and condition. There is no reason, on the other hand, to doubt that by breeding only from the best on both sides, and by a liberal mode of keeping, we may produce a dairy stock and a stock for labour as well adapted to our pastures, climate, and husbandry as can be found. Perhaps I should be authorized to add for beef also, that is, producing as many pounds according to the expense of their keep. The average weight of bullocks slaughtered at Smithfield, the great cattle market of England, is 656 lbs. At Brighton, in this county, the average weight of oxen is 875 lbs., and of steers 600 lbs. each. The last is thought by some persons to be overrated. The weight used at Brighton is net weight; 1 cwt. being now reckoned at 100 lbs. avoirdupois.

"The great cattle fair of the state, and indeed of New England, is held at the beautiful village of Brighton, about six miles from Boston, on the Monday of every week. Here capacious pens are erected for the reception of such livestock as may be brought in, and the drovers and butchers assemble from all directions. The business of selling and buying is principally got through with on Monday, though cattle and other stock, when prices are not satisfactory to the seller, are frequently kept over, for a week or fortnight, for a better market. With the exception of a small fair at Danvers, in Essex county, held occasionally in the fall, I know of no other cattle fair in New England. Cattle, sheep, and swine are brought here from the interior of the state, from Maine, New Hampshire, Vermont,—from New York, and sometimes from Pennsylvania, Ohio, Indiana, and Kentucky.

"I ascertained some time since at the Bull's Head Market, in New York, that the expense of a drove of cattle, consisting of one hundred head, from the vicinity of Lexington, Kentucky, to that place, including the expenses of one night and a day in New York, was 1,300 dollars.

or 13 dollars per head. This was at a season when the drovers could avail themselves of pasturage. The price of corn is not recollected. They came in in good condition.

"Store hogs or shoats, driven moderately in the mild season and well fed on the road, will gain in flesh, it is said by some, almost sufficiently to pay the expenses of their drift."

The number of cattle of all descriptions brought to Brighton frequently exceeds 8,000 head on a market day. Many of these, and the proportion increases, instead of being slaughtered, are sold on the hoof. The mathematical rules and tables, so much in use in England for determining the live weight of animals, are seldom resorted to in the United States, although they are said to give very exact results. A diagram and table have been given in the preceding part of this article, to show the mode and facilitate the process of making estimates of live weight.

By the revised statutes of Massachusetts it is declared that "All beef cattle, except bulls, sold in market by weight, shall, when slaughtered, be prepared for weighing in the following manner:—the legs shall be taken off at the knee and gambrel joint, the skin shall be taken from all other parts of the animal, the head shall be taken off at the second joint of the neck, the entrails taken out, and all the fat of the same be taken off and weighed as rough tallow; and every other part of the animal, including the hide and rough tallow (the udder of cows excepted), shall be weighed.

"All beef shall be weighed upon the first week-day succeeding that on which it may be slaughtered," &c.

Rearing Calves.—As so many different opinions are entertained upon the subject of rearing calves, some of the views derived from high sources of intelligence will be stated.

In Pennsylvania, heifers intended for milch cows are generally put to the bull at fifteen to eighteen months of age, in preference to leaving them run to a greater age. Mr. Isaac W. Roberts, of Montgomery county, has been very successful in raising and fattening cattle, chiefly of the Durham breed. It is his practice to take the calves of this fine breed, and, when two or three weeks old, put them with common native-bred cows. He weans at three or four months old, when the calf is able to thrive well on grass alone, and the native cow, going dry, is soon fit for the butcher, at a price that will nearly, if not quite, pay for her first cost and a fair allowance for pasturage. He thinks that calves thus raised and entering the winter in good condition, being properly housed and fed during cold and inclement weather, gain nearly a year on such as are prematurely weaned or fed on skimmed milk. He entirely disapproves of letting calves run three or four months with valuable cows intended for breeding, and especially where milching properties are to be retained.

With all those who desire to possess an improved and select stock, it is deemed highly important that they should raise their own calves; and this is rendered the more important from the high prices usually to be obtained for calves of the best breeds. Mr. Colman

gives the following information upon this subject, derived from his observations in Massachusetts. "A farmer of my acquaintance in the interior raises all his calves from a large stock of cows. His cows are known to be of prime quality. His heifers are allowed to come in at two years old, and are then sold with their first calf generally for thirty-five dollars, which he deems a fair compensation for the expense of raising. His calves are raised mainly upon skim-milk and whey, until they can support themselves on hay and grass. His steers pay a proportional profit when sold at three to four years old.

"The English authorities say, that upon two cows calving at different times, seven calves may be fattened for the butcher in the course of the year. More than this may be done if the calves are to be reared for stock, and if some little addition of meal or vegetables is added to their feed.

"Mr. Jaques remarks, on the subject of raising calves, that 'he generally lets them take a portion of milk from the cows for about three months, and prefers keeping them in the stall until they are about a year old, thinking that he gets better forms, rounder barrels, straighter backs, greater broadness on the loin and hips, by this management. Calves turned to grass at two and three months old become pot-bellied, their backs bent, acquire a narrowness in the loins, and seldom get over the defect entirely.'

"I believe that it is decidedly better to raise them in the stall or yard the first season, as their feed is much more uniform, and their growth not interrupted by sudden changes. They soon learn to eat hay; and carrots or potatoes cut fine for them will be found highly beneficial. In all cases the calf should be taken from the cow as soon after his birth as the cow's udder is brought into good condition and her milk fit for use, and then should be fed by hand. 'In my opinion,' says a highly intelligent farmer of Stockbridge, 'calves raised for other purposes than veal should be early weaned from the dam, and nursed at least one year upon food adapted to give firmness and expansion of muscle, rather than to fatten them.' The observation of another farmer, a plain man, but one of the most observing and practical farmers in the state, is deserving of attention. 'One of the most important points,' says he, 'in the feeding of the calf, is to feed him well when the grass first fails in the fall by frost. If suffered to fall off then, he does not recover, and suffers more by scanty food than other animals.'

There are many able papers on subjects relating to cattle dispersed in the best agricultural periodicals, which the breeder may wish to refer to, such as "On Stall-feeding Cows in Summer," by Mr. Collett of Christiana in Norway (*Com. Board of Agr.* vol. vi. p. 60; "On Soiling," by Mr. Curwen (*Ibid.* p. 49); "On their Treatment in Winter," (*Quart. Journ. of Agr.* vol. ii. p. 228; "On Fattening Cattle on different Kinds of Food," by Mr. Brodie, (*Ibid.* vol. viii. p. 327); "On Feeding Cattle on Sugar," by Mr. Ellis, (*Com. Board of Agr.* vol. vii. p. 327); and "On Potatoes," by Sir C. Burrell (*Ibid.* p. 323); "On House and Yard-feeding

Milk Cows for the Supply of Milk," by Mr. Harley, (*Quart. Journ. Agr.* vol. i. p. 170); see also "The Harleian Dairy System" by the same gentleman, and "On a celebrated Yarded Cow," the property of Mr. Cramp of Lewes, (*Com. Board of Agr.* vol. vii. p. 53). It will, perhaps, surprise an English farmer to learn to what coarse unnatural kind of food use will accustom animals. The cows of Shetland live upon the coarsest moss and seaweed; those of still more northerly regions on even animal food. In Lapland and Iceland, according to Mr. De Broke, the cattle are uniformly fed on fish. "The English farmer's surprise," says Mr. Broke, "will not be lessened when he learns that the animals not only devour this kind of food with the greatest eagerness, but thrive and do well upon it; it seems that fish heads and bones are boiled together with some hay into a kind of soup, and poured into the mangers of the poor beasts." (*Quart. Journ. of Agr.* vol. x. p. 299.) There is a paper "On Live-Stock and Crossing," by Mr. Ferguson, (*Ibid.* vol. i. p. 33); "On the Comparative Advantages of Feeding Stock with Mangel-Wurzel, Turnips, and Potatoes," by Mr. Howden, (*Trans. High. Soc.* vol. iii. p. 268); and "On Raw and Prepared Food," by Messrs. Walker, Howden, Boswell, and Walker, (*Ibid.* vol. iv. p. 253); and again by Mr. Walker, (*Ibid.* vol. v. p. 52); and "On different Descriptions of Food," by Mr. Stephenson. (*Ibid.* vol. vi. p. 61.) On the disease called the "Muir-ill," by Mr. McFarlane, (*Ibid.* vol. iv. p. 388); on the disease called "The Tail-slip," by Mr. Dick, (*Quarterly Journal of Agriculture*, vol. iii. p. 308); "On Calculi," (*Ibid.* p. 642); "On Diseases of the Udder," (*Ibid.* p. 871); "On the Navel-ill," by Mr. Sitwell, (*Com. Board of Agr.* vol. vi. p. 401); "On acclimating Cattle, by Dr. Smith of Kentucky, (*Ibid.* vol. ii. p. 93; On determining the Weight of Cattle by Admeasurement, (*Quart. Journ. of Agr.* vol. v. p. 612); and Mr. Ferguson "On the value of Live-Stock with relation to the Weight of Offal, (*Ibid.* vol. ii. p. 207); "On their External Conformation," by Mr. Sparrow, (*Veterinarian* for 1839; *Farmer's Mag.* vol. iii. p. 95, n. 5; *Baron Malthus*; *McCulloch's Dict. Com.*; *Youatt on Cattle*; *Quart. Journ. of Agr.*; *Farmer's Mag.*; *Trans. of Highland Soc.*; *Lowe's Illustrations of the Breeds of Domestic Animals.*)

CATTLE, REMEDIES FOR DISEASES OF.

Abortion. See **ABORTION**.

Blackwater is the concluding and commonly fatal stage of redwater. See **REDWATER**.

Cleansing drink.—1 oz. of bayberry powdered, 1 oz. of brimstone powdered, 1 oz. of cummin-seed powdered, 1 oz. of diapente. Boil these together for ten minutes; give when cold in a gruel.

Colic.—The best remedy is 1 pint of linseed oil mixed with $\frac{1}{2}$ oz. of laudanum.

A cordial is easily made by 1 oz. of caraway seeds, 1 oz. of aniseeds, $\frac{1}{4}$ oz. of ginger powdered, 2 oz. of fenugreek seeds. Boil these in a pint and a half of beer for ten minutes, and administer when cold.

Diarrhœa.—Give $\frac{1}{2}$ oz. of powdered catechu,

and 10 grs. of powdered opium, in a little gruel. See **DIARRHŒA**.

Dysentery.—The same as for diarrhœa.

Fever.—Bleed; and then if the bowels are constipated, give $\frac{1}{2}$ lb. of Epsom salts in three pints of water daily, in gruel.

Hoove or Hoven.—Use the elastic tube; as a prevention, let them be well supplied with common salt, and restrained from rapid feeding when first feeding upon rank grass or clover. See **HOOVE**.

Mange.— $\frac{1}{2}$ lb. of black brimstone, $\frac{1}{4}$ pint of turpentine, 1 pint of train oil. Mix them together, and rub the mixture well in over the affected parts.

Milk fever, or Garget.—2 oz. of brimstone, 1 oz. of diapente, 1 oz. of cummin-seed powdered, 1 oz. of powdered nitre. Give this daily in a little gruel, and well rub the udder with a little goose-grease. See **GARGET**.

Murrain.— $\frac{1}{2}$ lb. of salts, 2 oz. of bruised coriander-seed, 1 oz. of gentian powder. Give these in a little water. See **MURRAIN**.

Poisons swallowed by oxen are commonly the yew, the water dropwort, and the common and the water hemlock. $1\frac{1}{2}$ pint of linseed oil is the best remedy.

Purge, in poisoning—either 1 lb. of salts in a quart of water or gruel, or a pint to a pint and a half of linseed oil.

Redwater.—Bleed, says Youatt, first, and then give a dose of 1 lb. of Epsom salts, and $\frac{1}{2}$ lb. doses repeated every eight hours until the bowels are acted upon. In Hampshire they give 4 oz. bole armeniac and 2 oz. of spirits of turpentine in a pint of gruel.

Sprains.—Embrocation: 8 oz. of sweet oil, 4 oz. spirits of hartshorn, $\frac{1}{2}$ oz. of thyme.

Sting of the adder, or slowworm—Apply immediately to the part strong spirits of hartshorn; for sting of bees apply chalk or whitening mixed with vinegar. See **BITES AND BEES**.

Worms.—Bots: give $\frac{1}{2}$ lb. of Epsom salts with 2 oz. of coriander-seed bruised in a quart of water. See **BOTS**.

Yellows.—2 oz. of diapente, 2 oz. of cummin-seed powdered, 2 oz. of fenugreek powdered. Boil these for ten minutes in a quart of water, and give daily in a little gruel. See **YELLOW**.

CATTLE SHEDS. The cow-house should be a capacious, well-lighted, and well-ventilated building, in which the cows or oxen can be kept dry, clean, and moderately warm; a temperature of about 60° is perhaps the best. It is a mistaken idea that cattle suffer materially by dry cold. It is the wet and the damp walls, yard, and driving rains, and fogs of winter, that are so injurious to them. In this respect the Dutch farmers are very particular. They have their cows regularly groomed, and the walks behind them sprinkled with sand. A clean and dry bed, a portion of a trough to give them water, and another portion for their oil cake, or mangel, or turnips, and a rack for their dry food, will all be necessary comforts. These, with regular feeding, a lump of rock-salt in the manger, and occasional variations if possible in the food, are the chief points to be attended to in the stall management of cat-

tle. (*Brit. Husb.* vol. i. p. 202; vol. ii. p. 399.)
See VENTILATION.

CAUF. A chest with holes in the top to keep fish alive in the water.

CAUKER, or CALKERS. A term employed in farriery to signify bending or turning up of the heels of the shoes of horses, and intended to prevent the animal slipping. This method, though once general, is now commonly limited to the outside heel of the shoes of the hind feet.

CAULIFEROUS (From *caulis*, a stalk, and *fero*, to bear). A term applied to such plants as are furnished with a stalk which bear shoots, as the cauliflower, cabbage, &c.

CAULIFLOWER (From Lat. *caulis*; *Brassica oleracea botrytis*). A species of brassica, of which there are two varieties;—the early, which is smallest and most fit for growth under lights, for the winter-standing crop; and the large, for the open ground plantations. Cauliflower is propagated by seed; the first sowing to take place at the close of January or early in February, in a slight hot-bed, or warm border, in either situation to have the protection of a frame. The plants are fit to be pricked out in March in similar situations, and for final removal into the open ground during April and May; and some to be placed under hand-glasses for more immediately succeeding the winter-standing crop. At the beginning of March and April another sowing is to be performed in a sheltered border, the seedlings of which may be pricked out in May, and planted finally in June for protection at the end of summer. Again, another sowing may be done in the last week of May; for pricking out, in June; and for final planting, the end of July; to produce during October and November, and in favourable seasons until Christmas. The seed of these sowings must be inserted broadcast, and covered half an inch thick with fine mould. The seedlings are of sufficient size for pricking out when they have four or five leaves, about an inch in breadth; they must be set three or four inches apart each way. Water must be given moderately, both in the seed-bed and at the time of removal, if the weather is at all dry. When finally set out, they must be planted in rows two inches and a half apart each way. The mould must be frequently loosened by the hoe, and drawn up about their stems. In dry weather during summer, a cup-like hollow should be formed round each plant, and filled twice a week with water; but as soon as the flower makes its appearance, it must be applied every other day. As the head appears exposed, it is advantageous to break some of the leaves, and turn them over it as a shelter from the sun: this preserves them from becoming of a yellow hue, as well as retards their advancing to seed.

Winter-standing crop.—The seed for this crop must be sown in the third week of August, in a warm border or an old hot-bed, with the protection of a frame or hand-glass. That the cauliflower, though the most tender of the brassica tribe, is not so impatient of cold as some gardeners are led to imagine, is demonstrated by the fact, that the imperfect covering of mats will almost always preserve the plants

uninjured through the winter; and the practice of Mr. Bull, of Rossie Priory, North Britain, proves that it is scarcely more so than the broccoli. He sows in the last week of August, transplants in the middle or end of November, and often does not even afford the plants the protection of a south wall, and no description of covering. Plants thus raised are healthier, and produce finer heads than those which have additional shelter, though they are not so forward, neither are they subject to be *black-shanked*. (*Mem. Caled. Hort. Soc.* vol. iii. p. 192.)

The seed-bed, if not one that has grown cucumbers, &c., must be well manured with dung from a cucumber bed, or, as is sometimes recommended, a basis five or six inches thick of dung in a perfectly decayed state must be formed, firmly trodden down, and covered with a similar thickness of light rich mould: in this the seed is to be sown and buried a quarter of an inch deep, and, during the meridian of hot days, shaded with matting. Moderate waterings must be given, as may seem necessary. The plants appear in about a week, and the shading and watering must in like manner be afforded.

The plants are fit for pricking out at the close of September, when their leaves are rather more than an inch wide. They should be placed in a similar soil and situation to that from which they were removed. Towards the end of October, or first week in November, they must be removed, and planted in patches of from three to six together, these clusters being in rows three feet apart each way are to be sheltered with hand-glasses until the spring. At the end of February, if an open season, or not until March if otherwise, part of the plants may be removed from under the hand-glasses, two strong ones being left under each glass, and set out in the open ground; the soil and sheltered situation being as nearly similar to that from which they are taken as possible. Some, also, may be planted out from the frames; but from either situation these removals must be concluded by the middle of April. Care must be taken to remove the plants with as much earth as possible retained to their roots, and they are to be planted at a similar distance as was recommended for the other open-ground crops.

Those continued under the glasses must have air admitted as freely as possible, and other precautions adopted that were recommended during their winter growth. Earth should be drawn carefully about their stems, without any being allowed to fall into their hearts. When they fill the glasses, these last are easily raised by a circular mound, four or five inches high, thrown up round them. In mild weather, hot sunny days, and during genial showers, the glasses may be taken completely off, but replaced at night. The plants being thus hardened by degrees, and when all danger of frost is past, about the end of April or early in May the glasses may be entirely removed. The leaves are to be broken down over the heads, as before directed. For the production of seed, some plants of the winter-standing crop which have fine and firm head must be selected, as these will produce

best seed, though not in such quantity as those of a looser texture. For the necessary treatment, see BROCCOLI. The seed ripens in September, and the branches should be gathered as soon as this occurs, and not allowed to remain until the whole is fit for collecting. The seed remains, if carefully preserved, in a good state for use until it is three or four years old. (*G. W. Johnson's Kitchen Gard.*)

CAUSTIC. In farriery, a substance which, by its powerful operation, destroys the texture of the part to which it is applied. Corrosive sublimate is the best caustic; but that requires skilful hands, for it is a dangerous remedy except in the hands of the veterinarian. Mix one drachm of powdered verdigris with one ounce of basilicon ointment; apply this upon a piece of tow: or a drachm of blue stone (sulphate of copper), dissolved in one ounce of water may be used; or lunar caustic in a quill may be rubbed on to the diseased part.

CAUTERY, or CAUTING-IRON (Old Fr. *cautere*). In farriery, a name given to a searing-iron, which is made *white hot*, and used to destroy fungous flesh, &c.

CAVESSON, or CAVEZON (Fr.). In horsemanship, a term applied to an apparatus resembling the musrol, which is used in the breaking of horses. From its formation, it binds and pinches the nose, and regulates the action of the animal to which it is applied.

CAZZONS. A provincial word used to signify the dried dung of cattle for fuel.

CEDARS. See CYPRESS.

CEDARS OF LEBANON (*Abies cedrus*). This sovereign of the forest appears to have been indigenous to Mount Lebanon: but at what period it was first introduced into England is not known. This noble tree is now so well naturalized in England, that the seeds not only ripen, but propagate themselves without care or trouble. One of the cedars at Chiswick measures 13 feet 4 inches in circumference, and is 80 feet high; but the largest now remaining on Lebanon is 9 feet in diameter, or 27 in circumference. Cedar wood is known to be very durable; the ancients believed it to be imperishable. But according to Mr. Drummond Hay's observations at Tangier, the indestructible cedar wood is the timber of the Sandarac tree (*Thuja articulata*).

CEDAR, RED (*Juniperus Virginiana*). This North American tree belonging to the junipers, is the most common species of its genus in the United States, and the only one which attains a size adapting it to the useful arts. Next to that found in Bermuda, it is the largest of the junipers hitherto discovered. It is found along the lands bordering the Atlantic, from Maine to the extreme South, and even passing round Cape Florida, shows itself beyond St. Bernard's Bay in the Gulf of Mexico. In retiring from the shore, it becomes gradually less common and less vigorous, and in Virginia and the more Southern States it is rare above tide-water. Farther inland, it is seen only in the form of a shrub in open, dry, sandy places. In the most favourable situations along the southern sea shore, it attains a height of 40 or 45 feet, with a diameter of 12 or 13 inches.

The leaves are evergreen, numerous sub-

divided, and when bruised diffuse a resinous, aromatic odour. The seeds are small ovate berries, bluish when ripe, and coated with a whitish exudation. They arrive at perfection in the beginning of the fall, and are greedily devoured by cedar birds, robins, &c. If sown immediately, the greater part of them will come up the following spring; but they will not shoot before the second year if they are kept for several months.

The wood is odorless, compact, fine-grained and very light, though heavier and stronger than that of the white cedar and cypress. To these qualities it unites the still more precious character of durability, and is consequently highly esteemed for such purposes as require it in an eminent degree. But as it is procured with difficulty, and is every day becoming more scarce, it is reserved exclusively for the most important uses. The name of *Red Cedar* is only applicable to the perfect wood, which is of a bright tint; the sap is perfectly white. The nearer the red cedar grows to the sea and the farther southward, the better is its wood. The chief supply now comes from East Florida. (*Michaux.*) See CYPRESS, and FIR.

CELANDINE, COMMON (*Chelidonium majus*). Celandine is a wild plant with large leaves and bright yellow flowers, growing in shady places, waste and untilled lands, and thickets, &c., especially on a chalky soil, and flowering from April through the summer. It grows two feet high, and the stalks are round and green. The leaves are large, long, and deeply divided at the edges, and of a yellowish green, standing two at each joint. The flowers are small; several together upon long foot-stalks. Every part is brittle, and if you crush the stalk or leaves an orange-coloured acid juice is expressed, which is medicinal.

There are two species of *celandine*, or *horned poppy*, found in the United States. The greater, or common celandine, (*C. majus*), has an acrimonious juice of a saffron colour, which is a popular remedy for warty excrescences, as well as for ring-worms, tetter, the itch, &c.

The *sea celandine*, (*C. glaucum*), or *yellow-horned poppy*, flourishes in the sandy soil along the sea and bay shores where it is quite ornamental. Its juice is said to be poisonous.

CELERY (*Apium graveolens*). This is the wild original of cultivated celery. The name probably proceeded from *apex*, a tuft or crest, which its umbels form). This class of plants flourish best in a moist soil, friable, and rather inclining to lightness; it must be rich, and that rather from prior application than the immediate addition of manure; celery and celeriac, however, appear benefited even by its abundant application at the time of sowing and planting. The parsleys, likewise, prefer their soil to incline rather to dryness. For all it must be deep, and all equally refuse to thrive on a strong clayey soil. The situation they thrive the most in is one that is as open and as free from the influence of trees as possible. The common parsley is the one that bears best a confined or shady compartment.

There are six varieties of celery in general cultivation:—the gigantic, the dwarf-curved, the common upright, red-stalked upright, giant no.

low upright, and the solid-stalked (red and white). The red is reared chiefly for soups, the white being much more delicate in flavour. It is propagated by seed. The first sowing should be performed either in a hotbed or on a warm, light border, towards the end of February; some gardeners even insert it as early as the middle of January. The border is by many gardeners considered the best situation, inasmuch as the plants are more hardy, and with proper care come forward with scarcely any difference as to time. This is to be repeated in March; but the principal sowings must take place in April and May, and the last one in June. As the produce of the early sowings will not continue long in a state fit for use, from their leaf-stalks becoming piped or hollow, they must be proportionably small; they must all be inserted broadcast, and the seed scattered thinly. The seed-beds of the early sowings should be light and dry, with the full enjoyment of the sun throughout the day, but for the three last in a moist situation; and it is advantageous for them to have a free exposure to the morning sun only, yet free from the drip of trees; so advantageous is it to have the plants of these sowings as luxuriant as possible in their first stage of growth, that to afford them as regular and unstinted a supply of nourishment as possible, the mould of the seed-bed is often formed artificially. Mr. Walker, gardener to J. Walker, Esq., of Longford, Scotland, recommends it to be formed of black loamy soil and old hotbed dung in equal parts. (*Mem. Caled. Hort. Soc.* vol. ii. p. 295.) The plants from these several sowings will in general be ready for pricking out in four or six weeks from the time of insertion, and for final planting after a further continued growth of two months. A more determinate datum for judging the appropriate time for performing these operations is the size of the plants, they being fit for the first removal when three or four inches in height, and for the second when seven or eight. From the above enumerated sowings, monthly plantings may be successionaly made from the commencement of June until September closes; but for the supply of a family, a sowing at the close of February for production during the same year, and another about the middle of May, to yield a produce in the winter and the following spring, will in general be amply sufficient.

They are usually planted out finally in trenches, from twelve to eighteen inches wide, and at least four feet apart. To cut the trench straight and with firm sides, the spade should be thrust down all along the line which marks the boundary on each side, previous to digging out the earth: the top spit of mould throughout the length must be turned alternately on either side, for this is required in the after cultivation for earthing up the plants. Some well putrefied dung, two or three inches thick, must be then spread along the bottom and dug in, care being taken that its surface is not more than four inches below the regular surface of the soil. Mr. Walker here recommends the same unsparing application of manure; he forms the soil in his trenches of three parts dung and one part fresh, strong soil. (*Mem.*

Caled. Hort. Soc. vol. ii. p. 296.) By this abundant application of manure his celery undoubtedly obtains a fine growth, being often 4½ feet long, and averaging 6 lbs. weight; but at the same time it is to be remarked, that many soils will grow it equally fine without such immoderate application.

Celery, as before mentioned, delights in a soil abounding in fertilizing matter; the mode adopted to effect this, as practised by Mr. Judd, gardener to C. Campbell, Esq., of Edmonton, is one which with equal advantage may be adopted for any crop requiring a very rich soil; he prepares his ground in the winter preceding the time of planting, or as long before as convenient, by manuring and trenching it two spades deep, performing this last operation twice, that the dung may be better incorporated with the soil, and then leaves it as rough as possible until the time arrives for forming the trenches, at the bottom of which he also turns in some manure. (*Trans. Hort. Soc. Lond.* vol. iii. p. 46.) As celery is very apt to decay in winter on account of excessive moisture, it would undoubtedly be a good practice, after preparing the ground as just detailed, to plant in rows five or six feet apart on the surface, taking the mould required for earthing them up from this allotted space.

Before planting, the long straggling leaves are to be cut away, and any side offsets removed; but if the plants are older or larger in growth than before mentioned, the tops of the leaves may be generally removed, which serves to check their running to seed, which they are otherwise apt to do. After this preparation, they may be planted, a single row in each trench, about eighteen inches apart. Mr. Judd says that he finds the plants much injured in their future growth if, during any of their removals, their roots become at all dry; therefore, when taking them either from the seed-bed or for final planting, he lays them, as he draws them from the ground, in a garden pan containing a little water. (*Ibid.* p. 45.) Planting is best performed in the evening, and water should be given plentifully at the time, as well as every other day subsequently until they are well established. Earthing them up must commence when they are about a foot high, and may be continued until the plants are fit for use, or are one foot and a half high and upwards. In performing it one person must hold the bases of the plants together, whilst a second regularly follows and throws in the soil, otherwise the mould separating the leaves breaks them and induces decay, and oftentimes destroys them by injuring the heart. (*Ibid.* p. 47.)

The earthing is best performed gradually, a few inches being added once a week, and a dry day always selected to perform it in. In very severe weather the winter standing crops should be covered with straw or other litter, care being taken always to remove it in mild days. On the arrival of frost a quantity may be taken up and buried in sand under shelter. As celery will not continue in perfection except in winter more than three or four weeks after bleaching, it is advisable for family use only to make small plantations of the early crops at a time. To raise seed, some plants must be left where

grown; or in February or March some may be carefully taken up, and, after the outside leaves are cut off and all laterals removed, planted in a moist soil a foot apart. Those which are most solid and of a middling size are to be selected. When they branch for seed they must be each attached to a stake, to preserve them from being broken by the violence of winds. The flower appears in June, and when the seed is swelling in July, if dry weather occurs, they should be watered every other night. In August the seed will be ripe, and when perfectly dry, may be rubbed out and stored. A variety of celery with a roundish root (*Apium rapaceum*), is sometimes cultivated in gardens. (*G. W. Johnson's Kitch. Gard.*; *Brit. Husb.* vol. ii. p. 575; *Willich's Dom. Encyc.*)

CELERY, WILD, or SMALLAGE PARSLEY (*Apium graveolens*). This is a biennial, found in ditches and marshy ground, especially towards the sea; root tap-shaped, herb smooth and shining. Flowers numerous, small, greenish white. The seeds and whole plant in its native ditches are acrid and dangerous, with a peculiar strong taste and smell; but by culture it becomes the mild and grateful garden celery, for which and its name we are indebted to the Italians, and which has now supplanted our native Alexanders (*Smyrnum olusatrum*). (*Smith's Eng. Flora*, vol. ii. p. 75.)

CELL (Lat. *cella*). In botany, the hollow part of a capsule in which the seeds are lodged, and also the part of the anthers which contains the pollen.

CELLS. The small divisions in honeycombs, which have been observed to be always regular hexagons. They also denote the hollow places between the partitions in the pods, husks, and other seed-vessels of plants.

CENTAURY (*Sabbatia angularis*). An annual and biennial, of which there are seven or eight additional species found in the United States. Centaury is commonly found in barren fields, is intensely bitter, and deservedly a popular tonic.

CENTAURY, COMMON (*Erythræa centaureum*). From *erythros*, red, alluding to the pink colour of the flowers. The species of this genus are pretty, but not easy of cultivation; the herbaceous species require an open, loamy soil, and may be increased by divisions. The annuals and biennials require sowing in the open border in autumn, or they will not come up. (*Paxton's Bot. Dict.*) In England there are three native species of centaury, viz. the broad leaved tufted (*E. latifolia*), the dwarf tufted (*E. littoralis*), and the common centaury, to the last of which the following observations more especially apply. The two first-named varieties are found mostly in sandy ground near the sea shore. (*Smith's Eng. Flora*, vol. i. p. 320.) This pretty plant (*E. centaurium*), grows in sunny, dry places, and in gravelly pastures; its roots are to be taken up in autumn, when out of flower. It is about eight or ten inches high. The leaves are radicle, or grow in a cluster from the root, and are about an inch long; the stalks divide towards the top into several branches, and the flowers, which are of a bright pink, are long and slender, and stand in a cluster. The leaves growing upon the stalk

are oblong, broad, and acute at the point. Common centaury has all the medicinal properties which distinguish the family (the *Gentianeæ*), to which it belongs. Its bitter is agreeable; and it might be advantageously used as a stomachic instead of gentian root. The dose of the plant in powder is from a scruple to a drachm.

CENTIPEDE (Lat. *centum*, a hundred, and *pes*, foot). The name of the myriapodous insects belonging to the genus *Scolopendra* of Linnæus. They are wingless; and the largest species possess, when full grown, more than fifty, and less than two hundred pairs of feet; they are sometimes called *forty-legs*. (*Brand's Dict. of Science*.)

CERATE (derived from *cera*, wax.) Cerates are ointments of rather stiff consistence; *simple cerate* is made by melting together sweet oil and beeswax, or hog's lard and beeswax, or all three together. The oil or lard employed should always be fresh, as nothing irritates or prevents the healing of wounds more than rancid applications.

CERES. The Roman Pagan goddess of corn and harvests; the Isis of the Egyptians. The festivals to her honour were denominated, at Rome, the *Cerealia* or *Cerealion*, hence the term *Cerealian* grass; and Sicily, long celebrated for its corn, was supposed to be her favourite retreat.

CEREAL, relating to corn or grain. Cereal plants are the various kinds of grain. Cereal grasses are all those raised to supply bread-stuffs, such as wheat, rye, Indian corn, &c.

CERINE. A substance which forms from seventy to eighty per cent. of beeswax. It may be obtained by digesting wax, for some time, in spirits of wine, at a boiling temperature, after which the cerine is decanted with the liquor, from which it is cleared by evaporation. It is white, analogous to wax, and melts at 134° Fahrenheit.

CHACK. A term used in horsemanship when a horse *beats upon the hand*, and does not hold his head steady, but tosses up his nose, and shakes it all of a sudden, to avoid the subjection of the bridle. In order to fix and secure his head, it is only necessary to put under his nose-band a small flat ligature of iron, bent archwise, which serves as a martingale.

CHAFF (Sax. *ceaf*; Dutch, *kaf*). The husks of corn which are separated by thrashing and winnowing. It likewise implies hay, straw, &c. cut small, for the purpose of being given to horses and other cattle.

CHAFF-ENGINES. That chaff has been employed as provender for live-stock from a very early period, we have abundant evidence. Cato (lib. 54) recommends it for oxen; and two centuries since, Hartlib recommended its use, mixed with *cut oats* and *peas*. The mode of preparing the chaff, however, from hay and straw by the knife, was a later improvement, and the first machines were rude and incomplete.

We are not aware (says Mr. J. A. Ransome of Ipswich, to whom I am indebted for this and other valuable articles on the implements of agriculture) of any attempt to improve upon the plan of pressing the hay in a trough, and

by hand bringing it by small portions to the front edge, where it was severed by a long knife attached to the end of a lever, till in 1794-5 the Rev. J. Cooke of Holborn, London, and W. Naylor of Langstock, respectively obtained patents for machines for expediting the process.

In the year 1797 we find Robert Salmon, of Woburn, whose inventive talent and practical experience added many and various original ideas and improvements to the then limited knowledge of agricultural mechanics, constructed a chaff-engine, which, although cumbersome in its appearance, was effective in its operation, and furnished the original idea, which was subsequently improved upon; first, by Rowntree, and afterwards by Thos. Passmore of Doncaster; the latter of whom, in 1804, patented the machine known as the Doncaster engine, upon the plan of which, for many years, most of the engines in the midland and eastern counties were made; and even at the present time, few of the machines in general use are found more effective. A reward of thirty guineas was conferred on Salmon by the Society for the Encouragement of Arts, &c. for this improved machine.

Passmore's machine was a simplification and improvement on Salmon's straw-cutter.

In 1800 and 1801, W. Lester of Paddington patented a straw-cutter, which, with some alterations, is much used at the present day, and is known as the "Lester engine." It is a very simple machine, having but one knife, placed on a fly-wheel; the fly-wheel turns on a cranked spindle, which communicates motion to a ratchet-wheel fixed at the end of one of the feeding-rollers by means of a small hook or catch, which is capable of being so adjusted as to lift one, two, three, or four teeth at each revolution, and by this is regulated the length of the straw projected in front of the face-plate, and which is severed by the knife. On the roller was fixed a revolving cloth or endless web, which passed over another roller at the hinder end of the box; a heavy block was used to compress the straw. In the more modern engines the rolling-cloth is entirely dispensed with, as the purpose for which it was intended is effected by the introduction of an upper feeding-roller, to which motion is communicated by a pair of cog-wheels, one of which is attached to the lower feeding-roller before described; the heavy block is substituted by a pressing-piece, which receives its motion from the cranked spindle, alternately presses down the straw previous to the cut, and rises afterwards to allow the straw free passage. The improved machine is made of different sizes, and the larger are frequently used with horse-power.

This is the best modern chaff-engine; it will adjust and vary the work to the following lengths of cut:— $\frac{1}{4}$ inch, $\frac{1}{2}$ inch, and $\frac{3}{4}$ inch.

	Bushels of fodder per hour.
At $\frac{1}{4}$ inch it will cut from	18 to 20
$\frac{1}{2}$ —	40 to 50
$\frac{3}{4}$ —	50 to 60

Another chaff-cutter is made on the same principle, but a size smaller, which

	Bushels of fodder per hour.
at $\frac{1}{4}$ inch will cut from	10 to 12
$\frac{1}{2}$ —	30 to 40
$\frac{3}{4}$ —	40 to 50

A still smaller engine can also be had, cutting $\frac{1}{2}$ inch lengths only, suited to gentlemen's stables and small establishments, made entirely of metal, and adapted for hot climates. This will cut from 15 to 20 bushels of fodder per hour.

Passing by several, which in the course of the next fifteen years were introduced, but which, however ingenious, were too complicated and cumbersome for general use, in 1818 we find a simple invention was patented by Thomas Heppenstall, of Doncaster. It consisted in the application of a worm to turn two wheels, which in their revolution meet each other. These wheels are attached to two feeding-rollers, which convey the straw forwards to the knives. Two of these knives are placed on a fly-wheel, which is fixed upon the same spindle as the worm. This is the simplest form of chaff-engine, and, with a slight alteration, substituting wheels with the cogs on the face instead of on the outer edge, is the common form for the small engines now in use.

Two patents have also, within the last year or two, been taken out for considerable improvements on this machine, one by Lord Ducie in connection with Messrs. Clyburn and Budding, two engineers residing at Uley.

The only remaining machine we have to bring before the notice of our readers, is one for which a patent was obtained a few months ago by Mr. Charles May, engineer of Ipswich, a partner in the house of Ransome. We saw this among the machines exhibited at the Royal Agricultural Society's meeting at Cambridge, where it appeared to perform its work admirably. It is intended to be used by horse-power, and is so contrived that cog-wheels of different diameters may be placed on the spindle to which motion is first communicated; these, working in different movable wheels upon another spindle, will regulate the speed of the feeding-rollers, so as to vary the length of the chaff to be cut, from three-eighths of an inch to three inches. Its capabilities are estimated to cut 8 cwt. of straw per hour in half-inch lengths.

A chaff-cutter is indispensable on a large farm establishment. This implement, as has been shown, is either constructed with a good deal of expensive machinery, or of very simple mechanism; it may be made up at the cost of only 1*l.* or 1*l.* 5*s.*

Patent straw-cutters in great variety are to be found in the United States. They are perhaps in most general use in the Eastern States, for which reason we extract the opinions of their respective merits held by an Eastern authority of high repute, Mr. T. G. Fessenden, editor of that valuable periodical, the *New England Farmer*. In his very instructive little volume, "The Complete Farmer," Mr. Fessenden makes the following remarks:—

"There is not only much saving and gain in cutting fodder when hay is low, but the animal is kept in better health, more particularly old

horses, and such as may have been injured in their wind.

"It is a fact that horses will live and continue serviceable much longer when fed on cut fodder. The machine invented and manufactured by Willis, known as 'Willis's Improved Straw and Hay-Cutter,' is the most durable and best operating machine that has come to our knowledge; and, what is worthy of notice, they require but one person to work them, which is not the case with many other machines; in this respect there is a great saving in cutting feed, and likewise the fodder may be cut of any length required: the knives, being placed in front of the machine, can be at all times examined and put in good order. The feeding-rollers are so constructed, that while the machine is in the act of cutting, the rollers cease to feed, which renders the cutting operation very easy. When properly constructed, this machine works free and easy, and is not liable to get out of order. It will cut from thirty-five to forty bushels per hour. Price thirty-five dollars.

"Eastman's Straw-Cutter, with improved side-gearing and cylindrical knives. This machine is well calculated for large and extensive establishments. Price, fifty to sixty dollars.

"The Common Dutch Hand Cutting-Machine is one of those implements in common use, and known to every practical farmer; and is considered as good a machine for a small establishment as any in use. It will cut from ten to twenty bushels per hour.

"Safford's Improved and Common Straw-Cutter with side-gearing. Well approved, and is in very general use.

"Green's Patent Straw-Cutter, one of the most approved machines now in use for cutting fodder: very simple in its construction, and not liable to get out of order; does the work with great ease and despatch."

"Green's Patent Straw, Hay, and Stalk-Cutter," says another excellent authority, "is very simple in its construction, and being made and put together very strong, is not liable to get out of order. By the application of a mechanical principle not before applied to any implement for this purpose, the machine will cut easily two bushels per minute, requiring only the strength of a boy to work it. The knives require less sharpening than those of any other straw-cutter, owing to the peculiar manner in which they cut."

The Albany Cultivator states, on the authority of an intelligent and worthy farmer, that two active men will, with this machine, by the application of manual power alone, cut five tons of hay per day! The machine called No. 2, which cuts three-fourths of an inch long, is now sold for thirty-three dollars.

The saving effected by the use of straw-cutters often amounts to 50 per cent. The profits and advantages accruing from cutting provender, especially when this happens to be a high price, is strikingly demonstrated by the following statement.

Mr. Benjamin Hale's account of the savings made by the use of Straw-Cutters, employed to cut hay and straw as fodder for horses.

Mr. Hale is proprietor of a line of stages

running between Newburyport and Boston. He says,

The whole amount of hay purchased from April 1 to Oct. 1, 1816 (six months), and used at the stage stable, was

Tons.	cwt.	qrs.	lbs.
32	4	0	10

At twenty-five dollars per ton (the lowest price at which hay was purchased in 1816,) \$800 00

From Oct. 1, 1816, to April 1, 1817, whole amount of hay and straw purchased for and consumed by the same number of horses, viz.

	T.	cwt.	qrs.	lbs.	Cost.
Straw	16	13	3	10	\$160 22
Hay	13	14	1	00	350 00

\$510 23

Deduct on hand April 1, 1817, by estimation, four tons more than there was Oct. 1, 1816, at twenty-five dollars per ton, 100

\$410 23

Saving by the use of the straw-cutter, four months out of the last six months, or the difference in expense in feeding with cut fodder and that which is uncut \$399 77

Whole amount of hay used for the horses of the Salem stage, twenty-five in number, from April 1 to Oct. 1, 1816, viz.

T.	cwt.	qrs.	lbs.
22	9	0	0

At thirty dollars per ton (the lowest price in Salem), \$660 00

Whole amount consumed by the same number of horses from Oct. 1, 1816, to April 1, 1817,

	T.	cwt.	qrs.	lbs.	Cost.
Straw	15	13	0	0	\$187 80
Hay	2	15	0	0	81 00

\$268 86

Saving in using chopped fodder five months, \$391 20

Total saving in using the straw-cutter nine months, viz. at Newburyport four months 389 77
At Salem five months 391 20

Total, \$789 97

The members of the board of trustees of the Massachusetts Agricultural Society, to whom the above account was communicated by Mr. Hale, were informed by that gentleman that he used no more grain from Oct., 1816, to April, 1817, than was used from April, 1816, to Oct., 1816.

At a late exhibition of the Philadelphia Agricultural Society, a premium was awarded for a new chaff or straw-cutter, invented by Mr. C. T. Botts, editor of the "Southern Planter," published at Richmond, Va. The improvement upon other machines for a similar purpose consists chiefly in shortening the knives, which are not wider than a common carpenter's plane-iron, and like them can be easily ground and set. It is a self-feeder, the operator having nothing else to do but turn the crank. The inventor remarks, that many straw-cutters at present in use are sufficiently effective whilst in order, but from the difficulty of bringing them within the power of common management, they have generally been abandoned for the imperfect cutters made by the common blacksmiths of the country. The inventor therefore applied himself to the construction of an implement which, if less rapid in execution, would be more durable, and within the control of the simplest capacity. These are the strongest testimonials in favour of the excellence of Mr. Botts's straw-cutter, the cost of which varies from \$25 for the smallest to \$30 for the largest size.

An extensive farmer residing near Phila-

delphia, who enjoys a high reputation for his agricultural management, and especially for his success in feeding cattle, has returned to the common old cutting-knife and box, so long used by the German farmers in Pennsylvania, an improvement of which is certainly a very efficient implement. He says that he has expended much money for what were pronounced the best patent straw-cutters, and finds it to his advantage to lay them aside and return to the old and simple machine, which costs but five or six dollars. He had not seen the machine invented by Mr. Botts.

CHALDRON. An English measure, containing 36 bushels, or 12 sacks of 3 bushels each.

CHALK (Sax. *cealc*; Welsh, *calck*; Celtic, *cal* or *kal*). The carbonate of lime, or lime united with carbonic acid. See **LIME**. Carbonate of lime exists abundantly in various parts of the earth's surface in the state of chalk, limestone, and marble; and in smaller masses, as the arragonite, &c., of which between one and two hundred varieties (all carbonate of lime) are known to mineralogists. For the purposes of agriculture they may be all classed under one head. Common chalk has a dull white colour, is soft, adhesive when applied to the tongue, stains the fingers, and thence is in common use for marking. In European agriculture chalk is perhaps the most extensively employed of the limestone species; it varies slightly in composition, containing usually some silica (flint), alumina (clay), and some red oxide of iron, and the remainder carbonate of lime, 100 parts of which contain,

	Parts
Carbonic acid - - - - -	45
Lime - - - - -	55

100 parts of common limestone are composed, according to MM. Thenard and Biot, of

	Parts.
Carbonate of lime - - - - -	95.05
Water - - - - -	1.63
Silica - - - - -	1.12
Alumina - - - - -	1.
Oxide of iron - - - - -	.75
	100

These carbonates, when burnt, form lime, for the heat drives off the carbonic acid. By exposure to the air the lime absorbs carbonic acid gas, and again becomes converted into carbonate of lime. A knowledge of these facts is of considerable value to the farmer even on the score of carriage, independent of the greater value of lime as a manure; for in some cases the object of the needless weight of water and carbonic acid in chalk is very material, as will be readily seen by the following analysis of the chalk of Kent, which is the variety largely employed in the county of Essex, although it has to be brought by sea nearly 70 miles, and then often carted several miles. I found by careful experiment 100 parts of chalk from Kent, in the state in which it was carted on the land in December, contained, besides some oxide of iron and silica,—

	Parts.
Water - - - - -	21.
Carbonic acid - - - - -	34.2
Lime - - - - -	41.8
	100

So that, when the farmer carts 41 tons of fresh lime, he conveys as much real manure to his soil as if he carried 100 tons of chalk. This must be assuredly a question of the highest importance to those farmers who have to carry the earth a considerable distance, especially if they can procure lime at a reasonable rate; which, in the large quantities required for agricultural purposes, must in most situations be the case.

Carbonate of lime is found in almost all vegetables; it is an essential food of plants. The cultivator will see, by the results of the experiments which I shall give under the head **LIME**, that the quantity of carbonate of lime contained in the cultivated grasses is very considerable, and still more so in trees; and that, as might be expected, the proportion increases with the quantity of this substance found in the soil. To the planter this fact offers an unanswerable reason in favour of the addition of chalk, marl, or limestone to all poor soils intended for plantations, in the manner long successfully practised on the black heathy sands of Norfolk by Mr. Withers of Holt, and which he has shown to be equally advantageous to trees, whether planted for ornamental or profitable purposes.

There is no fact more necessary to be understood by the agriculturist, than that no land can be productive which does not contain a fair proportion of carbonate of lime. It is, perhaps, even in excess much less prejudicial to any cultivated soil than either silica or alumina. But, on the other hand, no soil can be productive if it contain more than nineteen parts in twenty of chalk. The earth of the fine sandy hop gardens near Tonbridge, in Kent, contain about five per cent. of chalk. The good turnip soils near Holkham, in Norfolk, are seven-eighths sand and the remaining eighth is composed of

	Parts.
Carbonate of lime or chalk - - - - -	63
Silica (flint) - - - - -	15
Alumina (clay) - - - - -	11
Oxide of iron - - - - -	3
Vegetable and saline matter - - - - -	5
Water - - - - -	3
	100

The soil at Sheffield Place, in Sussex, which is so admirably adapted for the growth of the oak, contains three per cent. of chalk. The fine wheat soils of West Drayton, in Middlesex, contain more than ten per cent. That of Bagshot Heath contains less than one per cent. The richest soils on the banks of the Parret, in Somersetshire, contain more than seventy per cent. Those of the valley of Evesham about six per cent. A specimen of a good soil from Tiviotdale, examined by Davy, was composed of five-sixths sand and the remainder of the following substances (*Lectures, 202*):—

	Parts.
Clay - - - - -	41
Silica (flint) - - - - -	42
Chalk - - - - -	4
Oxide of iron - - - - -	5
Vegetable, animal, and saline matter - - - - -	8

A soil yielding excellent pasture, from the banks of the Wiltshire Avon, near Salisbury, yielded the same chemist one-eleventh of its

weight of siliceous sand. The remainder was composed of

	Paris.
Chalk - - - - -	63
Silica (flint) - - - - -	14
Vegetable, animal, and saline matter - - - - -	14
Alumina (clay) - - - - -	7
Oxide of iron - - - - -	2

Many soils also contain a small proportion of carbonate of magnesia; but it very rarely amounts to a sufficient quantity to be worth estimating in the mode of analysis I shall presently give.

It is difficult to say in what form the carbonate of lime enters the system of plants, as it is an insoluble compound: unless we can suppose that it attracts an excess of carbonic acid from the air, becoming a bicarbonate, in which state it is soluble in water. But whatever may be the cause of its being taken up by plants, its influence on soils is undoubted.

The mode of applying chalk as a manure. In the county of Essex, where chalking is practised to a very large extent, the chalk is brought in sailing barges from the Kentish shore of the Thames, at an expense of about two shillings per ton, and afterwards carted for some miles into the country. It is applied in quantities which vary from ten to thirty tons per acre, according to the description of the soil; the poor light soils requiring a larger addition of chalk than the richer lands. It is usually applied without any preparation; the larger lumps of chalk are not even broken, and the chalk being once ploughed in, the action of the frost, the plough, and the harrow, in time sufficiently pulverizes it. It is often mixed in smaller proportions with common farm-yard manure, ditch scrapings, pond mud, &c., and suffered to remain some time before it is carried into the field. An equally excellent plan is followed by some of the best Essex farmers, who spread quantities of chalk over head lands, banks, &c., which require lowering, and then fallow those portions of land, ploughing them often, and letting the chalked earth remain as long as possible, incorporating before they carry and spread the mixed chalk and earth on to the field; by this means the effects of a few loads of chalk are diffused over a field. It is a plan admirably adapted for those situations where chalk is very expensive.

The good effects of chalk are more permanent than immediate; for, although a good dressing with chalk will remain in the soil for from ten to twenty years, yet, on some soils, one or even two years will elapse before the farmer perceives a decided improvement. There is hardly any manure that answers better for grass than chalk, especially on light, sandy soils. If, however, the soil already contains an abundance of chalk, its addition to that land cannot constitute a manure. The cultivator can easily form a rough estimate of the quantity of chalk in a soil, by taking a quantity of it from three inches beneath the surface, well drying it in an oven, and adding to, say 400 grains, 800 grains of muriatic acid; the mixture, which weighs 1200 grains, will, if it contains chalk, effervesce; and the carbonic acid of the chalk being expelled, will, of

course, lessen the weight of the mixture. When the effervescence has entirely ceased, weigh the mass; every 4½ grains deficient the experimenter may consider to indicate the presence of 10 grains of chalk in the soil. The agriculturist will then be able to judge, by comparing the quantity of chalk existing in the examined soils with that in other lands, the analyses of which I have given, whether his land requires the addition of chalk. In the United States chalk is nowhere found, and the lime applied to agricultural purposes, except it be in the form of gypsum or plaster of Paris, is obtained from burning limestone, marble, shells, either recent or fossil—and lastly from bones and calcareous deposits called marl. (C. W. Johnson's work *On Fertilizers*, p. 256; *Brit. Farm. Mag.* vol. iii. p. 129.)

CHAMPIGNONS (*Agaricus orcadus*). A species of mushroom, growing wild in England, having a much higher flavour than the common mushroom, but tough and leathery and consequently very indigestible. They are chiefly used for making catsup, or in the form of powder to flavour sauces, &c., for all which purposes they are admirable.

CHAR. A species of lake trout found in Windermere; in length never exceeding fifteen or sixteen inches spotted like a trout, with very few bones. (*Walton*, p. 173.) It is also found in Loch Tay, in Scotland.

CHARBON. The little black spot or mark remaining after the large spot in the cavity of the corner tooth of a horse is gone.

CHARCOAL (From *charck*, to burn, and was formerly written *charke coal*). The remaining portion of wood after it has been heated to redness for some time, which dissipates all the hydrogen and oxygen of which, with carbon, it is composed. (See **CARBON**.) Charcoal-burning is a regular trade, followed in some of the woody districts by persons who do hardly any thing else.

For making gunpowder-charcoal, the lighter woods, such as the willow, dogwood, and alder answer best; and in their carbonization care should be taken to let the vapours freely escape, especially towards the end of the operation, for when they are re-absorbed, they greatly impair the combustibility of the charcoal.

By the common process of the forests, about 18 per cent. of the weight of the wood is obtained; by the process of Foucauld about 24 per cent. are obtained, with 20 of crude pyroligneous acid of 10 degrees Baumé.

The charcoal of some woods contains silica, and is therefore useful for polishing metals. Being a bad conductor of heat, charcoal is employed sometimes in powder to encase small furnaces and steam-pipes. It is not affected by water; and hence the extremities of charred stakes driven into moist grounds are not liable to decomposition. In like manner casks when charred inside preserve water much better than common casks, because they furnish no soluble matter for fermentation or for food to animalcules.

Lowitz discovered that wood charcoal removes offensive smells from animal and vegetable substances, and counteracts their

putrefaction. He found the odour of succinic and benzoic acids, of bugs, of empyreumatic oils, of infusions of valerian, essence of wormwood, spirits distilled from bad grain, and sulphureous substances were all absorbable by freshly calcined charcoal properly applied. A very ingenious filter has been constructed for purifying water, by passing it through strata of charcoal of different fineness.

When charcoal is burned, one-third of the heat is discharged by radiation, and two-thirds by conduction.

The following table of the quantity of charcoal yielded by different woods was published by Mr. Mushet, as the result of experiments carefully made upon the small scale. He says, the woods before being charred were thoroughly dried, and pieces of each kind were selected as nearly alike in every respect as possible. One hundred parts of each sort were taken, and they produced as under:—

Lignum Vitæ	afforded	26.0	of charcoal of a grayish colour, resembling coke.
Mahogany	- -	25.4	tinged with brown, spongy and porous.
Laburnum	- -	24.5	velvet black, compact, very hard.
Chestnut	- -	23.2	glossy black, compact, firm.
Oak	- -	22.6	black, close, very firm.
Walnut	- -	20.6	dull black, close, firm.
Holly	- -	19.9	dull black, loose and bulky.
Beech	- -	19.9	dull black, spongy, firm.
Sycamore	- -	19.7	fine black, bulky, moderately firm.
Eln	- -	19.5	fine black, moderately firm.
Norway Pine	- -	19.2	shining black, bulky, very soft.
Sallow or willow	- -	18.4	velvet black, bulky, loose, and soft.
Ash	- -	17.9	shining black, spongy, firm.
Birch	- -	17.4	velvet black, bulky, firm.
Scottish Pine	- -	16.4	tinged with brown, moderately firm.

Messrs. Allen and Pepys, from 100 parts of the following woods, obtained the quantities of charcoal as under:—

Beech	-	15.00	Oak	-	-	17.40
Mahogany	-	15.75	Fir	-	-	18.17
Lignum Vitæ	-	17.25	Box	-	-	20.25

It is observable that the quantities obtained by Messrs. Allen and Pepys are in general less than those given by Mr. Mushet, which may be owing to Mr. Mushet not having applied sufficient heat, or operated long enough, to dissipate the aqueous matter of the gaseous products.

To those persons who buy charcoal by weight, it is important to purchase it as soon after it is made as possible, as it quickly absorbs a considerable portion of water from the atmosphere. Different woods, however, differ in this respect. Messrs. Allen and Pepys found, that by a week's exposure to the air, the charcoal of

Lignum Vitæ	gained	- - -	9.6	per cent.
Fir	- - -	- - -	13.0	ditto.
Box	- - -	- - -	14.0	ditto.
Beech	- - -	- - -	16.3	ditto.
Oak	- - -	- - -	16.5	ditto.
Mahogany	- - -	- - -	18.0	ditto.

The following is a tabular view of the volumes of the different gases which were absorbed in the course of twenty-four hours, by one volume of charcoal, in the experiments of M. Theodore de Saussure, which were conducted in a way likely to produce correct results.

Each portion of charcoal was heated afresh to a red heat, and allowed to cool under mercury. When taken from the mercury, it was instantly plunged into the vessel of gas:

Ammoniacal gas	-	90	Bicarburated hydrogen	35	00
Muriatic acid gas	-	85	Carbonic oxyde	-	9.42
Sulphurous acid	-	65	Oxygen gas	-	9.25
Sulphureted hydrogen	55		Nitrogen	-	7.50
Nitrous oxyde	-	40	Carburated hydrogen	5.00	
Carbonic acid gas	-	35	Hydrogen gas	-	1.75

(Ure's Dict. of Arts.)

In England charcoal is prepared in two different ways. In one, billets of wood are formed into a heap, which is covered with turf, and a few small openings only left for the admission of the air requisite to maintain it in a state of low combustion after it is lighted. When the whole heap is on fire, the holes are stopped; and, after the mass has cooled, the residue is charcoal. In the other mode the wood is distilled in iron cylinders, in which case the products are pyroligneous acids, and empyreumatic oil; and what remains in the retort is charcoal. The quantity of the distilled products, as well as of the charcoal, depends on the kind of wood employed. 100 parts of dried oak yields, of

					Parts.
Pyroligneous acid	-	-	-	-	43.
Carbonate of potassa	-	-	-	-	4.5
Empyreumatic oil	-	-	-	-	9.06
Charcoal	-	-	-	-	26.2

The charcoal thus procured is lighter than common charcoal. Charcoal should be black, sonorous, brittle, and retain the texture of the wood. It has a powerful attraction for water, gases, and odorous and colouring principles. It is a powerful antiseptic, and well adapted for preserving animal substances from putrefaction. In fine powder it is much used as a tooth-powder, for which purpose, however, it is exceptional, since, being insoluble, it gets between the teeth and gums and thus leads to their separation and much mischief.

Ivory, or bone black, is animal charcoal, prepared in the same manner as the second kind of vegetable charcoal. It has a remarkable property of abstracting colour from many vegetable solutions, on which account it is much used by sugar refiners.

"Plants," says Liebig, "thrive in powdered charcoal, and may be brought to blossom and bear fruit, if exposed to the influence of the rain and the atmosphere; the charcoal may be previously heated to redness. Charcoal is the most unchangeable substance known; it may be kept for centuries without change, and is therefore not subject to decomposition. The only substances which it can yield to plants are some salts which it contains, amongst which is silicate of potash. It is known, however, to possess the power of condensing gases within its pores, and particularly carbonic acid. And it is by virtue of this power that the roots of plants are supplied in charcoal exactly as in humus, with an atmosphere of carbonic acid and air, which is renewed as quickly as it is abstracted."

"In charcoal powder, which had been used for this purpose by Lukas for several years, Buchner found a brown substance soluble in alkalis. This substance was evidently due

to the secretions from the roots of the plants which grew in it.

"A plant placed in a closed vessel in which the air, and therefore the carbonic acid, cannot be renewed, dies exactly as it would do in the vacuum of an air-pump, or in an atmosphere of nitrogen or carbonic acid, even though its roots be fixed in the richest mould.

"Plants do not, however, attain maturity, under ordinary circumstances, in charcoal powder, when they are moistened with pure distilled water instead of rain or river water. Rain water must, therefore, contain within it one of the essentials of vegetable life; and it will be shown, that this is the presence of a compound containing nitrogen, the exclusion of which entirely deprives humus and charcoal of their influence upon vegetation." (*Liebig's Organic Chemistry.*)

"Dr. Webster, editor of the American edition of Liebig's Organic Chemistry, observes: 'A few years since, I had an opportunity of observing a striking instance of the effect of carbonic acid upon vegetation in the volcanic island of St. Michael (Azores). The gas issued from a fissure in the base of a hill of trachyte and tuffa from which a level field of some acres extended. This field, at the time of my visit, was in part covered with Indian corn. The corn at the distance of ten or fifteen yards from the fissure, was nearly full grown, and of the usual height, but the height regularly diminished until within five or six feet of the hill, where it attained but a few inches. This effect was owing to the great specific gravity of the carbonic acid, and its spreading upon the ground, but as the distance increased, and it became more and more mingled with atmospheric air, it had produced less and less effect.'

CHARD. See BEET.

CHARLOCK (*Sax. ceptice*). Pl. 10 g. A troublesome weed, which abounds in most arable soils, and is very difficult to expel. In England it is frequently called *chadlock*, *catlock*, *corlock*, *corn-kale*, and *white-rape*. There are four different species of plants, says Sinclair, confounded under the name of charlock, viz. *Sinapis arvensis*, or common wild mustard; yellow blossom, in May; annual. *S. nigra*, black, or Durham mustard; blossom, pale yellow, in June; annual. *Raphanus raphanistrum*, wild radish; straw-yellow blossom, in June and July; annual. *Brassica napus*, wild navew (this last is the least common); yellow blossom, in May; biennial.

The seeds derived from the hard pods of the variety of the yellow-flowered charlock, called wild mustard, are collected in England and sold under the name of *Durham Mustard*. They furnish by expression an excellent oil, which it has been thought might be rendered profitable. In Germany 30 lbs. of pure lamp-oil has been obtained from 100 lbs. of seed.

Charlock has been introduced from Europe, and has become quite extensively naturalized in several parts of the United States. Being an annual plant it is very difficult to get rid of, and when once in possession of a spot will long bid defiance to all attempts made for its total extirpation. It infests clayey grounds,

such as are particularly well adapted to the culture of wheat and other most valuable grains. Its seeds contain a preservative oil, which, with their great firmness enables them to remain sound under ground for an almost unlimited period. Those only which are brought by tillage within a certain distance of the surface, sprout and grow, whilst the deeper covered remain for the production of another crop when brought up by the plough sufficiently near the surface. The only practicable mode of eradicating this and other pests of annual growth, is to *prevent the plants from coming to seed*, by cutting down when in blossom. The greatest care should be taken to inspect seed-grain before sowing, and see that no seeds of charlock or other troublesome weeds are in the samples. The leaves, flowers, long, round and irregular seed-pods and odour of the root are very similar to those of the common radish. Farm stock generally are fond of the plant, and especially sheep, which, when it is possible to turn upon the field sufficiently early, will keep it from growing up to seed.

In Ireland and the northern parts of Europe, as well as in some parts of America, young charlock is boiled for greens in the same manner as cabbage-sprouts, &c. The flowers are much frequented by bees. (*Weeds of Agriculture*, p. 45; *Smith's Flora*, vol. iii. p. 321-6.)

CHARRING OF POSTS. The reducing that part of the surface of posts which is to be put into the ground to the state of charcoal. This method is highly useful where the parts are to be placed in wet situations, or to stand between wet and dry. This was a practice common to the ancients.

CHEAT AND CHESS. See DARNEL.

CHEDDER CHEESE. A kind of cheese so named from its being made at Cheddar, a village near the Mendip-hills in Somersetshire, famous for its pastures. The richness and fine flavour of Cheddar cheese is supposed to be derived chiefly from a species of *Agrostis* upon which the cows feed.

CHEESE (*Lat. caseus*; *Sax. cere*). A well-known kind of food, prepared from milk by coagulation, and separated from the serum or whey, by means of pressure, after which it is dried for use. See BUTTER. Cheese has been made from a very ancient period; it is mentioned by Job, and also by Homer. According to Strabo, our British ancestors did not understand how to make cheese, a deficiency with which their descendants cannot now well be charged.

Good cheese, says Dr. Thomson, melts at a moderate heat; but bad cheese, when heated, dries, curls, and exhibits all the phenomena of burning horn. From this it is evident that good cheese contains a quantity of the peculiar oil of cream; hence its flavour and smell. Proust found in cheese a peculiar acid, which he called the caseic. (*System of Chem.* vol. iv. p. 499.)

The best season for making cheese is during those months when the cows can be fed on the pastures; that is, from the beginning of May till towards the end of September, or, in favourable seasons, the middle of October. In England, on many of the large dairy farms, in se

veral districts, cheese is frequently made throughout the year; but that made during the winter months is considerably inferior in quality, and much longer in becoming fit for sale, or for use, than that which is made within the periods which have been just mentioned. In Gloucestershire, the season of making thin cheese is from April to November; but the principal one for making thick is during the months of May, June, and the beginning of July. If made late in the summer, the cheese does not acquire a sufficient degree of firmness to be marketable in the ensuing spring.

The *milking* in Cheshire, during the summer season is at six o'clock, both morning and evening; and in winter, at daylight in the morning, and immediately before dark in the evening. But in other districts, as Wilts, Suffolk, &c., the people are frequently employed in milking by four o'clock in the morning in summer; and the business in a dairy of forty or fifty cows is nearly completed before the usual period at which it commences in Cheshire.

The *colouring* of cheese has been so long common in the cheese districts, that it is probable that cheese of the best quality would be in a great measure unsaleable if it did not possess the requisite colour. The degree of colour is regulated chiefly by the name under which it is intended the cheese should be sold, as Gloucester, Cheshire, &c. The object of the introduction of this practice was no doubt to convey an idea of richness which the cheese did not really possess. This is the more evident, as it is universally allowed that the poorest cheese always requires the greatest quantity of dye to bring it to the proper degree of colour. The material which is employed for this purpose is the Spanish annotta. (See *ANNOTTA*.) The weight of a guinea and a half of it is considered in Cheshire sufficient for a cheese of 60 lbs.; and in Gloucestershire an ounce is the common allowance to 1 cwt.

In regard to the *rennet*, it may be observed, that milk may be coagulated, or curdled, by the application of any sort of acid; but the substance which is most commonly used is the maws or stomachs of young calves prepared for the purpose. These are most generally denominated *rennets*; but they are also often provincially called *vells*, and in Scotland *yearnings*. See *RENNET*.

In Cheshire, after the rennet is added to the milk, and as soon as the curd is firm enough to discharge its whey, the dairy woman plunges her hands to the bottom of the vessel, and, with a wooden dish, stirs the curd and whey; then lets go the dish, and by her hand agitates the whole, carefully breaking every part of the curd; and, at intervals, stirring it hard to the bottom with the dish, so that no curd remains unbroken larger than a hazel-nut. This is done to prevent what is called slip-curd, or lumps of curd, which, by retaining the whey, do not press uniformly with the other curd, but in a few days, if it happens to be situated towards the rind of the cheese, turns livid and jelly-like, and soon becomes faulty and rotten. In a few minutes the curd subsides. The dairy-woman then takes her dish, and lades off

the whey into a milk-lead to stand for cream, to be churned for whey-butter. This is a practice peculiar to the cheese counties. In Norfolk the whey, even from new milk, passes from the cheese-vessels immediately to the hog-tub. Having laded off all the whey she can, she spreads a straining cloth, and strains the whey through it, returning the curd retained in the cloth into the cheese-tub. When she has got all the whey she can by pressing the curd with her hand and the lading-dish, she takes a knife and cuts it into square pieces of about two or three inches. This lets out more of the whey, and makes the curd more handy to be taken up in order to be broken into the vats.

Having made choice of a vat or vats proportioned to the quantity of curd, so that the cheese when fully pressed shall exactly fill the vat, she spreads a cheese-cloth loosely over the mouth of the vat, into which she rebreaks the curd, carefully squeezing every part of it in her hands; and having filled the vat heaped up, and rounded above its top, she folds over it the cloth and places it in the press, on the construction and power of which much depends.

When the vat is properly placed in the press, the ordinary degree of pressure is applied, which is more or less, according to the sizes of the cheeses usually made. At all large dairies, there are two or three presses, all varying in respect to weight or pressure. There are various kinds of cheese-presses; one made entirely of iron by the Shotts Foundry Company is described in the *Trans. High. Soc.* vol. iv. p. 52. As soon as the vat is placed in the press, and the weight applied, skewers are thrust in through the holes in the side of the vat; this is done repeatedly during the first day when the vat is in the press. From the time the vat is first placed in the press till it is again taken out does not, in ordinary cases, exceed two or three hours. When taken out, the cheese is put into a vessel with hot whey, with a view of hardening its coat or skin, where it stands for an hour or two; it is then removed, wiped dry, and after having remained some time to cool, is covered with a clean cloth; and the vat being wiped dry, and the cheese replaced, it is again put into the press. In the evening, supposing the cheese to have been made in the morning, which is the usual time, it is again taken out of the vat; and another dry cloth being applied, it is turned and replaced; what was formerly the upper becoming now the under side. In this manner it is taken out, wrapped in clean cloths, and turned in the vat twice a day for two days, when it is finally removed.

The *salting* is the next operation. The cheese, on being for the last time taken out of the vat, is carried to the salting-house, and placed in the vat in a tub filled to a considerable depth with brine, in which it stands for several days, being regularly turned once at least every day. The vat is then removed from the brine-tub; and the cheese being taken out, is placed on the salting-bench, where it stands for eight or ten days, salt being carefully rubbed over the whole every day during the period. When the cheese is of a large size, it is com-

monly surrounded with a wooden hoop or fillet of cloth to prevent renting. After it is supposed to be sufficiently salted, it is washed in warm water or whey, and when well dried with a cloth, is placed on what is called the drying-bench, where it remains a like period before it is removed to the keeping-house or cheese-chamber.

The last part of the business is the management in the cheese-room. In Gloucestershire the young cheeses are turned every day, or every two or three days, according to the state of the weather, or the fancy or judgment of the dairy-woman. If the air be cold and dry, the windows and door are kept shut as much as may be; if close and moist, as much fresh air as possible is admitted. Having remained about ten days in the dairy (more or less, according to the space of time between the washings), the cheeses are cleaned; that is, washed and scraped.

The produce of a dairy of cows, where the milk is converted into cheese, is very variously stated by different writers. In some districts $2\frac{1}{2}$ cwts. from each cow, whether a good or a bad milker, if at all in milk, is considered a good return. In others, the average runs as high as 3 cwt.; and in the county of Wilts in particular, from $3\frac{1}{2}$ to 4 cwts. is the usual quantity. From accurate calculations made by Mr. Marshall, and these several times repeated, he found that in Gloucestershire about 15 gallons of milk were requisite for making little more than 11 lbs. of two-meal cheese, and that one gallon of new milk produced a pound of curd. It is the general opinion of dairy farmers that the produce from two and a half to three and a half acres is necessary to maintain a cow all the year round. Taking, therefore, the medium of the three averages of cheese above mentioned (amounting to 355 lbs. from each cow), the quantity of cheese by the acre is 118 lbs. Every calculation of this kind must, however, be extremely vague and uncertain. See DAIRY.

In the making of *Parmesan* cheese, we are informed by Mr. Price, in the *Papers of the Bath and W. Engl. Society* (vol. vii.), that the method is "to put, at ten o'clock in the morning, five brents and a half of milk, each brent about forty-eight quarts, into a large copper, which turns on a crane over a slow wood fire, made about two feet below the surface of the ground; the milk is stirred from time to time, and about eleven o'clock, when just lukewarm, or considerably under a blood-heat, a ball of rennet, big as a large walnut, is squeezed through a cloth into the milk, which is kept stirred. By the help of the crane the copper is turned from over the fire, and left till a few minutes past twelve; at which time the rennet has sufficiently operated. It is now stirred up, and left for a short time. Part of the whey is then taken out, and the copper again turned over a fire sufficiently brisk to give a strongish heat, but below that of boiling. A quarter of an ounce of saffron is now put into the milk to give it a little colour; and it is well stirred from time to time. The dairy-man frequently feels the curd. When the small, and, as it were, granulated parts, feel rather firm, which

is in about an hour and a half, the copper is taken from the fire, and the curd left to fall to the bottom. Part of the whey is taken out, and the curd brought up in a coarse cloth, hanging together in a tough state. It is then put into a hoop, and about a half hundred weight laid upon it for about an hour; after which the cloth is taken off, and the cheese placed on a shelf in the same hoop. At the end of two, or from that to three days, it is sprinkled all over with salt; the same is repeated every second day for about forty or forty-five days, after which no further attention is required. While salting, they generally place two cheeses one upon another; in which state they are said to take the salt better than singly. The country between Cremona and Lodi, says Mr. Evans, comprises the richest part of the Milanese. The irrigation, too, is brought to the highest degree of perfection; the grass is cut four times a year as fodder for the cows, from whose milk is made the well-known *Parmesan* cheese. The cows, which are kept in the stall nearly all the year round, are fed during summer on two of these crops of grass or clover, which are cut green; and in the winter on the other two, which are hayed. The milk of at least fifty cows is required for the manufacture of one *Parmesan* cheese. Hence, as one farm rarely affords pasture for such a number, it is usual for the farmers or metayers of a district to club together. (*Quart. Journ. of Agr.* vol. v. p. 622.)

Cream cheese is made in various places; but that which is generally known by the name of *Stilton* is made in Leicestershire, in the following manner, according to the *Agricultural Report* of that county:—The night's cream is put into the morning's new milk with the rennet; but when the curd is come it is not broken, as is done with other cheeses, but is taken out with a soildish altogether, and placed in a sieve to drain gradually; and, as it drains, it is pressed, till it becomes firm and dry; being then placed in a wooden hoop, and afterwards kept dry on boards, it is turned frequently, with cloth binders round it, which are tightened as occasion requires. Cream cheese of good quality is likewise made, in some districts, by adding the cream of one meal's milk to the milk which is immediately taken from the cow. This, after being made and pressed gently two or three times, and carefully turned for a day or two, is fit for use.

Since the late reduction of duties in England upon provisions introduced from abroad, cheese has been among the articles extensively shipped from the United States to that country, where the complaint against American cheese is, that it is generally insufficiently pressed, a fault which gives it, when cut, a porous or honeycomb appearance. Its flavour is also rendered unpleasant by the too free use of rennet. The removal of these defects would very much enhance the value of American cheese both at home and abroad. Nevertheless, cheese of excellent qualities as to richness, flavour, and other requisites, is made in the northern portions of the Middle and Western States and throughout New England. See DAIRY.

Pine Apple Cheese.—E. Perkins, of Herkimer county, New York, a fine dairy district, gives the following description of the mode of making those cheeses moulded in the pine-apple form. These weigh from 7 to 8 lbs., and are chiefly made in the small dairy establishments. The cheese-making process, until fit for the press, is pretty much like that usually pursued in making common cheeses. Some add a little more salt. The pressing is performed in wooden blocks, griped together, and, after this process, the cheeses are suspended in nets, till so hardened as to stand on a trencher made for the purpose, where they remain till fit for market. This kind of cheese is chiefly made under contract. If the purchaser finds the pressers, nets, and trenchers, the price is from 7 to 7½ cents per lb. When the maker finds every thing he gets about 8 or 9 cents per lb. In the preparation of pine-apple cheese, more allowance is made for shrinkage than in the manufacture of common cheese. (*Farmer's Instructor.*)

All new cheeses require to be well dried to fit them for the market, and when taken out of the moulds must be laid upon a shelf and turned every day for some time. This operation was formerly done by hand, which proved very laborious. But contrivances have been invented by which the work can now be done very quickly and without the least exertion of strength. Some of these will be found mentioned under the head **DAIRY**.

After the cheeses have passed through the different processes, and the drying is completed, they are to be deposited in the cheese or store-room. This should be dry and airy, and the hard and soft cheeses ought not to be kept in the same room. In some of the best dairy districts in the United States, it is thought best not to darken the cheese rooms, or attempt to keep out the flies, but in hot, sultry weather, the doors and windows are opened to admit the air freely. Cool dry air blowing directly upon the cheeses, is apt to crack them. These cracks are to be filled up with pepper, either black or cayenne. To mature cheese fast, the room should be kept warm in the fall and spring.

We learn from the *Transactions of the Highland Agricultural Society in Scotland*, that the flavour of an old cheese may be communicated to a new one of whatever species, by the insertion of some portions of the old into the new cheese. Small pieces are to be extracted with a sample-scoop from each cheese, and those taken from the old are to be inserted into the new, and those from the new put into the old. After this interchange, the new one, if kept well excluded from the air, will, in a few weeks, become thoroughly impregnated with the mould, and have a flavour hardly to be distinguished from the old one. The cheese selected must be dry, and the blue mould should be free from any portion of a more decayed appearance.

A great variety of cheeses are made in Switzerland, the most celebrated of which are the *Schabzieger*, (or *sap-sago* as we commonly call it.) and the *Gruyère*. Of the quantity of cheeses exported from Switzerland, we have

no information that can be relied upon; but it is computed that 30,000 cwt. of *Gruyère* cheese alone, fit for exportation, is annually made; and that, from the middle of July to October, 300 horses, weekly, are employed in transporting Swiss cheese over Mount Grias. (*For. Rev. and Cont. Misc.*)

"The *Schabzieger* cheese is made by the mountaineers of the canton of Glarus alone; and, in its greatest perfection, in the valley of Kloen. It is readily distinguished by its marbled appearance and aromatic flavour, both produced by the bruised leaves of the melilot. The dairy is built near a stream of water; the vessels containing the milk are placed on gravel or stone in the dairy, and the water conducted into it in such a manner as to reach their brim. The milk is exposed to the temperature of about six degrees of Reaumur (forty-six degrees of Fahrenheit), for five or six days, and in that time the cream is completely formed. After this it is drained off, the caseous particles are separated, by the addition of some sour milk, and not by rennet. The curd thus obtained is pressed strongly in bags, on which stones are laid; when sufficiently pressed and dried, it is ground to powder in autumn, salted, and mixed with either the pressed flowers, powdered and sifted, or the seeds of the melilot trefoil (*Melilotus officinalis*, Pl. 10, f). The practice of mixing the flowers or the seeds of plants with cheese was common among the Romans, who used those of the thyme for that purpose. The entire separation of the cream or unctuous portion of the milk is indispensable in the manufacture of *Schabzieger*. The unprepared curd never sells for more than three halfpence a pound; whereas, prepared as *Schabzieger*, it sells for sixpence or seven-pence. (*For. Rev. and Cont. Misc.*)

"The *Gruyère* cheese of Switzerland is so named after a valley, where the best of that kind is made. Its merit depends chiefly on the herbage of the mountain pastures, and partly on the custom of mixing the flowers of bruised seeds of *Melilotus officinalis* with the curd, before it is pressed. The mountain pastures are rented at so much per cow's feed from the 15th of May to the 18th of October; and the cows are hired from the peasants, at so much, for the same period. On the precise day both land and cows return to their owners. It is estimated that 15,000 cows are so grazed, and 30,000 cwt. of cheese made fit for exportation, besides what is reserved for home use.

"*Ewe-milk* cheese of Switzerland. One measure of ewe's milk is added to three measures of cow's milk; little rennet is used, and no acid. The best Swiss cheese of this kind is made by the Bergamese sheep-masters, on Mount Splügen." (*For. Rev. and Cont. Misc.*)

Sage Cheese, an humble imitation of the Swiss green cheese much relished in some parts of the United States. "To make this cheese, take the tops of young red sage, and having pressed the juice from them by beating in a mortar, do the same with the leaves of spinach, and then mix the two juices together. After putting the rennet to the milk, pour in some of this juice, regulating the quantity by the degree of

colour and taste it is intended to give the cheese. As the curd appears, break it gently, and in an equal manner, then emptying it into the cheese vat, let it be a little pressed, in order to make it eat mellow. Having stood for about seven hours, salt and turn it daily for four or five weeks, then it will be fit for the table. The spinach besides improving the flavour, and correcting the bitterness of the sage, will give it a much more pleasing colour than can be obtained from sage alone."

Cream Cheese.—Excellent cream cheeses are supplied to the Philadelphia market by the neighbouring Pennsylvania farmers. They are round, generally from six to ten inches in diameter, and about one inch thick. The mode of preparing cream cheese is as follows. Expose cream to the air and it will be found to grow thick gradually, so that in three or four days the vessel containing it may be turned upside down without loss. In eight or ten days more, its surface will become coated over with a kind of mucus and a woolly moss or byssi. After this, it no longer retains the flavour of cream, but of a very fat cheese. This rich dainty differs from butter in containing both curd, and serum or whey, together with the oily matter; whereas in butter the oil is obtained separate from the whey and curd or cheesy matter.

Another mode of making cream cheese is the following, given by the late Judge Cooper, whose endorsement makes it worthy of the highest credit. "Take of the top or surface cream that has been collected for three or four days in the cream-croak so as to be slightly acid, one pint: on each of two common plates lay a dry napkin four-doubled: put half a pint of cream on each napkin. Next day have ready another plate covered with a folded wet napkin, turn the two cheeses one on top of the other upon the wet napkin, cover them over with the ends of this wet napkin, and change it every day for a week till the cheese is ripe. It must not be done in a cellar or damp place, but in a room, otherwise it will mould."

In Lincolnshire, England, as well as in the neighbourhoods of Bath and York, rich and excellent cream cheeses are made. These, like all such kind of soft and rich cheeses, are used when but a few days old, to be eaten with radishes, salad, &c.

For the mode of preparing the celebrated *Stilton cream cheese* see p. 315.

There are papers, by Mr. P. Miller, "On making cheese resembling that of Gloucester and Wiltshire" (*Trans. High. Soc.* vol. iii. p. 228); and "In Imitation of Double Gloucester," by Mr. Bell (*Ibid.* vol. i. p. 155); and "On communicating the Flavour of old to new Cheese by Inoculation," by Mr. Robinson (*Ibid.* p. 232). "On making Cheese from Potatoes in Thuringia." (*Farmer's Mag.* vol. viii. p. 144.)

CHEESE CLOTHS are large towels to put inside the chessel or vat, while the cheese is pressing. They are of home manufacture, and should be of strong and open texture: every time they are used for this purpose, they should be wrung out of boiling water, and dried in the sun, or before the fire.

CHEESE COLOURING. See *ANNOTTA*.

CHEESE-FLY and **MAGGOT** (*Piophilæ casei*). The small white larvæ found in old and putrescent cheese, produce a small two-winged fly, about two lines in length, which has a greenish-black, smooth, and shining body. It is fully described in the *Quart. Journ. of Agr.* vol. xii. p. 125.

Dr. Harris describes the cheese-maggots found in Massachusetts as the young of a fly (*Piophilæ casei*) not more than three-twentieths of an inch long, of a shining black colour, with the middle and hinder legs mostly yellowish, and the wings transparent like glass. See his *Report, &c.*

CHEESE-KNIFE. A large sort of knife, or spatula, made use of in dairies for the purpose of cutting or breaking down the curd whilst in the cheese-tub.

CHEESE-LEP. The bag in which dairy-women keep the rennet for making cheese.

CHEESE-MITES. This is the *Acarus siro*, an almost microscopic apterous insect, furnished with eight legs, on the four first of which, between two claws, is a vesicle with a long neck, to which the insect can give every kind of inflexion. "When it sets its foot down, it enlarges and inflates; and when it lifts it up, it contracts it, so that the vesicle almost entirely disappears." (*De Geer*, quoted by Kirby, vol. xxxiv. p. 321.) It is not possible to say how this insect gets into cheeses. The brown powder, so valued by epicures, in which the mites live, is their excrement.

CHEESE-PRESS. A press employed in cheese dairies, to force the whey from the curd when in the cheese vat.

Cheese presses are of different forms. The most simple and primitive press is merely a long beam, one end of which is placed in a hole of the wall, and frequently it is fixed to a bolt, or in the trunk of a tree. The sinker forms the fulcrum, a weight consisting of two or three undressed stones being placed on the other end of the lever. A second kind is formed by a large square stone, suspended by a screw between the side posts of a timber frame. The chessel is placed underneath it, and the stone is lowered upon the sinker by turning the screw to the left hand. The cheese vat is removed at pleasure by turning the screw to the right hand, which elevates the stone. To preserve the screw, a small block of timber is placed underneath the stone during the period that cheese-making is suspended.

Another kind of press consists of a timber frame formed of two perpendicular side posts and a cross top with a parallel beam, which is suspended from the top by two screws. The cheese vat is placed upon the beam, which is lifted up when the screws are turned to the right hand; and the sinker of the chessel or vat being pressed against the cross top, squeezes or *stanes* the cheese. When the chessel requires to be removed, the screws are turned to the left hand.

But more complicated presses, and therefore in many instances more convenient, can be adopted. The most complete, effective, and approved press consists of a frame of cast iron with a perpendicular piston, flat below to cover

the sinker of the chessel. The piston is raised or depressed by a small pinion attached to a ratchet wheel and malleable iron lever, three feet in length. The lever is grooved in several places on the upper side to hold the ring of the weight for increasing or diminishing the power, in proportion to its distance from the ratchet wheel. The weight of this press is about two stone, cost 1l. 4s. pressure 20 tons. (*Martin Doyle's Pract. Husband.*; *Prof. Lowe's Elem. of Agr.*) See DAIRY.

CHEESE RENNET, or **YELLOW BED-STRAW** (*Galium verum*), is a perennial plant, common in waste places and the borders of fields, flowering in July and August. The stem, which is woody and much branched, rises eighteen inches, and sends off, in the same plane, narrow, deep green, deflexed leaves, rough with minute points, each tipped with a hair. The flowers are golden yellow, in dense tufted panicles, and smell strongly of honey in the evening and before rain. The flowers of this weed were formerly used in Cheshire for curdling milk. (*Paxton's Bot. Dict.*; *Smith's Eng. Flor.* vol. i. p. 208.)

CHELIDONIUM. From *cheledon*, a swallow; it being said to flower at the arrival and wither at the departure of the swallows. See CELANDINE.

CHELONE (*Chelone barbata*. From *chelone*, a tortoise; to the back of which the helmet of the flowers is fancifully compared). Known in Pennsylvania and other Middle States by the names of Shell-flower, and Snake-head. This plant is a native of North America, and a hardy perennial; blowing beautiful red flowers in July and August. It loves shade and moisture, and grows three feet high. The white chelone is hardy, and likes any soil. The downy chelone blows a flower which is yellow inside, and light purple outside. It is propagated by seed, and by separating the roots in autumn. It belongs to a hardy herbaceous genus, that ought to have a place in every collection: the species succeed well in a mixture of peat and loam. (*Paxton's Bot. Dict.*)

CHEMISTRY. The importance of this science to the agriculturist no intelligent modern farmer will doubt. Its triumphs in the cause of the cultivator have been far too many for him to hesitate in acknowledging the obligation. I have, in this work, under the heads **EARTHS, ANALYSIS OF SOILS, GASES, WATER, SALTS, ORGANIC CHEMISTRY, &c.**, endeavoured, to the best of my power, to illustrate some of the many chemical facts on which the successful practice of agriculture depends; and to these I must refer the farmer. Most of the substances belonging to our globe, says Davy, (*Chem. Philosophy*, p. 1), are constantly undergoing alterations in sensible qualities, and one variety of matter becomes, as it were, transmuted into another. Such changes, whether natural or artificial, whether slowly or rapidly performed, are called chemical; thus, the gradual and almost imperceptible decay of the leaves and branches of a fallen tree exposed to the atmosphere, and the rapid combustion of wood in our fires, are both chemical operations. The object of chemical philosophy is to ascertain the causes of all phenomena of this kind,

and to discover the laws by which they are governed. The ends of this branch of knowledge are the applications of natural substances to new uses, for increasing the comforts and enjoyments of man; and the demonstration of the order, harmony, and intelligent design of the system of the earth. The foundations of chemical philosophy are observation, experiment, and analogy. By observation, facts are distinctly and minutely impressed on the mind. By analogy, similar facts are collected. By experiment, new facts are discovered; and, in the progression of knowledge, observation, guided by analogy, leads to experiment; and analogy, confirmed by experiment, becomes scientific truth. To give an instance,—whoever will consider with attention the slender green vegetable filaments (*Conferva rivularis*) which in the summer exist in almost all streams, lakes, or pools, under the different circumstances of shade and sunshine, will discover globules of air upon the filaments exposed under water to the sun, but no air on the filaments that are shaded. He will find that the effect is owing to the presence of light. This is an *observation*; but it gives no information respecting the nature of the air. Let a wine-glass filled with water be inverted over the conferva thus acted upon by the light. The air-bubbles, as they rise, will collect in the upper part of the glass; and, when the glass is filled with air, it may be closed with the hand, placed in its usual position, and an inflamed taper introduced into it: the taper will burn with more brilliancy than in the atmosphere. This is an *experiment*. If the phenomena are reasoned upon, and the question is put, whether all vegetables of this kind, in fresh or in salt water, do not produce such air under like circumstances, the inquirer is guided by *analogy*; and, when this is determined to be the case by new trials, a general scientific truth is established,—that all confervæ in the sunshine produce a species of air (oxygen gas) which supports flame in a superior degree: a fact which has been shown to be the case by various minute investigations.

By such researches the chemist ascertains the composition and uses of the various other gases, and also of the earths, metals, and salts, of which the materials of the earth we inhabit are composed; delightful inquiries, which will well repay the cultivator in more ways than one for the labour he may bestow upon them. They will speedily teach him that nothing in this world of ours is ever lost or *destroyed*; that the decaying materials of his most noisome manures speedily again make their appearance in new forms, and in salubrious and fragrant plants; that the expired breath of himself and his live-stock is the inhaled food of all vegetation; and that vegetables purify the very air which animals have vitiated. And again, the correct *rotation* of crops, the use of permanent or *earthy* additions to the soil, (which see), the fattening of live-stock, the origin of diseases, are a few only of the facts connected with the cultivation of the soil which the chemist's operations illustrate. "The nature of soils" (as it is remarked by Mr. G. W. Johnson), "of manures, of the food and functions of plants,

would all be unknown but from the analyses which chemists have made." We know that every plant has a particular temperature in which it thrives best, a particular modification of food, a particular degree of moisture, a particular intensity of light; and those particularities vary at different periods of their growth. It is certain that plants are subject, like all other organized bodies, to various influences. Acids are injurious to some, alkalies to others; the excess of some of their constituents, and the deficiency of others, insure disease to the plants to which such irregularities occur. Disease is accompanied by decay more or less extensive and rapid; and if these cannot be checked by salutary applications and treatment, death ultimately ensues. Now, if it was possible for any science or sciences to teach the cultivator of plants how to provide for them all the favourable contingencies, all the appropriate necessaries above alluded to, and to protect them from all those which are noxious to them, the art of cultivation would be far advanced to perfection. Such sciences are botany and chemistry. It is not asserted that they can, at present, do all that is desired of them,—all of which they are capable; but they can do much. As evidence of what can be effected by a combination of chemical and practical knowledge in the cultivation of the soil, we may quote the example of Lavoisier. He cultivated 240 acres in La Vendée, actuated by the beneficent desire of demonstrating to his countrymen the importance of sustaining the art of cultivation on scientific principles. In nine years his produce was doubled, and his crops afforded one-third more than those of ordinary cultivators. It is unnecessary to dwell upon the importance of such improvements. Science can never supersede the use of the dunghill, the plough, the spade, and the hoe; but it can be one of their best guides,—it can be a pilot even to the most experienced. (*Baxter's Lib. of Agr.*; *Gard. Mag.* vols. iii. and iv.; *Davy's Chem. Phil.*; *Leibig's Organic Chemistry.*)

So many important facts bearing upon agricultural subjects have been discovered of late years through chemical experiments and researches, as to render it imperative upon every well-instructed farmer to make himself acquainted with them. It has long been known to common observers, that certain crops will grow in some situations and not in others, and that after having flourished in a place for a considerable period, crops will decline in quality and quantity, and finally cease to compensate for the expenses of seed and tillage. That certain kinds of manure are most beneficial to some soils and plants, whilst another produces the best effects upon others. But the causes operating in the production of such effects have not been understood, and hence, great waste of means and labour have resulted in experiments often useless, for want of that chemical knowledge through which the precise defects of the soil could be detected and the deficiencies directly supplied.

Agricultural chemistry points out the respective elements entering into the formation of plants, and even those required at each stage of their growth from germination to the perfec-

tion of the seed or fruit. It shows which of these elements are absorbed from the gases of the atmosphere, and what saline and other materials are furnished by the soil. The seed itself, like the egg, contains the first supply of nourishment for the roots of the infant germ of the plant. To assist its first growth before it rises above ground, the humus of the soil supplies carbonic acid, and the looser the soil the more of this essential food for the young plant can be retained. When it rises above the surface, and its stems and leaves are fully developed, its main, and, according to Liebig and others,—its entire dependence for nourishment, is upon the atmosphere. Chemistry points out the different gases which plants absorb from the atmosphere or the soil in the progress of their growth. It also shows that plants have other constituents, such as potash, soda, lime, magnesia, &c., without which, in due quantities, they cannot come to perfection. The proportions of these, though often very minute, are all important. The chemical processes described for analyzing soils, will show what elements for the growth of plants are present and what are wanting. Knowing this, the object of the skilful farmer will be to supply the deficiencies, in a way the most acceptable to plants. Some crops may be repeated on the same soil more frequently than others, because some consume more of the alkalies than others. One hundred parts of the stalks of wheat yield 15.5 parts of ashes. The same quantity of barley, 8.54 parts; and of oats, only 4.42 parts. Thus, as the demands of each of these plants for the alkaline elements of their growth is different, one may be raised on ground which has ceased to produce the others; and this is what is daily witnessed,—land, refusing to yield wheat, and yet affording good crops of barley and oats;—and when ceasing to yield compensating crops of wheat and barley, still affording excellent crops of oats, the proportion of alkali required by which is so comparatively small compared with the demands of the wheat-crop. How readily, then, may a good soil for oats be rendered productive in wheat by the simple addition of some alkaline dressing, all the other requisites of fertility having been before present. Chemistry teaches that the salts and other organic constituents removed from soils in the crops, is returned in the dung of animals fed upon such crops. It teaches the precise proportions of these, and explains the well-known facts,—that the excrements of some animals, such as man, are more fertilizing than those of others; that those of men living upon animal food are stronger than those of men confined to vegetable food. All these matters may be found explained under the different heads of *Animal Manures*, *Ammonia*, *Nitrogen*, &c. Men of science engaged in these useful subjects of investigation, are every day unfolding new and important facts, and what at one time was regarded as inscrutable mystery becomes so well understood as to be comprehended by a child.

CHERRY TREE (*Prunus Cerasus*). It derives its name from Cerasus, a city of Pontus, whence the tree was brought by Lucullus, about half a century before the Christian era.

It soon after spread into most parts of Europe, and is supposed to have been carried to Britain about a century after it came to Rome. The cherry is pretty generally cultivated throughout the kingdom, as an agreeable summer fruit. The varieties are very numerous. The Horticultural Society's Catalogue embraces 246; but the following list is recommended by Mawe, as containing the best varieties for general cultivation, the whole being arranged in the order in which they ripen in England:—*June*: Early May, May Duke, Knight's Early Black, and Late Duke. *July*: Archduke, Black Tartarian, White Tartarian, Black Eagle, Kentish, Bigarreau, Holmon's Duke, Elton, Herefordshire Heart, Bleeding Heart, Carnation, and Waterloo. *August*: Harrison's Heart, Black Heart, Waterloo, Couronne, Lukeward, Black Geen, Small Black, Small Red Wild, White Swiss, Lundie Geen, Transparent Geen, Cluster, Yellow Spanish. *September*: Florence, Amber Heart, Flemish Heart, Red Heart, White Heart. *October*: Morello or Milan. For small gardens, either as wall trees, espaliers, or standards, the following varieties are recommended:—The May Duke, Morello, Archduke, Black Heart, White Heart, Bigarreau, Harrison's Heart, and Kentish Cherries. Miller considers the common Red or Kentish, the Duke, and the Lukeward as the best trees for an orchard; they are plentiful bearers. This tree prefers a light dry sandy loam, with a free exposure. The wood of the cherry tree is close, takes a fine polish, and is not liable to split. It is used in the manufacture of chairs, musical instruments &c., and stained to imitate mahogany. The principal supplies of cherries for the London market are brought from the cherry orchards in Kent and Herts. The wild cherry tree is found frequently in the woods and hedges of England, and has round branches with a polished ash-coloured bark. The leaves, in all the varieties are simply folded flat while young, by which cherries differ from the Bullace tribe. (*Phil. Hist. Fruits*, p. 76; *Willich's Domestic Encyclopædia*; *McCulloch's Commercial Dictionary*; *Baxter's Library of Agriculture*; *Smith's Eng. Flora*, vol. ii. p. 354; *American Orchardist's Companion*; *Kenrick's New American Orchardist*, &c.)

CHERRY, WILD. Several kinds of wild cherry are found in the United States, and Michaux describes the following species.

Red Cherry Tree (Cerasus borealis). Red cherry. Small cherry; common only in the Northern States, (including the highlands in the northern parts of Pennsylvania), in Canada, New Brunswick, Nova Scotia. The tree attains a height of twenty-five or thirty feet, with a diameter of five or six inches. Flowers are collected in small white bunches, and the fruit, which is of a bright red colour, considerable size, and intensely acid taste, ripens in the month of July. The wood is fine grained and of a redish hue, but its inferior size limits its use in the mechanical arts. This species of cherry tree offers the same remarkable peculiarity with the canoe birch of reproducing itself, as it were, spontaneously in cleared grounds, and in such forests as have been

burnt, which is observable in spots where fire has been kindled by travellers. Of all the native species of North America, Michaux thinks the red cherry tree bears the greatest analogy to the cultivated cherry tree of Europe, and hence the most proper for receiving grafts, though it has been found difficult to make the grafts succeed.

Wild Cherry (Cerasus Virginiana). This is one of the largest productions of the American forests. Its wood is of an excellent quality and elegant appearance, and is usefully employed in the arts. In Maine, where the winter is long and intense, it hardly exceeds thirty or forty feet in height, and eight to twelve inches in diameter; in the southern and maritime parts of the Carolinas and of Georgia, where the soil is arid and sandy, it is rarely seen, and even when found on the banks of rivers its growth is stunted. A milder climate and more fertile soil favour its growth, and it abounds in Virginia, Pennsylvania, and all the Atlantic States, and also in Western New York, and Illinois, uniting with the overcup white oak, black walnut, honey locust, red elm, and coffee tree of the forests covering the fertile regions of the West. On the banks of the Ohio Michaux measured trees twelve to sixteen feet in circumference, and from eighty to one hundred feet in height, with undivided trunks of uniform size to the height of twenty-five or thirty feet.

The flowers of the wild cherry are white and collected in spikes. The fruit is about the size of a pea and nearly black, at maturity, soon after which, notwithstanding its abundance and bitterness, it is devoured by birds. It is employed either alone or mixed with cultivated cherries,—generally the morillos or mazzards—in making a domestic cordial called cherry bounce, which consists of an infusion of the cherries in rum or brandy with a certain quantity of sugar. It is a faint imitation of the *Kirschenwasser* of the Germans, and *Marasquin* of the Venetians, both of which liqueurs or cordials are prepared by distillation, from wild cherries found in the north and south of Europe.

The wood of this tree is highly valuable, being compact, fine-grained and brilliant, and not liable to warp when perfectly seasoned. When chosen near the ramification of the trunk it rivals mahogany in the beauty of its curls. The bark of the wild cherry tree infused in cold water and drank to the extent of half a pint or a pint a day is a popular and useful tonic.

Wild Orange Tree (Cerasus Caroliniana). This beautiful species of cherry tree is found in the Bahama Islands, to which, with the islands on the coast of the Carolinas, Georgia, and Florida it appears to be nearly confined. The fruit is small, oval, and nearly black, the greenish pulp which covers the soft stone not being eatable. The wild orange, as it is there called, is one of the most beautiful productions of the Southern States on the sea-board, where it is a favourite ornamental and shade tree. The flowers are more frequented by bees than those of any other southern tree.

CHERRY TREE BORER. See BORERS.

CHERRY-LAUREL (*Cerasus lauro-cerasus*).

This shrub is an exotic, although it is now naturalized to this climate, and was brought to Europe from Trebisonde, in 1576. It is an evergreen, with smooth bark, and short-stalked, oblong, lanceolate, remotely serrated, coriaceous, shining leaves, with two or four glands at their base. The flower is white, with round spreading petals, and the fruit a small, black drupe or cherry. The leaves of the cherry-laurel have long been employed both in medicine and in confectionary, on account of the agreeable odour and flavour of the bitter almond which they possess. They lose their odour after they are dried, but retain their flavour.

CHERRY TREE WEEVIL. See **PLUM TREE WEEVIL** and **CURCULIO**.

CHERVIL, GARDEN (*Cherophyllum sativum*). This herb grows in gardens, and sometimes wild in waste ground; perhaps the outcast of gardens. The flowers are white, and bitter-tasted; the seeds are smooth, furrowed, and large; altogether the plant resembles parsley, only the leaves are paler and more divided. The roots are given in decoction. Chervil is slightly diuretic; the cutters of simples distil a water from its leaves, which they consider excellent in colics. It is much used in France for salads; and is mentioned as a potherb by Gerarde. The parsley-leaved chervil (*Scandix cerifolium*) and fern-leaved chervil (*S. odorata*), are still cultivated by the Dutch for soups, salads, &c.; but in this country they are not often found in the kitchen garden. Seed may be said to be the only means of propagation, and the only sowing of this that can be depended upon must be performed in early autumn, immediately after it is ripe; for if kept until the following spring, it will seldom germinate; or if this first grade of vegetation takes place, the seedlings are generally weak, and die away during the hot weather.

The seed may be sown in drills eight inches apart, or broadcast; in either mode being only just covered. The plants are to be thinned to eight inches asunder, and to remain where they are raised. The only after-cultivation required by them is the keeping them clear of weeds.

CHESSEL. The mould or vat in which the cheese is formed. It is made of thick staves, generally of white or American oak, bound with two strong iron hoops to withstand the necessary pressure. The chessel is perforated with many small holes in the bottom and sides to let the whey drain out of the curd.

CHEST. The breast; or that part of an animal's body which contains the heart and the lungs.

CHEST-FOUNDER. In farriery, a disease incident to horses, which proceeds from inflammation about the chest and ribs.

CHESTNUT, or CHESNUT (*Fagus-castanea*). The species cultivated in England are the common or sweet chestnut, of which there are two kinds, the Spanish (*Cas. vesca*) and the American (*Cas. Americana*);—and the horse chestnut, which belongs to a distinct genus. The true chestnut tree flourishes on poor gravelly or sandy soils, and will thrive in any but

moist or marshy situations. It has been much questioned whether the chestnut is indigenous or exotic. It was at one time very common in England, and a great many chestnuts have been planted within the last thirty years. It is long-lived, grows to an immense size, and is very ornamental. The wood is hard and compact; when young, it is tough and flexible; but when old it is brittle and often shaky. When divested of its sap wood, this timber will stand in situations exposed to wet and dry longer than oak; and for gate-posts it ranks in durability next after the acacia, the yew, and probably it lasts longer than the larch. The nuts form an article for our dessert. In some parts of the continent they are frequently used as a substitute for bread, and form a large proportion of the food of the inhabitants. In England, during the three years ending with 1831, the entries of foreign chestnuts for home consumption averaged 20,948 bushels a year, and they pay a duty of 2s. per bushel.

The fruit is used either boiled, roasted, or in a raw state. Phillips informs us that in the south of France, in Italy, and Savoy, they are made into puddings, cakes, and bread. And "chestnuts stewed with cream make a much admired dish; they make excellent soup; and stewed and served with salt fish they are much admired." We are also further informed that there is now at Fortsworth, in Gloucestershire, a great chestnut tree, fifty-two feet round, which in 1150 was so remarkable that it was called *The great chestnut of Fortsworth*. And Marsham states that this tree is 1100 years old. Lastly, the timber of this tree is almost incorruptible, and more durable than oak. Its durability is commensurate with the long life of the tree. Corsica, it is said, exports annually of this fruit to the amount of 100,000 crowns. The American chestnut differs very little from that of Europe. The fruit is smaller, but equally good. Its growth is very rapid. The bark for tanning is superior to oak.

The chestnut is raised from the seeds, planted in autumn; the second year, they are transplanted, and fine varieties are extended by grafting. A sandy or gravelly loam, with a dry subsoil, best suits them.

The Spanish or Portuguese chestnut succeeds well in the United States, and produces fruit in about seven years from the seed. Its growth is more rapid than that of the native kind. The fruit is more than four times larger, and brings a much higher price in the market. It may be budded on the common chestnut, but is apt to overgrow the stock. The large Spanish chestnut deserves to be extensively propagated.

Michaux, in his *North American Sylva*, vol iii., gives the following directions for the culture of the chestnut:

"After the ground has been carefully loosened with the plough and harrow, lines are drawn six feet apart, in which holes abc. a foot in depth and diameter are formed, at the distances of four feet. A chestnut is placed in each corner of the hole, and covered with about three inches of earth. As the soil has been thoroughly subdued, the nuts will spring and strike root with facility. Early in the second

year, three of the young plants are removed from each hole, and only the most thriving is left. The third or fourth year, when the branches begin to interfere with each other, every second tree is suppressed. To insure its success, the plantation should be begun in March or April, with nuts that have been kept in the cellar during the winter, in sand or vegetable mould, and that have already begun to germinate."

Mr. Hopkins of Cayuga county, made some experiments in planting chestnuts. In his first attempt, he kept the nuts till the setting in of winter, or December, when he planted them four feet apart every way, and not one of them grew. The next year he procured a quantity of nuts as soon as gathered, planted them immediately, and covered them superficially with leaves and light earth, at the same distance as before. Most of them came up and grew well. There can be no doubt, where the ground is so situated as to be free from the attacks of squirrels, mice, &c., that immediate planting after the nuts are gathered is the best mode, otherwise the plan of Michaux may be preferred. The best soil is a clay loam. (*Tredgold's Princip. of Carpentry*; *McCulloch's Com. Dict.*; *Willich's Dom. Ency.*; *Phillip's Hist. of Fruits*, p. 84.)

CHESTNUT, HORSE (*Æsculus hippocastanum*). This ornamental tree, now so common throughout Europe, is a native of Asia. The first plant is said to have been brought into Europe by the celebrated botanist Clusius in a portmanteau. It is too well known to require description. The wood is soft and of little value. The fruit contains much nutritive matter, but it is combined with a nauseous bitter extractive, which renders it unfit for the food of man; but horses, kine, goats, and sheep are fond of it. The bark of the tree contains an astringent, bitter principle, which operates as a tonic. It has cured agues, and some authors affirm that it might be a substitute for the Peruvian bark; but trials and experience have not justified their opinion. Given in a decoction, made with an ounce of the bark to a pint of water, it may be advantageously taken, to strengthen the habit weakened by previous disease. See **BUCKEYE**.

CHEVIOT SHEEP. See **SHEEP**.

CHEWING-BALL. In farriery, the name of a medicine in the form of balls adapted to restore lost appetite in horses.

CHEWING THE CUD. The operation of leisurely re-chewing or masticating the food in ruminating animals, as the cow, sheep, &c.: by this means the food is more effectually broken down, and mixed with the saliva. If a ruminant animal ceases to chew the cud, immediate illness may be expected, as the digestive organs cannot act without this natural process. See an excellent article "On Rumination, or Chewing the Cud," in the *Quart. Journ. of Agr.*, p. 344. Rumination, in certain graminivorous animals, has plainly for one object a renewed and repeated introduction of oxygen, for a more minute mechanical division of the food only shortens the time required for solution. (*Liebig's Animal Chemistry*.)

CHICORY, or SUCCORY (*Cichorium inty-*

bus). An English perennial weed, the wild endive, common on the borders of corn-fields and poor gravelly soils; extensively cultivated in Belgium, Holland, and Germany. The cultivated variety was much brought into notice by the late Arthur Young, as a forage plant. He brought the seed from France in 1788, and grew it extensively on his own farm; and reports (*Annals of Agr.* xxxix.), "The quantity of seed required to sow one acre is 13 lbs. The root runs deep into the ground, and is white, fleshy, and yields a milky juice. On the Continent, the dried root is roasted and used instead of coffee, and it is now allowed by the excise to be mixed with coffee. The root contains a strong bitter, which may be extracted by infusion; it is also used in the brewing of beer to save hops." Mr. Gorrie (*Quart. Journ. of Agr.* N. S. vol. iv. p. 206) says, "No plant cultivated in this country will bring the cow-feeder nearly an equal return with the chicory." It should be added, however, that the leaves give a bad taste to the milk of the cows which eat them. (*Brit. Husb.* vol. iii. art. "Flem. Husb." p. 42.) And Von Thäer, in his *Principles of Agriculture* (2d ed. vol. iv. p. 322), asserts that it is extremely difficult to eradicate from the land, and has been found to materially impoverish the soil.

Wild succory, or chicory is becoming extensively naturalized in many parts of the United States. The species called *Endive*, (*C. endiva*), especially the variety called *Crispa* with very narrow and ragged leaves, is much cultivated in the vicinity of Philadelphia as an early salad. There are no native species of chicory in the United States. (*Flor. Cest.*)

When cultivated for soiling or feeding horses and cattle in the farm-yard, for which purpose it is admirably adapted, its rapid and luxuriant growth admits of its being cut three or four times a year.

When the roots are used as a substitute for coffee, they should be first cleaned, then put into an oven after the bread has been taken out, and allowed to remain until cool. Should once baking be not sufficient, the process is to be repeated, after which, mix with one-half of coffee.

The fresh root of chicory, when sliced and pressed, yields a juice which is slightly tonic; and has been used in chronic affections of the stomach, connected with torpid liver. See **ENDIVE**. (*Sinclair's Hort. Gram. Wob.* p. 412; *McCulloch's Com. Dict.*; *Willich's Dom. Encyc.*; *Brit. Husb.* vol. ii. p. 303.)

CHICK, or CHICKEN. See **POULTRY**.

CHICK PEA (*Cicer arictinum*). Pl. 7, t. A plant too delicate for field culture in England; but in the south of France it is grown for the same purpose as vetches in England. The seeds are used in Germany and some other parts of Europe as a substitute for coffee, and the plant is sometimes called the coffee-pea. It is called by the Spaniards, who cultivate it largely, *Garbanza*. It is likewise a great favourite with the French, who call it *Poischiche*. It grows well in several of the Middle States, where it might doubtless be made a valuable crop, as it maintains a high price in European markets.

In every part of America and the West Indian islands settled by Spaniards, they have always made the culture of the garbanza a primary object, and it is somewhat singular that it has not become better known and appreciated in the United States, in most parts of which it grows well. Trials made with it in the vicinity of Dover, Delaware, have proved very successful. The Spanish pea or garbanza, is perhaps the most delicious vegetable of its class ever placed upon the table, possessing, when served up in the manner of green peas, the flavour of these, mixed with that of green corn, or, as others think, something between the marrow fat pea and Lima bean. They do not yield so abundantly as the common pea, but both in a green and dry state are much superior in flavour and richness. A meal made of the dried garbanzas is much used in Paris and other parts of Europe for thickening soup, which it renders extremely fine. In Provence and other parts of southern Europe, the chick pea is a great favourite when roasted or parched, like ground or pea nuts, and hawked about the streets. In Paris, the dried garbanzas retail for about twenty-four cents per pound. They grow best in a rich sandy loam, and may be cultivated in rows, much after the manner of the common pea. Not being a trailing vine, they require no sticking, the plants growing only about eighteen or twenty inches high, and branching out so as very much to resemble a small locust tree or bunch of rue. The pods, are very short and round, containing only two, three, or four peas each, somewhat larger than common pulse. Being very tender, they will not, perhaps, bear to be planted at the same time with common peas. In Spain, where the chick pea is very abundant and in general use, two kinds are distinguished by the names of garbanzos and garbanzas, the last being the largest, most delicate, and tender. Those raised in Spain are considered superior to such as are the product of the south of France. The pellicle which covers them seems to be almost entirely removed by the process of cooking. After being dried they require soaking in cold water during the night previous to the day they are used. They do not seem to be the prey of any insect, and will keep sound and sweet for years. It is the *gram* of India. (*Paxton's Bot. Dict.*; *Low's Agr.* p. 286.)

CHICKWEED. A low, creeping weed, of which there are several varieties. The common chickweed, or stitch-wort (*Stellaria media*), has an annual, small, tapering root; flowering from March to December. Small birds and poultry eat the seeds, and whole herb; whence its name. Swine are extremely fond of it; and it is eaten by cows and horses; but is not relished by sheep, and is refused by goats. The herb may be boiled for the table like spinach: it is reported to be nutritive. This foreigner is extensively naturalized in the United States. It is a hardy little plant, and when the winters are mild in the Middle States, may be found in flower in every month of the year. (*Flor. Cestrica*.) The field chickweed (*Cerastium arvense*) is a perennial, from four inches to a foot in length, found in fields and on banks and hillocks, on a gravelly or chalky soil. In this

order there are seven other species of mouse-ear chickweed, viz., two kinds of broad-leaved (*C. vulgatum* and *C. latifolium*); the narrow-leaved (*C. viscosum*); the little mouse-ear (*C. semi-decandum*); the four-cleft (*C. tetrandum*); the alpine (*C. alpinum*); and the water (*C. aquaticum*). These call for no observation. The berry-bearing sort, which grows with smooth erect stalks, and the stamens longer than the petals, is the wild lychnis, or white behen, and is a very rambling weed, natural to most parts of England, frequently called spatting-poppy. Its roots are perennial, and strike so deep into the earth that they are not easily destroyed by the plough; for which reason, bunches of this plant are too common among corn, in land which has not been perfectly well tilled. Summer-fallowing, and carefully harrowing out the roots, which should then be burnt, is the best and most effectual remedy.

The common chickweed grows in almost every situation, in damp or even boggy woods, and on the driest gravel-walks in gardens. In its wild state, this plant frequently exceeds half a yard in height; and varies so much from the garden chickweed, that if a person were acquainted only with the latter, he would with difficulty recognise it in the woods. Its small white flowers, and pale green leaves spreading in all directions, sufficiently point it out to our notice. It may be considered as a natural barometer; for if the flowers are closed, it is a certain sign of rain, while, during dry weather, they are regularly open from nine o'clock in the morning till noon. The plant boiled in vinegar and salt is said to cleanse breakings-out or eruptions of the hands and legs. (*Smith's Eng. Flor.* vol. ii. p. 301; *Sinclair's Weeds*, p. 52; *Willich's Dom. Encyc.*)

CHILIAN CLOVER. This plant, which is called Spanish clover, and in South America, *Alfalfa*, is identical with luzerne. Two communications upon the subject, by a person who had spent some time in Chili, may be found in the 14th volume of the *American Farmer*, pages 108 and 153.

CHINCAPIN, or CHINQUEPIN (*Castanea pumila*). The limits of this American tree, which bears a very small kind of round and pointed chestnut, is bounded northward by the river Delaware, on which it is found to the distance of nearly 100 miles from Cape May. It is very common in Delaware and Maryland, still more so in the lower part of Virginia and other southern and Southwestern States both east and west of the Mississippi. It abounds most where the common chestnut is wanting. Though in its northern limits, this dwarf chestnut seldom rises higher than from six to ten feet; much further south it often grows to the height of thirty or forty feet, with a diameter of twelve or fifteen inches. The leaves, flower, and fruit-bur, resemble those of the common chestnut in miniature, being about half the size. The wood of the chincapin is finer-grained, more compact, heavier, and even more durable than that of the chestnut, and is admirably adapted for fence-posts, lasting in the ground more than forty years. But the tree rarely attains a size adapting it to such a useful purpose in agriculture.

A species of the chincapin (*Castanea alni-folia*), remarkable for its dwarf growth, is found in the Carolinas and Floridas. Mr. Nuttall, who met with it in the vicinity of Charleston, S. C., says it grows in small patches in sandy pine barrens, has creeping roots, and seldom exceeds a foot in height. The nut is larger than that of the other species of chincapins. (See *Nuttall's Supplement to Michaux.*)

CHINCH BUG. A name, which, from some resemblance to the bed-bug, especially in the disgusting smell, has been popularly applied to an insect often of late years occasioning wide-spread destruction in the wheat, Indian corn, and other grain fields of the South and Southwestern States. Not being able to find any scientific description of this insect and its habits, we shall of course be compelled to cull the best information we can collect from the most intelligent correspondents of agricultural periodicals, &c.

In the 7th volume of Ruffin's Farmer's Register, there are several communications relative to the chinch bug, some of which draw a most deplorable picture of its ravages in the old counties of Virginia, where they not only often destroy the corn, wheat, and other grain-crops, but lay waste the pastures. They are described as small and black, with white wings; in their form, close and compact, and about the size of a bed-bug. They creep on the ground, seldom using their wings, and appear to be hardy. Whatever crop they get into, they generally stick about the plants near the ground, although they may sometimes be seen scattered all over stalks of Indian corn, the blades, and even down into the bud. When they attack wheat, oats, &c., they cluster around the stalk in incredible numbers, and seem to suck out its substance, so that it soon withers and falls to the ground. When they take to the Indian corn, the stalk and leaves sometimes become perfectly black with them, for two feet from the ground, leaving not a spot of green to be seen, except about five or six inches of the tips of the blades, the bugs hanging to the lower portions like bees when swarming. "We are," says one of Dr. Ruffin's correspondents, "harvesting our wheat crop, in which they got rather too late to destroy it entirely, but on many farms have seriously injured it, many places in the fields being quite destroyed. On following after the scythes, you may see millions of the bugs, of all sizes and colours, red, black, and gray, running in the greatest consternation in every possible direction, seeking shelter under the sheaves of wheat, and bunches of grass, which may happen to be near. But all those on the borders of the field, and indeed on every part of it, very soon quit the dry and hard stubble for the more tender and juicy corn or oats, whichever may be nearest at hand; and now commences their havoc and dreadful devastation. We see the healthy, dark-green, luxuriant oat, which a few days before looked so beautiful and rich, turn pale, wither and die, almost at their very touch. It would seem exaggeration and almost incredible to state how very prolific this devouring insect is, their increase being so pro-

digiously great as to appear to be the work of magic.

"In one day and night they had been known to advance fifteen or twenty yards deep in a field, destroying as they proceed. Unless some kind dispensation of Providence delivers us from this ruthless enemy to the farming interest, it is impossible to say to what extent their ravages will, and may extend, in the course of a year or two. To us farmers, who are dependent on the productions of the earth, for our every thing, it is truly awful. And if their increase in future is commensurate with the past, it must be but a short time before this section of country will be laid waste by this dreadful depredator, and its inhabitants reduced to want and misery. Every attempt hitherto made to arrest their progress, or destroy them, has proved abortive. Some have attempted to drive them from their corn by pouring boiling water over them; a remedy, for the corn, as bad as the disease. Others try to stop their ingress to the corn-fields by digging ditches around the fields; but with no avail, as they are furnished with wings in a short time after they are hatched, and of course can easily fly over the ditches. Would it not be advisable always to sow clover, or some other tender grass, with all small grain, to induce the bug to remain in the field after the grain is taken away long enough to enable the corn crop to get size and age, so as not to be seriously injured by them? I have observed that the older the plant, the much less liable it is to be either injured or attacked." (*Farmer's Register.*)

Among the remedies proposed against this destructive insect, are the following:—Burning up the leaves and rubbish of any woods in the vicinity of grain fields, so as to kill the insects in their winter retreats; also the stalks of corn, &c., where they are often found. It is said that they are natives of the forest, and that where these are occasionally burnt they never become troublesome. Digging ditches so as to intercept the progress of the bugs, filling the excavations with straw in which the insects generally halt a little while, during which time the straw is to be burnt so as to carry destruction to the enemy. This operation is to be repeated during the day. Burning them up, corn and all, has been attended with advantage in preventing further destruction, and also put an end to the further multiplication of the swarm.

CHINE. In horsemanship, the back-bone, or ridge of the back. In pork, that part of the back which contains the back-bone.

CHISLEY LAND. Soil between sandy and clayey, containing a large admixture of small pebbles or gravel.

CHIVES or CIVES (*Allium schanoprasum*). This plant is a perennial, flowering in May and June. It is easily propagated by offsets of the roots. The time for making plantations is January or February: however, March is the month to be preferred to either; but if previously neglected, it may be performed as late as June. It is also planted in the autumn. They are to be inserted by the dibble, eight or ten inches apart, and eight or ten offsets in

each hole. The only cultivation required is to keep them free from weeds. By autumn they multiply into large-sized bunches; and if required may be taken up as soon as the leaves decay, and be stored, after the necessary precautions, as a substitute for the onion: the leaves, which are fit for use as long as they remain green, must, when required, be cut down close to the ground, when they will speedily be succeeded by others. (*G. W. Johnson's Kitch. Garden.*)

CHLORINE. One of the elements found always in vegetable substances, among the inorganic or mineral constituents derived from the soil. It is a kind of gas of a greenish colour, with a peculiarly strong odour, and so much heavier than common air, that, like carbonic acid gas, it may be poured from one vessel into another. A taper will burn in it, giving a feeble reddish light, which soon goes out. It exists in all fertile soils, not separate, but combined with soda, in the familiar form of common salt, every 10 lbs. of which contains about 6 lbs. of chlorine gas.

CHLORIDE OF SODIUM: *Muriate of Soda*, or *Common Salt*. This mineral production, so necessary to the wants of mankind, is universally distributed over the globe, either in solution, as in sea water and mineral springs, or in beds and solid rocks, forming mountains, from which it is procured in masses by blasting and regular mining operations. Most animals have an instinctive taste for this salt, and all fertile soils contain it, so that to the growth and well-being of both animals and vegetables, salt is indispensable. For its uses as a fertilizer, see **SALT**.

CHLORIDE OF SODA. A well known powerful disinfectant or destroyer of offensive smells, discovered and brought into use by a French chemist, who prepared from it a solution sold extensively under the name of **LABARRAQUE'S DISINFECTIVE SOLUTION**. It is employed by sprinkling in sick rooms, privies, &c. Like the chloride of lime, it possesses the extraordinary property of preventing or arresting animal and vegetable putrefaction, and of destroying those effluvia which are not only offensive to the smell but injurious to the health of men and other animals. To preserve animal bodies from putrefaction, or correct their offensive odours, the solution of chloride of soda may be applied by sprinkling or covering them with wet cloths. The chloride of *soda*, in which chlorine gas is combined with the alkali *soda*, must not be confounded with chloride of *sodium*, in which the same gas is united with the metallic base sodium, to form common salt.

CHLORIDE OF LIME. Commonly known as *Bleaching Salt*, or *Bleaching Powder*, is a dry grayish-white powder, possessing a hot penetrating taste, and, when pure, soluble in water. It is used by putting a few table-spoonfuls of the salt in a plate or shallow earthen vessel, and pouring on, from time to time, a little oil of vitriol or vinegar, which brings out the chlorine gas, that corrects offensive smells and deleterious airs in houses, privies, stables, &c. It has been proposed as a fertilizer.

Davy reports that he steeped some radish seeds for twelve hours in a solution of chlorine, some in nitric acid, some in very dilute oil of vitriol, some in a weak solution of green vitriol, and some in common water. "The seeds in so-

lutions of chlorine and ox-sulphate of iron threw out the germ in two days, those in nitric acid in three days, in sulphuric acid in five, and those in water in five. But in every case of premature germination, though the plume was very vigorous for a short time, yet it became at the end of a fortnight weak and sickly, and at that period less vigorous in its growth than the sprouts which had been naturally developed, so that there can be scarcely any useful application of these experiments. Too rapid growth and premature decay seem invariably connected in organized structures, and it is only by following the slow operations of natural causes that we are capable of making improvements." (*Agr. Chem.* p. 217.)

Chloride of lime is prepared in large quantities for the service of the bleachers in most of the manufacturing districts. It is composed, according to the analysis of Dr. Marcet, of

	Parts.
Chlorine - - - - -	63.23
Lime - - - - -	36.77
	100

Dr. Ingenhouz, in a paper published by the Board of Agriculture in 1816, remarks, in alluding to some experiments he had tried at Hertford in company with the Baron Dimsdale with various salts,—“Be it sufficient to say here, that of all the neutral salts we tried, the glauber salt did seem to be one of the best in promoting vegetation; and the steeping the seeds in water, impregnated with oxygenated marine salt (which is now employed in bleaching linen in an expeditious way), had a particularly beneficial effect in producing vigorous and early plants. We were somewhat astonished that those seeds, viz. of wheat, rye, barley, and oats, which had been steeped in the above mentioned oxygenated muriatic liquid, even during forty-eight hours, did thrive admirably well; whereas, the same seeds steeped during so long a time, in some of the other medicated liquids, were much hurt, or had lost their vegetative power. The same oxygenated liquid poured upon the ground had also a beneficial effect.” These experiments of Ingenhouz were made, it appears, in 1795. See **SALTS**, their uses to vegetation. Leibig regards chloride of lime as a fertilizing salt, its virtues being similar to that of plaster of Paris, both of which, he says, fix the ammonia which is brought into the soil in rain water, which ammonia is indispensable for the nourishment of plants. A few table-spoonfuls of chloride of lime or bleaching salts, sprinkled occasionally in privies and other places where it may be required, corrects offensive odours. (*Brit. Farm. Mag.* vol. ii. p. 258; “*On Fertilizers*,” p. 366.)

CHOCOLATE is an alimentary preparation of very ancient use in Mexico, from which country it was introduced into Europe by the Spaniards in the year 1520, and by them long kept a secret from the rest of the world. Linnæus was so fond of it, that he gave the specific name, *theobroma*, food of the gods, to the cacao tree which produced it. The cacao beans lie in a fruit somewhat like a cucumber, about five inches long and three and a half

thick, which contains from 20 to 30 beans, arranged in five regular rows with partitions between, and which are surrounded with a rose-coloured spongy substance, like that of water-melons. There are fruits, however, so large as to contain from 40 to 50 beans. Those grown in the West India islands, Berbice and Demarara, are much smaller, and have only from 6 to 15; their development being less perfect than in South America. After the maturation of the fruit, when their green colour has changed to a dark-yellow, they are plucked, opened, their beans cleared of the marrowy substance, and spread out to dry in the air. Like almonds, they are covered with a thin skin or husk. In the West Indies they are immediately packed up for the market when they are dried; but in the Caraccas they are subjected to a species of slight fermentation, by putting them into tubs or chests, covering them with boards or stones, and turning them over every morning, to equalize the operation. They emit a good deal of moisture, lose the natural bitterness and acrimony of their taste by this process, as well as some of their weight. Instead of wooden tubs, pits or trenches dug in the ground are sometimes had recourse to for curing the beads; an operation called *earthing* (*terrer*). They are lastly exposed to the sun, and dried. The latter kind are reckoned the best; being larger, rougher, of a darker brown colour, and, when roasted, throw off their husk readily, and split into several irregular fragments; they have an agreeable, mild, bitterish taste, without acrimony. The Guinea and West India sorts are smaller, flatter, smoother-skinned, lighter-coloured, more sharp and bitter to the taste. They answer best for the extraction of the butter of cacao, but afford a less aromatic and agreeable chocolate. According to Lampadius, the kernels of the West India cacao beans contain, in 100 parts, besides water, 53.1 of fat or oil, 16.7 of an albuminous brown matter, which contains all the aroma of the bean, 10.91 of starch, $7\frac{3}{4}$ of gum or mucilage, 0.9 of lignine, and 2.01 of a reddish dye-stuff somewhat akin to the pigment of cochineal. The husks form twelve per cent. of the weight of the beans; they contain no fat, but, besides lignine, or woody fibre, which constitutes half their weight, they yield a light-brown mucilaginous extract by boiling in water. The fatty matter is of the consistence of tallow, white, of a mild, agreeable taste, called butter of cacao, and not apt to turn rancid by keeping. It melts only at 122° Fahr., and should, therefore, make tolerable candles. It is soluble in boiling alcohol, but precipitates in the cold. It is obtained by exposing the beans to strong pressure in canvass bags, after they have been steamed or soaked in boiling water for some time. From five to six ounces of butter may be thus obtained from a pound of cacao. It has a reddish tinge when first expressed, but it becomes white by boiling with water.

"The beans, being freed from all spoiled and mouldy portions, are to be gently roasted over a fire in an iron cylinder, with holes in its ends for allowing the vapors to escape; the apparatus being similar to a coffee-roaster. When the aroma begins to be well developed,

the roasting is known to be finished; and the beans must be turned out, cooled, and freed by fanning and sifting from their husks. The kernels are then to be converted into a paste, by trituration in a mortar heated to 130° Fahr. The chocolate paste has usually in France a little vanilla incorporated with it, and a considerable quantity of sugar, which varies from one-third of its weight to equal parts. For a pound and a half of cacao, one pod of vanilla is sufficient. Chocolate paste improves in its flavour by keeping, and should therefore be made in large quantities at a time. But the roasted beans soon lose their aroma, if exposed to the air.

"Chocolate is flavoured with cinnamon and cloves, in several countries, instead of the more expensive vanilla. In roasting the beans, the heat should be at first very slow, to give time to the humidity to escape; a quick fire hardens the surface, and injures the process. In putting the paste into the tin plate, or other moulds, it must be well shaken down, to insure its filling up all the cavities, and giving the sharp and polished impression so much admired by connoisseurs. Chocolate is, sometimes adulterated with starch; in which case it will form a pasty consistenced mass when treated with boiling water. The harder the slab upon which the beans are triturated, the better; and hence porphyry is far preferable to marble. The grinding rollers of the mill should be made of iron, and kept very clean." (*Ure's Dict. of Arts, &c.*)

A substance called *theobromin* has been recently obtained from chocolate by a European chemist. It contains thirty-five per cent. of nitrogen, a larger proportion than that contained in *cafféine*.

CHOKE-DAMP, a common term applied to a kind of foul air, often met with in wells, pits, mines, &c. It consists of carbonic acid gas, with or without a mixture of nitrogen. It is a source of great danger to persons descending into wells and pits. See **CARBONIC ACID GASS**.

CHOLIC, or COLIC. See **HORSES, CATTLE, SHEEP, DISEASES OF**.

CHOPPER, HAY. See **CHAFF-ENGINES**. A new and very efficient straw-cutter under the title of the "Canadian Straw and Hay-chopper," is figured and described in the *Trans. High. Soc.* vol. vi. p. 336. One person driving the machine can, it is said, cut with ease 5 cwt. of hay or straw in an hour.

CHOUGH, or RED LEGGED CROW (*Fregilus graculus*). The plumage of this British bird is uniformly black, glossed with blue; beak, legs, and toes, vermilion red; claws, black.

CHRONIC COUGH. In horses, this is a frequent consequence of chest diseases. In a few instances this seems to be connected with worms; and if the coat is unthrifty, the flanks tucked up, and there is mucus around the anus, it will be proper to put the connexion between the worms and the cough to the test; otherwise a sedative medicine may suffice to allay the irritation. (*Clater's Far.* p. 123.)

CHRYSALIS. Many worms or larvæ, after they have attained their full growth, leave off eating entirely and remain at rest in a death-like sleep. This is called the *pupa* state, from

a fancied resemblance to the manner in which the Roman children were trussed in bandages. The pupæ from caterpillars are most commonly called *chrysalids* and *aurelia*. Grubs, after their transformation, are often called *nymphs*. Having passed through its change, the insect merges from its chrysalis, or pupa, perforates the shell and silken envelope, and makes its appearance in a winged form, which is its last or perfect state.

"In every species there may be distinguished two sides; the one of which is the back, and the other the belly of the animal. On the anterior part of the latter there may always be observed certain little elevations running in ridges: the other side, or the back, in most of the chrysalises, is smooth, and of a rounded figure: but some have ridges on the anterior part and sides of this part, usually terminating in a point and making an angular appearance. From this difference is drawn the first general distinction of these bodies, by which they are divided into two classes; the round and the angular. The first, French naturalists call *feves*; the chrysalis of the silk-worm being of this description, and so named. This division is extremely convenient to classification, the *phalanæ* or moths being almost universally produced by the rounded chrysalises, and the *papilios*, day-flies, from the angular. Among the latter, are some whose colours are as worthy of observation as the forms of others. Many of them appear superbly clothed in gold. These species obtained the names of *chrysalis* and *aurelia*; derived, the one from a Greek, the other from a Latin word, signifying *gold*." (*Domestic Ency.*)

CHURN (ceɹnan; Goth. *kerna*; Dutch, *kernen*. Our old authors wrote it *cherne*, and *kern* is yet a local word, and generally used north of the Tweed). A vessel in which cream is coagulated by long and violent agitation. There are many different kinds of churns, but those most generally used are the upright or Dutch plunge churn and the barrel-churn. In large dairies churns are frequently turned by means of a horse; this is particularly the case in Flanders, where churns are used which will make forty or fifty pounds of butter at a time. In the large dairies of Cheshire they are now often driven by small high pressure steam-engines. On such farms as have thrashing-mills, churns might be very conveniently attached to and wrought by them. An improved butter-churn by Mr. C. Harley of Fenchurch-street, and another by Mr. W. Bowler, to which the Society for the Improvement of the Arts, &c., awarded a prize of thirty guineas, are described in *Willich's Domestic Encyc.* Churns should admit the air; and hence it has been argued that the common churn, which allows this most conveniently, is, after all, the best.

CIBOULE, or **WELSH ONION**. See **ONION**.

CICADA. See **GRASSHOPPER** and **LOCUSTS**.

CIDER, or **CYDER** (Fr. *cidre*; Ger. *zider*; Ital. *cidro*; Russ. *sidor*; Span. *sidra*). A sharp and vinous beverage made by fermenting the juice of apples.

Cider, or the fermented juice of the apple, constitutes the principal vinous beverage of the

citizens of New England, of the Middle States, and of the older states of the West. Good cider is deemed a pleasant, wholesome liquor, during the heats of summer; and Mr. Knight has asserted, and also eminent medical men, that strong, astringent ciders have been found to produce nearly the same effect in cases of putrid fever as Port wine.

The unfermented juice of the apple consists of water and a peculiar acid called the *malic acid*, combined with the saccharine principle. Where a just proportion of the latter is wanting, the liquor will be poor and watery, without body, very difficult to preserve and manage. In the process of fermentation, the saccharine principle is in part converted to alcohol. Where the proportion of the saccharine principle is wanting, the deficiency must be supplied, either by the addition of a saccharine substance before fermentation, or by the addition of alcohol after fermentation; for every one must know that all good wine or cider contains it, elaborated by fermentation, either in the cask or in the reservoirs at the distillery. The best and the cheapest kind is the *neutral spirit*—a highly rectified and tasteless spirit, obtained from New England rum. Some, however, object to any addition of either sugar or alcohol to supply deficiencies, forgetful that these substances are the very elements of which all wine, cider, and vinous liquors are composed.

The strength of the cider depends on the specific gravity of the juice on expression: this may be easily ascertained by weighing, or by the hydrometer.

According to the experiments of Major Adlum, of Georgetown, District of Columbia, it appeared that when two pounds of sugar were dissolved in a gallon of rain water, the bulk occupied by 1000 grains of rain water weighed 1087 grains. From this it would appear that the juice produced by the best known apple contains about two pounds of sugar in a gallon. Mr. Marshall has asserted that a gentleman, Mr. Bellamy, of Herefordshire, England, has by skill "produced cider from an apple called Hagloe Crab, which, for richness, flavour, and price on the spot, exceeds, perhaps, every other liquor which nature or art has produced. He has been offered sixty guineas for a hogshead of 110 gallons of this liquor." Newark, in New Jersey, is reputed one of the most famous places in America for its cider. The cider apple most celebrated there is the Harrison apple, a native fruit; and cider made from this fruit, when fined and fit for bottling, frequently brings \$10 per barrel, according to Mr. Coxe. This and the Hughs' Virginia Crab are the two most celebrated cider apples of America. Old trees, growing in dry soils, produce, it is said, the best cider. A good cider apple is saccharine and astringent.

To make good cider, the first requisite is suitable fruit; it is equally necessary that the fruit should be not merely mellow, but *thoroughly mature*, rotten apples being excluded; and ripe, if possible, at the suitable period, or about the first of November, or from the first to the middle, after the excessive heat of the season:

is past, and while sufficient warmth yet remains to enable the fermentation to progress slowly, as it ought.

The fruit should be gathered by hand, or shaken from the tree in dry weather, when it is at perfect maturity; and the ground should be covered with coarse cloths or Russia mats beneath, to prevent bruising, and consequent rottenness, before the grinding commences. Unripe fruit should be laid in large masses, protected from dews and rain, to sweat and hurry on its maturity, when the suitable time for making approaches. The earlier fruits should be laid in thin layers on stagings, to preserve them to the suitable period for making, protected alike from rain and dews, and where they may be benefited by currents of cool, dry air.

Each variety should be kept separate, that those ripening at the same period may be ground together.

In grinding, the most perfect machinery should be used to reduce the whole fruit, skin, and seeds to a fine pulp. This should, if possible, be performed in cool weather. The late Joseph Cooper, of New Jersey, has observed emphatically, that "*the longer a cheese lies after being ground, before pressing, the better for the cider, provided it escapes fermentation until the pressing is completed;*" and he further observes, "that a sour apple, after being bruised on one side, becomes rich and sweet after it has changed to a brown colour, while it yet retains its acid taste on the opposite side." When the pomace united to the juice is thus suffered for a time to remain, it undergoes a chemical change; the saccharine principle is developed; it will be found rich and sweet; sugar is in this case produced by the prolonged union of the bruised pulp and juice, which could never have been formed in that quantity had they been sooner separated.

Mr. Jonathan Rice, of Marlborough, who made the premium cider so much admired at Concord, Massachusetts, appears so sensible of the important effects of mature or *fully ripe* fruit, that, provided this is the case, he is willing even to forego the disadvantage of having a portion of them quite rotten. Let me observe, that this rottenness must be the effect, in part, of bruises by improper modes of gathering, or by improper mixtures of ripe and unripe fruit. He always chooses cool weather for the operation of grinding; and, instead of suffering the pomace to remain but twenty-four or forty-eight hours at most before pressing, as others have directed, he suffers it to remain from *a week to ten days*, provided the weather will admit, stirring the mass daily till it is put to the press. See his communication in vol. vii. p. 123, *N. E. Farmer*.

The first fermentation in cider is termed the vinous; in this the sugar is decomposed, and loses its sweetness, and is converted into alcohol; if the fermentation goes on too rapidly, the cider is injured; a portion of alcohol passes off with the carbonic acid.

The design of frequent rackings is principally to restrain the fermentation; but it seems to be generally acknowledged that it weakens the liquor. It is not generally practised, al-

though the finest cider is often produced by this mode.

Various other modes are adopted with the view of restraining fermentation, one of which is the following. After a few gallons of cider are poured into the hogshead into which the cider is to be placed when racked off, a rag six inches long, previously dipped in melted brimstone, is attached by a wire to a very long, tapering bung; on the match being lighted the bung is loosely inserted; after this is consumed, the cask is rolled or tumbled till the liquor has imbibed the gas, and then filled with the liquid. This checks the fermentation. Yet the French writers assure us that the effect of much sulphuring must necessarily render such liquors unwholesome.

Black oxide of manganese has a similar effect; the crude oxide is rendered friable by being repeatedly heated red hot, and as often suddenly cooled by immersion in cold water. When finely pulverised, it is exposed for a while to the atmosphere, till it has imbibed again the oxygen which had been expelled by fire. An ounce of powder is deemed sufficient for a barrel. If the cider is desired to be very sweet, it must be added before fermentation, otherwise not till afterwards. Mr. Knight, from his long experience and observation in a country (Herefordshire, England) famous for its cider, has lately, in a letter to the Hon. John Lowell, stated that the acetous fermentation generally takes place during the progress of the vinous, and that the liquor from the commencement is imbibing oxygen at its surface. He highly recommends that new charcoal, in a finely pulverized state, be added to the liquor as it comes from the press, in the proportion of eight pounds to the hogshead, to be intimately incorporated; "this makes the liquor at first as black as ink, but it finally becomes remarkably fine."

Dr. Darwin has recommended that the liquor, as soon as the pulp has risen, should be placed in a cool situation, in casks of remarkable strength, and the liquor closely confined from the beginning. The experiment has been tried with good success; the fermentation goes on slowly, and an excellent cider is generally the result.

A handful of well-powdered clay to a barrel is said to check the fermentation. This is stated by Dr. Mease. And with the view of preventing the escape of the carbonic acid, and to prevent the liquid from imbibing oxygen from the atmosphere, a pint of olive oil has been recommended to each hogshead. The excellent cider exhibited by Mr. Rice was prepared by adding two gallons of New England rum to each barrel when first made. In February or March it was racked off in clear weather, and two quarts more of New England rum added to each barrel. Cider well fermented may be frozen down to any requisite degree of strength. In freezing, the watery parts are separated and freeze first, and the stronger parts are drawn off from the centre.—I finish by adding the following general rules; they will answer for all general purposes; they are the conclusions from what is previously stated:

1. Gather the fruit according to the foregoing

rules; let it be *thoroughly ripe* when ground, which should be about the middle of November. 2. Let the pomace remain from two to four days, according to the state of the weather, stirring it every day till it is put to the press. 3. If the liquor is deficient in the saccharine principle, the defect may be remedied in the beginning by the addition of saccharine substances or alcohol. 4. Let the liquor be immediately placed in a cool cellar, in *remarkably strong, tight, sweet* casks; after the pulp has all overflowed, confine the liquor down by driving the bung hard and by sealing; a vent must be left, and the spile carefully drawn at times, but only when absolutely necessary to prevent the cask from bursting. The charcoal, as recommended by Mr. Knight, deserves trial.

Fresh and sweet pomace directly from the press, and boiled or steamed and mixed with a small portion of meal, is a valuable article of food, or for fattening horses, cattle, and swine.

Sour casks are purified by pouring in a small quantity of hot water, and adding unslacked lime; bung up the cask, and continue shaking it till the lime is slacked. Soda and chloride of lime are good for purifying. When casks are emptied to be laid by, let them be thoroughly rinsed with water and drained, then pour into each a pint of cheap alcohol, shake the cask and bung it tight, and it will remain sweet for years. Musty casks should be condemned to other uses. Cider should not be bottled till *perfectly fine*, otherwise it may burst the bottles. The bottles should be strong, and filled to the bottom of the neck. After standing an hour, they should be corked with velvet corks. The lower end of the cork is held for an instant in hot water, and it is then instantly after driven down with a mallet. The bottles must be either sealed or laid on their sides in boxes, or in the bottom of a cellar, and covered with layers of sand.

Most of the above information relative to cider-making is derived from the *American Orchardist*, by W. Kenrick, of Boston, Massachusetts, whose list of apple and other nursery trees comprehends almost every kind desirable for any purpose.

The reader will find very explicit instructions for the manufacture of cider in the *Penny Cyclop.* vol. vii. p. 161; in the *Lib. of Useful Know.*; *Brit. Husb.* vol. ii. p. 364; *Low's Pract. Agr.* p. 379; Croker, *On the Art of Making and Managing Cyder*; in the *Quart. Journ. of Agr.* vol. viii. p. 332, by Mr. Towers; and in *Baxter's Agr. Lib.* p. 135, by Andrew Crosse, Esq., of Somerset. The following instructions for making cider are by a Devonshire lady.

Gather the fruit when ripe; let it remain in a heap till the apples begin to get damp, then grind them in a mill (similar to a malt mill); take the pulp and put it into a large press like a cheese-press, only on a much larger scale place a layer of reed in the bottom of the vat and a layer of pulp alternately until the vat is full. The vat is square, and the ends of the reed must be allowed to turn over every layer of pulp, so as to keep it from being pressed out at the sides: the layers of pulp must be five or six inches thick. When you have

finished making your cheese, press it as hard as you can, and let it remain three or four hours; then cut down the corners of it, and lay them on the top with reed as before; then press it again, and allow it to remain for another three or four hours. Repeat this process as long as necessary, or until the cheese is quite dry. It takes seven bags of apples for one hogshead of cider, and the vat ought to be large enough to make from three to four hogsheads at a time. The best sort of apple to make mild cider is the hard bitter-sweet. Any sort of sour apple will do to make the harsh cider. The liquor must be strained through a fine sieve into a large vessel, and allowed to ferment for three or four days, taking off the scum as it rises; then rack it, and put it into casks stopped down quite close. Before the cider is put into the cask, a match made of new linen and attached to a wire is lighted and put into the cask, and the bung is put in to keep the wire from falling into it. After a few minutes the match is removed, and the cider poured into the cask while yet full of the smoke.

A person would require three or four years' experience before he would be qualified to superintend the making of sweet or made cider. Much depends on the year, or rather on the ripening of the apples; it should be the *second*, not the *first falling*; and the "green bitter-sweet" and the "pocket apple" are the best for making it. After pounding, isinglass and brimstone are used to sweeten and fine it, and many other ingredients. (*A. M. K.*)

The *sweet cider*, above described, is distinct from the other two kinds of cider (the harsh and mild). Cider, according to Brande, contains about 9.87 parts per cent. of alcohol. It is a wholesome beverage for those who use much bodily exercise. (*Willich's Dom. Ency.*; *McCulloch's Com. Dict.*)

CINQUE-FOIL, COMMON CREEPING, or FIVE FINGERED GRASS (*Potentilla reptans*). This creeping plant is common about waysides, and in meadows and pastures in England, where it is a perennial, flowering in June. Its stalks are round, smooth, and red, lying upon the ground, and taking root at the joints. The leaves stand five in number on each foot-stalk, long and narrow in form, and indented at the edges. The flowers are large, of a bright yellow colour, standing upon long foot-stalks. The root is long and large, covered with a brown rind. Smith (*Eng. Flora*, vol. ii. p. 423) describes this and ten other species of cinque-foil, all belonging to the same genus. The root is the medicinal part, and once was an officinal plant; but is now discarded: dig it up in April, take off the outer bark or rind, and dry it. The powdered bark of the root is astringent.

There are a dozen or more species of *cinque-foil* in the United States, among which is that usually called the barren strawberry (*Potentilla Pennsylvanica*). It is a small, perennial, creeping plant, very frequent on road-sides, fence-rows, and banks, having thick, branching, fibrous roots. The petals of the flowers are bright-yellow, the first flowers often appearing when the stems are very short, but others appear afterwards on runners, which

runners resemble those of the strawberry. This common kind of cinque-foil in the Middle and Northern States is frequent in worn-out and neglected fields, and, where abundant, indicates thriftless farming. The Latin name of the genus is derived from *potens*, powerful; in reference to the supposed medical virtues of the cinque-foil family. Another species, commonly called five-fingers (*Potentilla simplex*), is also a very common, yellow flowered perennial, along the borders of woods, &c.

CINQUE-FOIL, PURPLE MARSH (*Comarum palustre*). A perennial, found in spongy, muddy bogs and ditches. Root, creeping extensively, with many long fibres. Stems, round, reddish, a foot or more in height. Flowers, several, without scent, but handsome, an inch broad, all over of a dark purplish blood colour, as well as the fruit. They appear in June. (*Smith's Eng. Flora*, vol. ii. p. 433.)

CITRIC ACIDS. Acids contained in lemons and some other kinds of fruit. See ACIDS, VEGETABLE.

CLARY, or SAGE (*Salvia*). *Smith (Eng. Flora*, vol. i. p. 34) describes two kinds, the meadow clary (*S. pratensis*), and wild English clary (*S. verbenaca*). The first is very uncommon, but sometimes met with in dry meadows and about hedges; grows three feet high, erect; not very aromatic; leaves, dark-green; flowers, large and handsome, of a fine purplish blue. The second species is more common on gravelly or chalky soils, a foot or eighteen inches high; leaves, grayish-green; flowers, small, violet-blue. Seeds, black, smooth; blows from June to October. This plant is of great virtue, and is kept in gardens on account of its excellent flavour. The whole herb is medicinal, and is equally good, freshly gathered, or dried. It is cordial and astringent in its quality.

CLASPERS. The threads or tendrils of creeping plants.
