 v.23

REV. H. T. ELLACOMBE, M.A., F.S.A.

AN

ILLUSTRATED WEEKLY JOURNAL

OF

HORTICULTURE IN ALL ITS BRANCHES.

FOUNDED BY

W. Robinson, F.L.S., Author of "Alpine Flowers," etc.

You see, sweet maid, we marry
A gentle scion to the wildest stock
And make conceive a bark of baser kind
By bud of nobler race: This is an art
Which does mend nature: change it rather
'The art itself is nature'—*Shakespeare.*

VOL. XXIII.—MIDSUMMER, 1883.

LONDON:

OFFICE: 37, SOUTHAMPTON STREET, COVENT GARDEN, W.C.

TO THE

REV. H. T. ELLACOMBE, M.A., F.S.A.,

Of Clyst St. George (formerly of Bitton),

"A GRAND OLD GARDENER."

THE TWENTY-THIRD VOLUME OF "THE GARDEN"

IS DEDICATED.

W. R., June, 1883.

INDEX TO VOLUME XXIII.

A.

Abonia villosa, 116
Abutilon and *Hibiscus*, a cross between, 301
Abutilon, cultivated species of, 225;
 venosum, 238; vexillarium, 288; viti-
 folium, 224, 264
Abutilons in winter, 193
Acacia dealbata, 8; Drummondii, 290;
 lineata, 299
Acacias at Kew, 440
Acanthophippium Curtisi, 457
Acer crataegifolium variegatum, 551,
 576; insignis, 520; polymorphum, 576;
 macrophyllum, 553
Acers, ornamental, 507
Aconite, Golden, 9
Acroclinium roseum fl. pl., 117
Ada aurantiaca, 291, 344
 Adaptations of plants, lecture on, 323
Adenocarpus decorticans, 349
 Adhesion in trees, 98
Adiantum cydoniaefolia, 178
Adiantum dolabriforme, 534; *Novae*
Caledoniae, 547, 551; the genus, 9, 62;
 coloured fronds of, 486
Adiantopsis radiata, 78
Echmea Lalindei, 297
Ethionema grandiflorum, 508
Agave, a new, 97
Ageratum, *Perle Bleu*, 402
Ageratum, two new, 220
Aglaomorpha Meyeniana, 78
Ailanthus, sex of the, 258
Alexandra Park, the, 296, 344, 539; the
 future of the, 280
Allamanda violacea, 30, 343
Alibertia intermedia, 97
Allium giganteum, 492; *Ostrowskianum*,
 462
 Almond blossom, forcing, 174
Alnus cordata, 221
Alnus Peacocki, 106
 Alpine flowers, books on, 514; exhibit-
 ing, 568
 Alpine garden, winter colouring in the,
 281
 Alps, notes from the Southern, 466, 490,
 512, 535, 538, 601
Alsophila, the genus, 78
Amaryllis acis, 168; *Adolphus Kent*,
 389; at Chelsea, 193; Byron, 300; Dr.
 Hogg, 256; A. F. Barron, 256; George
 Gordon, 256; Henry Little, 302; Ho-
 mer, 302; Lady of the Lake, 300; lec-
 ture on the, 313; Mrs. Burbridge, 392;
 Mrs. Garfield, 312; Queen of Holland,
 392; Southey, 302; Star of India, 457;
 Tennyson, 300; Thomas Moore, 392;
 Wordsworth, 300; Achillea, 168
Amaryllisea at Upper Holloway, 298; at
 Westouber, 348; hybrid, 313; new,
 60; prizes for, 148
American Aloe in flower, 395
American notes, 20, 69, 97, 144, 184, 212,
 258, 295, 370, 515
America, Orchids in, 292
 American Pomological Society, 412
Amherstia nobilis, 300
Ampelopsis Veitchi, 562
Andea, plants from the, 557
Andromeda japonica, 213, 302
Androsace carnea, 400
Anemone apennina, 272, 379, 393; blan-
 da, 106; *cœrulea*, 377; *coronaria*, 311;
 Empress, 443; raising, 500; The Bride,
 299; fulgens, 213, 245; *nemorosa alba*,
 379; *paniculata*, 506; the Pau, 220;
coronaria, varieties of, 400
Anemone, garden, 189, 500; in winter,
 28; single, 57; soil for, 163, 236;
 spring, 332; summer, 505; Victoria,
 398
Anemia, the genus, 129
Angræcum citratum, 44, 171; *eburneum*,
 44; *modestum*, 520; *sequepedale*, 52,
 168, 170, 216

Annuals, sowing, 84, 378; tender, 358
Angiopteris evecta, 129
Anthericum Liliago, 567
Anthurium andegavense, 411; *Andrea-*
num, 502, 553; a large, 348; well grown,
 106; *articulatum*, 299; *ferriense*,
 299; *Gustavi*, 412; *Scherzerianum*,
 new forms of, 368; *Warocqueanum*,
 419
Antirrhinums, dwarf, 544
 Ants, 192, 214
 Ants and Peach blooms, 27
Apbelandra aurantiaca, 28; *nitens*, 28;
pumila splendens, 214; *punctata*, 79
 Aphides and sulphur fumes, 361
 Aphides and their food, 214, 256
Aponogeton distachyon, 79; and mice,
 50, 116
Aponogeton distachyon dying off, 189
 Apple and Pear show, 92
 Apple, Blenheim Orange, origin of, 459;
 Bramley's Seedling, 395; Coe's Quince,
 20; Newtown Pippin, 96; Switzer, 70;
 Warner's Seedling, 258
 Apples, American, 149; attacked by
 caterpillars, 548; Australian, paper on,
 487; for export, 370; red, 20; well
 preserved, 347
 Apricot, the Musch-Musch, 350
 April flowers, 423
Aquilegia cœrulea alba, 116; glandulosa,
 500, 503, 510; Stuarti, 510
Aralia gemma, 214
Araucaria, a fine, at Woodstock, 185
 Arboretum, the Arnold, 124
Arbutus Milleri, 440
Arctotis speciosa, 520
Aristolochia Sipho, 139
 Aroids, hardy, 544; propagating, 381
 Arnold arboretum, the, 124
 Artichoke, the Jerusalem, 43, 236
 Artichokes, Globe, 592
 Arum *Dioscoridis*, 412
 Arum Lilies, 43; finely grown, 28
 Asparagus beds, 515
 Asparagus competition, the, 482; forc-
 ing, 17; or Buda Kale, 475; prize com-
 petition, 547, 575; sowing and plant-
 ing, 311, 593; for ornament, 580
Aspidium, the genus, 129
Asplenium, the genus, 218, 279
Aster alpinus, 533, 554; *peregrinus*, 502
 Asters for cutting, 114
Athyrium Filix-femina kalothrix, 551;
 the genus, 316
Atragene cœrulea, 311
 Aucuba as a pot plant, 264
Auricula, A. Lloyd, 435; Dr. Hogg, 392;
 Conservative, 392; culture at Roch-
 dale, 72; delicate, 435; florists', 529;
 hardness of, 498; Homer, 435; notes
 by the way, 163; Onda, 457; resplen-
 dens, 435, 457; Richard Gorton, 457;
 Rob Roy, 435, 457; Roysterer, 435
Auricula, the, 363
Auriculas, alpine, 288, 393; and show,
 521
Auriculas and Polyanthus, 134, 347; for
 bedding, 223; new, 59, 391, 397; show,
 168; show and alpine, 187; surface
 dressing, 109
 Australian Apples, 445
 Australian fruits, 323
 Autumn transplanting, 307
 Avenues of Beeches, 240
 Avenues, sheltered, 184
 Avocado Pear in Madeira, 354
Azalea Antigone, 389; Baron N. Roths-
 child, 412, 435, 457; Comte de Cham-
 bord, 435; Deutsche Perle, 256, 392;
 Dr. Hermann Weigel, 482; Duchess of
 Albany, 45; J. N. Verschaffelt, 301;
 mollis, 508; for forcing, 468; Madame
 Van Houtte, 457; obtusa alba, 304;
 pontica narissiflora, 59; Princess
 Louise, 435; rhombica, 417; rosaceflora,
 503; Souvenir de Prince Napoleon,
 435; glauca, 585
 Azaleas, culture of, 19; hybrid, 502;
 Indian, out of doors, 503; new, 387

Azaleas at Ghent, 366
Azolla pinuata, 438

B.

Babiana ringens, 2
 Baden-Baden, new and rare plants at,
 520
Balanium, the genus, 316
 Balsams from seeds, 77
 Bamboos, hardy, 131
 Banana trade in Jamaica, 71
 Banks for Tea Roses, 78
 Banner plant, the, 445
Barbacia purpurea, 394
 Barton Hall, 511
Batemannia Burti, 492
 Battersea, new palace at, 322
 Battersea Park, 528
Beaufortia sparsa, 404; *splendens*, 404
 Bean, Dutch or Case Kidney, 166; John
 Harrison, 43; the Lima, 72; White-
 seeded Kidney, 571
 Beans, Flageolet, 551; French, forcing,
 16; Lima, 45; Runner, culture of,
 407
 Bedford, new park at, 216
 Beds in span-roofed stove, 284
 Beech avenues, 240
Begonia Canary Bird, 457; *Clarinda*,
 457; Dr. Duke, 457, 482; *Frœbeli*,
 198; *glaucophylla*, 410; *gogoensis*,
 457; *Little Gem*, 457; *Marchioness of*
Bute, 551; Mrs. Anson, 551; Mrs.
 Foster, 551; Novelty, 551; Orange
 Boven, 551; Prince of Wales, 457, 482;
 Roelzi, 79, 106; Sir Garnet, 457; wel-
 tenensis, 266; double flowered, 412;
 new Brazilian, 575
Begonias, fine foliaged, from seed, 76,
 374; new, 59; rare, 233; tuberous,
 357; for bedding, 198; at Stanstead,
 554
 Belgian horticulturists, congress of, 148
 Belgrove, flowering plants at, 236
Belladonna Lily, 53
 Bellflowers, 580
 Belvoir spring gardening, 379
Bonicasa cœrifera, 560
Benthamia fragifera, 82
Berberis Darwini and *japonica*, 441;
stenophylla, 82, 394, 477; *japonica*,
 477; *japonica* and rabbits, 346
 Berwickshire, notes from, 325
 Biennials, sowing, 596
Bignonia radicans, 139; *venusta* in Ma-
 deira, 353; *Unguicula*, 278; *speciosa*, 582
Billbergia Portea, 143; *Morelii*, 28
Billbergias, 582
 Birch, flow of sap in the, 376
 Bird-plant of Mexico, 457
 Birds and Wellingtonias, 157
 Birds, notes on, 303, 333, 348, 384, 402
 Birds and Primroses, 498; and slugs,
 455, 528, 533
 Birds, our song, 272
 Bit of garden, a, 21
 Blacking bottles for flowers, 416
Blandfordia flammea elegans, 502
Blandfordias, notes on, 169
 Blechnum, the genus, 316
 Bluebell and Halrbell, 523
 Bluebell in a London garden, 503
 Blue flowers, 426
 Blue Paris Daisy, the, 233
 Bodnant Hall, a visit to, 523
 Bog land, vegetables on, 230
 Boiler setting, 38, 54
Bomarea conferta, 79; *patacoccensis*, 520;
Caldasiana, 558
Bomarea in fruit, 109; the cultivated,
 84
 Bonrœul white Cucumber, 560
 BOOKS—
 "A Lady's Travels Round the World,"
 327
 "European Butterflies and Moths," 24

BOOKS—(Continued)

H. T. ELLACOMBE, M.A., F.S.A.

WE cannot give a more appropriate portrait for this volume of *THE GARDEN* than that of the Rev. H. T. Ellacombe, rector of Clyst St. George, Devon. Mr. Ellacombe was born in 1790, and was educated at Oriel College, Oxford, where, in 1812, he was enabled to add B.A. to his name. Between that year and 1816 he devoted himself to the study of engineering in Chatham Dockyard, under Brunel, and an account of his life as an engineer is given in Beamish's "Life of Sir J. Brunel," pp. 118-124, from which the following is an extract: "However much the Church may have gained by the accession of an active and earnest minister, it is certain that the civil engineering profession lost a conscientious and accomplished member. . . . Of a highly respectable family in Devonshire, directly descended from Sir Hugh Myddelton . . . and inheriting with his distinguished brother, General Sir Charles Ellacombe, R.E., many of the engineering qualifications of their ancestor, he was unable to resist the impulses of his nature, and every hour which he could command from his more serious studies was devoted to mechanical drawing and the construction of models. While still at Oxford he submitted to Brunel the result of his stolen hours, and the delicacy, accuracy, and beauty of the workmanship at once secured the favourable opinion of the great mechanist." In 1816 he took his M.A. degree, and was ordained deacon by the then Bishop of Exeter, and served as curate of Crickdale in 1816-17. He was ordained priest in 1817 by the Bishop of Gloucester, and entered on the curacy of Bitton in that diocese. Of this parish he was curate from 1817 to 1835, when he became vicar of it, and remained so till 1850. Church restoration and extension was not so universal in those days as it is now, yet Mr. Ellacombe, with indomitable energy, and in spite of many difficulties, did a great deal in that way, as well as in the building of schools and the education of the young. It is, however, with Mr. Ellacombe as a gardener we are most concerned. Few men have done more to promote the culture of both hardy plants and trees than he has done. When at Bitton he had a grand collection of them, the catalogue of which was published in *THE GARDEN* for December 24, 1881. He was in correspondence with all the leading gardeners of that time; but, except in the columns of *THE GARDEN*, he has never published anything on the subject. As an author, however, he stands alone as one who has published large books after he was ninety. His "History of Bitton," in two quarto volumes, was published when he was ninety-two. It may also be worth mentioning that he occupies an interesting chapter in the recently published "Reminiscences of Oriel College," by Mozley.

In 1850 Mr. Ellacombe was preferred to the rectory of Clyst St. George, and was succeeded in the vicarage of Bitton by his son, the Rev. Canon Ellacombe, the present incumbent. Mr. Ellacombe, sen., speedily rebuilt the body of the church at Clyst St. George, and in 1860 opened a new school-house and master's residence. His name is known far and near as being the great authority on bells, and he has written several valuable treatises respecting them. He is a learned antiquarian, especially in all ecclesiastical affairs. Though within a few years of being a centenarian, he is vigorous both in mind and body, and as enthusiastic a gardener as ever. Even in the closing number of this volume of *THE GARDEN* (p. 590) will be found an interesting paragraph from him on *Lathyrus Sibthorpei*, seeds of which, with his usual generosity, he offers to distribute. The old garden at Bitton, more richly stocked with hardy plants than most of the largest botanic gardens, has been the refuge as it were of many a fine plant that but for it would perhaps have vanished altogether from cultivation during the time when the bedding-out fashion was rife. The Bitton garden has, however, remained unchanged through all the caprices of fashion, and under the fostering care of Canon Ellacombe well maintains its reputation. It is one of the most interesting gardens in the country—one in which hardy herbaceous plants, shrubs, and trees find a congenial home, and in which the climate is favourable to the growth of a host of subjects not hardy in more northerly districts. The shrub collection is particularly rich, especially that of species of *Roses*, which is as complete a collection as any in the country.

THE GARDEN.

VOL. XXIII.

DROPMORE.

UNLIKE the majority of notable English gardens, the fame of Dropmore is not due to an elaborate display of glasshouses or extensive collections of plants, but simply to its magnificent coniferous and other tree growth. Ever since the commencement of the present century Dropmore has been steadily rising in celebrity for about that time Lord Grenville began to plant ornamental trees extensively, the result being the matchless specimens now dispersed throughout the grounds. The first plantings seem to have been made in about the year 1800, consisting of Cedars of Lebanon, now noble trees, and from that early date ornamental tree planting has been carried out almost uninterruptedly. Lord Grenville, an enthusiastic lover of gardening, seems to have devoted a great deal of attention to the improvement of Dropmore, gradually developing a beautiful garden out of what was little more than a barren waste, productive only of Heath and Furze. Indeed, the poor soil which everywhere prevails at Dropmore, consisting of little more than a bed of gravel on a hard impervious pan, would never have been able to develop such noble trees had Mr. Frost not taken unusual pains to start them in better material. Until fairly within the grounds there is nothing in the surrounding scenery of Dropmore at all remarkable.

The house, however, occupies a pleasant position embowered amidst luxuriant tree growth, and in front of it lies a wide extent of Berkshire scenery with Windsor Forest for a boundary and the Castle as a fine object in the middle distance. A dull, cold winter's day is by no means the best season in which to see any, and more particularly this, garden, though its Conifers always look fresh and green. Early summer is the time to see Dropmore; then the place everywhere is aglow with colour, produced by huge masses of Rhododendrons, Kalmias, Azaleas, and other flowering trees and shrubs, and the very air is laden with their delightful fragrance. The Rhododendrons and similar shrubs are interspersed throughout the place, and so thoroughly do they luxuriate, that seedlings spring up by thousands and supplant the native growth of Heath, Furze, Blackthorn, and other bushes. A charming feature, too, in summer is the little bits of well-kept

lawn beneath the cool shade of the towering Beeches and other forest trees, a verdant carpet lighted up here and there by huge specimens of Pelargonium, Fuchsia, and other tender plants sunk in the turf. These are kept for the purpose and housed under glass in winter. Dropmore being naturally somewhat flat, its surface was diversified years ago by artificial mounds raised here and there so as to enable the visitor to obtain a better view of the grounds and surrounding country. There are what are called the Beech Mount and the Stub Mount, both of which are charming spots, as they are embowered in foliage, and from them can be enjoyed a view of a rich and varied landscape.

The Conifers are scattered about the place in an informal way, no fixed plan being followed. A good many are in the immediate vicinity of the house, but in most cases clearings have been made in the woods for groups of them. This mode of planting obviates much of the artificial look which many Pinetums possess, some being planted not unlike an Apple orchard, in which all the trees can be seen at a glance. At Dropmore each isolated specimen or group has an individuality of its own, as it were. The groups consist either of one species or a mixture, but there is a sort of grandeur and unity of expression about groups consisting wholly of one kind not seen in the case of mixtures. It was, we believe, Lady Grenville's plan to plant mixtures, but Mr. Frost advocates nature-like groups of one kind. There are some magnificent groups of Araucaria, Deodar, and Cedar of Lebanon, and there can be no doubt that Mr. Frost's particular mode of giving Coniferae plenty of good soil to grow in has been chiefly instrumental in making the Dropmore collection what it now is. Miserable, half-starved specimens find no place here, and it would be well if they were less common elsewhere. "Plant well at the outset," says Mr. Frost; "no tree can be expected to do well if not thoroughly well planted at first." First of all he has a hole made not less than 3 feet deep: he takes away the natural soil and replaces it by good soil, consisting of sods from the road-sides, old potting mould, and similar material, the rougher the better. In planting he always puts the tap root perpendicularly in the bed of new soil, and spreads the others out on the surface. He invariably raises the soil some 3 feet above the

surrounding surface, giving the plant really 6 feet of soil in which to root. The mound is made sloping, so as to throw water off the base of the bole when there are but few roots to parts in which the feeding roots exist. Every coniferous tree at Dropmore is set on a mound consisting in some cases of as many as 50 cartloads of new soil. Moreover, now and then, as the tree requires it, a top-dressing is applied a foot or two in thickness around the stem from 10 feet to 40 feet in radius. Mr. Frost does not believe in pruning Conifers; the only attention they receive in this way is cutting away superfluous leaders. The big specimen of the Douglas Fir, for instance, had three leaders for the first few years of its existence; two of these were cut away and the third carried the tree upwards; the scars of the others may still be seen on the trunk. Mr. Frost prefers planting in October or early in March, but he says, with care, all Conifers may be planted with success at any season of the year.

The great Araucaria more than all other trees has been the object of Mr. Frost's special care, and it has certainly well repaid the extra attention which it has received, for it is without question the grandest specimen of the kind that exists in a cultivated state. Its dimensions at the present time are 61½ feet high, the diameter of the space covered by the branches which rest on the ground on all sides is 33 feet, while the girth of the trunk at 3 feet from the surface is 7 feet 4 inches. This tree was planted in 1830, and it has grown unscathed by frost into a perfect specimen, every part of it being free from blemish. It is planted on a mound of prepared soil to begin with, and ever since it has received periodical top-dressings, so that now the roots sustain an enormous weight of soil in which they are so firmly anchored that no amount of wind produces the least effect upon the tree. Through the courtesy of Messrs. Veitch we are enabled to place before our readers the annexed portrait of this noble Araucaria specially prepared from a photograph taken in 1881 for their "Manual of Coniferae." It shows admirably the aspect of the tree at the present time. There are numbers of Araucaria about the grounds, some planted singly, others in picturesque groups. The groups consist of from five to a dozen

trees planted at irregular distances apart, but always sufficiently far asunder to enable each to develop itself properly. Mr. Frost asserts that there are distinct forms of *A. imbricata*, which differ in habit and rate of growth, and certainly at Dropmore several of distinct growth may be singled out. There is also a difference in the growth of the male and female trees, the former being much more dense than the latter, which, as a rule, has slender branches more loosely arranged around the stem. The big tree is a male, and some 80 yards from it is a female tree which cones and ripens seeds—the cones being doubtless fertilised by pollen from the large tree.

The Douglas Fir is undoubtedly the glory of Dropmore. Its height is 114 feet, and its wide-spreading branches, which lie on the ground on all sides, cover a space 70 feet or more. The bole at about a yard from the surface is just about 10 feet in girth. This gigantic Fir, which is unsurpassed in cultivation, is in every respect perfect, its towering pyramidal form being only marred on one side, caused by a heavy fall of snow breaking off a few branches some years ago. The history of this magnificent tree, is as follows: Early in December, 1827, Mr. Frost received from the late Lord Grenville a packet of seeds of this Fir, then called *Picea taxifolia*, sent to Dropmore from the Royal Horticultural Society. Of these seeds but three germinated—one the parent of the tree under notice; another is also living; and the third was cut down some time ago. This tree has responded well to Mr. Frost's attention, and now is alone worth going a long journey to see. Among other kinds of Abies the most striking are *A. Menziesii*, planted in 1841, now nearly 60 feet high, with a girth of trunk of over 4 feet; *A. taxifolia*, a near ally of *A. Douglasii*, is between 50 feet and 60 feet, with a girth of bole of over 4 feet; *A. Albertii*, the finest of all the Hemlock Spruces, is represented by a grand specimen, 48 feet high, planted in 1861, and now about 25 feet in height. It stands at the junction of two walks, and is, therefore, seen to the best advantage.

The Piceas, all of which are ornamental in a high degree are, represented by some fine trees. By the side of one of the carriage drives there is a noble example of *P. Pinsapo*, some 40 feet in height, with a spread of branches about 35 feet in diameter. This tree was planted in 1843. Planted about the same date is a *P. cephalonica*, which is about the same height, and a perfect specimen. The finest *P. nobilis* was planted in the autumn of 1835. It is now nearly 70 feet high, and has a girth of stem but little short of 5 feet at a yard from the ground. Of *P. amabilis* there is a specimen nearly 50 feet in height with a girth of bole of 4 feet. It was raised from a cutting and planted thirty-five years ago. *P. Webbiana*, one of the most beautiful of Himalayan Conifers, and remarkable for its violet, or rather purple, cones, is represented by a tree about 14 feet in height. It was raised from a cutting, and was planted out in 1843; hence it may be inferred that it is a very slow grower. Other fine examples of *Picea* are *P. grandis* (true)—planted in 1861, is now 49 feet high—and *Nordmanniana*, both handsome and in vigorous health.

The Pines are the most numerous of all the conifers here. Even before Mr. Frost's time they numbered over thirty and forty species, and now they exceed that number. The finest specimen among the several trees of *Pinus insignis* was planted in 1839, a cutting plant obtained at Messrs. Lee's nursery, Hammersmith. It is now about 80 feet in height, and its huge wide-spreading head, massive limbs, and trunk over 90 feet in girth make it a grand object. Near it is an example of *P. Pallasiana*, a Crimean species in the way of the Corsican Pine. This, too, is some 80 feet in height, and possesses three leaders, a living example, says Mr. Frost, of the baneful results of neglecting to remove two of them when the tree was small. Of the handsome *P. excelsa*, among the noblest of Himalayan conifers, there is a splendid specimen planted thirty-seven years ago. It is now about 70 feet in height, and has a ponderous bole, and huge wide-spreading limbs so symmetrically arranged as to make a well-balanced

tree. This occupies rather a sheltered situation, surrounded by forest trees, with which the bluish-grey tint of its feathery, drooping foliage makes a pleasing contrast. There are many other specimens of *Pinus excelsa* about the place, but this is one of the finest. *P. Benthamiana*, planted in 1843, is now fully 50 feet in height, with a girth of some 5 feet. Near this is a specimen of the rarely seen *P. densiflora*, Japanese species, scarcely suitable for our English climate, as, though planted twenty years ago, it is only now about 15 feet high, and has an ugly habit of growth. A specimen of *P. monticola* is one of the finest in the country, a noble object between 50 feet and 60 feet in height and some 5 feet in girth. It was planted in 1835, and is a very hardy Californian species. The Weymouth Pine (*P. Strobus*) is, of course, a common tree at Dropmore, and some very fine examples of it exist there. There is a variety of it called *alba*, which Mr. Frost treasures highly. It differs from the type in the foliage being altogether of a whiter hue and shorter. It makes a beautiful contrast with some of the more sombre tinted Coniferæ. The Stone Pine (*P. Pinaster*) may be seen in its characteristic picturesqueness, now that most of the trees of it have gained maturity. A variety of it named *Escarena* is a remarkable one—different from the type in growth, as it does not assume the tabulated form so much as the type; it is, however, said to be less hardy. *P. Lambertiana*, planted in 1841, has grown into a lofty specimen, 50 feet in height or more. Other species of Pines represented by handsome specimens are *P. ponderosa* (80 feet high), *P. pungens rigida*, *Brunoniana*, *Mughus*, *pyrenaica*, *Cembra*, and *Lemoniana*, mostly reared from seeds sown about 1829.

The Deodar thrives to perfection at Dropmore, every tree of it seeming to be thoroughly at home. The largest specimen is 70 feet in height, perfectly symmetrical in shape, and in luxuriant health. It was planted in the autumn of 1834, from a cutting bought for three guineas. There was a larger Deodar than this, but a few years ago its stem was riven from top to bottom nearly by lightning. There are numerous fine Deodars about the grounds; one, said to have been grafted on a Larch, is much looser in habit than usual. A good many of the trees here have been reared from cuttings, and all have become fine specimens. Of the Atlantic Cedar (*Cedrus atlantica*), which by the way is not plentiful here, the largest tree planted in 1843 is now about 70 feet high, and finely proportioned.

The Cedar of Lebanon is one of the chief features of Dropmore. As soon as the lodge gates are passed a magnificent group of it comes in view. The trees of which it consists were all planted in the first year of the present century, though they are not so large as one would suppose; in fact, they have not made good use of their time, a circumstance attributed to their being planted in the naturally gravelly soil of the place without any preparation or addition of new material. The way in which the trees are grouped, however, is very picturesque, though they are too much crowded, only the outermost ones being furnished with wide-spreading limbs. There is a huge specimen on the lawn near the house, planted in 1792, on the day Lord Grenville took possession. This is a very handsome tree. The Cedar drive is a remarkable and uncommon feature, it consists of a winding avenue about a third of a mile in length, backed on either side by plantations. The trees are planted only 25 feet apart and 50 feet between the rows, consequently they are much too crowded; if double the space had been given between the trees, and 80 feet allowed between the rows, they would have had room in which to develop themselves properly. This avenue was also planted early in the present century. A variety of *Cedrus Libani*, called *glauca*, is a distinct and handsome tree, with a decided glaucous hue.

The Wellingtonia is represented by some well developed specimens. The largest was planted in 1857, and is now fully 53 feet high, with a girth of bole of some 8½ feet. Another,

planted in 1862, is nearly as large. There are also some uncommonly fine specimens of its ally, the Red Cedar (*Taxodium sempervirens*), a tree which thrives here admirably. There is an example of it, planted thirty-seven years ago, which is now about 45 feet in height, with a spread of branches some 30 feet in diameter. All the specimens of the Red Cedar are very healthy, and do not appear to have suffered so much from severe winters as it has in some localities.

Cryptomeria Lobbi, a variety of *C. japonica*, is represented by a specimen 46 feet in height, having a spread of branches 16 feet in diameter, and a girth of trunk 3½ feet. This is probably the finest cultivated specimen in existence; of *C. japonica* there is likewise a fine example. Among other remarkable conifers may be noted *Cupressus thurifera*, planted in 1847; *Larix microcarpa*, a rare species with pendulous branches, planted in 1822; *Thuja gigantea* (Lobbi), a perfect specimen some 50 feet high, though planted so recently as 1862. There are some large specimens of *Cunninghamia laccolata*, but every one of them has a woe-be-gone look about it, the branches and foliage being discoloured by frosts. There are, however, one or two very old examples of it here; one planted in 1822 withstood even the famous "Murphy's" winter, which made such havoc among vegetation generally. *Thujopsis dolabrata* is another conifer that does not appear to do well at Dropmore, but this we were assured was owing to rabbits injuring it; indeed, they seem to be so excessively fond of it that every plant has to be closely wired round, and even then they somehow contrive to get at it.

The above comprise the principal coniferous trees on the Dropmore arboretum, but there are more, some only planted a few months ago, that are gradually developing into fine specimens under Mr. Frost's fostering care.

W. GOLDRING.

RECENT PLANT PORTRAITS.

THE number of the *Botanical Magazine* for January contains coloured portraits of the following plants, mostly from specimens which have flowered at the Royal Gardens at Kew during the course of the year 1882.

Doryanthes Palmeri (double plate), a magnificent Amaryllid allied to the Agaves and Fourcroyas, producing a flower-stem from 8 feet to 10 feet in height, the topmost 3 feet of which are covered with bunches of flowers, the outer petals of which are of a deep red colour and the insides white. The specimen figured continued in bloom during the whole of March and April, and ripened seed in October of last year.

Nemastylis acuta.—A pretty light purple flowered Irid, indigenous to the South-Western States of America. The flowers are, unfortunately, very fugacious, falling to pieces within a few hours of their opening, as is also the case with most of the members of this family. It is also known as *N. geminiflora* and *Isia acuta*. It resembles the *Tigridia* in habit.

Babiana ringens.—One of the most curious and striking of Cape bulbs, with bright red tubular flowers, quite unlike those of any other *Babiana*, and more resembling those of a *Hedychium* in shape; it is also known under the name of *Antholyza ringens*.

Microstylis metallica.—A curious foliaged and somewhat insignificant flowered member of the Orchid family, belonging to the tribe of Epidendrum, with brown deeply-ribbed leaves resembling those of an *Anæctochilus*, and a short spike of small pinkish flowers, a native of Borneo. If the leaves of this plant are plunged in boiling water, and then dried, they become green. The specimen figured was sent to Kew by Messrs. Low, of Clapton.

Cereus cespitosus.—One of the Echinocereus section of the Cactus family, native of New Mexico and Texas, usually grown under the name of *C. pectinatus* from which it only differs in some slight and hardly distinguishable points of

botanical structure. Its spines are very small and fine in texture, and its flowers of a conspicuous deep rosy colour, somewhat resembling those of *Echinocereus Fendleri*. W. E. G.

COLOUR IN THE FLOWER GARDEN.

THERE are one or two statements which "R. A. H. G." makes in regard to this subject which I thought

I had sufficiently demolished. He still maintains that all the colours in the rainbow combine to make white; they do nothing of the kind. Each shade of colour is produced by a separate length, or rate of regular waves, while white is produced by a jumbled flood of regular waves; grey is produced by irregular waves of less intensity; black is the absence of all motion. Red and yellow do not form orange, or anything like it, any more than yellow and blue make green. Red pigment and yellow pigment mixed form a pigment which reflects orange, most likely for the same reason that the red and yellow lines described by "R. A. H. G." produce orange, namely, because the colour waves, moving at different rates of speed, jar and produce uniform waves of a speed differing from that of the two component colours. "R. A. H. G." must distinctly understand that it is proved by experiment, that the sensation of colour is produced by waves of light either entering the eye at a definite rate of speed, and that rate varies for every hue in the spectrum, so that it is a mistake to imagine that any combination of two colours can produce a third; this is not a "vexed question," but has passed into the domain of undisputed fact. It will not do for "R. A. H. G." to deprecate the introduction of the scientific side of the question, and then make statements which can only be shown to be fallacious by appealing to what science has discovered. "R. A. H. G." maintains that all that is necessary to produce harmony is that red, blue, and yellow be present in some form; cannot he see that this is in reality begging the whole question? If we allow him to assume that these colours combined

all the others as well as white, grey, and black, we can scarcely make a single combination of colour, not even red and grey, or white and gold, but he will assume it to be an illustration of the complementary code.

Science has proved that every colour in the spectrum is distinct, so that red and green, for instance, are not red, blue, and yellow, but simply red and green. No combination of colours but red, blue, and yellow, pure and simple, contains or consists of those three colours in any

form or combination whatever. Until "R. A. H. G." can disprove these results of accurate and scientific investigation, and show conclusively that his idea of three primary colours, combining the four secondary and tertiary colours, is founded on a solid basis of scientific fact, no argument he can advance in favour of the complementary code can possess the weight of a straw. What "R. A. H. G." advised originally was to

with red, for that reasoning is incorrect. Combinations of one bright colour with a tertiary ground quickly right themselves, as people find out almost at once that the right combination is with the tertiary tints which the complementary code makes out to be discordant, but errors with the bright pure colours of flowers are flagrant. I should like to trouble "R. A. H. G." with just one little bit more science, after which I think we may consider

make the subject threshed out, and agree to differ.

Colour, when we come to the visible and enjoyable part of it, is not like form. Form is a thing which has a definite existence apart from us, but colour as we know it has no existence apart from our senses. The waves of light ether are a reality, but what we call colour is not these waves, but the effect which they produce on our senses. These waves enter the eyes of colour-blind persons, and of persons who are blind to red, exactly as they do the eyes of others, but they produce no sensation of colour. Colour is a thing, therefore, about which it is difficult to reason; it is truly a matter of taste, and as thoroughly so as the productions of the skilled cook; no hard and fast rules can be laid down about it. The one difficulty we have in dealing with colour is this: In the fifteenth century it became the fashion to imitate the arts of the later periods of the Roman empire instead of making progress and improvement in such art as then existed. People ceased to follow their own taste, and all art, from high to low, became matter of book learning. By processes far too long to describe here, colour faded out of everything of human manufacture; colour became vulgar, and, as Mr. Ruskin describes, we were "legalised into grey." Compare the male costumes of even 1782 with those of 1882. Now, if any faculty of the human mind is allowed to lie dormant or habitually outraged it becomes weak, and three centuries of bad colouring have without doubt weakened the perception of colour in the northern races. This can only be corrected by following the lead of Nature and of those nations and periods

in the arts of which good colour forms a feature, and also by following the lead of people distinguished by sensitiveness to colour. A person whose eye is so sensitive to colour as to be unable to look at a truss of *Vesuvius Pelargonium* for five minutes at a time without becoming red blind for the time being is assuredly a much better guide in matters of colour than a person who can enjoy gazing at a bed of scarlet *Pelargoniums* or red and yellow *Tulips* for half an hour at a time. The most charitable way a

The great Araucaria imbricata at Dropp ore. Height, (1½ feet. (From a photograph taken in 1881.)

place "red, yellow, and blue flowers next each other; his purple Pansies, for instance, with their green foliage next his golden ones." Also, "we should be correct in placing purple alongside yellow, green alongside red, and orange or golden alongside blue." If "R. A. H. G." likes green and red together, by all means let him have it and recommend others to try them, but that is quite another thing from saying that because green is a combination of blue and yellow, and is equal to all the colours but red, therefore it must harmonise

colourist can regard those terrible beds of red, blue, and yellow, which one saw so much of in the hey-day of the bedding system, is to imagine that those who enjoyed them were to a certain extent colour-blind, and that colour of that strength was required to produce to their eyes the pleasing sensation which would be conveyed to the mind by a combination of a quiet, soft red, primrose, and bluish grey. All that anyone can recommend for general adoption is such

Combinations of colour as were formerly considered beautiful, and which are still considered so by people who make colour their study and business. The difficulty in writing about colour consists in the want of definiteness in the language obliged to be used, but with flowers this is to some degree obviated by known flowers having known colours, so that we can use them to give definiteness to our descriptions. I can assure "R. A. H. G." that when my promised article on colour for bedding appears he will find many combinations recommended which cannot by any stretch of imagination be said to consist of the three primaries, as well as some which consist of these and secondary and tertiary colours as well, but I shall not recommend red, blue, and yellow as harmony of any of those combinations which his diagram would lead us to believe are harmonious.

J. D.

HOW TO DRY PLANTS.

MR. LEO H. GRINDON, whose name is well known in scientific circles, gives the following practical hints on this subject in a recent article in the *Field Naturalist* :—

"The very ancient adage, that if a thing be worth doing at all it is worth doing well, applies to the preservation of plants for the herbarium as much as to any great and important work or business. Specimens that are no better than fragments of brown stick, or that seem effigies of plants cut out of thin brown paper, the flowers shrivelled and shrunk so as to be no longer intelligible, the leaves crumpled and doubled up, everything confused and mashed together, such as one may see sometimes in collections, are altogether undeserving of the name. Nothing that is not dried in the best manner possible, its colours and configuration preserved as perfectly as the nature of the plant will admit, ought ever to be allowed a permanent place in the herbarium, the bad may be tolerated a while, in default of better, but the further a specimen is from vivid and pleasing resemblance to the living thing, the speedier should be the endeavour to supersede it. Specimens from abroad that cannot be superseded of course we do not speak of. In the plants within reach, none but admirable representatives of their best features while alive should be considered worthy of a place. Plants dry very variously. Some require not a moment's trouble; others demand patience. Now and then the case is hopeless, and we are constrained to fall back upon the pencil, and prefer drawings, coloured ones if possible. Grasses and their allies, most kinds of Ferns, plants that resemble Heather, Everlastings, the mature leaves of shrubs and trees, call for only the minimum. Those which try the patience, and can be mauaged only after considerable experience with easy ones, are such as may be illustrated by citation of the Hyacinth. To secure the best results, obtain first half-a-dozen pieces of stout millboard cut to about 18 inches by 12 inches. Then gather together a hundred old newspapers, and fold them neat and square to about the dimensions of the millboards. Four or 5 yards of common white cotton wadding, a score of sheets of tissue paper and as many of blotting paper, all cut to the same size, complete the apparatus. One of the boards serves for the foundation; on this only a newspaper, then a piece of wadding, and upon this place the specimen intended to be dried. The cotton being soft and retentive, every portion can be laid in a proper and natural way, including the petals of the flowers. A newspaper above, two or three if the specimens have thick stems, and so on, till all shall be deposited in the way of the first. If the specimens are sticky, or hairy, or of a kind that

the wadding seems likely to adhere to, then, before depositing them on it, introduce a half sheet of the tissue paper. A heavy weight must be put on the top of all, sufficient to imbue the specimens in the wadding; then leave the whole to rest for twenty-four hours. All the papers must then be changed, dry ones being put in their place; and if the plant seems to throw off a very considerable amount of moisture, such as will render the wadding quite damp, change the wadding also. A second and even a third change is desirable at the end of two or three days or a week; and when this is made introduce the blotting paper, pressing again till everything is perfectly flat, and the specimens are absolutely dry.

"Such is the simple process by which the writer of these lines has succeeded in the art of preserving the colours and forms, not only of robust and tractable plants, but of the most delicate and very many of the obdurate. Every petal, every leaflet, retains the form it had in life, and nine specimens out of ten keep their colours excellently. To insure the keeping of colour, it is well, if time can be spared, to change the blotting paper many times, and to dry it thoroughly before the fire, but this need not be done until after the third day from the beginning."

INDOOR GARDEN.

SEEDLING FREESIAS.

IN a little note of mine on Freesias which you published last summer I spoke of some seedlings which I hoped to see in bloom before Christmas. I have not been disappointed. The seed was sown on May 19 and 21, 1882; the seedlings were found appearing above the soil on July 5, and the first bloom expanded in my greenhouse on December 10. Every seed, I think, must have germinated, and every seedling almost is now bearing bloom or bud. Last year I spoilt my chances by sowing the seed too thickly in too small a pot. Obviously, the young seedlings, in order that they may make adequate growth, must have plenty of room.

On the other hand, some seed which I sowed September 16 to 23, which also had only just ripened, and came fresh from the capsule immediately upon dehiscence makes no sign at all, though I have tried to help it on by putting it into heat. I imagine that now it will not start till the spring comes. The seed which is now blooming was from hybridised flowers from F. alba and F. Leichtlini, and from F. Leichtlini and F. alba.

The first (alba × Leichtlini) has given me so far a spike of somewhat large yellow flowers, which, as far as I can remember, reproduces almost exactly the form raised by Mr. Smith, of Guernsey, and figured in THE GARDEN (p. 94, Vol. XXII.), and other spikes with flowers in form like Leichtlini, but varying from pale white to pale yellow.

The second (Leichtlini × alba) has so far given flowers of the form of the mother, but varying in colour; some are nearly pure white, others pale yellow, and still others of a deeper yellow with a tendency to violet blotches, more marked than in the typical Leichtlini. This last fact tends to confirm me in my belief that most of the forms with names are mere varieties. With the exception of the first spike mentioned, the flowers are rather small, but I have some hopes that they will grow larger when the bulbs get older, i.e., next year or the year after.

I have not got to the bottom of the culture of these bulbs yet. Of the pots, taken from the same stock, potted at same time, and treated, as far as I know, in the same way, one is showing goodly growth, the other nearly dormant. There must be some reason for this, and I must try and find it out.

Coleuses for winter decoration.

Everyone admires the glorious tints of colour that may be seen during the summer months, but how seldom do we find them in winter when plants or flowers for decorative purposes are so desirable. Old plants lose their foliage, and too often are victimised by scale and other insects, and young plants often damp off. Then how are we

to have their bright colours? Visiting the stove and Orchid houses at Birdhill the other day, I was much struck with the glowing, vivid colours, filling up space and hiding pots, just as in mid-summer. The secret seemed to be propagation of the best and brightest in October, and placing the cuttings in very small pots, about four in each, the colours to be contrasted. The Coleus requires very slight feeding material, the less the better, during winter. The colours were brighter than several of the Orchids.—W. J. M., *Clonmel*.

GREENHOUSE RHODODENDRONS.

WHAT are commonly known as greenhouse Rhododendrons, viz., the various hybrids belonging to the Princess Royal section, might be with truth described as perpetual flowerers, for where numbers of them are grown they are seldom without flowers if kept in a somewhat higher temperature than that of an ordinary greenhouse. Although they will exist therein, they neither grow nor flower so freely as when kept during the winter in a temperature of from 50° to 60°. Although, however, their blooming season extends over such a long period of time, the greater number of their beautiful flowers are produced during the autumn and winter months, and, owing to that circumstance, they are especially valuable. If the atmosphere of the house is not too heavily surcharged with moisture the blossoms will remain in good condition for at least a fortnight. They do not appear to have any particular season of growth. If kept in the temperature just named young shoots are even produced more or less throughout the winter. These Rhododendrons also possess the merit of flowering freely in a small state, as when only in 4-inch, 5-inch, or 6-inch pots every shoot will frequently be terminated by a head of blossoms. Not only, too, do they flower when small, but, being naturally of a short bushy habit, they are well suited for structures where more vigorous kinds would soon outgrow the space allotted to them. The beautiful kinds raised by Messrs. Veitch give us great variety in the way of colour, some of the later hybrids being very striking in that respect. The varieties of this type which I grow, all of which are very distinct, consist of the following, viz., Princess Royal, a rich pink-flowered kind, one of the oldest and still unsurpassed in its colour, that is, when a good form of it is obtained, but I find that plants of it vary a good deal in the tint of their blossoms, probably owing to some having been raised from seed. Princess Alexandria is pure white at first, but after being expanded a few days becomes slightly suffused with blush; Duchess of Teck is a light buff yellow-shaded with rose; Duchess of Edinburgh, bright orange crimson, a very brilliant coloured and effective flower; Taylori, rich pink with white tube; this is quite distinct from Princess Royal. Besides these hybrids the beautiful pure white jasminiflorum is well entitled to a place in any collection; in continuous blooming qualities it ranks with the best of its class.

The soil in which I find these Rhododendrons to do well is good fibrous peat, with a liberal admixture of silver sand and some pieces of charcoal, their size varying with that of the plants. For those in 10-inch pots pieces as large as one's thumb may be used with advantage; while for those in 6-inch pots they should not be larger than beans. The partiality of the roots for the charcoal may be seen by the way in which they envelop it. The best time to pot is as soon as the plants are out of flower, and as most of them are in that stage during spring or early summer, no better season could be selected for the general potting. Be sure the pots are thoroughly clean and well drained, then pot firmly, and do bury the stems deeper than before. For small plants annual repotting is necessary, but when larger they may remain some time undisturbed. At all times overpotting must be strictly guarded against. The only insect pests that trouble these Rhododendrons are thrips, and they are easily kept down by the use of the syringe, which will also benefit the plants.

Propagation may be effected by means of cuttings, grafts, or seeds; but I like cuttings best. They should consist of the young growth, taken off when in a half-ripened condition. As the shoot is formed of a tuft of leaves with a certain amount of bare stem below, cut it off at its base, that is immediately above the next cluster of foliage; in this way the whole of the young growth will be removed. Roots are produced more freely from the base of the young shoot than if taken off half-way up. Such being the case, if the shoot is not too long, leave it in its entirety, but if it is more than 6 inches it should be shortened, and in that case a long slanting cut gives a larger rooting surface than a horizontal one. The cuttings may be put singly in small pots, which should be filled with peat, sand, charcoal, and crocks, the two latter broken very small. If put in a close case in a temperature some few degrees higher than that in which they have been growing, roots will soon be produced, when air must be given by degrees, and the young plants hardened off. In this way if attention be paid to stopping in their earlier stages dwarf plants may be produced without the bare stem common to those that are grafted. Grafting certainly possesses one great advantage, inasmuch as small shoots that would not be large enough for cuttings may be grafted; therefore for the newer kinds it is commonly employed. Side grafting is the method generally employed, and as the older variety, Princess Royal, is oftentimes at hand, it is used as a stock for the newer kinds. Seed is the way by which new varieties are obtained, and to any one who does not mind waiting some years for the fruits of his labour, seedling Rhododendrons offer a tempting prospect. There is no difficulty in obtaining plenty of seeds if the flowers are properly fertilised; when ripe they should be sown in pans of light sandy peat, just sprinkling a little dry sand over them when sown, not enough to cover them, but to partially hold them in their places. Either put the pan in a close case in the stove, or lay a pane of glass over it, and when the seeds germinate give air by degrees. The young seedlings are very liable to damp off, so a sharp look out must be kept, and when any symptoms of damping show themselves, prick the young plants off into other pans—a very delicate operation, as great care must be exercised not to bruise the tender tissues. As the young plants require rather a high temperature in their earlier stages care must be taken that they do not suffer from thrips, which will sometimes attack them, even as soon as they become visible.

H. P.

HEATING THE NEW LAW COURTS.

To understand how this is effected, says the *Times*, the building may be divided, by lines running at right angles, through the centre of the Great Hall into four nearly equal parts. To each of these is fitted a separate apparatus, all alike in power and character, but capable of acting separately or together at will, and each arranged so as to be interchangeable in working upon or into each other's divisions. By these means what was once seen to be a serious difficulty in dealing with a building of this magnitude has been overcome—that, namely, of directing the power along lines of nearly equal resistances. It also provides for contingencies of various kinds, for one division is a duplicate of the other, and capable of working on the other's ground by a system of arterial mains, which encircles the crypt, and which connects and embraces the whole. The medium employed is hot water, circulating through pipes formed into ranges and clusters. The whole of the warmth, therefore, is derived from surfaces heated by means of hot water on the low-pressure principle. The range of pipes in the whole system measures a little over 11 miles in length. The boilers attached to these for heating the water are equal to the power of 200 horses, one boiler of 50-horse power being apportioned to each of the four divisions, and situated in the crypt under the four angles of the Great Hall. There are two other boilers of the

same dimensions and power, which are for steam, to be employed for working the engines, for propelling the air into the Courts, and for heating the several coils of pipes in the ventilating shafts connected with the Courts. These two boilers have been fitted and are coupled in such a manner that they may be used singly or together, as may be required. The scheme will thus be seen to have been arranged broadly into four main divisions, all of which have again been sub-divided into sections of high and low levels. Each of these sections and divisions is connected, not with the boilers directly, but with the arterial mains, which are carried round the crypt, linking the four boilers together by means of larger mains, the whole being arranged in a way that will allow of the sections working together or independently, so that anything going wrong in one section need not interfere with the proper working of the other parts. Further, in the low-level sections the arrangement provides for the repairing or removal of any one of the systems below the Courts, while the hot water may be working perfectly through all the others. Each Court is separately treated both as regards its heating and air-propelling power, and below each Court is a chamber divided into two equal compartments. In one the requisite power is provided to warm and maintain the Courts to a temperature of from 58° to 60° Fahr. in the coldest season, with an interchange of air equal, if necessary, to 10,000 cubic feet a minute. The other compartment is used for cold air. These two chambers merge into one, and are covered with a coarse cloth (a kind of gauze), which is used for mixing and filtering the air, after which the air passes into the Courts at a temperature little above that required in the Courts themselves. The air enters through numerous vertical openings provided behind the wall linings and at other convenient points. The supply of fresh air to the other parts of the building is from the staircase areas on the outer circle. This is warmed in winter by systems of pipes placed at convenient points in the corridors and other parts. The warming of the Great Hall is effected by means of the arterial mains and eight powerful batteries of hot-water pipes, which are placed under the floor in the crypt, all being supplied with fresh air filtered before passing into the hall. As to the summer season, it was felt that without some

Special arrangement for cooling the air the system would be wanting in a most essential part. A machine, therefore, for cooling the large quantity of air required to ventilate the Courts in hot weather was seen to be an absolute necessity. The system of refrigeration adopted is what is known as the "ether process," which was, after duly weighing the merits of the different systems in use, considered the best for the purpose. A complete ether machine, therefore, has been constructed in the crypt, consisting of a pair of engines, vapour pumps, refrigerator and condenser, but no brine pump or tanks for ice-making, as in its application none are required. The air, in its passage to the Courts, will pass through a fine water spray. The instrument for the production of this is an "atomizer." The water for these atomizers is supplied from a tank in the roof of the building, and is passed through the refrigerator, being thereby reduced in temperature to the required degree. It has been calculated that the atomizers will, when in full use, consume 1000 gallons of water an hour. The temperature of the water in the tank will be but little below 70° Fahr. in the summer. Therefore the machine laid down is sufficient to reduce from 70° to 40° Fahr. 1200 gallons of water an hour; and this is considered to be slightly in excess of what is necessary to cool from 78° to 62° Fahr. the largest quantity of air that would be passed into the Courts at any time. The water which feeds the sprays will, as before stated, pass through the ether cooler, and be reduced to 40° Fahr., or lower if required. This cold water, after falling from the atomizers, is collected in a cistern by a system of drains, and is drawn thence by a pump fixed to the machine and conveyed to the condenser, where, flowing among the tubes, it abstracts the heat given off by the working charge

of ether while reliquifying; and thus, after serving two purposes, it is allowed to run to waste, which it will do at a temperature of about 90°. A recording thermometer is attached to the inlet and outlet pipes of the cooler, so that the temperature of the service water to the sprays can be adjusted to a nicety. The whole arrangement is simple and easily understood, and is now partly in operation. The works in question have been executed by Messrs. Haden and Son, of Trowbridge, and carried out under the personal supervision of Mr. Blake, of Manchester, who assisted the late Mr. Street in working out the scheme.

NOTES AND READINGS.

COLOUR IN THE FLOWER GARDEN.—Red, blue and yellow, the writer on this subject in *THE GARDEN* says, "are enough to produce lunacy," which we do not credit for a moment, because plenty of examples could be found who, for a great portion of their flower gardening existence, have gazed on gardens planted exclusively with clear yellow, *Calceolarias*, bright blue *Lobelias*, and scarlet *Geraniums*, and are yet perfectly sane. Does not "J. D." know that red, blue, and yellow formed the original base of mostly all bedding out combinations, and were the predominating colours of many a parterre? There is a good deal of sense in "J. D.'s" remarks on colour, and no doubt he is right on many of the obscure points he raises; but if the planting of our gardens simply and naturally is to be preceded by such a probation on the subject of colour, and carried out with such elaborate intricacy of detail, it is to be feared some of us will go back to "first principles"—like the rustic who, overcome by the elaborate bill of fare presented to him, "guessed he would go back to beans and bacon." Is it worth while troubling our heads with such fine distinctions on the subject of colour in gardens of hardy plants when we know that hardly any one of them can be exemplified in practice, owing to the nature of the materials at our disposal? This, indeed, seems to be what "J. D." realises fully when he sums up with the remark "that nearly all that can be done with herbaceous plants is to avoid a spotty effect by massing the colours;" and the gardener will understand such language as "families of plants produce related tints among their different varieties," meaning, as he explains, that "all *Roses* harmonize, also all *Gladioli*, all *Carnations*, nearly all *Pansies*, *Poppies*, *Auriculas*, *Phloxes*, and *Lilies*," &c. If this was understood before, the knowledge has not hitherto been generally acted upon.

*

MORTALITY AMONG HORTICULTURAL PAPERS.—The obituary notices of these have been rather frequent of late—*Floral Magazine*, *Horticulture*, *Record*, *Irish Gardeners' Record*, *Gardener* and, lastly, the *Journal of Botany*; while those who read the signs of the times know it has been a time of trial for others. What has been the cause of these failures? It cannot be that less interest is taken in gardening, for it is expanding everywhere; nor is it because there are fewer readers, for they are more numerous now than ever. The only explanation that suggests itself is that the defunct journals have been somehow out of joint with the times. It is curious to think, too, that "horticultural" Scotland is now virtually disfranchised; is, in the matter of gardening papers drawing her inspiration from south of the Tweed. Even the paper which was lately supposed to represent Scotland more especially was mostly written by Englishmen or gardeners living in England, which is much the same thing. The land of gardeners had better look to its laurels.

*

"VISCUM ALBUM."—Are those auto biographical sketches of our garden shrubs, in another paper, to be continued, and who are they intended for—the real rising generation or their fathers? We thought "Aunt Judy" monopolised that sort of thing in her magazine for babies and small folk; but these

two late leaders in your contemporary are quite in the "shilling's-worth-of-wonder" vein. Gardeners of sober years read their old friends "Aucuba japonicas" and "Viscum album" garrulous account of themselves with that kind of shame-faced feeling which prompts the enquiry, if the writer knows "who he is talking to." Many feel as if either they or the editor had suddenly gone back to their "Children's Magazine" days when

There were books full of pictures for presents and prizes,
Of all sorts of colours and all sorts of sizes;
And thousands of gay things and playthings and toys,
With dolls for the girls and toys for the boys.

TRADE ADVERTISEMENTS.—The advertisements of some of the horticultural papers are not by any means the least interesting portion of their contents now-a-days. It is said the trade read nothing else, but they are worth the gardener's perusal as well. Our growing penny friend, *Gardening Illustrated*, now enjoying such an immense and increasing circulation while other papers have fallen off, has gathered quite a new and numerous class of readers within the fold of the gardening fraternity, and the wants of these are in turn bringing out a new class of advertisers. The catalogues will soon not be needed. Nothing indicates the direction of the popular taste better than these advertisements, and those who want bargains would do well to consult them. Everybody who has anything to sell seems to find their way before the public, and no doubt the parcels post will greatly facilitate trade in this direction. Some buyers complain that they are disappointed with their bargains after having prepaid them, the goods not always turning out as was represented. This, however, should be no difficulty. We know gardeners in important places who consult the advertising pages for their wants, and meet this difficulty by making post office orders payable ten days after date.

ROCKERIES.—Some of your contemporaries have done good service lately in holding up to public criticism the worst examples of "British gardening." The last example of this kind is a formal rockery, which, like Artemus Ward's jokes, it is explained is a rockery, and to sustain the delusion to the spectator the rocks are periodically washed with a scrubbing brush, so it is stated. This scrubbing is to keep down the "cryptogamic vegetation," and occupies the time of nine or ten men for as many weeks. It is an "original" rockery also, and deserves the compliment because it does not resemble anything of the same kind in creation. "If you, gentle reader, wish to experience a feeling of surprise and astonishment," you are to "make your way" to this rockery, and you are if possible to "get the gardener to lead you to the garden by some back way." Like the productions of some great composers, one must ascend from the "depths" to understand the conception.

FLOWER GARDENS.—The next example is a flower garden—a new one too, that is the point—designed on the baldest and the barest, and the worst form of the bedding-out style—a grand architectural pile with an utterly barren garden. One of those mismanaged examples in which great wealth and high influence are prostituted to a miserable end, for the garden in question is an acknowledged failure of its kind, and the original looks worse than the illustration given of it in a contemporary about six weeks ago.

STYLES IN GARDENING.—In some ways the various styles of landscape gardening which have prevailed have had a baneful influence on garden design. People have followed them because they were fashionable only, without staying to inquire into their merits or demerits. And yet it does seem necessary to have some recognised style in gardening just as we recognise standards and principles in other matters. Without some guide of this kind it is evident that great mistakes must be committed, for people will just do what seemeth right in their eyes, and garden design will become a mere matter of chance and caprice, just like the

comical rockery and bald flower garden we have been speaking of. The landscape gardener is after all a necessity in a country like ours, but he must be worthy of the name—not a mere empiric—versed in his profession in all its bearing, free from prejudice and the fetters of fashion, a student of Nature, and skilled in all trees and plants, and their nature and adaptabilities. Only a school can produce such men, and that does not exist at present. No book has yet been written that goes beyond the mere routine of propagating and planting since the older authors wrote sixty or a hundred years ago, modern authors not seeming to recognise any broader or higher view of garden art than is compassed by the narrow limits of their summer flower beds and borders and their own limited experience.

SELF-HELP FOR GARDENERS.—An acquaintance occupying a position of influence in the horticultural world suggests that the time has come when institutions for the benefit of gardeners should rely on something better and more certain than the benevolence of the public. The Gardeners' Benevolent Society, although doing good in a small and disproportionate way, and worthily discharging its functions, has too much of the "frozen-out gardener's" ring about it—is, in fact, a "begging" institution. He proposes a union or brotherhood to promote a superannuation fund on self-help principles, and thinks such a numerous and intelligent community should be able to sustain such an institution as many other professions do—the Schoolmasters' Association, for example, or the Law Clerks' Society, &c. Very probably, if such a society was set on foot, it would at once succeed. Such projects need at starting an impetus to make them succeed.

VINE PLAGUES.—"Cambrian," I observe, "recommends frequent syringing up to the time the fruit is ripe." In the case of Vines infected by mealy bug, he will "venture to say anyone who will try this in a viney where bug is rampant will be astonished at the result." No one, we should think, doubts this. The result will be that instead of the pest being localised—confined to a few Vines and a few bunches—it will be evenly distributed over every leaf and every bunch in the viney, and the Grapes spoiled as well. Who ever heard of mealy bug being reduced by driving it broadcast over a house with the syringe and clean water? The idea is preposterous. It is too bad, also, to put down the examples of Grapes at the Edinburgh show as the result of "one quart of tar and four quarts of water," applied to the Vines "cleared of mealy bug in the manner just indicated." The way to keep mealy bug down on Vines is never to let it get into the viney, and that this can be done, let alone allowing the pest to get "rampant," is proved every day in gardens—at least where ordinary accommodation exists for the culture of plants that are wanted.

PEREGRINE.

Shoddy.—"A. D." (p. 586, Vol. XXII.) seeks information respecting this. Cotton shoddy is eagerly sought after in this district by farmers and market gardeners. I have not had an opportunity of using it myself. Those gardeners, however, who have been fortunate enough to get it pass very high encomiums on its fertilising properties for out-door crops as well as for all kinds of soft-wooded plants in pots. One of my acquaintances, gardener to a mill owner, uses it for hotbeds, covering bulbs in pots, plunging plants in pots, &c., and when it has become thoroughly decayed it is used for potting. What he has for hotbeds has a greater proportion of the larger particles of cotton in it than what the ordinary consumer could get, which is nothing more than coarse dust from the mills. As a manure for pot plants it has one advantage over the usual hotbed manure—it is free from worms, which are always a source of annoyance to cultivators. I am informed that Mr. Troughton, 4, Church Street, Preston, supplies shoddy in large or small quan-

ties. The exact price I am unable to give, but it is only a few pence per bushel.—R.

FLOWER GARDEN.

THE CARNATION AND PICOTEE.

Perdita: The fairest flowers of the season
Are our Carnations and streaked Gillyflowers,
Which some call Nature's bastards.
—*Winter's Tale*, Act iv., sec. 3.

No flower is perhaps so widely cultivated as the Carnation, for in what garden, great or small, do we not find some specimen or representative of it? The *Dianthus* family is divided by florists into various sections, the principal of which are as follows:—

Carnations.—Flowers containing a white ground, on which are striped or flaked one or more colours. They include (1) flakes, which have stripes of one colour traversing the petal from centre to outside; (2) bizarres, which have two colours, one light and the other dark, traversing in the same way the white ground. There are scarlet, purple, and rose flakes, and crimson, scarlet, and pink and purple bizarres. "Fancies" would include any flakes or bizarres of any other colours or neutral tints.

Picotees.—Flowers having the colour evenly pencilled round the edge. The edges, which are either heavy or light, are red, rose, and purple. (The word Picotee is derived from the French *picoté*—pricked with little flecks and spots, which is not the florist's idea of a Picotee; such a flower would be a "fancy.")

Yellow ground Picotees.—Flowers having a pure yellow ground, either flecked, fringed, or edged with colour. These have not been brought to such perfection of form, &c., as the others, but they are making rapid strides towards that end.

Self Cloves are flowers having only one colour distributed all over the petal. They are of all shades and colours except black, green, and blue.

Carnations and Picotees are cultivated in beds or pots for bouquets, exhibition, and other purposes, and as flowers for exhibition are required to have certain "properties," an article on the Carnation would not be complete without an enumeration of these.

Properties of a "perfect" Carnation.

—(1) The flower should be from 2½ inches to 3 inches across, but, it must be borne in mind, size is a very secondary consideration, the other properties, of form and colouring, being the most important. (I have myself beaten badly-marked flowers 3 inches in diameter with a flower less than 2 inches across perfectly marked.) (2) The largest petals must be outside, the others arranged above them according to colour, size, and to hide defects in those below. Each petal must be of good substance, and quite smooth at the edge, without the slightest notch or serrature in its outline; any unevenness is surely fatal to the stand. (3) The white ground should be pure and brilliant, not specked or tinged with colour of any sort. (4) The colour, or colours, should traverse the entire petal from the centre as much as possible in broad bands, clearly defined. In the case of a bizarre, the light colour should be bright and pure, the dark colour deep and rich, the two colours distinct, not confused or running into one another. (5) Each petal must contain the white ground as well as the marking; any petal entirely suffused with colour and showing no ground would disqualify the whole stand infallibly, as would any petal pure white not showing the colour, or in the case of a bizarre, both colours. (6) The pod of the bloom must not be split or burst by the opening flower.

A perfect Picotee would be one in form exactly the same as prescribed for a Carnation. The colour must be pencilled round the edge as if drawn by a careful hand, not tinging, or feathering, or barring into the ground, which must be pure white.

Disqualifications for exhibition.—(1) If any petal is dead or damaged; (2) if any petal has been substituted for another; (3) if any petal contains no white ground, or no colour, or in a bizarre only one colour; (4) if a pod is split too far down; and above all (5) if any petal be in the slightest degree notched or serrated in the edge. Flowers shown as fancies are not subject to any of these rules, but may be shown in any way, or lacking any of the above qualities.

Stock-taking.—Always get your plants as rooted layers in the autumn; September is the best month, and as soon as they arrive put them into their permanent positions about 8 inches or 10 inches apart in the bed, or singly, or a pair in a 3-inch or 4-inch pot if they are choice exhibition kinds, or you have no bed ready for them. In the pots let them remain in a cold frame all the winter, giving as much air as possible on fine days, but guarding them zealously from damp, wind, or rain, all which will worry them dreadfully if the layers were not well rooted when potted. In the beds they will require no attention. Neither in beds nor pots do they require more water than is necessary to keep them just reasonably moist, as the roots are dormant till the spring. If the plants are shifted or got in in the spring it often gives them a severe check not easily recovered. If the young plants are lanky and tall, tie a little stick to them, which will protect them from wind and rain, and prevent their getting twisted at the root, which is always dangerous. Keep them scrupulously clean.

Culture for exhibition.—About the end of July cover over the bed intended to be devoted to Carnations with 2 inches of good rotted manure, and add to this, if the soil is sandy, 2 inches of good mellow loam; or if it is stiff, the same quantity of sand. Then whenever you can spare time spread it regularly, and dig the bed over. As soon as the plants arrive put them in firmly, all of one sort in a row with a good legible label at the end. Thus they will need no attention till next spring, being perfectly hardy. At the same time take up and put in in the same way any seedlings sown in the spring, which will now be fine strong plants. Next spring when the continued cold has ceased (about March or April) fork over carefully between the rows, and water them if dry in fine weather. When the flower-stems begin to rise place a stick about 30 inches long to each plant. They should be painted a light whitish green. The flower-stems must be kept well tied up as they grow, tying quite loosely, as if the stems are tied tightly they will knee and bend, and finally break. About the 20th of June, or later, when the buds have appeared, take off all the buds but three on each shoot, so as to leave each bud a little footstalk to itself when it grows. What you lose by this in quantity will be repaid you twenty-fold in quality. From this time until the buds are nearly showing colour give them occasionally a little weak manure water, *i.e.*, a handful of well rotted stable litter to a large pot of water. As soon as the buds show colour at the top, tie them round about half way down with a little strip of bast. This should be done every morning early in July, as it will save much trouble and the unsightly peculiarity termed a "split pod." If, in spite of this, the pods split on one side, carefully open the bud all round at the other segments. For this purpose I use the flat wedge handle of the knife that I use for layering. Unless you intend saving seed, cut off dead blooms as soon as they wither, and the flower-stems as soon as no more buds are left to come out, which will be about the end of August or beginning of September. The last week in July, not later, see about layering. As soon as the layers are ready rooted, which will be early in September, take them off and lay them in by the heels for a time whilst you take up and throw away the old stools; top-dress and fork over the bed, giving it a couple of inches of well rotted stable litter or cow-house sweepings; replace your layers, and then you are in the same condition as you started.

Cultivation in pots.—As soon as the plants come in in the autumn or the layers are

ready from the old stock they should be put singly into 3-inch, or pairs of the same sort into 4-inch pots and placed in a cold frame, the pots plunged up to the rim in Cocoa-nut fibre. Here keep them all the winter, giving only just enough water to keep them from getting dust-dry. When you put them away see that they are scrupulously clean, dusting them over with a little brush. Between the 1st and 20th of October is the best time to store the plants away. Occasionally, when fine, go over the stock, cleaning off any dirt which settles itself on the leaves, &c., and give as much air as possible when fine. Remember that the greatest enemy is damp, which must most zealously be guarded against. In spring, when nothing but the late frosts are to be apprehended, say about the end of March, the plants should be put into their blooming pots. The best sizes are 7-inch for a single plant, or a pair of the same sort in a 10-inch pot. The best compost for potting the plants in the spring as well as the layers in autumn is one of good mellow loam, leaf-mould, cow manure, and silver sand in equal proportions. Each ingredient should be well rotted and quite sweet, and the mixture should be made as long before use as possible. I always take particular care to make my compost for layering into and for potting the layers in April or May, and my compost for the blooming pots next spring in the July of the preceding year. These heaps I turn over and pull about as much as possible all the year round, to thoroughly mix and sweeten them. When the potting season arrives take the blooming pot and invert an oyster shell or large crock over the hole at the bottom, and cover it with at least 2½ inches of broken crocks; over this lay a fine layer of moss in order to prevent the earth choking the drainage. Carefully turn the little plant out of its winter pot, remove the drainage from the ball, and put into the blooming pot enough compost to make the top of the ball come an inch from the top of the pot, mixing in with it as you put it in a handful or so of little lumps of charcoal, to keep all sweet; fill in up to within an inch of the rim of the pot. When all the plants are potted place them in masses—bizarres in one, flakes in another, Picotees, fancies, and so on, either on stages or on an ash bed. Stages are best formed of rafters 4 feet long 3 inches across 1 inch thick. Stand six inverted 10-inch pots on the ground in an oblong 8 feet by 2½ feet, with two pots in the middle; lay six pairs of rafters on them; from one end to the centre pots three pairs, and from the centre to the other end three pairs; thus you have a staging 10 inches high, 8 feet long, 2½ feet broad on which three rows of pots will stand, which is eminently portable, and can be stowed away for the winter every autumn. Arrange as many stages as you want with walks, 2 feet between them. If you cannot arrange stages thus, make an ash bed on which to stand the regiments of pots, by levelling the ground over an area the requisite size, treading it down and spreading over it 3 inches of ashes on which the pots may be placed. The best position for stages or ash bed is under the shelter of a wall facing south. It is as well, if possible, to erect a temporary shelter over the pots to protect them from late frosts and early cutting winds, but it may be taken off as soon as all chance of frost has gone. When the plants are potted, if any show signs of weakness or crooked growth, tie them up to a little stick. (I tie all my young plants thus.) If a plant gets twisted at the root, it is almost fatal, though, when a plant has got twisted, never try to straighten it. Early in June the flower-stems will be beginning to rise, when sticks must be placed to them, and the stems kept carefully tied up, tying loosely for reasons already given. As soon as the buds appear, disbud, leaving from three to six buds on each plant, according to its strength. Considerable judgment must be used in this matter, so as not to leave too many on a weak plant, or too few on a strong plant, for, in the first case, the flowers would be weak and poor, and, in the second, the flowers would be coarse and rough. As to the buds to be taken off and those to be left on,

leave the first, or top, bud on each shoot. As a rule, when a bud is blunt, and thick at the top it promises well for the flower, so leave that bud; but when fine and pointed, it generally is a bad sign, so if there are better promising buds take these consumptive ones off. In the matter of manure water, I have been successful with very weak decoctions (a trowel full of horse litter well rotted to a large pot of water) given from June 10 to July 10 (remember I am a southern grower) at every fourth watering. If a flower begins to open too much on one side towards the sun turn the pot round. As soon as the first flower shows colour invert on the top of each stick the broken-off bowl of a common clay tobacco pipe (which may be bought at 1s. 9d. per 100). These should be searched every morning for earwigs.

HARDY FLOWERS FOR CUTTING.

"J. H." says (p. 502), "How can I get a complete list of hardy plants to afford cut flowers, &c.?" Such a list would be longer than I can undertake to give, but I will endeavour to name a few which I have found to be useful for the purpose just named. By hardy flowers, I suppose "J. H." means plants which will unfold their blooms in the open air without or at least with slight protection, and to such I will confine my remarks. But it may at the same time be as well to say that where an abundant and continuous supply of cut flowers is required throughout the season this can hardly be accomplished without the necessary appliances of forcing pits or glass structures of some kind.

Amongst hardy plants likely to be useful for cutting may be named the Christmas Rose, the flowering of which, although it varies somewhat in accordance with the character of the seasons, may generally be said to be from the early part of December to the end of February. But in order to obtain clean, pure white blooms for cutting the plants should during inclement weather be covered with hand-glasses or a frame. Various other species of Hellebores are also useful in a cut state and succeed the Christmas Rose as regards their time of flowering, such as *H. maximus* and *H. intermedius*, both probably cross-bred varieties between *H. niger* and some of the spring flowering species. The *Sternbergia lutea*, or the Lily of the Field, produces clear bright yellow blooms in the very depth of winter, or, at all events, when the soil is not altogether frost-bound, and its flowers keep well in water, as do also those of the winter Aconite. The clear yellow flowers of these contrast agreeably with those of the Snowdrop, and also with those of the pretty *Leucojum vernum*, which comes into bloom somewhat later. The pretty blue flowers of *Scilla biflora* and *Chionodoxa Lucilia*, the various varieties of *Hepatica*, European Cyclamens, early Tulips, Hyacinths, and Grape Hyacinths, Violets of different sorts, single and double Anemones—all these will be found to be exceedingly useful in a cut state; and as the season advances plants whose flowers are still better adapted for this purpose will become plentiful, such as Daffodils, including double and single sweet-scented Jonquils, the Hoop Petticoat (*Bulbocodium vernum*), *Narcissus Campbrellii*, *N. poeticus* or Pheasant's-eye *Narcissus* and its double variety, which in purity of colour as well as delicious perfume rivals the blooms of the *Gardenia* itself. To these may be added the Dog's-tooth Violet, *Triteleia uniflora*, *T. conspicua*, *Ixia*, *Sparaxis*, *Babianas*, &c. Primroses, Polyanthus, alpine Auriculas, double-flowered varieties of the Pansy, double and single Wallflowers, *Alstroemerias*, the blooms of which are all admirably suited for cutting, and also those of many of the early Irises and Gladioli; the old *Tigridia Pavonia*, a charming flower, which unfortunately lasts for only one day cut or uncut; *Lily of the Valley*, *Solomon's Seal*, *Spiraea japonica* and *palmaria*, and *Dielytra spectabilis* with its gracefully depending blooms. To the above-named hardy plants and early flowering bulbs, the list of which might be greatly extended, may also be added the names of various

Early-flowering hardy shrubs, the blooms of which are all useful for cutting, such

as *Chimonanthus fragrans* and its large-flowered variety, both of which bloom profusely in the very depth of winter, and the flowers are also highly perfumed. This shrub, however, being a native of Japan, requires in this country the protection of a wall or a sheltered situation, as does also *Jasminum nudiflorum*, which blooms profusely at midwinter; its long spikes of yellow flowers, devoid of foliage and of scent, mingle well with the flowers and foliage of other plants in vases or glasses. With these might be associated the *Forsythia viridissima*, *Coronilla glauca*, *Magnolia fuscata*, and the Pomegranate, all of which will bloom in the open air in a sheltered situation or on the south side of a wall. For forming a succession to these may be named the *Edwardsia macrophylla* and *E. microphylla*, *Escallonia rubra*, *Illicium floridanum*, *Olea fragrans* or the Olive, *Indigofera*s, *Lonicera*s or Honey-suckles, the single and double varieties of *Kerria japonica*, *Calycanthus floridus*, *Buddleia globosa*, the hardy *Fuchsia Riccartoni*, *Ceanothus azureus*, the latter a very pretty profuse flowering plant. There is, too, the *Laurustinus*, well known to be one of the prettiest winter flowering shrubs we have; also *Berberis Aquifolium* and *Fortunei*, and *Choisya ternata*. The last is a pretty Mexican shrub which is quite hardy, and which blooms in February; its flowers resemble those of the Orange, and are also sweet scented. The blossoms of the various *Daphnes* are likewise great favourites, as are also those of various species of the *Cistus* or Rock Rose, all very beautiful and well adapted for cutting. There are also the varieties of hardy Heaths and *Menziesia*, or Irish Heath. Some of the early flowering *Rhododendrons*, *Azalea amena*, and the pretty Ghent varieties of this genus, with the various *Kalmias*, &c., all of which are useful in a cut state. Most of the above are what may be considered evergreen or sub-evergreen shrubs. But many useful varieties may also be found among what are known as

Flowering deciduous shrubs, such as the *Philadelphus* or Mock Orange, *Persica fl.-pl.* or the double blossomed Peach, the double flowered Almond, &c., *Cerasus Padus* or Bird Cherry, and *Cerasus fl.-pl.* or double flowering Cherry. The latter is an admirable plant for the production of white rosette-like flowers. Most of the *Deutzias* are also useful for this purpose, particularly *D. crenata fl.-pl.* and *D. gracilis*, *Viburnum Opulus*, or the Guelder Rose, the *Colutea*, or Bladder Senna, and *Cytisus*es of different sorts, all of which, including the *Laburnums*, are exceedingly handsome free-flowering shrubs; as are also the *Syringa*, or Lilac, more particularly the Persian varieties. Also various species and varieties of the Honey-suckle, the *Jasmine*, and the *Clematis*. Many of the *Ribes*, or flowering Currants, bear pretty flowers, and the *Potentilla fruticosa* is a very free flowering shrub; also the *Rhus Cotinus* or Sumach on account of its fine foliage and curious wig-like inflorescence, together with flowering Thorns and *Roses* of many kinds. As summer approaches many of the most suitable plants for the production of cut flowers will naturally be in bloom, such as the *Pink* and the *Carnation*, *Aquilegia*s, *Delphiniums*, and many annual flowers, such as the *Sweet Pea*, *Mignonette*, &c. For the autumn months the blooms of some of the late flowering *Phloxes*, *Anemone japonica* and its white flowered variety (*Honorine Jobert*), *Aconitum japonicum*, which blooms very late in the season, single and bouquet *Dahlias*, *Chrysanthemums*, &c., all of which will yield a more or less abundant supply of cut flowers throughout the greater part, if not during the whole year. P. G.

Violets.—The mild weather the last week in the old year has certainly brought with it a charm, as though it would steal some of the pleasures of spring in the form of sweet Violets. Although the autumn and winter cannot be said to have been particularly cold (a few days excepted), Violets have not been so plentiful with us this winter as last, although we have a greater stock planted about the same time (*viz.*, early in May, 1882) as the preceding year. But the recent mild weather

has brought with it abundance of bloom both in frames and out-of-doors; the former is one sheet of blue, and the fragrance around them is delightful and may be detected in the breeze some distance off. It would appear as though the damp mild weather supplied them with all they required for their proper development, and I may state that, added to this just now, the chattering and singing of small birds lend additional charms, and almost makes one imagine we have arrived at spring, although the old year has only just passed away.—C. WARDEN, *Clarendon*.

Early Primroses.—Of winter flowers few are so persistent in making their appearance at every mild break in the weather as Primroses. I find the single white even more precocious than the common wild Primrose of our woods, but these under cultivation seem to take the habit of garden varieties, and to flower more or less plentifully, according to temperature, from October to March, when the display they make is quite charming. I find some of the coloured kinds to be very floriferous in autumn, and more or less through the winter, and none the less able to hold their own in spring with other kinds. Possibly indeed in time we may get these characteristics more fixed, for until recently the Primrose has received but very scanty attention. I am now gathering flowers from plants lifted and replanted quite late in autumn, and though not so good as those from plants transplanted in spring directly after flowering, they are nevertheless welcome at this season of the year. I may mention that I find the shelter of a hedge to act both as a screen from cutting winds in winter and from scorching sun-rays in summer, most useful in the case of the Primrose. I have planted a thick hedge of young bushy *Hollies* specially for a Primrose shelter.—JAMES GROOM, *Seafeld, Gosport*.

Cultivation of show Auriculas.—May I be allowed to say that the two articles on the Auricula published in *Gardening* last June probably comprise the lecture on the Auricula which I was asked to give at the Royal Horticultural Gardens. That was simply an attempt to trace the long and touching history of the flower, and was not intended to be a cultural treatise. This I stated briefly, but pointedly, in the few very general remarks I made on the cultivation of the Auricula. "M. R." has therefore only not found that which was avowedly not within the plan and province of the lecture. "The filling up for beginners," which I think has not been forgotten in its proper place by writers, may be found in Mr. Douglas' book called "Hardy Florist Flowers," and I have also left a legacy on the subject in the pages of the "Florist and Pomologist" from May, 1876, to July, 1877. Those papers follow the Auricula from month to month throughout the year; and I so strongly recognised the truth of what "M. R." states respecting the value of minute details in practical directions, that at the time of writing I often thought I was even erring on that safe side.—F. D. HORNER, *Kirkby Malzeard, Ripon*.

Wallflowers.—I have on this, the 1st of January, just gathered quite a handsome nosegay of Wallflowers, and so deliciously perfumed that the odour pervades the house. I might have gathered many such bunches, but doing so sacrifices too much of the woody part of the plants, and therefore flowers are picked out and thrown down that the plants may bloom later and at a more suitable season. A good bunch of the rich crimson kind, lit up with a few heads of bloom of the bright yellow and golden variety, gives a nosegay that in this mid-winter season few would despise and myriads would be delighted to possess. Wallflowers have been furnishing to the market growers abundance of flowers during the recent mild weather, but dull skies and very bright sunshine are both unfavourable to colour, for in neither case is the rich blood-red hue seen that is the prominent feature of the London market strain in the spring. A few plants perhaps are steadfast, but usually the colour now is washy. The yellow kinds, on the other hand, are very constant, and

the purity of the flowers renders them just now specially attractive. Wallflowers will always bloom early if sown early, but still early strains are more productive of precocious flowers than are those in which special selection of early kinds for seeding has not been practised. I have seen in market fields plants from seed sown in February that were dwarf and dense and quite 18 inches through. One such plant would of itself give a good bunch of bloom at the cutting season. By selecting the very earliest flowering plants, if allied to that feature are rich colour and a good habit, a strain in a few years becomes so even that it can always be relied upon to produce flowers of rich hue very early and of the finest quality. Strains of this kind once secured are held with great tenacity by the growers, who pride themselves on the possession of them.—A. D.

PLANTS IN FLOWER.

PINGUICULA CAUDATA.—As an instance of the remarkably protracted flowering season of this charming new Butterwort, we may mention that it is still in bloom in the vestibule adjoining the Orchid house at Kew. Its large carmine-tinted blossoms rival in beauty those of the choicest forms of *Masdevallia Harryana* and *Lindeni*, to which, singularly enough, they bear some resemblance.

CYCLAMEN BRILLIANT is one of the finest forms of the Persian Cyclamen we have seen, the colour being peculiarly brilliant—of a kind of carmine-crimson as near as it can be described. The flowers, moreover, though not monstrously large, are, as the florists term it, of refined form, and it seems to be extremely floriferous. We singled it out from a large group in flower in Mr. B. S. Williams' nursery, Holloway, as being specially worthy of note.

ACACIA DEALBATA.—In a week or so the fine specimen of this tree, about 40 feet high in the temperate house at Kew, will be a magnificent sight. It will then be a mass of primrose-yellow bloom, which, contrasted with the silvery foliage, is lovely. Nowhere else in gardens can such a plant of this *Acacia* be seen, and every successive year it seems to become more beautiful. Small plants of this *Acacia* flower freely, and few more beautiful plants could be recommended for winter decoration.

WINTER-FLOWERING HEATHS.—Among those in flower in the Heath house at Kew, the prettiest are *Erica melanthera*, with myriads of tiny wax-like white flowers with black-tipped stamens in the centre; *E. hyemalis superba*, much superior in colour to the ordinary form; *E. mammosa* and varieties, all very fine; *E. cerinthoides* and its variety *coronata*, two of the most beautiful of all Heaths, both with clusters of large scarlet blossoms; *E. colorans*, *Lambertiana*, *Juliana*, *caffra*, are also desirable and distinct kinds.

RHODODENDRON JASMINIFLORUM, with its clusters of waxy white tubular flowers, is a singularly beautiful winter flowering shrub, as indeed are all *Rhododendrons* of the Japanese type. We notice even small plants in the greenhouse at Kew furnished with a quantity of bloom. It requires to be grown in a higher and moister atmosphere than that of an ordinary greenhouse, which, however, conduces to preserve the flowers longer. Those who desire beautiful winter-flowering plants for cutting or otherwise cannot do better than make a note of this and other Japanese *Rhododendrons*.

NEW MARGUERITE.—From Messrs. Cannell, Swanley Nurseries, we have received quite a novel kind of single Daisy or Marguerite, but it is neither more nor less than the single-flowered or typical *Pomponé Chrysanthemum* which for so many years appears to have been involved in obscurity. The variety is called *New Departure*, as it is so different from any other Marguerite. The flowers are about 1½ inches across, and have two or three rows of narrow snow-white ray florets,

but which do not in any way hide the golden central disc. It is said to be very free flowering and graceful, and the stems are very slender. The plant bids fair to become very popular for cutting from, particularly as it flowers in autumn and winter. Messrs. Cannell possess, we understand, a few other new varieties of this section of *Pompone Chrysanthemum*, varying in the colour of the flowers.

PELARGONIUM CHARLES DARWIN.—This double-flowered zonal *Pelargonium* is with me one of the best for winter flowering. Amongst a large collection kept in an ordinary greenhouse two sorts stand out prominently in this respect; they are *Guillon Mangilli* (mentioned the other day in *THE GARDEN*) and *Charles Darwin*. The latter is rather vigorous in habit, and the flowers rich violet-crimson in colour with an undescribable metallic lustre about them like that of the well-known single kind named *Dr. John Denny*.—H. P.

GARDENIA CITRIODORA.—One does not often meet with this neat little shrub in ordinary gardens, though in a sense it is quite as beautiful as its popular congener, the button-hole double *Gardenia*. The *citriodora*, as its name implies, has flowers scented like Orange blossoms. They are about the size of a florin, borne in numerous clusters on short twigs, profusely even on small plants. It is neat in growth, and never fails to produce a good crop of bloom in winter. It is now in flower at Kew, and though an old garden plant, is one of those that well merit attention from the general cultivator. It thrives under ordinary stove treatment.

GOLDEN ACONITES.—Just a few spikes of this, the earliest of our hardy bulbs, to show you how pretty they are. I like them so much that I anticipate their our-door season by planting a few roots in pots or boxes and placing them in a cool house. They do not force well in the ordinary acceptance of the term, but come on readily under the stage of a greenhouse until just about to expand, when they are placed in a more prominent position, and very pretty they are, and I may say useful, especially for amateurs, to whom any kind of flower is welcome at this season. I find boxes of common *Stonecrop*, planted in autumn, also make very pretty greenhouse ornaments.—JAMES GROOM, *Seafield, Gosport*.

ROSES ON NEW YEAR'S DAY.—I send you a box of General Jacquemont *Rose* blooms gathered in the gardens here to-day (January 1), showing how well this *Rose* does here. They bloomed profusely all the summer and up to December 11, when we had severe frosts and 20 inches of snow, which remained on the ground until December 17 when the thaw came. Since then we have been having fine, mild, but showery weather and a little frost. They are again blooming, and if the weather continues favourable there is a great quantity of blooms just opening. We are 3000 feet above sea level, but well sheltered from the north winds.—EDWARD TATE, *Balcarras, Colinsburgh, Fife*. [Uncommonly fine blooms, particularly having regard to the untimely season.]

STRELITZIA REGINÆ.—Some time ago I sent you a brief account of this curiously formed and coloured flower. I now send a spike from the same plant, singularly coloured orange and blue, and I may mention that the flowers last a long time in perfection; as soon as one set of orange petals and the blue tongue begin to fade another set is pushed up from the base of the older ones, forming a double flower. It is rarely that one meets with this old inhabitant of our plant houses, *Coleuses* and similar plants that acquire quickly the dimensions of good-sized bushes having taken its place; but it is, nevertheless, a plant possessing more than ordinary interest, and requiring only a medium temperature in which to grow to perfection. It is by no means fastidious as to soil, and it keeps on producing fresh flowers for several weeks in succession. I feel sure, therefore, that it only needs to be made better known to be more extensively grown than it is at present.—JAMES GROOM, *Seafield Nursery, Gosport*. [*Strelitzia*

reginæ and also *S. ovata* are in flower at the present time in the Palm house at Kew.]

LACHENALIA PENDULA AND QUADRICOLOR.—Some remarkably fine spikes of these two plants have been sent to us by Messrs. Smith from their *Caledonia Nursery, Guernsey*. The first possesses a stout flower-spike nearly a foot high, densely furnished with coral red blossoms about an inch in length. They gracefully droop on all sides of the spike; hence the specific name, *L. quadricolor*, is a more slender-growing species—more in the way of the well-known *L. luteola*. The flowers, from eight to ten on each spike, are about an inch long. The calyx is an orange-yellow, tipped with green, while the petals are a greenish yellow, conspicuously tipped with claret-purple. Both these *Lachenalias* are particularly welcome in mid-winter, and should find favour with all who are fond of showy and, at the same time, flowers possessing a somewhat uncommon aspect.

MASSANGEA (TILLANDSIA) MUSAICA.—During the week we have seen this rare and handsome *Bromeliad* in flower at Kew, also at Mr. Bull's nursery, Chelsea, where there are numbers of plants of it. It is beautiful in a two-fold way. The foliage, which is long, broad, and of a leathery texture, is gracefully recurved in a vasiform manner, and is curiously marked on its upper surface with hieroglyphic-like tracings of pale green or almost white on a dark green ground. On account of the semblance of these markings to mosaic characters it was named *musaica*. The stout, erect flower-stem arises from the centre of the tuft of foliage for about a foot in height, and is furnished with reddish bracts, and terminated by a dense cluster of erect flowers, which are yellow on the lower part and white above. These three colours, the white, yellow, and red, make a singular combination, which makes the plant conspicuous. It is somewhat remarkable that handsome *Bromeliaceous* plants such as this should not be more appreciated in this country than they are. On the Continent, and especially in Belgium, *Bromeliads* are great favourites.

EUCHARIS CANDIDA.—The more we see of this beautiful bulbous plant the more we are convinced of its great value, particularly for affording an abundant and continuous supply of cut flowers during winter. It is not second even in beauty to its popular congener, *E. amazonica*, and, being smaller, it is even more desirable, especially for association with other cut flowers. The blossoms are about a third smaller than those of the *Amazon Lily*, but are of the same waxy texture and snowy whiteness, save the cup, which is tinged with a greenish yellow. It is a vigorous grower, and develops leaves as large or even larger than *E. amazonica*, and continues to produce flower-spikes throughout the winter if grown in a moist, warm stove. It may be successfully grown in a good, turfy loam, enriched by a little well decayed manure. In Messrs. Shuttleworth and Carder's nursery at Clapham, who have imported the plant from South America by the thousand, there is now a beautiful display of bloom; some huge specimens in 14-inch pots bearing a quantity of flower-spikes, as many as ten and a dozen blooms on each, is really a lovely sight at this season.

Re-appearance of certain plants.—I have read Mr. Webster's letter on this subject with great interest. In the cases mentioned the seeds probably laid dormant in the ground till circumstances favoured their germination. The subject affords an ample field for constant and careful observation. In this immediate neighbourhood the *Butterfly Orchis* and the broad-leaved *Helleborine* (*Epipactis latifolia*), which last grew abundantly, have been diminishing since the year 1873. I watch most carefully for them each summer. The succession of bad seasons may have something to do with this diminution, especially as the soil on which these two plants grow best is a heavy gault clay. I am sure they are not interfered with by botanists. One would be glad to know that the Durham clergyman had concealed his *Lady's Slippers* from the collectors,

who, if they once found them out, would not leave one behind.—WILLIAM WICKHAM, *Binsted-Wyck, Alton, Hants*.

FERNS.

ADIANTUMS.

(Continued from Vol. XXII., p. 569.)

A. curvatum.—A very fine species from Brazil, producing from a thick underground rhizome its fronds, which are very distinct from any other *Adiantum*, as the pinnae being much curved backwards give them a very peculiar appearance; they are large, tripinnate, and bright green in colour, and, under good cultivation, attain the height of 2 feet. If this beautiful species is not always seen in such good condition as to show its beauty it is because it requires more shade than any other *Maiden-hair* with which I am acquainted, a fact which is not generally known. Stove.

A. cyclosorum.—This grand species, from New Guinea, is very effective. Its fronds, which are tripinnate, and reach 2 feet in length, possess a very plumose appearance, as the pinnae and pinules are set far apart. They are gracefully arched, and of a beautiful bronzy pink when in a young state, whereas when matured their colour is of a very pleasing light green. The pinules, which are rather large, are semi-circular in shape and prettily serrated. Stove.

A. decorum.—A well-known and extremely handsome species from Peru, somewhat resembling *A. cuneatum*, but of gigantic proportions. The fronds are larger in all their parts than those of the above-named species, and they are produced in great numbers from a tufted crown. It is of a lighter green than most *Adiantums*, and is a very useful plant for decorations, and in that respect second only to *A. cuneatum*, from which it is easily distinguished by its pinules much more rounded and slightly serrated. Stove.

A. excisum multifidum.—This charming garden variety partakes somewhat of the characters of *A. concinnum* as regards the way in which its fronds are produced, and also their drooping habit, and of *A. cuneatum*, of which it possesses the dark green colour. The fronds are quadripinnate, the pinnae deeply cut, giving it a very graceful appearance; they grow from 15 inches to 18 inches in height; they are frequently divided at their apex into several branches, which very often are again divided, forming a beautiful tassel some 2 inches or 3 inches long. Stove.

A. excisum nanum.—This, also a variety of garden origin, is a plant of small dimensions. Its rigid fronds, which are produced in great abundance from a crown, seldom attain more than 8 inches in height. They are tripinnate, with pinnales wedge-shaped and densely set. It is very useful where dwarf Ferns are required for edging, or where small fronds for mixing with flowers are in demand. Stove.

A. farleyense.—This very elegant *Adiantum*, from Barbadoes, is by far the most interesting of the whole tribe, and might with justice be called the queen of the *Maiden-hair* Ferns. It is too well known to require a very elaborate description, which, however good and complete, would most likely fail to do it full justice; it has been given at different times as a natural spot or accidental seedling from *A. scutum* (*Ghiesbreghtii*) or a cristate form of *A. tenerum*. Be what it may, either a species or a variety, this evergreen East Indian plant is unrivalled for exhibition purposes, where it always attracts a great deal of attention, and shows the gardener's skill to great advantage with its immensely broad, quadripinnate, and gracefully-drooping fronds growing from 2½ feet to 3 feet high. When grown near to the glass, and with plenty of light, the pinnales, which are of an enormous size, beautifully cristate, deeply fringed, and with almost crispy lobes, are very prettily edged with a delicate pale crimson tint, turning to

a pleasing rich light green when quite a nature Stove.

A. Feei.—A most distinct species from Mexico, quite different from any other *Adiantum* in cultivation. It is of semi-scandent habit, seemingly a climbing Fern, with fronds extending to 2½ feet in length and tripinnate in shape and dull green in colour, their stalks covered with ferruginous short hairs. It is a capital kind for cutting purposes, as it stands well when cut and put in water, but it lacks the graceful appearance of most of the other *Adiantums*. Greenhouse.

A. formosum.—This fine strong-growing New Zealand species is one of the most ornamental Ferns in cultivation, and is on that account grown in immense quantities. The fronds, which are quadripinnate, light green in colour, and from 2 feet to 3 feet in height, are produced from slender underground creeping rhizomes. They are erect, or nearly so, with pinnules small and hairy rachis, and their stalks, which are proportionally very strong, are of a shining jet black. It is of very easy culture, and succeeds admirably in a greenhouse.

A. fulvum.—A very pretty compact plant, producing from a crown its bipinnate hairy fronds from 8 inches to 12 inches long; they are of a soft greyish green, slightly hairy on both surfaces; the stem is rough and also covered with small hairs. It is an excellent plant for the greenhouse.

A. glaucophyllum.—This is a very beautiful, neat, small growing species from Mexico, rarely exceeding 8 inches in height. The fronds, which are produced from a slender rhizome, are erect, bi or tripinnate, and of a pale green colour; the pinnules are sometimes wedge-shaped, sometimes spatulate; their underside is glaucous. It does well in a greenhouse.

A. Henslovianum (sessilifolium).—A distinct species from Peru, and certainly a good addition to the genus as an ornamental stove Fern. The fronds, produced from a creeping caudex, are tripinnate, arching, of a semi-drooping character; when fully developed they are from 2½ feet to 3 feet in height, proportionately broader with the lower pinnae slightly branched, very delicate in texture, and light green in colour. It is of quite a different aspect from all other *Adiantums*, as the stalk, instead of being thin, black, and shiny, is thick, fleshy, and slightly hairy. It is of easy culture. Stove.

A. Hendersoni.—This handsome species grows from 18 inches to 24 inches high. The fronds are produced from a decumbent rhizome; when mature they are of a beautiful dark green colour, the young ones being of a very rich bronzy crimson, which tint they retain for a very considerable time. It is of very distinct growth, the fronds being of a semi-drooping character, giving the plant a very graceful appearance. Stove.

A. hispidulum.—A very handsome species, with fronds profusely produced from a crown, and attaining the height of 15 inches to 20 inches. They are pedate or flabellate, dark green in colour; the stalk rough, being covered with short, stiff brown hairs. It is an Australian species of very easy culture, and does well in a greenhouse.

A. intermedium.—This Brazilian species is a very ornamental evergreen stove Fern, with fronds produced from a decumbent rhizome. They grow from 18 inches to 24 inches high, and are bipinnate, dark green in colour, and their stalks, which are rather thick for an *Adiantum*, are covered with short brown hairs. It is very distinct. Stove.

A. Lathomii.—A beautiful garden variety, probably a natural sport from *A. scutum* (Ghiesbreghtii), from which it differs in having a gracefully drooping instead of a semi-erect habit of growth. The fronds are produced from a tufted crown, and measure from 2½ feet to 3 feet high; they are triangular or rather pentangular in shape from the enlargement of the basal pinnules of the lowest pair of pinnae; they are quadripinnate and

borne on smooth black stalks; the pinnules, which are very large, are trapeziform. It is one of the most ornamental of the large growing species of Maiden-hair, and as useful in its way as the smaller growing *A. cuneatum*. Stove.

PELL-ÉA.

GARDEN FLORA.

PLATE CCCLXX.

VANDA HOOKERIANA.*

AFTER having been cultivated in European gardens for the past ten or fifteen years at least, this Bornean *Vanda* has at last been induced to flower. I am not quite sure who was the first to discover it, but believe it was either Mr. Low or Mr. Lobb. The wild plant is very common in Borneo, beside rivers as also in brackish swamps near the sea, and so far as my own personal observations go, always growing as an epiphyte on a slender-stemmed *Pandanus*, which is itself a most beautiful plant when laden with its bright red Horse Chestnut-like fruits. The *Vanda* is particularly abundant near Brunei, the great water city and capital of Borneo, a place resembling in many respects the ancient Swiss lake dwellings. Its native name is "Etek amas," or "Gold Duck," and its beauty is celebrated by the natives in songs and legends in common with many other beautiful plants and trees. It grows, fully exposed to the sun, on the slender *Pandanus* stems, and flowers at the commencement of the rainy season in great profusion.

One of the first Orchids which attracted my attention in Singaporean gardens was this plant (and its Burmese congener, *V. teres*) which was planted out in front of the bungalows, stout poles or stakes being driven into the ground near the plants, and up these supports the plants clambered, supporting themselves by means of their aerial roots. Well-established masses of *V. Hookeriana* so grown in that tropical paradise, warmed by a vertical sun, and deluged by nightly rains—rains compared to which our heaviest thunderstorms are but mere showers—are very beautiful objects. When so nourished by copious heat and moisture their profusion of flowers reminds one of clumps of Sweet Peas as seen in our gardens here at home. The plate is a faithful representation of the plant which first flowered in this country in the collection of Sir Nathaniel Rothschild, whose gardener, Mr. Hill, deserves great credit for having lifted the veil of curious conjecture from the face of such a dainty Oriental beauty. *V. teres* has the advantage in point of mere size, but in brilliance and delicacy of tinting and in the exquisite markings of the widely-expanded lip *V. Hookeriana* has no equal in the whole genus of beautiful species to which it belongs. Although the plate shows the blossoms only, the species has far greater potentialities. On referring to a sketch I made in the Botanical Gardens in Singapore in August, 1877, I find the spike which the curator allowed me to cut had only one flower open, and that near the end of the spike, the extreme end of which bore two or three of its singular sharp-angled buds, each bud bearing two curious tail-like points at its apex. But then

this spike had been blooming for some time, having already borne six or seven flowers, as attested by the scars whence the pedicels had parted, the ovaries having fallen away unfertilised. One singular trait of this and many other Orchids, as seen wild or "at home," is the gradual development of their indefinite inflorescence. Under cultivation this is not so evident; the flowers, being protected from rain, wind, and insect agency, endure fresh and fair for a much longer period; hence it is not uncommon to see every flower on the spike of a *Vanda* or of a *Phalænopsis* open at the same time in our Orchid houses.

In Mr. Lowe's Orange groves at Labuan I particularly noted at intervals extending over a year a plant of *Phalænopsis grandiflora*. One spike dangled down 4 feet or 5 feet below the tuft of leaves, and during all that time it bore at least one, and sometimes as many as three fully expanded flowers. All the time the point of the inflorescence grew and put forth fresh buds as flower after flower fell away below, and on the zig-zag spike I counted fifty-four scars from which the flowers had fallen. So much for light, heat, and fresh air, in all of which the majority of epiphytes delight, but which, as above hinted, do not conduce to the endurance of their individual blossoms. I make these notes because erroneous impressions are not unfrequently conveyed when old flower-spikes are exhibited—say, for example, of a *Cattleya* bearing thirteen or fourteen scars on each flower-spike—since it does not follow that like results are obtainable under our present conditions of culture, and even in a state of nature, it is rare to find all or half that number even fully open at the same moment. All this shows that the plant we now illustrate is likely to become a much more showy garden plant than even Mr. Moon's exquisite plate would lead one to expect.

Now and then its Indian ally, *V. teres* (which some find difficult to bloom because they starve it under the name of "rest"), when strongly grown surprises us by producing many flower-spikes. Perhaps the finest specimen plants, both as to growth and flower, ever seen were those in the Londesborough collection when at their best, and they were, I believe, never dried off. I must ask Mr. Bedford, who was Mr. Denning's foreman at the time, to say if he remembers the number of flowers each bore, and how many blossoms each spike gave, if he will kindly do so at his leisure. I remember they were specially awarded a medal by the Royal Horticultural Society at South Kensington as wonderful examples of good culture at the time I received the impression that they had experienced the very reverse of dry treatment—indeed, was told that they were watered, if not syringed also, every day in the year except when actually in bloom. As I turn up "*Vanda*" in my notes, I find one paragraph from a contemporary which may be quoted as showing the capabilities of *V. teres* when well grown. The writer is Mr. Duncan Munro, Finnart Gardens, Dumbartonshire: "We have just now in flower a plant of *Vanda teres*. The plant is about 3 feet high, and has three spikes upon it, and on each spike eleven flowers." Yes; no doubt that *Vanda teres* was "in flower," and I very much question if it is not the greatest number of blooms on a spike yet recorded. The name "*Vanda*" itself points to the epiphytal habits of the plants of the genus, it being the Sanscrit equivalent for *Loranthus*, or *Mistletoe*.

* Our plate was prepared from a plant that flowered in Sir Nathan et Rothschild's garden at Tring Park in the first week in September last.

Growers or introducers of new plants will oblige us much by early intimation of the flowering of new or rare species, with a view to their representation in our "*Garden Flora*," the aim of which is the illustration in colour, and in all cases where possible life size, of distinct plants of high value for our gardens.

VANDA HOOKERIANA

I have purposely avoided saying a word on the culture of *Vanda Hookeriana* in deference to Mr. Hill, who is so fortunate as to have succeeded in flowering a lovely species, in the culture of which myself and others have signally failed. F. W. B.

[Mr. Hill, Sir Nathaniel Rothschild's gardener at Tring Park, the person who first flowered *Vanda Hookeriana* in this country, thus writes respecting its culture: "I will briefly state my experience with regard to two plants of this *Vanda* that came to us from Messrs. Veitch about this time last year, and which for a few weeks were placed in the *Phalenopsis* house pending necessary arrangements for their removal to what we considered a more suitable place for them, viz., a hip-roofed pit with a south aspect. The plants in question were trained close to the glass, and not a particle of shading was given; consequently, during bright sunshine the temperature ranged very high, plenty of air being at all times admitted. The Teak block upon which the stems were fixed was covered with *Sphagnum*, and inserted a few inches in a pot, which was filled with crocks and *Sphagnum*, plenty of moisture being given by a free application of the syringe several times daily. One plant produced a flower-spike in July which attained half an inch in length, but failed to get any further. A few weeks later a spike appeared upon the second plant, which grew away rapidly and developed two flowers, which were accurately described in *THE GARDEN* (p. 239), and exhibited at the September meeting of the Royal Horticultural Society. After flowering, the plant was allowed to rest for a time, but it has again started into active growth, and is now freely supplied with moisture. I am thoroughly satisfied with the way in which our plants are going on, and hope to flower half-a-dozen next year."]

ORCHIDS.

ORCHIDS AT CLAPHAM.

THE following beautiful winter flowering Orchids are singled out as worthy of notice among those in bloom in Messrs. Shuttleworth and Carder's nursery, Park Road, Clapham:—

Comparettia macroplectron is one of the most beautiful amongst them, and we have never hitherto met with it so finely flowered. One plant here has a spike $1\frac{1}{2}$ feet long, with side branches widely spreading out and carrying about a score of blooms, though the recent fogs have greatly impaired their original beauty. The light, airy habit of growth of this plant and the singular form of the flowers, combined with their delicate colour, render it in every way charming. The flowers have a heart-shaped labellum an inch or so across, of a most delicate shade of rose-pink, copiously spotted and lined with markings of a richer colour. Added to this there is the beautiful colouration of the sepals, which are abundantly freckled with deep rose-pink on a light ground. The long, transparent white spur that projects from behind the flower for fully 2 inches gives a singular aspect to the plant. It is an intermediate house Orchid, easily grown on a suspended block of wood or in a basket. It flowers long and continuously throughout the autumn and winter. A coloured plate of this Orchid will shortly appear in *THE GARDEN*.

Spiranthes euphlebius is the name of a new terrestrial Orchid, lately introduced by this firm from South America. It may be best described as being similar to *Stenorrhynchus speciosus* or *Neottia picta*, but differs in several points. The broad foliage, produced in a tuft, is of a pale green colour, conspicuously blotched with white. From the tuft the slender stem arises a foot or more in height, terminated by a dense

spike of pink and white flowers, accompanied by membranous bracts of the same shade of pink. The flowers remain several weeks in perfection, and have a distinct and pretty appearance. It will be found to be a particularly useful plant, as it habitually flowers in the depth of winter. It is a thick rooted terrestrial kind, hence requires pot culture, but, as in the case of *Stenorrhynchus speciosus*, that is of the simplest kind, in a warm, moist house.

Masdevallia Shuttleworthi.—Before the recent foggy weather set in there was every promise of there being in this nursery one of the finest displays of bloom of this charming little Orchid that has yet been seen. But the fogs came and almost every bud turned yellow and died off. The buds not so far advanced survived and now are expanded, showing what an exquisite little species it is. The blossoms are triangular, each of the three sepals having attenuated tails. The sepals are hooded, the upper two being beautifully grained with a pinkish purple on a white ground; the lowermost one is a primrose-yellow lined with dark stripes. It is a veritable little gem for growing in suspended pans. It is, however, a pity that its flowers are so susceptible to injury by the London fogs, which prevail about the time that it flowers.

Zygopetalum Mackayi majus superbum is the name applied to a very fine variety of a favourite old Orchid, one, perhaps, that is more generally known than any other. The typical form is a handsome plant, but the flowers of this variety are fully a third or even half as large again, and the colours are brighter and more pronounced. The labellum measures just 2 inches across, and is marked with parallel lines of bright purple on a white ground, while the large sepals are a bright bronzy brown on a greenish ground. The specimen in this collection is carrying a massive spike of about ten flowers, and the strong and delightful violet-like fragrance they emit is widely diffused.

Cypripedium Schlimi.—This pretty little Lady's Slipper has been known for some years in Orchid collections, but it is not much grown even now, presumably on account of its weakly constitution and its susceptibility to insect attacks. We saw, however, the other day in this nursery a form of this species from a different locality from that the original importation came, and which evidently appears to be altogether more vigorous in growth, and, moreover, possesses a larger flower. Compared side by side with the old form, the leaves are twice as long and of a healthier tone of green, and the flowers, too, are fully a third larger, being quite 2 inches in diameter. The colour of the sepals is a bright cheery rose, while that of the globular pouch, about the size of a large marble, is a deeper hue, more intensified about the rim. If this form turns out to be really distinct and more vigorous than the type, it will indeed be welcomed by Orchid lovers, for Schlum's Lady's Slipper has always been thought highly of, and, moreover, it is one of the parents of some of the handsomest of hybrid *Cypripeds*, notably *Cypripedium Sedeni*, which is without doubt the most popular of all the hybrids.

Odontoglossum crispum Walkeri-anum.—Though the forms of this variable Orchid are now so numerous, there are continually some cropping up from importations which by their distinctness and exceptional merit are well deserving of a distinctive name. Such may be said of the variety under notice, which we saw in this nursery a few days ago. It is indisputably one of the most extraordinary forms of *O. crispum* yet introduced. The flowers measure over 3 inches in diameter, the two lateral sepals being three-quarters of an inch broad, exquisitely crisped at the margin, and snow-white, while the three outer or smaller sepals are white, heavily blotched with a sort of cinnamon-red, which with the spotted lateral sepals make a striking and beautiful contrast. Added to this the labellum is broad and finely crisped at the edge, the upper part is bright yellow, traversed by pencillings of chocolate, while the lower part has two large blotches of

cinnamon-red on a white ground. It is, in short, an uncommonly fine form, and one only among the thousands of plants of *O. crispum* in this nursery, though there is great promise of others of the same imported batch turning out as fine. These fine varieties, which possess such marked distinction, will always be much sought for by Orchid connoisseurs, and will, moreover, command high prices, fetching as many guineas as ordinary forms will shillings. Though we are adverse to the practice of appending varietal names to every form that shows a little variation from the type, we cannot but admit that such forms as these well deserve distinction. W. G.

Odontoglossum roseum.—Though this neat and pretty Orchid cannot compare favourably with *Mesospindium vulcanicum*, to which it bears such a strong resemblance, it is nevertheless a desirable cool house Orchid, as it flowers in mid-winter, and moreover the colour, a deep rose-magenta, is so uncommon, particularly among winter Orchids. It is grown very successfully in Mr. B. S. Williams' nursery in a cool house suspended in a pan near the light. It has been attractively in flower for some time past in this nursery.

Odontoglossum nebulosum candidulum.—The distinctive character of this rare and beautiful variety is the almost entire absence of any marking to mar the chaste beauty of the ivory whiteness of the large attractive blossoms. There is a dash of citron-yellow in the centre, which throws up the white sepals to better advantage. The flowers, as in the type, are 2 inches across, and possess that solidity of texture so much admired in Orchids. We saw this variety lately in bloom in the cool *Odontoglossum* house in Mr. B. S. Williams' nursery, Upper Holloway, where also we noticed the pretty little *O. Ehrenbergi* in bloom, besides crowds of *O. crispum* represented by the finest and richest varieties, one of which had a branching spike carrying fifteen blooms; likewise numerous specimens of *O. gloriosum*, and others of a similar stamp also with widely branching spikes.

Epidendrum pseud-epidendrum.—The flowers of this rare Orchid exhibit a combination of colour probably unequalled by any other Orchid. They are about $1\frac{1}{2}$ inches across; the long narrow sepals and petals are pea-green, while the labellum and column are brilliant vermilion inclining to orange. It is one of the tall, slender-stemmed species, growing some 5 feet or 6 feet high, and furnished with foliage on the upper part of the stem, which is terminated by a large drooping cluster of flowers. It is now in bloom in the Royal Exotic Nursery, Chelsea.

Maxillaria grandiflora.—Those who require a selection of beautiful winter flowering Orchids ought not to omit this one from the list, as it is one of the most beautiful of all. The flowers are large, over 3 inches across; the sepals are of firm texture and of ivory whiteness, while the labellum is marked with yellow, and blotched at the base with two large spots of reddish brown. The long time, often a month or more, the flowers remain in perfection adds considerably to its value combined with the delicious perfume it emits. We have seen it flowering lately in various collections about London, and notably in the Victoria and Paradise Nursery, Upper Holloway.

Oncidium unguiculatum is one of those Orchids only suitable for a large collection, but at the same time it is a desirable one; a very long flower-spike, often more than 6 feet, which is repeatedly branched, is the chief characteristic of this species. The flowers are large, and their most conspicuous part is the labellum, which is large and of a clear yellow, contrasting well with the dark coloured sepals. A fine specimen is now in bloom in Mr. Bull's nursery in the *Odontoglossum* house, where also a somewhat similar species, the old and well-known *O. tigrinum*, makes a showy display, and diffuses its delightful violet-like fragrance throughout the house.

Cœlogyne barbata, as it may now be seen in Mr. Williams' nursery, at Upper Holloway, is really a beautiful Orchid, notwithstanding all that has been said to the contrary. No other Orchid possesses flowers like it, and it is altogether a distinct-looking plant. Unlike other Cœlogyne, it bears its flower-spikes erect. They range from 12 inches to 18 inches high, and bear a good number of large showy blossoms, which are pure white, with the exception of the bearded lip, which is a very deep brown, surfaced, as it were, with a bronzy metallic hue. Being evergreen, its thick leathery foliage intermingles pleasingly with the flowers, and so sets them off to advantage. It is a plant of easy culture in a cool house, and the flowers possess the very desirable quality of being fog-proof; during the long spell of foggy weather experienced in London they have been unaffected, whereas those of *Calanthes*, *Phalænopsids*, and others have been sadly injured.

Cattleya Dodgsoni.—We saw this scarce variety in bloom the other day at Messrs. Veitch's nursery, at Chelsea, and thought it the loveliest late flowering *Cattleya* we had ever seen; indeed, it is hardly surpassable by any other in cultivation. It is of the *Trianae* type. The flowers are as large as those of a good *C. Mendelli*, the sepals and petals broad and of firm texture, and almost white, there being but the faintest suggestion of lilac, which gives them such a soft, pleasing appearance. The chief beauty lies in the labellum, the lobe of which is large, shallow, and exquisitely crisped. Two-thirds of the lip is white, the rest being of the richest carmine-crimson hue possible—a very striking contrast. The plant under notice was carrying nine such flowers from four sheaths, and the specimen was, as may be imagined, a beautiful sight. As this variety habitually flowers during mid-winter or in the early part of the year, its value is considerably increased.

Dendrobium Leechianum is the name of a new seedling Dendrobe which has been raised by Mr. Swan, gardener to Mr. Leech, Oakley, Fallowfield, Manchester, between *D. heterocarpum* and the well-known *D. nobile*. The hybrid is exactly intermediate, and, as may be imagined, is very beautiful, combining the chaste beauty of *D. nobile* with the delightful violet-like fragrance of *D. heterocarpum*. Mr. Swan sends us three superb blooms, the finest we have yet seen of it. They measure over 3 inches across. The sepals and petals are waxy white, delicately suffused at the tips with lilac-purple, while the broad-pointed labellum is of a splendid velvety maroon, broadly edged with primrose and tipped with pale pink. Altogether it is a lovely flower, as beautiful as that of any Dendrobe in cultivation. Those named *D. Ainsworthii* and *D. splendidissimum*, both hybrid varieties, are very similar to it. Judging from what Mr. Swan says, it appears to be very free flowering, for he has on one bulb 9 inches high as many as eighteen flowers.—W. G.

Temperature for Phalænopsids.—In reply to "J. D." (p. 562), I regret to say that some additions to my copy (p. 502) were unfortunately dispatched too late for publication, or the paragraph would have explained itself better. However, no one reading it as it stands could suppose that I would wish them to subject their *Phalænopsids* to a temperature of from 40° to 45°. I have never recommended them to be below 60°, and until a few years ago I thought they would be greatly damaged if placed in a lower temperature; repeated visits, however, during the winter to Mr. P. A. Philbrick's large and vigorous collection of these plants when they were at Avenue Road proved to me that they might be grown to perfection much cooler. Several times I found the thermometer in Mr. Philbrick's *Phalænopsis* house between 50° and 55° toward mid-day, and an unmistakably cold feeling in the house, and yet the plants which so thickly covered the roof would compare with any in the country. The cool temperature in which they were kept served a good end in London, as it kept the blooms back until the fogs were gone. But I could not help thinking that such treat-

ment would not answer in every Orchid house, and that the dry, sweet, equable temperature in Mr. Philbrick's house made it an exceptional case; it was therefore for that reason that I said they might be grown in a temperature of 50° at night, and 60° to 65° under certain circumstances. I always avoid recommending extremely low temperatures, knowing that the effects of a very low or a very high temperature vary so much in different houses, that the temperature which would keep a plant in perfect health in one house would be injurious to it in another, and that often without any cause being visible. It is for that reason that a grower always takes such pains to know his houses and their peculiarities.—JAMES O'BRIEN.

SEASONABLE WORK.

FLORAL DECORATIONS.

WHERE early Dutch bulbs are cultivated in quantity for decorative purposes other than for the conservatory or standing in small vases in the house, it is an excellent plan to follow to some extent the system pursued by those who grow for the trade. Of course appearances have to be studied more in a private establishment than in market producing places; and therefore in lieu of rough and ready boxes in which to bring forward the bulbs to a flowering stage, seed pans of goodly size (square ones will occupy least room) should be chosen. In these the bulbs can be grown more closely than in pots, and when required for decorations, can be taken, bulb and all for any uses other than vases where the bulb and rootlets would be unsightly. This system will be found to be preferable to any other for the making up of what might be termed rustic arrangements, and will afford a pleasing change where much decorative work has to be carried on. Too much sameness renders decorations of any kind monotonous and uninteresting, and therefore should be avoided. In table decorations especially it is well to add a fresh feature occasionally. This can be done with ease; when all the costly epergnes and vases have been exhausted to give variety, a very pretty effect can be produced by choosing a medium sized dish or a large dinner plate on which to arrange our chosen material. For a large table select an oblong dish, such as would be wanted for a fair sized joint. A slender-growing Palm, such as *Cocos Weddelliana*, *Enterpe edulis*, or *Chamedorea glaucifolia*, having a good healthy head of foliage in a 3-inch or 5-inch pot, might be set in the centre, after which some sand and fresh green moss or *Selaginella* should be at hand. Sand should be placed around the central plant at once. Then choose, say, of the early Dutch bulbs some scarlet and white varieties of the *Duc van Thol* Tulips, a few bulbs of each; two or three of the white Roman Hyacinth, bulbs, foliage, and spikes included (if the latter are not too much drawn up), and three or four small Chinese *Primulas* flowering in 3-inch pots, from which they should be removed. Fill up between these with the moss, so as to cover the sand, and dot in a seedling Fern or two where opportunity offers, but avoid crowding. Around the base use a few growths of small-leaved Ivy or other convenient material, to rest on the table cloth. Again, with the same Palm, as a change select some tiny plants of *Pandanus Veitchi* and *graminifolius*, or growths of either will do instead of plants, likewise a few tufts of the *Cyperus alternifolius*. Having arranged these, let us procure a few spikes of *Eucharis amazonica* that have say one perfect flower and another partially open; about three of such will be sufficient with a few small leaves. To these add a few spikes of *Lily of the Valley*, *Paper-white Narcissus*, or *Spiraea japonica*, using for colour either the yellow or scarlet *Duc van Thol* Tulip but sparingly. As a finish a few Fern fronds around the margin would add to the effect, and a few slender trailing growths of *Ficus repens* reaching beyond these would be a welcome addition. A slight bedewing with a syringe to either of these arrangements would tend to keep the flowers and foliage all the fresher. Other forms

of arrangement could be followed out, modified, of course, according to the supply and other circumstances.

FLOWER GARDEN.

Herbaceous and other plants of that class show off best in wide shrubby borders with low evergreens to back them up, but these latter ought not to be of a kind that root far about, or they rob the former, and so spoil their growth. *Irhododendrons*, *Berberis Darwini*, *B. stenophylla*, and such like do not do this, and therefore should be largely made use of, as they are not only valuable on this account, but they are more desirable than most others on account of their moderate habit and the great beauty of their flowers, which they bear so profusely in spring. For variety of foliage, *Aucubas*, *Euonymus*, and *Hollies* are the most suitable, and to these may be added the variegated *Dogwood* and *Acer fraxinifolium*, and by way of contrast to these one or two of the dark-coloured Nut, which, with its rich coppery leaves, shows up well. To make sure of old borders being perfectly free of roots from trees and shrubs near it is a good plan at this season to trench up the same, and when doing so to work well up around, cutting and removing all in the way. As most herbaceous plants are fond of rich soil, the opportunity afforded when trenching of giving a good dressing of manure should not be lost. The kind of manure most suitable for the purpose is that of a mild nature and which has been lying by for some time to get well decomposed. Such as this is agreeable to most plants, and may be used freely without fear of injuring the roots, but it is always best to keep it low down.

INDOOR PLANTS.

General winter treatment of stove plants.—There is nothing in the whole range of cultivated plants able individually to give such a lengthened succession of flowers as a few of the best stove species, such as *Ixoras*, *Allamandas*, and *Dipladenias*. If so managed as to enable them to continue in bloom for the greatest length of time throughout the year of which they are capable, it might almost be said that they are continuous flowerers, for it has been found that when all the conditions of cultivation are suited to their wants, that they, along with a good many other occupants of the stove, require only a short rest—very much less than they are often subjected to—but the length of time out of the twelve months that admits of their being submitted to enough heat to keep up this lengthened active growth depends upon two things, the houses in which they are cultivated being such as to admit a full amount of light, and, what is of equal consequence, their being kept close to the roof. This latter is a matter of importance not nearly so generally accepted as it should be. We train Vines, Cucumbers, Melons, and other fruit-bearing plants as close to the roof as we can get them without absolute contact with the glass, with the admitted result of increasing their fertility; it is just as necessary to keep plants that are intended to produce all the flowers we can get from them in a similar position so far as proximity to the roof of the house goes. The least experienced grower of plants under glass cannot fail to have noticed the strong, healthy leaves and short-jointed wood that are formed with plants of all sorts kept with their heads close to the glass, as compared with that which results from others, identical in every way, but stood further from the roof in the same house. Such subjects as I have named and many others can only be had in flower for the full length of time by submitting them to a corresponding amount of heat, and where the houses are comparatively dark through their construction, or the position they stand in, or where lofty, without the means of getting the plants well up to the roof, it will not do to use as much heat as will start them into active growth until the days are longer. Our own practice with houses as light as they could be made and adapted in their construction to have the plants occupying them continu-

ally within a very short distance of the roof, was to give all the rest that the majority of them received through the months of November, December, and the first week or two in the new year, during which time there is usually much less sun than after the turn of the days, and as soon as fairly into January the temperature used to be raised in the night to from 65° to 70°; by this means we had no difficulty in having the same plants of *Dipladenia*, *Allamanda*, and *Ixora* in flower from the middle of April until the beginning of October, or longer if the heat requisite was given them; under the same conditions, *Clerodendron Balfourii* and *Thomsoni*, *Bougainvillea glabra*, *Gardenias*, *Tabernæmontana*, *Scutellaria Mocciniana*, and others of like character gave several crops of bloom alternating with growth; consequently where the stock is in strong robust health, and has been subjected to a rest of a couple of months, preparations should be made for starting them into growth. Any examples of such things as require cutting in should be so treated at once previous to giving them more heat.

Stephanotis.—Where the flowers of this general favourite are wanted over as long a period as possible, several plants should be grown. There is the advantage of obtaining larger specimens when planted out, but this is over-balanced by the inability to retard or push them on at will in the way that can be done when they are moveable and grown in pots; moreover, the plant only requires a limited root space, and very large examples can be grown in good sized pots. It never succeeds so well as when trained close to the glass under the roof; we prefer thin string for thus supporting it rather than wire, as when it is necessary to remove the plant to a lower temperature to give a rest, the string can easily be taken down and the shoots wound round the trellis or a few temporary sticks. Plants that have been so rested may at once be put into active heat, distributing the shoots under the roof tolerably close. With this plant whatever cutting back is required should take place after the blooming is over.

Amaryllises.—Some bulbs of these may now be started, moistening the soil sufficiently to induce a healthy movement of the roots. With the deciduous kinds wherein the ball has been allowed to get dry, it is not a bad plan to soak them in tepid water for an hour or two, as with the ordinary application of water it often happens that the top of the ball looks moist when it is dust-dry below.

Gloxinias.—There are few flowers so useful as these, for with judicious management in arranging for successions they can be had nearly all the year round; but to have them in a condition to be really serviceable for cut purposes, they must not be too much hurried, and whilst growth is going on they cannot be too near the glass. It is much better to start the corms at different times; if a few are at once potted and placed at the coolest end of the stove they will come in early; do not use the soil too moist, and let them be put in heat immediately they are potted. We have seen the corms destroyed through two or three days' inattention by leaving them in a potting shed after they have been placed in contact with the new moist soil. It is scarcely worth while now going in for named varieties of *Gloxinia*, as really splendid flowers both in form and colour can be had from seed. If a little is sown at this time, the plants will bloom nicely through the later months of the year after the older examples have become exhausted; the seed should be sown thinly in a wide pan drained and filled with finely sifted soil, to which has been added a good deal of sand; make the surface smooth and firm, so that the seeds may not get down too deep, covering them very slightly with a little fine soil, pressing gently down and putting a sheet of glass over the pan, by which means the material will retain moisture so as to minimise the amount of water necessary to be applied, a matter that it is always needful to be careful about with small seeds that require heat to enable them to vegetate.

Eucharis.—Where *E. amazonica* and *E. candida* are treated under the system of alternate growth and rest, a few of the strongest plants that have had a dormant period may be put into a brisk heat; they will stand as much as most things.

Tuberous-rooted Gesneras.—These are a beautiful class of plants somewhat neglected. The old bright scarlet *G. Cooperi* may be taken as an example, and is still a very fine kind; there are numbers of hybrids equally deserving of places. There is an advantage in starting them early, as by so doing they may be induced to flower twice before autumn. All they require is such treatment as is needed by *Gloxinias*; they will thrive in either loam or peat. The time of flowering of the winter blooming *Gesneras*, such as *G. exoniensis* and *G. zebrina*, will depend upon the amount of heat they have been subjected to; where well managed they will now be very useful, their long spikes of bright flowers standing out conspicuously in the stove. They like a fair amount of heat up to the blooming period, but when in flower they will stand an intermediate temperature, not giving them too much water. When the flowers fade the plants must still be kept warm, applying less water until the well-matured foliage dies down slowly.

Lachenalias.—Where a sufficient stock of these are grown they are very useful, for, if after flowering, the bulbs are well attended to until their growth is matured, they go on increasing in size and numbers yearly. They will now be in a growing state without any artificial heat, and if put into warmth will come on apace. They are excellent subjects for hanging baskets, in which they are very effective.

ORCHIDS.

East India house.—The weather at present is all that can be desired for starting to surface-dress or re-pot any plants that may require it. Moderately dull mild weather is the best to do such work in, as under these circumstances the plants do not feel any root disturbance so much as if the weather was very cold and much artificial heat was required to bring the temperature up to the necessary heat. Care ought to be taken with the plants while they are being repotted that they do not suffer any unnecessary check. In places where the houses have been erected specially for Orchids, the potting shed would be somewhere in proximity to the plants, and so as they would not be required to be taken into the open air. In many places there is no such convenient arrangement, and all plants have to be taken into the open air to be conveyed to the potting shed; rather than do this we would erect a temporary potting shed in the house, and do all to the plants that they required without subjecting them to a change of temperature. It may have been stated before, but it cannot be repeated too often, that it is in what may be termed the minor details that success is to be achieved or failures made. For instance, many persons either do not know how to place the drainage in a pot, or they think it does not matter how it is done, and they are careless about it. The drainage and pots should be clean, the potsherds to be put in carefully in a way that the water may run off freely. The Sphagnum should be carefully picked over to remove all dirt and weeds; finally wash and lay it out to dry. Orchids resent any injury to their roots, and as a rule all the best of them are clinging firmly to the sides of the pots. It is better, therefore, to carefully break the pot with a hammer rather than to turn the plant out in the usual way to the serious injury of its roots. Many of the broken bits of potsherd to which the roots are clinging may be allowed to remain and be potted along with the usual compost. Owing to the mild weather it has not been difficult to keep up the required temperature of 65°.

Cattleya house.—The remarks just made referring to repotting apply equally well to this department and the cool house section.

Nearly all the strong-growing *Cattleyas* succeed best grown in pots, with good fibrous peat and Sphagnum in equal proportions, some broken potsherds and charcoal being added to keep the compost open and for the roots to lay hold of. The nature of nearly all Orchids is to lay hold with their roots to every firm substance with which they come in contact, and with a grasp so firm, that the roots cannot be removed from the substance to which they adhere without breaking or lacerating them seriously. *Cattleya* roots will either be amongst the drainage or else clinging firmly to the sides of the pots; few indeed of them will be amongst the compost, and yet give them nothing but drainage and the sides of the pots to grow in they would require more attention as regards watering, and they would not succeed so well. We are always very careful when repotting them to save all the roots; and any young roots that are being produced from the base of the last formed pseudo-bulbs are not buried in the compost. We have seen peat and Sphagnum piled round these to their hurt. If they are let alone they will lay hold of the material they like best; some will run along the surface and others will push into the potting material; and when the circumstances are favourable the roots will also push over the sides of the pots. *Cattleyas* like to be near the glass; many of the shy flowering species will not flower if placed on the stage, but if the pots containing the plants are placed in baskets and these are suspended near the roof glass, where the air can freely circulate under, over, and around them, they will flower freely. The smaller growing species may be placed in teak baskets or potted into small shallow pans to be suspended from the roof. Some of them will succeed well on blocks for a time, but after two or three seasons' growth, the plants that have nothing but the bare blocks to support them soon show signs of exhaustion. When these signs are evident, place the block in a pot with the base of the pseudo-bulbs well raised above the rims, and then place round them the usual potting material recommended for *Cattleyas*.

Cool house.—A look through some of the cool Orchid houses in the neighbourhood of London at this season of the year shows very conclusively what a very valuable adjunct to a garden the cool Orchid house is, and how easily the plants are to cultivate successfully. It will be a surprise to many, as it is to us, to read of the fastidiousness of cool Orchids as they are grown on the Continent (see page 585). We are sure with the instructions given from week to week in THE GARDEN anyone with an ordinary knowledge of plants may grow cool Orchids well. The principal thing to do is to build a house for them in a cool place. If the whole truth was known it would be found that in most cases where cool Orchids did not succeed well the result would be due to too much heat in summer. It is difficult, when the houses are exposed to the full blaze of the sun, to keep down the temperature sufficiently during hot weather, unless the shading is too thick, and in that case the plants are debilitated as much as they would be by too much heat. As far as we know the wants of Orchids, we believe they like as much light as can be afforded them; and if the shading is left on to do more than protect from the direct rays of the sun they are injured. It was stated last week that the attention required by the occupants of this house was of a very simple kind at present, but what attention they do require ought not to be omitted. A look through the house the first thing in the morning to ascertain the lowest night temperature is necessary; during the present mild weather if it does not fall below 50° it will be all the better for the plants; a very low temperature causes many of the delicate blooms to become damp spotted.

It is easy to see whether much or little moisture will be required by evaporation, and the person in charge ought to act accordingly. Too many, it is feared, throw water about every day, summer and winter, with no thought to the necessities of the case. Air ought to be on all night, and it may not be necessary to admit any more during

the day. It is also necessary to look through the houses between 8 p.m. and 10 p.m. to regulate the heating apparatus and see that no garden pests are enjoying themselves at the expense of the plants.

FRUIT.

Early houses.—If the Vines have been bent down to a horizontal position, to insure an even break, get them tied up to the wires as soon as the most backward buds are on the move. Syringe with warm water when the temperature begins to rise. Give air at 68°, close early, and syringe again if the afternoon is fine. If inside borders are well drained, a second supply of water at a temperature of 80° will help the young growths rapidly forward, and old Vines will benefit by the addition of a little clear liquid from the tank, or a dash of guano in the water, while vigorous young canes will produce more compact "shows," and set their fruit better if stimulants are withheld. Pay timely attention to disbanding, or rather the removal of weak breaks, from which bunches of Grapes cannot be expected, and when the best shows become prominent raise the night temperature to 58° or 60° on mild nights. If forcing has been commenced with fermenting material on the borders, make frequent additions, turn the whole mass, mixing the old with the new, and aim at a temperature of 70° to 75° on the surface of the soil. Where external borders have been well covered with a good body of dry warm Oak leaves, and protected from wet, they will retain their warmth much longer than when fermenting manure, which is objectionable, is used.

Hardy fruit.—The mild damp weather which has been so favourable for pruning and nailing will have held out inducements to many to postpone such work as top-dressing and mulching until walks and borders are in a better state for wheeling manure and compost. But so important an operation must not be longer neglected, as the timely application of a good covering to newly planted or root-pruned trees cannot be overrated. Where Pears are grown on the Quince stock and the roots have not been disturbed, the annual top-dressing of good rich manure may be wheeled out on frosty mornings as soon as the nailing is finished. It is well known that the successful culture of Pears on the Quince stock greatly depends upon rich top-dressings; and as the borders in course of time become too high, old top-dressing and exhausted soil may be forked off and placed on the vegetable quarters to make room for the new. After a few years heavy cropping puts an end to extension; blossom buds only are formed, and as many people are quite incompetent to thin their own fruit, the annual removal of old spurs at pruning time should not be neglected. If on wet, adhesive soils the planting of trees has not been completed, it will be better to allow them to remain "laid in" on a dry border and well protected with litter than to attempt to plant while the ground is saturated with cold water. Push on the pruning and cleaning of all kinds of fruit trees, as the time may be at hand when it will be cruel to force men to stand for hours at a stretch against cold brick walls. Unfortunately, the winter dressing of hardy trees is much neglected; many troublesome insects are allowed to rest in the bark and walls from which they almost precede the unfolding of the earliest buds in spring.

KITCHEN GARDEN.

If directions in former calendars have been attended to, the first sowing of Peas will be above ground. Cover them all over with coal-ash to ward off slugs, and by putting three strings of worsted 6 inches above the Peas, their tops when they peep above the ashes will be saved from the depredations of birds. Get in the second lot at once, sowing such as are hard and round—wrinkled Peas, as a rule, are the best flavoured, but not the safest to plant at present. Laxton's Earliest of All is both hard and round; therefore try it. Ringleader and William I. are also both good standard varieties. Successional sowings of

Broad Beans should be made. We have no great fancy for Leviathan, but prefer early Mazagan and good, old green Windsor to any yet offered. Now is a capital time to make plantations of Horse Radish; we merely sink the tops with an inch or two of the roots attached to them a foot deep in good land. Get ground for Onions dug up roughly and deeply—our site for them is the Celery quarter. Where these useful esculents go off from mildew or other causes, give the land a good dressing of soot and lime, allowing it to remain on the surface until the seed is to be sown. About the second week in March will be quite soon enough to get the seed in. Sowing early in February is a mistake; the young seedlings come up, and the March winds turn them yellow and cripple them so much that good bulbs cannot be expected. Land for Carrots should also be dug and treated in a similar manner to that for Onions. Early Vallery is an excellent variety, still a few Early Horns may be sown to draw early. The state of our Broccoli crop is most cheering, fine stout stems close to the ground, the result of sowing late and planting out directly the plants are large enough to handle. Never allow any kind of plants to become drawn or leggy before planting them out. We are cutting Snow's Broccoli in fine condition; those allowed to stand are far superior to those laid in. Working or turning over leaves and long manure, filling the pits for spring vegetables and salads will now be the order of the day. Keep up good supplies of Seakale, Rhubarb, Mushrooms, and French Beans, not forgetting small things, such as green Mint, Tarragon, and Mustard and Cress.

TREES AND SHRUBS.

MANAGEMENT OF HARD-WOOD PLANTATIONS.

In the rearing and management of plantations, the great aim is to produce the greatest quantity of timber of the best quality on a given space or area of ground in the shortest period of time; and to assure this result it is necessary that the best system of management be pursued. To rear hard-wood plantations so as to arrive at a profitable or satisfactory issue, it is necessary, first, that the plants should be healthy. Care should also be taken that the trees are planted in soils and situations specially suited to their growth; for, however suitable the soil and situation may be for the growing of certain kinds, trees of a different sort might not thrive in the same place. Further, it is generally advisable to have the ground prepared and improved by thorough draining and loosening of the soil. Another important matter is the laying out of the plantation, in deciding upon which, the natural rise or fall of the ground as well as the exposure of the situation, should be taken into consideration, and whether the plantation is intended for profit or ornament. Long, straight lines should, as far as possible, be avoided; and the shelter of the surrounding ground, as well as of the plantation, be kept in view. The outline should be formed so that the wind or storm will not strike against too much of the plantation at once, but rather be thrown off than received in full force on a long, flat line of fence. Again, the greater the mass of trees in one enclosure the better will be the result in every way; the plants will have more shelter and thrive better than in small enclosures, where storms blow right through the planting. The expense of managing large plantations is considerably less, and a much smaller length of fencing is required than if the same extent of ground were covered by several small enclosures. After the young trees are planted, it is necessary to see that they are not blown about by the wind and shaken at the roots. When planted in exposed situations, they are apt to be blown to one side, while the shaking two and fro by the wind in many cases works a hole in the ground round the collar of the plant down to the roots. When this happens, the plants should be raised erect, a little soil added and pressed down with

the foot. If these details are not attended to in proper time, the air gets down to the roots, or they are saturated with water, which may be frozen, causing the death of many plants, retarding the growth of the remainder, and making them one-sided. If attention is paid to keep the plants upright during the first year, great loss will be avoided, and there will be little after-trouble from this cause.

Clearing herbage.—The next operation is the keeping of the young plants from being smothered or choked with long Grass, Ferns, Whins, or growing herbage. Even, although not overtopping the young trees, this undergrowth, if allowed to remain, will destroy the lower branches of the plants, and deprive them of both sunshine and showers. On the other hand, in exposed situations, it is preferable merely to clear a space round the plants, or to clear early in the season, so that a certain amount of growth may rise before winter, and afford slight protection to the young trees. In no case should the branches of the plants be roughly treated where profitable timber is the object in view. The smothering of plants by rank herbage is as detrimental to their health as the want of thinning after they have grown into one another. It is equally important to keep them free and open when planted out, as in the nursery lines. When the plants are kept as above indicated, they require little attention or expense, except slight pruning, until their side branches have begun to encroach upon one another, when thinning operations will have to be considered.

Thinning.—The style and extent of thinning hard-wood plantations greatly depend upon the kind of trees constituting them. Some trees require more room to mature than others, while some ought to be kept close together, to check their straggling habit and ramifying side branches. The Oak, for instance, requires ample space to develop itself, and as considerable revenue is derived from the bark, and in some places from the branches, as cord-wood, it should at all times have plenty of room. The Wych Elm and the Beech, on the other hand, although growing to large dimensions, and of a wide-spreading habit, should not be allowed more room than is necessary for their healthy growth, as neither the bark nor the branches are of much value. They also exhibit a tendency to grow much to rough branches and short stems, and the timber, if not of good quality, is unsaleable. The Ash, English Elm, Sycamore, and Birch require plenty of room, and are not so straggling in plantations, especially in their young state. The great point to be kept in view in thinning hard-wood plantations is to commence in good time, and not to wait until the trees become drawn up and weakly. It is not uncommon to see plantations left without thinning until the sapplings have arrived at a marketable size. This is false economy, for it is better for the main crop to thin in time, even if the first thinnings are of no value. The loss on the thinnings will be made up in the health and extra growth of the trees left. It is equally objectionable to continue thinning longer than necessary, with the view of deriving immediate revenue. In both cases the value of the main crop, which ought to be the principal object, is lost sight of, and the certain result is material loss in the end. It is by some recommended in thinning with a view to profit, that operations should commence as soon as the branches touch one another. A little careful pruning may sometimes defer it for a year. The thinning of hard-wood plantations should, of course, commence before any injury is sustained; but not in ordinary circumstances, in the writer's opinion, before the second or third year after the side branches have met, and in no case should the operation be deferred until the side branches show signs of decay, or till they have closed into one another well up the stem towards the leaders, as in such a case the trees will be deprived of the amount of such light and air necessary for their healthy growth. Hard-wood trees require more room for the spread of their branches and healthy growth than conifers; but the plantations are generally filled in

with Larch, Spruce, or Scotch Fir, as nurses for the intended crop. Under such circumstances the first thinning will generally remove such conifers as are encroaching upon the hard-woods. Although Firs are the best nurses for hard-wood plantations when young, and also more valuable when of small size, great care must be taken not to let them crowd or overshadow the hard-woods. While their shelter is better than that of hard-woods, they are more ready to overgrow and destroy them. In the case of any hard-wood tree dying out or getting damaged beyond a chance of becoming a good timber tree, it is advisable to leave one of the nurses to take its place for the time being. Any such tree left during early thinnings can be removed as opportunity occurs. The great aim should be to preserve the hard-wood sorts, however irregular the appearance may be at early thinnings. Presuming that the nurses have all been removed, it is desirable to preserve the best and most healthy trees, irrespective of sorts, and never to cut a healthy, vigorous, growing tree to make room for a small unhealthy neighbour for the sake of regularity. Such thinning must in the end turn out a great loss and disappointment to the owner. A little opening or larger gap is preferable to a sickly or ill grown tree, and such openings can be rectified at the next thinning. No definite age can be given for commencing to thin for the first time, as all depends upon the soil and situation in which the trees are growing. Thinning may be performed too early as well as too late, and it may be overdone as well as underdone. Great care should be taken not to err in either direction. When hard-wood trees are mixed with Firs as nurses, they generally have to be thinned sooner than if the plantation consisted of all hard-wood trees, because the Firs, as already noted, generally outgrow and overshadow the hard-woods, thereby drawing the hard-woods up into a weak state.

Over-thinning.—When hard-wood trees are over-thinned, they seldom rise to valuable length, and the timber is of a rough and branchy nature, never so valuable as clean, well-grown timber of moderate length. On the other hand, trees drawn up for want of thinning are equally unprofitable, as they never arrive at proper size, neither is the timber so well grown and durable as when judicious thinning has been carried out. In many instances, where plantations have been overdrawn from want of timely thinning, the trees are bark-bound and stunted, and never reach the dimensions and value they would have done had they been treated so as to induce the growth of a proper amount of branches and foliage. When such neglected plantations are afterwards thinned, it is advisable to do it sparingly at first, and to continue every second or third year until they are in a satisfactory state. Roots and foliage are the main organs of nutrition in trees, and to ensure their healthy growth it is necessary that there be a proper complement of lateral branches as well as sufficient room for the ramification of their roots. In plantations, these cannot be provided without resort to thinning operations. The importance of this branch of management cannot well be overrated, and attention to it is necessary to ensure success; and if thinning is neglected altogether, or done injudiciously, there is but little chance of a profitable crop of timber. If the work is done in due time, and with good judgment, many other oversights in management will be thereby removed or greatly mitigated. When trees are grown entirely for shelter or ornament, thinning should be performed more freely than when grown for profitable timber, the object being to encourage branch growth; and to keep it within proper limits, pruning should be resorted to, but very little stem pruning will be necessary after the nurses have been thinned out, as it is desirable to have as much branch growth as possible towards the ground. Free thinning also shows more fully the natural habit and character of the different trees intended for ornamental purposes. They should therefore be thinned as soon as they begin to encroach on one another, and the operation should be repeated at intervals as may be necessary.

Bark stripping.—Hard-wood plantations should be thinned in winter, and where the thinnings are of considerable value, as much as possible should be done before the end of the year, with the exception of Oak, which should be felled in summer and stripped of its bark. As a rule, bark stripping may be commenced in the end of April or beginning of May; this depends on the earliness of the season. Small trees may be felled with the axe, but large trees should be rounded or "laid in" with the axe, and cut with the cross-cut saw, to avoid waste of timber. When Oak trees are to be felled and stripped of the bark, they should first be "hosed," or have their bark removed from about 2 feet of the base of the stem down to the ground. All loss of bark is thus avoided. If this is not done, the axemen, in rounding the tree, cut away much of the best of the bark, which is lost. After the trees are felled, the bark should be removed as much as possible without lopping the branches. If the branches are left, the trees are more easily peeled than when detached. The smaller branches only should be removed before peeling, and where it is necessary to cut off any large branch, the bark should be stripped before doing so. Mallets should only be used in removing the bark from the smallest branches, and never, except where unavoidable, should they be used in removing the larger bark, as it is thereby discoloured, and it is advisable to strip it with the peeling irons alone. Each day's work should be collected and put on ranges as the work proceeds. The ranges should be erected on the margins of the plantations, or in the most open and airy parts of the plantation, to ensure as much sunshine and wind as possible, in order to accelerate the drying and harvesting before putting it in stacks. Ranges should be made from 2 feet to 3 feet high, with a slope from back to front of at least 6 inches, to prevent the water from lodging. The ranges are generally formed of forked sticks driven into the ground, with spars laid thereon to hold the bark. All of these can be obtained from the peeled wood. The bark should never be laid thickly on the ranges, or it takes long to dry, and if laid to a great depth, it requires to be turned before it is ready for the stack, which should, if possible, be avoided. All the small bark should be laid on the ranges first, and the larger bark on the top, as the latter takes longer to dry, and it also acts as a cover to the whole. Placing the bark thin on the ranges, and well raised from the ground, allows the wind to blow through under it, and with plenty of air the whole gets ready at once. As soon as a sufficient quantity is dry, it should be put into a shed or stack, where it can be chopped or delivered in the rough, as the case may be.

Pruning.—As hard-wood trees require large space to develop properly, it is necessary that their ramifying side branches should be kept in due bounds by pruning. It is not contended that pruning adds to the quantity of timber grown in one tree, but it certainly improves the quality of the timber. Pruning, skilfully and regularly conducted, will also assist timber trees to produce more timber of greater value than if they were left unpruned, or allowed to shed their branches naturally, which is the result of trees growing too close for want of thinning. Although, therefore, the effect of pruning is highly beneficial, when conducted with care on sound principles, pruning done in a haphazard way, or by an inexperienced hand, without supervision, is often most injurious. Pruning operations should be begun when the trees are young. If they have been looked over before being planted, it will probably not be necessary till about the third year, and afterwards, perhaps, every second or third year, but a good deal will depend on the special features of each case. By regular and proper attention, each subsequent pruning will be reduced, and the great evil of having to amputate large side branches (which is damaging to the timber, and checks the growth of the trees) will be avoided. As already stated, the great object in pruning forest trees is to prevent the overgrowth of large side branches, and to increase the quantity

of sound timber in the stem of the tree; and not only is this result attained by skilful pruning, but the trees are rendered less liable to damage from storms; a free circulation amongst the leaves and branches is also promoted, and the trees are not so likely to be infested with Lichens, &c. There is probably no branch of wood management about which there is more diversity of opinion at present than the necessity, expediency, and effect of the different systems of pruning. Many uphold that no pruning whatever is necessary; but the writer humbly submits that where sound timber is the object, judicious thinning must be had recourse to, and, for the same reason, pruning also cannot be dispensed with. Pruning, to be performed with the best results, should reduce as little as possible the foliage of the trees while shortening all straggling side or lateral branches. The majority of the lower side branches should be shortened at an offshoot, to check their growth, a couple of years before being removed from the main stem. By this reduction of the side branches, they do not increase in proportion to the main stem or trunk of the tree, and their removal makes a small wound, which soon heals without damaging the timber. It is sometimes necessary to thin the side branches of the tree, to allow the sun to penetrate and the air to pass round the whole plant, thus encouraging healthy foliage and bark. When there are contending leaders, one should be removed, leaving the one which rises most natural from the tree (irrespective of size), and promises to make the best leader.

When to prune.—Pruning may be performed at almost any season, provided the weather is open—mild and free from frost. The writer prefers midsummer or early autumn, and considers September a very good time for pruning hard-woods. If trees are pruned in spring, when the sap begins to rise, they generally throw out if quantity of spray round the wound; whereas if done about the period indicated, the wounds soon heal, with little loss of sap, while the risk of the trees being damaged by hard weather is materially lessened. If drives or rides have not been made in the formation of plantations, it will be advantageous to have them formed at the early thinning. Drives are necessary for the removal of timber and other purposes, and should be at least 15 feet wide. In large plantations they likewise promote the health of the trees, as they make room for and induce a current of air throughout them. Accordingly when drives are laid out, they should intersect the plantations at the places, and in the way which may be found most suitable for securing these objects, and they should be 100 yards to 200 yards apart. It is only in exceptional cases that

Underwood is to be recommended in plantations grown for profitable timber. In some districts a considerable revenue may be derived from underwood, but when thoroughly looked into, it may be found that the gain is merely apparent, being to a great extent obtained at the expense of the timber crop. On the other hand, there are many neighbourhoods where there is comparatively no demand for underwood of any description; and where such is the case, the growing of underwood adds to the expense of management, and is detrimental to the standing trees. It is certain that ground cannot carry two crops at the same time without one of them suffering. Where there is a heavy crop of underwood, it must absorb much nourishment from the soil, and deprive the timber trees of a great portion of the food necessary for their healthy development. Further, the roots of underwood form a network in the soil, which should be left entirely for the spread of the roots of the trees. The same reason may be adduced in favour of nursing hard-wood trees with Firs instead of hard-woods, as the latter not only throw out growing shoots from the stools, but their roots continue to spread, and thus deprive the trees of the full benefit of the ground in which they are planted. Another objection to the growing of underwood amongst hard-wood trees is the amount of shade caused thereby, shutting out in a great measure sunlight and air,

and thus defeating the objects of thinning plantations. In these observations I do not condemn the growing of underwood under all circumstances, but merely in conjunction with a crop of hard-wood trees. It must be admitted that there are exceptional cases where it is advantageous to grow underwood in hard-wood plantations, as in very exposed districts; but then only round the margins, and in well-selected masses throughout the plantation. Underwood may be grown for cover in game preserves, or in clumps for ornamental purposes, and along the sides of drives or rides, but for the reasons above set forth in most other cases it is open to serious objection. It has been said that the ground should be thoroughly drained before planting, especially where there is any tendency to wetness. In most cases open ditches are preferable in hard-wood plantations. They should not be less than 2 feet deep, nor more than 30 feet apart. Open drains should also be run along the sides of all plantation roads and drives. All open drains require to be inspected periodically, as they are soon filled up by the falling in of the sides, growth, and decay of herbage, &c., and it is especially necessary to overhaul them after every thinning, as many will be choked by the branches of the fallen trees. The distances at which hard-wood trees should be planted depend upon the soil and situation of the proposed plantation. In all cases it is necessary to calculate the size they are likely to attain in such soils and situations. Trees, if planted at too great distances apart in exposed situations, are liable to severe checks from cold winds, &c., and do not attain the height they would do if planted more closely, and sheltering one another. Thick planting is the safest method to adopt, provided thinning is attended to in proper time, before the trees injure one another.

Felling.—As to the time for cutting down a crop of hard-wood timber, much depends upon the soil and the position in which it is growing. When trees are planted in inaccessible places, it is sometimes almost impossible, or may cost more than the value of heavy timber, to have it removed. In such situations, therefore, trees should be felled before they reach full size, to render their removal possible without cutting them into unsuitable lengths.

Ash is most valuable when grown to a good length, and with a clean stem, and ought to be planted in a rich loam with a dry subsoil. In favourable soils, and in moderately sheltered situations, it may be planted from 12 feet to 15 feet apart, the spaces being filled in with Fir nurses, from 4 feet to 5 feet apart. From seventy to eighty years' growth will be found a profitable age to fell Ash grown for profit.

Alder, as a rule, is never allowed to attain a very large size before being cut down for profit, and may therefore be planted moderately close. It thrives best in a moist soil fairly sheltered, and may be planted 9 feet to 12 feet apart, filled in with Spruce nurses from 3 feet to 4 feet apart. When the ground cannot be thoroughly drained, it may be planted 5 feet to 6 feet apart, to avoid planting Firs as nurses. As the Alder is saleable of moderate size, before it becomes coarse, it may be felled to advantage at forty or fifty years.

Beech may be planted in light soils thoroughly dry and moderately sheltered, at from 4 yards to 5 yards apart, the spaces being filled in with Scotch and Larch Firs from 3 feet to 4 feet apart. Beech will generally be found to reach its most saleable size and quality at from eighty to a hundred years.

Birch may be planted from 9 feet to 12 feet apart, with Scotch Fir nurses from 3 feet to 4 feet. The Birch thrives in very poor soils, and in exposed situations, at high elevations. About fifty years' growth will generally be found a profitable age to cut down the Birch.

Chestnut (Horse) should be planted in a good rich soil, and in a sheltered situation, at moderate elevation, at 15 feet to 18 feet apart, and filled in

with nurses at from 4 feet to 5 feet apart. If the Horse Chestnut is planted in exposed situations, its foliage is sure to be damaged, and the branches, which are somewhat brittle, broken by the wind.

Elm (Scotch) is difficult to grow to any length of stem, from its spreading habit, and should therefore not be planted at too wide distances. In moderate soils of a dry nature, and a medium exposure, 12 feet to 16 feet, and filled in with nurses from 3 feet to 4 feet, will be suitable. Elm (English) grows more upright than the foregoing variety. Its branches are of less spread, and when planted in a good soil and sheltered situation it grows to very large dimensions. From its fast growth it should not be planted too close; in favourable situations, 18 feet to 20 feet, and filled in with nurses from 4 feet to 5 feet asunder. As a rule, both Scotch and English Elm may be cut down with advantage at from eighty to a hundred years.

Lime requires a good soil and sheltered situation to be either a profitable or ornamental tree. Sixteen feet to 18 feet apart is a good distance to plant the Lime tree, with nurses about 4 feet apart. In favourable situations it may be cut down from eighty to a hundred years.

Oak, when well grown, is the most valuable of all our hard-wood trees. Although it may be grown profitably as coppice wood on inferior soils, it should never be planted with the view of growing good heavy timber, except in good rich soils and at low elevations. In such situations the Oak may be planted at 15 feet to 20 feet apart with nurses 4 feet to 5 feet apart. The Oak is longer in arriving at maturity than most timber trees, and when of large size is most valuable, and should therefore never be cut down before its wood is well matured and hearted, which will be from a hundred to a hundred and twenty years in good soil.

Chestnut (Sweet).—The remarks above made regarding the Oak apply also in a great measure to this tree.

Poplars, of which there are many varieties grown for profitable timber, are all fast growing, and may be planted with or without nurses; in the former case, 9 feet to 12 feet apart; and the latter, 5 feet to 6 feet. Most of the varieties require good rich loam and sheltered positions, when they soon arrive at large size. If well grown, about sixty years' growth will be found advantageous for cutting down a crop of Poplar.

Willows may be planted about 6 feet apart, and cut down at fifty to sixty years old. They thrive best when planted in a rich, rather moist soil, and sheltered situation.

Sycamore is one of our hardiest trees, growing well in exposed situations, and even within the influence of the sea. This tree suits a variety of soils, and when of moderate quality, 12 feet to 16 feet apart will be suitable to plant, with intervening nurses 3 feet to 4 feet apart. As a rule, the Sycamore may be cut down profitably at about a hundred years old, when the timber will be of large size and high value.—*Arboricultural Society's Transactions*.

Gorse.—Though one of the commonest this is also one of the most ornamental of evergreen flowering shrubs. The tufted picturesque shape, deep green leaves and shoots, and brilliant yellow flowers render this plant a favourite with most people, and we can well excuse Dillenius for being in a perfect ecstasy of delight when he first saw our commons covered with its golden flowers. Linnaeus lamented that he could hardly preserve it alive in a greenhouse; and Gerard relates that in Poland there was not a branch of it growing, except some few plants he sent, which were most curiously kept in the fairest gardens. It is usually found growing on dry, rocky, or stoney places, and though of a hardy constitution is frequently killed in severe winters. The double flowered variety is one of the most gorgeous plants during summer, being literally one mass of bloom, which, in bright sunny weather, is very conspicuous and beautiful beyond description. The

Irish Furze is a very luxuriant upright variety with soft spines. It flowers in October, and is useful as a hedge plant.—ANGUS WEBSTER.

KITCHEN GARDEN.

FORCING FRENCH BEANS.

THROUGHOUT November and December French Beans have a greater disinclination to grow than during any other months in the year, but with the change of the day, and the gradual increase of light and heat which we will soon experience, there will be less difficulty to get them to succeed. The present is an excellent time to sow extensively for fruiting in March and onwards. Of all French Beans for growing under glass there is none to equal Osborn's Forcing. It is the earliest of the early and the latest of the late, and, further, it is dwarf and compact in habit, and most prolific—all points of the utmost importance in an under-glass Bean. There are various ways of sowing the seed and bringing the young plants forward, but modes of doing this which might be the best in April or May would not answer very well during the shortest days. For instance, when the spring is well advanced, the seed may be sown in boxes, or in 8-inch or 10-inch pots, in which the plants will bear pods; but if this was done now, many of the seeds would be liable to decay before they germinated, and the plants would not grow so strongly or rapidly as they will if the seed is sown in small pots, from which the plants will be transferred into larger ones as soon as large enough to handle. Our plan at this season is to fill a number of 3-inch pots half full of a light rough mixture of loam and horse droppings, and to put 6 or 8 seeds into each. The soil is pressed down as firmly as possible, and some of it is placed on the top of the seeds to the depth of half an inch or so. They are then placed in a house or pit in which the temperature ranges about 60°, and here they get little or no water until the first leaves are formed and a few roots have been made. This treatment prevents all damping or decaying, which must be guarded against at this season. When sufficiently advanced in growth to bear and require water they have a plentiful supply, and then they grow freely. It is a great advantage to have them near the light and in rather a dry atmosphere.

As soon as the plants are 5 inches or 6 inches high, and have made half-a-dozen leaves each, it will be found that the small pots are well crammed with roots, and they should then be shifted into larger pots. The 8-inch ones are our favourites. They should be well drained, and the potting mixture should consist of rough loam and horse droppings. Fine soil is to be avoided. After potting they may be returned to their old quarters, but water should be given sparingly until the roots have taken possession of the new soil, when more must be given. Those who wish to keep up a constant supply of Beans should sow a quantity every fortnight. We have kept up a fair supply by sowing five dozen potfuls at a time, but this, of course, must be done according to the demand. At times we have placed only one of the small potfuls of young plants in the 8-inch one, but where space was limited we have put three small potfuls into this size. When this can be conveniently done it is a profitable way of growing them, as a great many more Beans are secured from the pots with the most plants than the others, and the space required for both is just about the same.

We have generally to grow our spring Beans on back shelves in lean-to houses, but we would prefer to have them where air and light are admitted on both sides, as in such a position the crop would be even. When in bloom the flowers should be kept as dry as possible, as the fruit forms with more certainty than when the blooms are damp. We never allow any of the growths to fall over the sides of the pots, as this checks them; but when any of them are so tall or weak as not to be able to stand without support, pieces of birch from old brooms are put in to hold them up. Osborn's Bean does not, however, require so much

attention in this way as such kinds as Canadian Wonder, which cannot be grown without support. As soon as any of the pods become large enough to gather they should be removed from the plants at once, as there is nothing so much against the production of a long succession of fruit from the same plants as allowing some of the first formed pods to become old. Liberal quantities of liquid manure assist old plants to keep on fruiting, but we do not approve of paying too much attention to this matter, as plants are so very easily raised, and young vigorous ones are always the most fruitful. J. MUIR.

Margam.

FORCING ASPARAGUS.

I LIKE young plants best for forcing; they seem more vigorous, and require less heat to start them than older ones. Where much Asparagus has to be forced it is best to make the raising of the plants for forcing a separate affair, distinct from the beds or trenches kept to supply the table in spring. The ground for sowing the seed should be prepared now by manuring and deep digging or trenching. If the soil is of a clayey character, it must be opened, either by adding something to it, or by burning a part of it. The latter plan is not adopted so often as it might be, though there is no better—or, may I add, cheaper—way of warming and opening up heavy, cold clays. Six inches of the ashes from burnt clay spread over the surface will have a lasting effect, rendering land difficult to cultivate, and upon which some things only lingered, fertile and capable of carrying every crop usually cultivated in a garden. The roots of Asparagus plants have not the power of making their way in heavy, unworked soil; they are gouty-looking, and lack the penetrating power of the roots of most plants. Hence the importance of thoroughly breaking up the soil and making it light by mixing with it plenty of burnt or charred earth. The seeds should be sown thinly in March when the land is in a well pulverised condition. Sow in drills 1 inch deep, and, instead of dropping in the seeds all along the drill, place them in little patches 1 foot apart, 3 seeds in a patch. The drills should be 3 feet apart. When the young plants are up, and it can be seen which are taking the lead, take away all the plants but one, leaving, of course, the strongest. There is an advantage in having a power of selection, as some seeds, and the plants springing from them, possess more power from the first than others. A little artificial manure is a help if we are contending against time; either guano or superphosphate may be employed, scattering it along the drills when the seeds are sown. The first year nothing but cleanly culture will be necessary. A row of Lettuces or Spinach may be grown between the rows in summer, and in winter they should receive a mulching of good manure, and the spaces between the rows should be forked up roughly, though not, of course, to injure or expose the roots. Under very liberal culture, three-year-old roots from the seeds may be forced; and plants that have not been transplanted usually have the strongest crowns, as they have grown on unchecked. There are several ways of forcing, but scarcely anybody who has secured good strong Asparagus can fail to make it grow. A steady temperature at the roots of about 75°, with some 10° less in the atmosphere (which should be of a genial character) will grow Asparagus of the best quality. Where there is plenty of strong roots, the best plan is to make up gentle hotbeds of leaves and manure in succession. Place the roots as thickly as they will stand on the top, and cover with 2 inches or 3 inches of light, rich soil. Place in the centre of the bed a stick, to tell the temperature, and mat up the frame till the heads of the Asparagus are pushing through. The frame must then be uncovered daily, and air must be given on mild days. Asparagus may be forced in pans, pots, or boxes, and these may, until growth has commenced, be placed in the Mushroom house, as light is quite unnecessary till growth appears above ground. Weak, tepid manure watershould

be given when necessary; and at least a soaking should be given when the roots are placed in the frame, in order to settle the soil around them. The first batch that is forced in the autumn should have the tops cut off early, in order to send the plants to rest. E. H.

COLEWORTS.

THESE are most useful vegetables and always to the fore even when other varieties are killed or damaged by frost. Useful, however, as they are, they are, as a rule, but seldom grown either by amateurs or cottagers, while with market gardeners they form one of their principal winter crops. The Rosette is the best kind for early crops, as it forms compact heads early in the autumn and keeps in good condition for sometime afterwards. The hardy green Colewort seldom hearts like the Rosette, the leaves being loose and more spreading, and it is somewhat less tender when cooked. It is, however, very hardy, and will be found to be a desirable sort to grow for winter and spring use, and it seldom runs to seed.

Cultivation.—Ground that has been cropped with Peas comes in well for this crop, and sometimes an old Strawberry bed which has been destroyed after the fruit has been picked, deeply trenched and well manured, will be found to produce good crops of Coleworts; the ground, being well rested, will be sure to produce plants free from club. The ground for this crop should be deeply trenched if not done for the previous crop. Let the soil be moved from 2 feet to 2½ feet in depth, working into it plenty of rotten stable manure as the trenching proceeds. If not trenched it must be deeply dug, so that the manure may be buried well down, which encourages the roots to run deep in search of food and moisture, an important consideration especially in hot dry weather. Thus treated, they will require to be but seldom watered, while crops growing upon ground slightly dug will be suffering from want of moisture. Ground for the seed beds will often be found to be dry and hard; when dug, should such be the case, give it a good watering through a coarse-rosed watering-pot the day previous to sowing the seeds, otherwise they seldom germinate until rain comes. This course of treatment will be found better than frequent waterings after the seed is sown, as waterings form a hard crust difficult for the seedlings to get through. Two sowings should be made, the produce from which will carry one through the winter, furnishing a good supply from the time late Cabbages are finished till the early crop is fit for use. After thoroughly preparing the ground, the first sowing should be made in the second week in May, using the Rosette, which will come in early in the autumn. The second or main crop should be sown in the second or third week in June to come in in good time for winter use. Sow some soot and lime upon the beds as soon as the seedlings appear above ground, which will prevent the roots from clubbing. When large enough prepare a piece of ground and prick them into it 4 inches apart, when they will grow short and stocky before being planted in their permanent quarters. Dust occasionally with soot, which will help to destroy insects, which often injure the young plants, eating their hearts out, when they will be found to be of but little use. When large enough to plant out and the ground is ready for them, plant in rows 12 inches apart and 9 inches plant from plant. Hoe frequently between the rows to keep down weeds, and if thought desirable hoe into the ground deeply some artificial manure which will be found to be beneficial to the growth of the plants; or liquid manure may be applied with success, using it once a week when the plants are in full growth. Earth up slightly to keep them firm at the roots, when little more will be required until the crop is fit to eat.

Varieties.—Use, as I have said, the Rosette, an early hearting variety, which produces finely flavoured heads when cooked, and also the Hardy Green Colewort, a hardy variety, which produces

medium sized heads, which are very useful as winter greens. WM. CHRISTISON

NOTES OF THE WEEK.

IRISH HORTICULTURAL SOCIETY'S FIXTURES FOR 1883.—As set forth in the schedule of prizes for the coming year, just issued, the dates of the Royal Horticultural Society of Ireland's exhibitions for 1883 are as follows: Spring exhibition, Thursday, April 19; May exhibition, Thursday, May 17; summer exhibition, Thursday, July 5; autumn exhibition, Thursday, September 6; winter exhibition, Thursday, November 22.

RUSSIAN ENDOWMENT OF SCIENTIFIC RESEARCH.—The Emperor of Russia, says the "Zoologist," has ordered £2200 to be allotted from the Imperial Treasury to the Russian traveller in New Guinea and the Malay Archipelago, M. Miklucho Maklay, in order to enable him to work up the results of his explorations. His Majesty has also ordered M. Maklay to be informed that the cost of the publication of his book of travels will be defrayed by the privy purse.

PROFIT FROM TREE PLANTING IN IRELAND.—Mr. G. Dodds states in the *Irish Farmers' Gazette* that a few years ago, upon an estate in the county Kildare, there was drawn for thinning from a wood consisting of 112 Irish acres, about forty-five years planted, something near to £3000. Timber, principally Scotch Fir, Larch, some small Ash, and Oak. Part of this wood grows upon the Bog of Allen, consequently the land is of little or no value for agricultural purposes. Previous thinning, he feels sure, had paid both principal and interest for money expended.

BEAUTIFUL NEW HARDY FERN.—Messrs. Backhouse send us from their nurseries at York some fronds of the most elegant variety of Polypodium vulgare that we have ever seen. It is named trichomanoides, and very appropriately too, as it is more like the Killarney Fern (*T. radicans*) than any other with which we can compare it. The fronds are cut into very fine segments, which give them quite a feathery look, and they are, moreover, exquisitely crisped, which adds greatly to their charming appearance. For such a hardy Fern we predict a brilliant future.

THE ORIGIN OF THE POTATO.—At the last meeting of the California Academy of Sciences Mr. John O. Lemmon reported the results of a summer's tour of botanical exploration among the mountain ranges along the Mexican frontier of Arizona. Among his discoveries were two or three varieties of indigenous Potatoes, found growing abundantly in high mountain meadows surrounded by peaks attaining a height of 10,000 feet above the sea level. The tubers were about the size of Walnuts. Mr. Lemmon brought home a supply, which will be carefully cultivated. The *Scientific American* remarks that this interesting discovery goes far to settle the long-vexed question of the origin of the Potato.

FILMY FERNS AND FROST.—It is no small recommendation, says the *Irish Farmer's Gazette*, to the more extended culture of this charming section of the Fern tribe that the majority of those in cultivation ignore coddling and fire heat altogether, and will not vince even with the mercury inclined to touch zero. Looking in last week at that very interesting compartment—the Filmy Fern house at Glasnevin, nothing could look more happy than the Todeas, Hymenophyllums, and others in their garniture of richest green, profusely beaded with diamond dew-drops, notwithstanding that in their cool and humid quarters there must have been in the previous week some fifteen or more degrees of frost.

THE COAL TRADE IN 1882.—The demand for coke has increased, that for gas and manufacturing coal has risen, and locally and generally the household requirements have been enlarged, so that, with shipments on a larger scale than in 1881, there has been a very great increase in the way of consumption and stocks have fallen. This

having been the case, there will be an upward movement in prices, especially in the case of some kinds of coal. Northumberland has not felt that demand so fully as Durham, because a large part of the output of the former is sent out of the country by sea in the summer and autumn, while the latter finds the fullest demand for its gas coals very naturally in the winter; but in both counties manufacturing coal is dearer, and there is a tolerable certainty that the wages of the miners will be higher in 1883 than in 1882. Newcastle is still the chief of the coal-shipping ports, sending out now slightly over 7,230,000 tons of coal and coke; Sunderland, with 3,230,000 tons yearly, follows; while West Hartlepool, with 1,090,000, is the only other one of the north-eastern ports that ships over a million tons yearly.

LUCULIA GRATISSIMA.—The large bush of this grand flowering and most deliciously fragrant greenhouse shrub growing in the central portion of the cool conservatory range at Glasnevin has been unusually floriferous, and the Hydrangea-like flower-heads, particularly large and fine this winter, from 150 to 200 being open at a time, and still plenty to succeed them. It is certainly a charming shrub, which no conservatory should be without. Now that it has been demonstrated that nice dwarf plants with fine heads of flower can be produced grown in 6-inch pots, its popularity will be largely increased, and the appearance of such plants as familiar at Christmas as those of the gorgeously coloured, but scentless Poinsettia. —*Irish Farmer's Gazette.*

A TEMPERANT NUT.—The virtues of the Kola nut, as a rival to the celebrated Coca of South America, in the possession of the property of enabling persons partaking of it to endure prolonged fast and fatigue, are pretty well known, but this peculiarity does not by any means exhaust the list of the wonderful properties possessed by this West African product. Mr. Christy, Fenchurch Street, has had specimens of this nut submitted to analysis, and reports that it has been found to contain the same active principle as coffee, viz., caffeine, only in greater proportion than the best coffee, while it also contains the same active principle as cocoa, but less fatty matter. He therefore thinks that with proper treatment it might be able to compete successfully with those beverages, for the nuts are used to form a refreshing and invigorating drink throughout a large portion of Tropical Africa.

THE OLIVE IN CALIFORNIA.—It appears that Mr. Cooper, of San Barbara, San Diego, and other places, has demonstrated by his cultivation of the Olive that the tree thrives well and bears well in California, and also that it is profitable to cultivate it. The trees begin to pay at three years, and when five years old will pay all expenses of tillage and harvesting with a surplus, while the sixth year the crop will pay for the land, the trees, and the tillage for the five years previous, and, with good care, the increase is larger from year to year for a century longer. Indeed, there are now alive in Asia Minor trees known to be upwards of 1200 years old, and they are still in full bearing. In a pamphlet published by Mr. Ellwood Cooper, the statement is made that some of his best trees, eight years old, produced 2000 gallons of berries to the acre, and the European standard is eight gallons of berries for one gallon of oil, so that this gives a product of 250 gallons of oil per acre. The oil finds a ready market at £1 a gallon, which gives an income of £250 an acre for the best eight-year-old trees in an exceptionally good year.

Soil for Eucharis amazonica.—Would any reader of THE GARDEN kindly tell me what is the best soil for this plant and the best time for repotting it? I have got two large pots full of good-sized bulbs, one of which has at the present time got a flower-spike, but there is no sign of more flowers, and this is the first that has appeared during the last twelve months. At present they are supplied with a fair amount of bottom-heat. —J. W.

FRUIT GARDEN.

SUCCESS WITH FRUIT.

A YOUNG cultivator asks us to name or describe the essential points of success in planting a collection of fruit trees for the supply of a family. He also wishes to know if he can connect with such a plantation an orchard for market. In answer, we may state that all localities will admit the growing of fruit for home use, by a proper selection; but for profitable marketing such localities are to be chosen as have proved themselves peculiarly adapted to certain fruits or certain varieties, in order that after deducting all the necessary expenses of shipping and sale, a fair profit may remain. But in planting for home use these expenses are not incurred, the owner finding the market on his own table.

To the novice who is about setting out a collection of fruit for family use, we would recommend in the first place an examination, so far as may be practicable, of the orchards and fruit gardens in the same or similar regions of country, to see what fruits grow and succeed well under fair culture, and then choose these for similar ones. This will save much labour and expense in planting and then losing such kinds as are unadapted to that locality. Next, select a good piece of ground, and if not naturally well drained, provide good artificial drainage. Thirdly, prepare it well by deep cultivation, and if practicable by subsoiling, applying and working in manure as the soil may seem to need it, although the manuring given to previous crops will generally be best. This work having been done in autumn, the ground will be all ready for planting in spring. Or if there is time, a part of the planting of the hardiest kinds, such as Apples, may be done in autumn, lessening the labour of spring.

Fourthly, a very important part of the work is selecting and procuring the trees. In making the selection, depend on three or four sources for information, as for example, the experience of good fruit-growers in that part of the country, the catalogues of reliable nurserymen, your own personal observation, &c. Get old proved sorts, and avoid costly new varieties which may prove valuable or not, unless you have money to spare for experiments. If you purchase of nursery agents, deal with those only of known probity, or who can show late and ample credentials from nurserymen whose character you know to be well established. If you buy trees in autumn to set out in spring, heel them in well by filling with fine earth all possible interstices among the roots, and raise a bed of smooth earth around the whole to exclude mice.

Fifthly, in setting out, little instruction is needed by those who know that the roots should be evenly spread on all sides, and the earth packed closely among them. Young, or one or two-year trees, if 4 feet or 5 feet high, are better than old, stiff, heavy-topped ones. The small ones have better roots in proportion to their size, grow freely the first season without check, and if well cultivated will overtake the old-set ones by the end of the second or third year. It is well to shorten back all the one-year shoots when setting out the trees—Peach trees most freely, Cherries and Apples more sparingly.

Sixthly, and lastly, comes the most important work of all, namely, taking good care of the young orchard after it is set out. Keep the whole ground clean and mellow, and allow no weeds and Grass to grow. You may plant a hoed crop, such as Potatoes, Cabbages, &c., if you keep that crop clean by cultivation. The difference in the growth between cultivated trees and those which are neglected, is not unfrequently ten to one. But you must exercise your observation and judgment. If the growth is rank, cultivate less; if feeble, top-dress with manure in autumn besides cultivating. It is well to cease cultivating all half-tender trees before the end of summer, that the wood may ripen and prevent winter-killing. As a general rule, young trees should grow 2 feet or more yearly, and if they much exceed this, check

their growth early; and if they do not reach it, employ both cultivation and manure. If you attend to all these requisites, namely, well prepared ground, well selected varieties, careful transplanting, and good cultivation, you can hardly fail in having an ample family supply of fine fruit before many years have passed away; and if by that time you choose to plant more largely for market, you can judge by your own experience, and by the success of the most promising sorts, which to select for this purpose.—*Country Gentleman.*

PRUNING ORCHARD HOUSE TREES.

THOSE about to commence the culture of orchard house trees would do well to purchase fruiting trees in pots to begin with; but I have found that in the course of a few years some of the trees get scraggy and unsightly, and in replacing these it is best to purchase trees one year from the bud. I get mine in November, and as soon as they come to hand they are potted. We plunge them in Cocoa-nut fibre, where they remain until January, which is a good time to prune them. The question is, whether the form of tree is to be bush or pyramid. I prefer a few of each. In some positions the bush form works in best and in others the pyramid, and to fill up spaces in the centre border of large span-roofed houses standards come in well. A tree that has made one year's growth from the bud has a straight centre stem and usually a number of lateral branches. In order to form a pyramid about a third must be cut off the main stem and the side growths should be cut back, those near the top close to the stem, gradually leaving the lower ones longer until the lowest side growth is reached, which should be the longest, so that the tree will be of a pyramidal form to start with.

A bush tree is formed by cutting the main stem down to within a foot of the bud, and cutting back any side growths to 4 inches or 6 inches from the stem. It is easy enough to form standards by cutting the side or lateral growths off close to the stem, leaving the latter the entire length. The trees ought not to be placed in a forcing temperature, but be allowed to grow on slowly with plenty of air; under those circumstances they will break freely, but they grow most freely from the highest part of the trees; and to prevent these growths from taking more than their due share of nutriment their points should be pinched off at the fifth or sixth leaf; this allows the lower growths to run out more strongly, but they also ought to be stopped in the same way. The second growths will not be so strong as the first, but they will be strong enough to produce fruitful wood—the object in view. The strongest growths will require to be pinched a second time, and the weaker ones must not be pinched at all. Anyone acquainted with Peach and Nectarine trees in pots (and it is these only with which I am now treating) will know that weak growths are furnished their entire length with blossom buds, the terminal bud only being a leaf-bud, and if that terminal bud is removed there will be no young growth beyond the fruit. The strong shoots are furnished with triple buds as well as leaf-buds, and usually the centre one will be a leaf bud, and the two side ones blossom-buds. If the strong shoots have to be shortened, it is always best to cut to a leaf-bud. Pear, Plum, and Cherry trees may be pinched, pruned, and trained in the same way, and they may be pruned at any time and cut to any bud. J. DOUGLAS.

Pruning Vines.—The note (p. 517) as to pruning Duke of Buccleuch and Golden Champion varieties of Vines is in exact accord with my own experience. Spur pruning, as that term is generally understood—that is, the cutting back of the side shoots to within one or two eyes of the previous year's pruning—does not ensure either as many "shows" or as fine, as does pruning on the long-rod system; and I am told that Mr. Thomson himself finds it necessary to have a goodly length of new wood every year, to which fact no doubt must be attributed at least some portion of the credit of these varieties doing so well at

Clovenfords. This peculiarity is not, however, confined to the varieties named, as Gros Guillaume (Barbarossa) can only be kept in good fruitful condition for a number of years by constant renewal of the rods. Mrs Pince, Chasselas Musqué, and the white Frontignan also in a lesser degree possess the same peculiarity, but with enthusiastic Grape growers this will not be accepted as a valid reason for neglect of culture of these varieties, the exceptional treatment needed to obtain the best results being an incentive to their extended culture rather than otherwise.—H. W.

PEAR GROWING FOR PROFIT.

ALLOW me to assure Mr. Bridgeman (p. 575) that I do not claim to have a monopoly of knowledge on this subject. On the question of cordon Pear growing I simply recorded the results of my own practice, and as "S. S." particularly asked for the names of the best late varieties, those only were named that have never failed with us. Our soil is very much the same as that with which Mr. Bridgeman has to deal, and yet the "pretty toys" of which he speaks cover the wall, and have been loaded with fruit for twelve years consecutively; moreover, at present they manifest no disposition to give up the ghost; therefore the question of light soil not suiting the Quince stock falls to the ground. I have indeed proved that the Quince is a suitable stock for Pear growing on any description of soil, provided the cultural treatment is adapted to the requirements of the particular kind of soil to be dealt with; for instance, on our light sandy soil we find it necessary to give heavy manurial mulchings every autumn; this remains throughout the year, and sometimes, in dry, hot weather, a supplementary mulching of long stable litter is given, and artificial watering when time can be afforded for applying it. Added to this, we every alternate year remove the whole of the mulching, prick up the surface soil, and add about 4 inches in thickness of new soil, again mulching with rotten manure. Of course in heavier soils there would be less of such work, and the trees would probably be longer lived, the only advantages. The success of "R. A." (p. 545, Vol. XXII.), who for twenty years has had good crops of fruit on his cordon trees, ought to be sufficient evidence of the merits of the system and suitability of the Quince stock were it not that we gardeners are such notorious copyists, that we take for granted—without proving for ourselves—the saying of some would-be-great authority that the Quince stock is only suited to heavy soils. W. W. H.

LATE GRAPES IN COOL HOUSES.

A GENERAL opinion prevails that really late Grapes, to keep in prime condition, fit for dessert after Christmas, require a great amount of fire-heat to bring them to perfection, and thus many owners of gardens are deterred from planting not only the most valuable of market Grapes, but, what is of more importance to many, the only varieties that can be kept for mid-winter desserts, the very time when home-grown Grapes are most appreciated. There is no lack of Vines or vineries, but in nine cases out of ten Black Hamburgs, or other equally thin-skinned Grapes, are planted; and in October and November, during the damp, muggy weather that usually accompanies the fall of the leaf, these kinds turn mouldy and drop off, no matter what precautions are taken to preserve them, for although a dry, buoyant atmosphere will do much to lengthen the season of even these popular summer Grapes, it will not make the supply of good sound Grapes a certainty after the beginning of December, when home-grown Grapes are practically over, even in many fair-sized gardens. Now, this is intolerable after the number of years during which really good late keeping sorts have been before the public, and, where judiciously managed, have done away with the necessity for very early forcing. After trying and testing most of the late sorts in cultivation, I find Lady Downes to be the best late black Grape in cultivation, and the true Mus-

cat of Alexandria the best white companion for it. As a proof that these can be kept in good condition until the new year, I send a small bunch of each from a vinery that is in the usual meaning of the term unheated; it has only a flow and return 3-inch pipe in it, and these are a long way from the boiler, a saddle one of by no means recent date, and which, having to heat a quantity of piping besides, those in the vinery are never anything more than warm; therefore the maintenance of anything like the temperature supposed to be necessary for the varieties of Grapes mentioned is out of the question. Yet as regards any loss from decay I can safely say that there has not been a dozen berries cut out of the entire house, though it contains a heavy crop of moderate sized bunches. I would by no means recommend the use of 3-inch pipes in vineries or in any other houses, larger ones being better. The examples of fruit sent are merely to show the possibility of having home-grown Grapes fit for dessert early in the new year with simply ordinary appliances such as are available in most gardens. But I may add that really late Grapes should have compartments to themselves. There should be no pot plants in such houses, and if this were done there would be no difficulty in keeping the fruit sound, for that in question had no fire heat at all until many consider it time for late crops to be ripe, and then, as has just been explained, heat was applied, but in a very mild form.

Seaford, Gosport.

JAMES GROOM.

[Better Grapes than those sent to us by Mr. Groom could not be desired. They were as plump and fresh looking as Grapes just ripe, and their flavour excellent.]

Strawberry Pelissier.—In the *Revue Horticole* for 1880 (p. 298) there is a note about this Strawberry by M. E. A. Carrière, who says that the variety was obtained by a gardener at Lectoure of the name of Pelissier. It is said to be a large-fruited and long-bearing Strawberry. Dr. A. Miran, of Lectoure, states that it was obtained about 1873 or 1874. It likes a half-shaded situation, in which it yields larger and more fruit than in the full sun. It bears from April 15 till August, and again in October. It came first into the trade in the autumn of 1880. We have it, but have not yet been able to judge of its merits.—J. H. KRELLAGE, *Haarlem*.

Mealy bug.—"Cobham" should give his Vines a thorough cleaning when at rest; paint them with Fir tree oil at the strength of half a pint of the oil to a gallon of warm water. When they have started into growth give them another dressing of the same, but be careful not to allow it to get on the young growths; when the berries are set, tie a small piece of cotton wool round the stem of each bunch which will prevent any bug from getting amongst the fruit. If time can be spared, it is well to hand-pick the Vines once a week. This done year after year will thin their numbers considerably; but in the case of old Vines it is impossible to clean them. Lime is a useless remedy; it does the Vines no harm, but it will not kill the mealy bug. We tried it on a house of old Vines some four or five years ago, and the year following the experiment the bugs were as numerous as ever.—J. R.

—"Cobham" will find a mixture consisting of a quarter of a pint of paraffin to four gallons of water perfectly safe and effective; an ounce of soft soap added is an improvement, as it causes the mixture to spread over the plant instead of standing in drops, as it does if paraffin and water only are used. In syringing with this mixture, the syringe must be drawn full and again discharged into the vessel, then quickly refilled and discharged on the plant, repeating this until all is used; as the oil rises to the surface immediately the mixture is still, it must always be kept in motion. When I came here I found a vinery badly infested with mealy bug. The fruit was just ripe, so I got it cut as quickly as possible, and commenced syringing with paraffin and water, thoroughly saturating every part of the house and everything in it. This was repeated

twice a week for some time, then once a week, until the leaves were off the Vines. After pruning, two ounces of soft soap were dissolved in two gallons of water, and a quarter of a pint of paraffin was added; one person kept this mixed with a syringe, while another dressed the Vines with it, working it well into all crevices, and round the spurs with a large paint-brush. The wood and glass were washed, the wall coated with hot lime wash, and before the Vines were started the house was again syringed with paraffin and water. As the season advanced a few bugs began to appear; the Vines were then looked over frequently, and every bug that could be seen was killed. If not well looked after at this season, they increase so rapidly that they are soon as plentiful as ever. After the fruit was cut, the same treatment as that given the previous year was commenced, and the number of mealy bugs seen the following summer was very few indeed, and for the last two years not one has made its appearance.—W. CRANE, *Quartern Park, Mallon*.

PROPAGATING.

AZALEAS.

WHEN Azaleas are forced early into bloom the young shoots produced at that time strike root far more readily than when growth takes place at the natural season, a remark which also holds good as regards many other subjects; indeed, a common practice, and one justified by results, is to place the plant from which cuttings are wanted in a somewhat higher temperature if possible than that in which it has been growing for two or three weeks before taking the cuttings off, just to draw out the young shoots a little and weaken them, as roots are produced more freely in that case than on stout succulent shoots. In the case of subjects that strike root easily, such as Fuchsias, Pelargoniums, &c., of course good stout cuttings are preferred, as they naturally form a more vigorous specimen than that from the weaker shoots, but with difficult subjects the case is different, the principal aim being to get the cutting to push forth roots. Azaleas cannot be classed amongst plants very difficult to root, nor, on the other hand, do they belong to the easiest to manage in that respect; but, as has been stated, cuttings from forced plants strike more readily than those taken from shoots produced later in the season. They should consist entirely of the current season's growth; catch it between the finger and thumb, then pull it steadily downwards, when it will come clean away as if it were from a socket, thus giving a good base for the cutting from which roots are produced in less time than if cut off. Of course if the entire shoot is of an inconvenient length it must be cut to reasonable proportions; but, in any case, leaves that would be buried either wholly or partially when inserted, must be removed beforehand; on no account, however, take off more than is absolutely necessary. An extreme length of 5 inches or 6 inches is quite sufficient, and even then it will, no doubt, be found that the smaller cuttings strike first. In

Selecting the pots, those 5 inches in diameter will be found a convenient size if they are to be put in a close case, but if under bell-glasses of course the pots must be chosen to suit the glasses. As it is necessary to keep the cuttings perfectly air-tight, they are more commonly covered with bell-glasses than otherwise. The pots should be filled to within 2 inches of the top with broken crocks, rough at the bottom, and gradually becoming finer, till the uppermost layer consists of pieces that pass readily through a sieve with a quarter of an inch mesh, but from which the dust is removed. For soil, take peat, sifted through the sieve just named, and add to it a liberal quantity of sand—the amount will be influenced by that which the peat naturally contains, but in any case the soil should be very sandy. The compost must then be pressed down firmly in the pots,

leaving just room enough for a slight layer of sand on the top. All is then ready for the

Insertion of the cuttings, and care must be taken that the base rests solidly—that is to say, do not make the hole with the dibber so deep as to leave a vacancy just at the base of the cutting, as in that case it is very likely to shrivel up; also take care to press the soil firmly about the buried portion, as attention to these little matters tends greatly towards success. Where bell-glasses are used a good way is to press the edge of the glass in the sand before commencing to insert the cuttings, as the mark thus formed serves as a guide as to how near the edge the cuttings may come; but even then do not let them come too close, as, should the foliage spread out a little, it will be difficult to take off and put on the glasses without bruising some of the cuttings, although I have often noticed this peculiarity that those crushed down by the glass have been the first to root. When finished give a thorough watering through a fine rose to settle the sand and fill in any interstices that may exist. After such a watering leave the glasses off for a little time to enable the foliage to get somewhat dry, when they must be put on, or if in a small frame the lights must be shut down. The cuttings, when callused, will do well in a stove with a little bottom heat, but as the season advances and shoots are produced in a lower temperature, a proportionately less degree of heat must be maintained for the cuttings. A safe plan is to keep the latter in a slightly higher temperature than that in which they have been grown at whatever time of the year they are put in, and in all cases the same principle should be carried out. When rooted they must be hardened off by degrees and then potted in peat soil, using small, well drained pots.

Insects.—When preparing the cuttings keep a sharp look out for thrips, as if but two or three are allowed to remain on them they increase so rapidly in close cases as to soon do a great deal of damage. The pretty little *Azalea roseiflora* is readily propagated in this way, and plants so obtained form dwarf dense bushes, and are far more attractive than when grafted on a bare stem some inches high, although by the latter method the rate of growth is quicker. T.

AMERICAN NOTES.

Ill-flavoured Tomatoes.—Many complain that their Tomatoes are sour. All Tomatoes are sour, if we may judge from our own experience, that are grown in rich soil. We want a maximum of fruit and a minimum of leaves and stems if we would have sweet Tomatoes—by which is meant not sweet literally, but less acidity. Tomatoes raised in light, rather poor soil in a sheltered or warm situation are always sweet in favourable seasons, while those raised in rich soil or in partial shade are always sour. A rank growth of foliage shades the fruit densely and interferes with the development of the saccharine principle. Tomatoes raised in poorish light soil will ripen also ten days earlier than those raised in rich soil. We know this from actual test during the present season. If large, showy Tomatoes are wanted, regardless of flavour and time of ripening, then the rich soil and the rank growth are needed.—*Rural New Yorker*.

Pinching back Peas.—The *American Garden* gives the experience of H. J. Seymour in pinching back Peas to increase their productivity. They had already begun to show blossoms, when six hundred plants were counted off in a row and decapitated. New branches came out abundantly near the ground, and from the axils of the leaves. They blossomed and fruited more abundantly than their neighbours, although a week later. They were saved for seed, threshed, winnowed, and carefully measured. The six hundred pruned plants yielded five plump quarts, while the six hundred unpruned ones in the adjoining row yielded but four scant quarts. The

advantage was in increasing the crop and prolonging the season. The result would doubtless vary with variety, soil, season, and depth of planting.

Cure for scale.—Ordinary bar soap scraped and rubbed into a paste at the rate of 20 parts of soap to 10 parts of water, 30 parts of kerosene, and 1 part of fir balsam, will make, when diluted with water, an emulsion good enough for all purposes, as the slight cream which in time rises to the surface, or the flakiness that often follows is readily dissipated by a little shaking. Soap emulsions are, however, less satisfactory and efficient than those made with milk. Emulsions with milk may be made of varying strength, but one of the most satisfactory proportions is two parts of refined kerosene to one part of sour milk. Ordinary condensed milk may also be used by thoroughly stirring and beating in an equal or varying quantity of kerosene. The diluted emulsion when prepared for use should be finely sprayed on to the insects to be killed, its strength varying for different insects or plants, and its effect being enhanced when brought forcibly in contact with the insects. Of mucilaginous substances, that obtained from the root of *Zamia integrifolia*, a plant quite common in parts of Florida and from which the Florida arrowroot is obtained, has proved useful as an emulsifier. These emulsions have been used with success against the cotton worm without injury to the plant, but their chief value depends on their efficacy against the different scale insects which affect Citrus plants. Experience so far shows that such plants do not suffer from its judicious use, but that it must be applied with much more care to most deciduous fruit trees in order not to injure them.

Keeping fruit under water.—Dr. Hexamer says that some years ago when he had more Apples than he could store, he hired a cellar of a neighbour and put in it several hundred barrels. When he came to take them out he found water in the cellar 3 feet or 4 feet deep, and concluded they were a dead loss, till he examined them. Some weeks afterwards he found them in excellent condition, better than those which the water had not reached. The result was ascribed to the low temperature and exclusion of air, to which we would add a uniform degree of cold and freedom from the fluctuations caused by air currents. We suppose the water was near or at the freezing point.

Well up in botany.—Yes, she visited the country and considered herself superior to ignorant common cultivators. She was learned in botany, and with lofty airs told farmer D. she knew every plant that grew. The farmer coming from the field one day plucked a cluster of blossoms and carried them to the house. "Do you know these blossoms?" he asked of her. "Oh, yes, of course I do," she replied. "They are very rare, and so beautiful; too sweet for anything. I am familiar with these flowers; these grow on trees in the woods." "What is their name?" asked farmer D. "Why—really—I can't recall their botanical name just now; but I suppose you have some vulgar name for them." "Well," replied farmer D., "we ignorant farmers call them Potato blossoms."

The buyers all want red Apples.—They say they sell the best. This fancy for colour has given Baldwins a boom, as they are red and handle and ship well. There is another advantage for the fruit—the tree is hardy and a constant bearer. I do not like the Apple to eat, but on account of its market value and the hardness of the tree and strong bearing propensity; in an orchard of 100 trees I would plant seventy-five Baldwins. Too many varieties of fruit are a nuisance. They make an endless amount of work, and many kinds, while they have a value for home use, are unsuited for keeping or shipping. They do not pay. The *Esopus Spitzenburgh*, I think, is the daintiest flavoured Apple that grows.

Fences must go.—Village improvement, as discussed by Mr. Parsons, is well worthy of more space than has been given to it by the press. One thing only do I want to dissent from in Mr. Parsons' article: it is his commendation of "agreeably-designed fences." I live near one of the

neatest villages in New England, with plenty of nice fences—stone, iron, and wood. But by far the most tasteful streets are those where fences have been entirely discarded. The change is so great an improvement that it spreads rapidly and yard fences "must go."

Cole's Quince Apple.—The Red Astrachan succeeds from Montreal to New Orleans. I do not know how far south Cole's Quince Apple is found profitable, but it originated in Maine, and is reported favourably on all the way across to the plains. It seems quite hardy here in Northern Vermont, a good grower and bearer, with large and marketable fruit when on a strong soil, which it requires. It is one of the finest cooking Apples, and when very mellow is tender in flesh, mild and rich, with a distinct Quince flavour and aroma.

The Champion Quince.—So far as a brief trial indicates, this Quince stands high as regards value. It bears early, and the fruit is large and handsome. It is later than the Orange Quince by nearly half a month in the average of seasons, which gives it an important advantage, except so far north that it will not ripen in short seasons. Mr. S. Anderson, of Union Springs, N.Y., says he has had specimens weighing 18 ounces.—*Country Gentleman*.

OBITUARY.

THE death, in her ninety-sixth year, of ELIZABETH HARRIET COOKE has recently been recorded. The deceased lady was the widow of George Cooke, the well known engraver, and mother of E. A. Cooke, R.A., the marine painter. She had the sorrow to lose her son at an advanced age a few years ago at Glen Andred, in Sussex, where she resided with him. She took as much interest as most others in current events, and within the past few years sent some verses on flowers to THE GARDEN.

All editorial queries should be addressed to the Editor of THE GARDEN; by directing to individuals delays are incurred.

SOME of our correspondents who are applied to privately for information on subjects on which they have written in THE GARDEN complain that the inquirers forget to enclose a directed and stamped envelope; and we are asked to remind them that that should in all cases be done. We therefore hope that no one will fail to comply with so reasonable a request.

Naming plants.—Four plants, fruits, or flowers only can be named at one time, and this only when good specimens are sent. Readers who desire our help in naming fruit will kindly bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. Local varieties should be named by local growers, and are often only known to them. We can only undertake to name four varieties at a time, and these only when the above condition is observed. Unpaid parcels not received.

Hunt's vaporiser.—Will any reader of THE GARDEN inform me where this can be procured?—R.

Mowing machine (W. L. O.).—The Excelsior is a good machine, but surely the one you have ought to answer. A new machine always works stiffly. Oil it well and give it another trial.

Slugs (B. W.).—The slugs which you have forwarded are *Testacella halistiden*; they are very useful in gardens, and should never be destroyed, as they are animal feeders. They will certainly destroy and eat earthworms, and will probably treat wireworms in the same manner. Unfortunately these slugs are not common; they may always be distinguished from other slugs by the flat shell near their tails.—G. S. S.

Names of plants.—E. T.—*Miltonia Clowesi*.—D. E.—1, *Scutellaria Moeciniana*; 2, *Centropogon Lueyanus*.—J. M. B.—*Oncidium fuscum*.—*Orchid*.—1, *Dendrobium secundum*; 2, *Oncidium tigrinum*; 3, *Miltonia Clowesi*; 4, *Masdevallia ignea* (fine form); 5, *Vanda tricolor*.—G. L. (Smalley).—*Choisya ternata*.—G. K.—*Eriophorum polystachyum*.—S. P.—*Erica hyemalis* (winter-flowering Heath). Not hardy, but requires protection in a greenhouse. Do not disturb it, and keep it moderately dry.—S. C.—We do not recognise the *Orchid*.—J. E.—The Apple you send is apparently Golden Noble.

No. 582 SATURDAY, JAN. 13, 1883. Vol. XXII.

"This is an Art

Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

A BIT OF GARDEN.

MAN is by nature a gardener. We will go in one mental bound from Paradise to the gardens of our childhood, planted with twigs and wild flowers; from Chatsworth to a modest tea-pot in a garret window, from Burford Lodge to *Orchis maculata* in a nook of the rockery. These are long strides, but they comprise such a variety of grades as go to prove the statement, if indeed it needs any proof, that man is by nature a gardener. Wherever we may go we find him almost inseparable from a garden of some sort. I suppose this connection is inevitable, because we draw nearly all our sustenance from mother earth, directly in most cases, and where not directly, then only once removed by the interposition of herbivorous and graminivorous animals, and birds which feed upon cereals and other fruits, becoming themselves the food of man. Between the two, vegetable and animal, he finds everything he wants for his support, everything necessary without taking as food either carnivorous animals or birds, and even fish may be excluded as unnecessary. It is no wonder, then, that man should be assiduous in his cultivation of the soil. We find, however, each gardener showing a distinct preference for the useful or the beautiful in his garden, or one trying to see the beautiful in the useful, whilst another cultivates his plants in the hope of finding the useful in the beautiful, or both. One neighbour may say, "Give me some Cabbages and Cauliflowers, Lettuce and Leeks, Pears and Plums, something we can eat. Never mind Roses; I can buy beauties, fresh with dew, at four a penny, off a costermonger's barrow in London streets, and yours cost you more than that." Another may reply, "True, and give me but one bloom of Marie Baumann, Baroness Rothschild, or Harrison Weir of my own growing, from that visit to the nurseries one Saturday afternoon to the half-regretful snip of the scissors, and it is worth a barrowful of your Cabbages, which, equally with you, I may say, may be bought much cheaper than you can grow them." This doing a thing oneself enhances the cost and enjoyment of many things, I may remark, far removed from the garden.

Each of the disputants is right, each in his particular preference and hobby. Lord Bacon is credited with the saying, "Give me a man with a hobby," but I wish he had added, "and, if possible, let it be a garden." The hobby is comprehensive enough to hold us all in degrees upwards (or downwards) from the crippled youth with his window-box, who, as he watches his plant grow wondrously from seed to flower, is thankful for his bit of garden, to the scientific gardeners, whose works we read, who having wealth and space at command, busy themselves with microscopes and chemistry in the search for more light, often finding each new ray, each new process brought to light in the cells of the plant, revealing deeper and darker chasms of ignorance than they had hitherto believed to exist, just as the astronomer with each more perfect telescope finds objects still more remote, and which, by their movements, indicate the existence of stars still further off. These great teachers may say too, like the boy at the window, "Non nobis Domine." In our gardens we may occasionally hear some such remark as this, "Surely that man watches his plants grow. He and his long pipe are never out of the garden. What is he peeping at with a watchmaker's lens in one eye and a needle in his hand?" We can imagine the reply to be, "He is seeking, madam amongst the newly opening growths of spring for 'the worm i' th' bud,' and we only hope he is equally assiduous and anxious about the mental ones. He is perhaps thinking how one thing preys

upon another throughout the whole world, even man upon man, and if he is to have his pets in the garden he must protect them and be vigilant in quest of their enemies." When a neighbour locks his door for the night on some lovely summer's evening, and the white and yellow flowers are pouring forth their perfumes, bidding for the services of the *Lepidoptera*, and appealing to a far keener sense of smell than man possesses, our friend is in his garden. Next morning, when the said door is unbolted he is there, and is greeted with a jocular, "Have you been there ever since?" To him at that early hour the Rose has its sweetest perfume, its only dewdrops, and its most lovely tints. He thinks seven hours of sound sleep quite sufficient without spending half his life in a bedroom, and says, as each day comes round, "Give us health, happiness, and a bit of garden; let others have the wealth, power, and ambition." His pleasures, however, are not unmixed. There is an almost comical (if it were not painful) side to the question; but as the pains of gardening only serve to enhance the pleasures, I must not omit a few of the former. There is first and foremost the lumbago and rheumatism which seem to me inherent in gardeners, unless it be produced by so frequently "stooping to conquer," and persistently finishing that bed in a gentle Scotch mist, which we afterwards found had penetrated more rapidly than we thought of. So "at the peaceful midnight hour" our friend the enemy is at work—the slug feeding on his seedlings; the worm dragging things into his lair, which carry treasures along with them; the earwig eating his blooms, and then hiding securely in the seed capsules of Foxgloves or Irises, whence to dislodge him means wasting the seed. The *Coleoptera*, too, and all manner of creeping things, woodlice, wireworms, &c., are busy in many unseen ways, feeding on goodness knows what, but we know they are death to our plants if not kept in check. We take up a bush of *Gloire de Dijon*, wondering what on earth is wrong beneath it, to find a furrowed apple-like fungus on its roots in various stages of luxuriance, the root fibres eaten off probably by woodlice, and the very heart full of wireworms. We then cease to wonder why the most vigorous of its kind fails to flourish within three yards of its seedling daughter, Madame Berard, which is positively plunging along. Jack Frost also contributes very freely to the gardener's discomfiture, but we may overlook a good many of his mischievous pranks on account of the good he does us in other ways, although we have given him too much credit in the past as a grub destroyer. Then there is the viviparous aphid, with its long tandem of progeny, each with its beak pushed through the soft epidermis of the young shoot.

We read in our scientific works that if we encourage the enemies of our enemies, we do our best to assist our friends, and therefore resolve to spare the lady-bird and the ichneumon fly to help us as insecticides; we will also encourage small birds to visit us and build their nests in our shrub-beries, so as to help us in keeping down grubs, caterpillars, and pests of all sorts when the young birds are on hand. But, alas, there are other people who are equally bent on keeping down mice in their houses, and tortoise-shells, greys, blacks, and whites form spots and groups in our gardens of harmonious neutrals so far as colour is concerned, but positive discord indeed as to sound. Should cock-robin, thrush, blackbird, or homely aphid-eating small bird dare to show himself in the shrubbery, be it merely in search of temporary accommodation (seeking lodgings), or be he on an expedition prospecting for building-sites, he is forthwith warned off, or incontinentally (to use a slang expression) "run in." Pussy's friends say, "Look how carefully she walks up the paths and steps over the plants; she is as cautious as many of your visitors." True; but what about the amateur gardening of tabby, the efficient digging and filling up of holes in the seed bed? What of Lavender bush slept in till all its branches are broken off, and everything of an aromatic nature amongst our plants literally rolled in? Really one has serious thoughts of letting people who desire cats have them all within half a mile radius

assembled in their garden simultaneously by dropping a quantity of Valerian root "over the garden wall." Nature has disclosed to us one of her secrets—how to bring cats into gardens; would that she revealed the converse. Sum up the whole disadvantages and ask a veteran who is a martyr to lumbago to weigh them all against one single truss of good bloom he has raised from his own seed, and I am much mistaken if he will not say, "Give me a bit of garden."

Horsforth, near Leeds.

R. A. H. G.

COLOUR IN THE FLOWER GARDEN.

I WILL now endeavour to describe as briefly as possible consistent with clearness a few simple combinations, which will enable those whose colour faculty is naturally a little weak to arrange their flowers so as to avoid discordant combinations. I may premise, however, that those combinations are not by any means the best which can be carried out, but better ones can only be carried out, and perhaps could only be seen by those whose perception of colour is strong. This perception of colour is really at the root of all the differences about colour. The amount of colour perception possessed by one individual as compared with another is an extremely difficult matter to get at, we have so few means of comparison. One fact will be sufficient to show this. Country drapers complain that London warehousemen cannot match delicate shades of colour, and anyone living in the country near London can see the reason of this. On taking a delicately tinted water colour drawing from the clear country light into London, even in the height of summer when the air is purest, all the delicate shades and harmonies of subdued tints on which the whole beauty of the drawing depends totally disappear; a dozen delicately related greys merge into one even tint, and the same with all the other colours. It is just these last subtleties of colour which make all the difference between refinement and coarseness. Now to anyone whose perception of colour is in the least weak I am certain that these last refinements of colour are totally invisible. This certainly has been arrived at in a very peculiar, but sufficiently conclusive, way. Several years ago I was asked to look at an oil painting by a lad who was wholly self-taught. The drawing showed some perception of the forms of Nature, but the colouring was very peculiar; it was all yellowish bronze, brown, purple, blue, and grey. I tried to account for it by supposing it to be painted by gaslight, but that did not seem to explain it. What puzzled me most was a sort of purplish edge on the shadow margin of all the leaves in the foreground. I came to the conclusion that the lad's colour perception must be wrong. This last summer, through a slight ailment, I had several attacks of total blindness to red, each lasting about a minute. The first two were on bright sunny days, and I was surprised to see the landscape assume the colours of that poor lad's painting, even to the purplish edging to the sides of the leaves farthest from the light. As it was some minutes before I could again see red with ordinary distinctness, I could watch my scarlet flowers gradually merge from deep blue-black almost, first into brown, then maroon, then deep crimson-red, and so on to their true colour. All delicate shades of colour were indistinguishable; all the other colours were duller—in fact, yellowish bronzy greens, shaded with brown and an inky purple, with a faint blue in the sky, were the colours of the landscape. That was during the severest stage of the attack, when the scarlets appeared nearly black; there was every stage between that and my ordinary colour perception. Ever since I have been very lenient with errors in colouring.

The above experience will, I think, explain why red-blind people are unable to distinguish between red and green. Red-blind people may still be able to distinguish red although they do not see it as colour. Even when I could only see scarlet as black, there was a hot quality about it, just like the appearance of a piece of cooling iron when the red disappears, and before it turns blue. If the

perceptions of people who have weak colour sight are anything like mine as above described, they can only distinguish colour as such when in its brightest and purest forms, with the single exception of yellow.

If a person whose colour perception is weak gets talking about red, for instance, to one whose colour perception is strong, they are sure to differ, as what the one sees as bright scarlet, the other sees as dull red; and to the first all talk about the more delicate differences of colour will seem so much gibberish.

There is one test of keen feeling for colour that Mr. Ruskin mentions which may be useful here. He says a fondness for the contrast of orange and black distinguishes good colourists among artists from those who are even only slightly inferior. It is curious to note in our National Gallery how this is borne out. Turner and Leslie fairly revel in the contrast, other artists think it, even at the expense of truth. A curious instance of this may be seen by comparing the panthers in Titian's *Bacchus and Ariadne* with the painting of the jaguar's skin in the picture of "The Conversion of the Incas of Peru;" in the one case the spots are black, in the other brown.

The nomenclature of colour is so vague, that it is necessary in describing it to assume definite meanings for words which they do not possess in ordinary conversation in order to express one's ideas distinctly.

Colours harmonise or discord with each other when they touch each other, or when a patch of one is placed upon a ground of the other. If they discord, that discord is reduced in intensity if the colours are not allowed to touch, but are separated by a neutral which harmonises with both.

For colours to harmonise or otherwise, they must be seen together, so that the rays of light from the whole group enter the eye at the same time. We cannot strictly say that a carpet harmonises with a ceiling; neither can we say that the flowers seen in front of us in a garden harmonise with those we have to turn through a right angle to see. When the word "contrast" is used, I mean it to refer strictly to combinations seen together. There is another way in which colours affect each other. On looking at a patch of bright colour for some time it loses its freshness to the eye, but this freshness can be restored by looking at a patch of some other colour for a little and then looking again at the original colour. Colours which affect each other in this way I shall always call foils to each other. They are generally discords when placed together, and so should be used successively along borders or the margins of walks.

Blue and green are the only two colours Nature seems to intend us to gaze at without fatigue. The blue sky, the sapphire waves of the coast of Brittany, the green grass, the deep green of the North Sea waves are always delightful. Green Grass turf is perhaps the last feature of an English garden we should care to give up. Unfortunately green is the worst possible contrast for red, and through that we meet with our first difficulty. If we were content with just that amount of red Nature gives us in our temperate zones no difficulty would occur. But we hunt up all the red flowers that will grow in our gardens and place them together. We oblige our raisers of new varieties of flowers to advertise now and then a "march towards scarlet." Even our pansies have lately caught the scarlet fever, as we have now tolerably pure crimsons and orange-reds, and everything which can be called red in new annuals is advertised as crimson or scarlet.

It is useless attempting to stem this sanguinary torrent, although all those who care for good colour should avoid it as much as possible. I will first endeavour to describe briefly a few colour combinations which will be really harmonious in beds on the Grass, and then show how the largest amount of red possible can be introduced consistently with good taste.

When any colour is introduced in great quantity, as Grass turf in a garden, that colour rules by its mass, and brings all others into subordination;

all our flower-beds on turf must be gems in a green setting; there is no help for it. The best contrasts to place on a grass-green ground are the bluer shades of green, blue, yellow, white, and tinted white, the colours of our native spring flowers, but we can use other colours if well separated from the Grass, as will be seen presently. The bluer greens we do not have except in such pale form as in *Echeveria secunda glauca* and *Pinks* and *Carnations*. If we were able to surround our flowers with a broad band of greys and deep blue-greens, we could arrange our colours with more freedom. The best bedding combination that can be made is to surround the beds with a broad band of greenish grey. This band can be relieved by a line of yellow, brown, purple, or blue, margined by a line of white on each side. The centre of the bed can be treated in a variety of ways; for small beds, lines parallel to the edges or the beds or wavy bands across them would be the prettiest. Where the bordering line is yellow the centres will be best mauve and white, peach and white, or pink and white, or two shades of those colours; with brown, blue and white or purple and white, or two shades of purple or blue will come best; with purple, scarlet and white or bands of white, pink, and scarlet will come best; and with blue, white and primrose, orange-brown and crimson, or green and creamy white with pink would be suitable.

With hardy plants picturesquely arranged we are at once relieved of the necessity of separating our flowers from the Grass. We have still to avoid discords, and especially the red and green one. The simplest way of doing this is to keep our red and yellow dwarf spring flowers towards the back of the borders, where they will be seen against the shadows of the shrubs, bringing a few towards the front to contrast with deep purple and white, relieving, for instance, a mass of purple Pansies, with a patch of white ones surrounding a clump of flaming scarlet double Anemones. Another colour arrangement which can be carried out with hardy plants almost as easily as it can be thought of is shading related tints into each other, and relieving them by points of emphasis and contrast. Take a mixed lot of Pansies or Auriculas, or Primroses and Polyanthus, for instance; we can shade the colours of the first from blue through purple to black, and then contrast the black with a patch of white surrounding crimson, yellow, and brown. In the same way we can shade the Primroses from lilac through rose to deep crimson, and relieve that with white and yellow or white Polyanthus and scarlet Anemones. That is how Nature uses colour—the strongest light against the deepest shadow; most intense orange and scarlet against the purest white and the deepest black. But these points of emphasis are only used here and there, and supported by lesser points of emphasis and quieter contrasts and masses of related tints, fading and changing into each other. That is the only kind of arrangement of flowers which can really be called natural, it being the only kind of colouring we find in Nature, especially in sunrises and sunsets, where she means to be gorgeous. The best way to get the colours in a garden of hardy flowers arranged harmoniously is to keep the spring flowers which are evergreen about the front of the borders, and interperse those which require to be shaded in summer and those which disappear when out of bloom with the taller plants which bloom later. This allows the spring flowers to be massed, and at the same time prevents bad contrasts between Tulips and Anemones and the fresh greens of the springing summer and autumn flowers. Wherever a puzzle occurs, it can be got over by planting white flowers.

Spaces can be left in the front of the borders for summer flowers to brighten what would otherwise be foliage only. If these are placed next things with grey or very neutral foliage, such as *Achilleas*, *Iberis*, *Alyssum saxatile*, *Aubrietias*, *Arabis*, and the mossy *Phloxes*, pinks, reds, crimsons, and yellows can be used and all discord avoided. Neutral-tinted foliage, whether grey or green shading into brown, harmonises with all colours. Nature has two ways of changing green

into red in autumn, both of which avoid discord. The green either changes to yellow, salmon-pink, and scarlet in succession, or into dark grey, purple-grey, dull red, and so up to crimson and scarlet.

In large gardens many different kinds of colour arrangement should be carried out. In one section of a border blue might rule, in another scarlet, in another crimson, in another yellow, in another white. There is no end to the beautiful combinations which could be carried out if people would only set about it in an intelligent way without shirking any small difficulty which may occur at first. Now with regard to the introduction of masses of red in bedding, as red and green are a discord, bright red can only be introduced in any quantity in large beds, and the further it is separated from the Grass turf the brighter and better it will look. I should always surround a bed of scarlet *Pelargoniums* with a very broad band of neutral greens and greys relieved by white and dark blue, dark maroon, or dark violet *Petunias*, and separate the scarlet from the border by deep maroon; dark, rich purple would be better, but that we do not have. The best contrast with scarlet is the almost invariably Indian one—full magenta-pink. A good harmony of red, blue, and yellow, with red as principal, could be arranged in a group of seven beds, all bordered alike with neutral foliage relieved by a line of contrasting colour. The centre one and two smaller ones might be reds with a blue line in the border; another two might be blue with a red and brown line in the border, and other two yellow and orange, with a deep purple line in the border; other two might have their centres white and green, and other two pink and white or pale purple and white. The fault of all the combinations commonly seen under the bedding system was not only discord, but crudeness. The designers of parterres were evidently destitute of knowledge of the first rudiments of colour treatment; even when they stumbled across a harmony they spoiled it by not knowing how to treat it. They also used far too much red and far too little blue, and ruined their reds by using intense magenta-crimson and intense scarlet together, which should always be kept separate. Their combinations were crude through their not leading up to their pure colours through quieter and more neutral related shades. This was no doubt owing to their beds being cut out on grass green, which they tried to overpower by using a quantity of red which rendered good colour impossible. In the few instances where the beds were divided by gravel and no grass came in with the flowers, some of the bedding combinations were simply faultless in colour, although such a style of gardening could never be defended on any reasonable grounds. I will now, in conclusion, recapitulate the

Discords which should be avoided: Red—green; yellow—purple; orange—blue; brick-red—blue; orange—olive; purple—citrine; green—russet. These last three are beautiful as Nature uses them, with the two tints shading into each other; they are objectionable only as patches of flat colour placed together. Scarlet and blue are passable, but not good. Red and yellow should never be placed together, but may shade into each other. Red, blue, and yellow are bad, also orange, green, and purple; green and purple are passable. In the discords of two colours, the two colours act as foils to each other; thus, although orange and blue discord, to look at blue is a good preparation for seeing orange, and *vice versa*, so that in arrangements which cannot be seen together, but will be seen in succession, these colours should follow each other.

I will now leave the readers of THE GARDEN to test the value of these combinations in their own gardens, and will only say, in conclusion, that the most important matter of all is for each and all to endeavour to test the amount of colour perception they are possessed of. No one can design colour unless they see it, and it is most important that we should be relieved of all criticism of, and all interference with, colour arrangements by those who neither see nor enjoy it. J. D.

THE NEW YEAR.

It almost seems as if vegetation was somehow conscious of the lapse of time—the death of the old year and the birth of the new. Practical men conversant with forcing find an amazing difference in what may be called, for lack of a better term, the moveable force of vegetation after the turn of the season. Less heat and less time or both are needed to produce the same results in the new year than in the old. The same amount of force yields, perhaps, double the produce in January than it does in December. Doubtless there are obvious physical causes at work to produce and explain the difference, such, for example, as more and clearer light, and a greater readiness of vegetable fluid to respond with more alacrity to the stimulus of warmth and the more insidious allurements of moisture. But who shall say that the new-born year with that fiery zeal that mostly inspires youth, and with all its work before it, has not something to do with the more impressionable and excitable state of vegetation? Neither is the quickening influence of the new-born year by any means confined to vegetable life. Possibly all forms of life are more or less affected by it. Assuredly, horticulturists, even more than horticulture, are quickening and, as it were, re-inspired by the new year. The time of rest, if indeed there be such a time in modern horticulture, is past. Hard necessity is laid upon horticulturists to be up and doing, for should we take further rest, Nature will not; and if we would lead and guide her either with ease or profit we must seize the reins vigorously at once, for it is a fact that horticultural success cannot be commanded by pushing behind. Vegetation may be led, not driven or pushed into beauty, fruitfulness, or profit. This difference is vital, as most cultivators have found to their cost in these days of rigid retrenchment and ever enlarging demand. Spend less and get less and give us more is the unceasing cry that is arising from not a few centres of horticultural light and leading on the dawn of the new year 1883. With little time and less inclination to quarrel about the unreasonableness of such demands, most horticulturists are doing their very best in both directions. Never were they so severely handicapped within the memory of the oldest cultivators. Horticulture used to be recognised as the leisure profession. Leisure is now one of the last things to be found in its pursuit. It has become more of a race than a staid business. Of course amateurs may find a delightful, learned leisure in its pursuit; but practical gardeners and commercial horticulturists might as reasonably search for a pin in the ocean as for leisure in their business. Horticulture has become more than ever a race of seasons, of novelty, and for mass flowers. Fruits and vegetables in season have lost their old relish and significance. Early and late have now little or no meaning. The best of everything always in season is the imperious demand of modern fashion and luxury, and the wide world, with all its various products, is now the only limit known to horticultural seasons and products.

Thus the race of novelty is as, or even more, exacting than the one of seasons. Hardly has a good variety of anything been established than it is pushed aside for a so-called better, and so on and on, for ever apparently. Those who enter in this race have, indeed, a feverish time of it, and never find real satisfaction in their horticultural pursuits. The race for mere mass is still more exhausting. Hundreds are constantly superseding tens, thousands hundreds, and single thousands giving place to tens and hundreds of thousands. All this shows that horticulture is full of energy, life, and vigour. There is perhaps no art, science, nor practice advancing with such rapid leaps and bounds. But it would assuredly be at once more safe and wholesome were the progress a little less feverish, and the pace somewhat less killing. A race now and then is all very well, but to be always going at full speed makes short work of the runners. One way of getting a little breathing time on the journey is to see to it that we

start fair with the year, and keep well abreast of time as well as opportunity all through it.

D. T. F.

ROSE GARDEN.

ARE SCOTCH ROSES WORTH GROWING?

OF course "A. H." has never seen them, or the question could never have been asked. And yet it is astonishing how little they are grown out of Scotland. Those who only or chiefly know show Roses would not think the Scotch species worth growing, and yet they are beautiful, fragrant, and most useful for decorative purposes either as cut flowers or on the plants. But in masses or groups on lawns or shrubberies few plants are more ornamental or interesting than Scotch Roses.

And few Scotch gardens are without them. Once planted, too, they mostly last a lifetime. They are of course grown on their own roots and propagated by suckers. Any of the Edinburgh or other Scotch nurserymen would supply lists of sorts and prices. The leaves are remarkably neat and beautiful, as different from other Roses as the flowers, and the two together would make a fairy dinner table or room decoration as unlike as anything well could be to the prevailing fashion.

There are two or more pure white varieties, Iris and Celeste; the Princess is also a blush white, two yellows, Mary Stuart and Josephus, and numbers of red, pink, purple, and lilac sorts. From eighteen to twenty-four varieties may be had by name in the Scotch nurseries. As these Roses seed freely, those who grow a few sorts may soon have almost any number of shades of colour; they are mostly double, the flowers being small, round, almost globular. The Scotch Rose is a distinct native species—*Rosa spinosissima*, and a more suitable name could not possibly have been given, for the spines are far more formidable than would appear from their size, while the whole of the wood is covered with them.

There are two so-called perpetual flowering Scotch Roses, the Scotch and the Stanwell, with much larger rosy blush coloured fragrant flowers than any of the other Scotch varieties; these also bloom twice or oftener throughout the year and seem true hybrids.

D. T. FISH.

ROSES AND THEIR CULTURE.

Position and soil.—The first requisite in the culture of Roses is the selection and preparation of a suitable place for planting. This is very important, as all that follows depends upon the care used in this first step. To begin with, then, choose the best place you have in the garden, a place where you can offer sufficient protection by means of hedges or board fences from bleak sweeping winds. When fences are used, their general ugliness can be more appropriately clothed by Roses themselves. A warm, sunny position is also requisite; if so situated that there is an exposure to the morning sun, and the hot rays during the afternoon are in part or wholly shaded, all the better, but a certain amount of sunlight is as essential to a Rose's welfare as to our own, though many of us do not show our appreciation of the blessings of sunlight as gratefully as do our Roses. Besides scattering them through our gardens, Roses may be made very effective planted in borders about our lawns, either individually or in groups, and also planted in beds on the lawn. Thoughtlessness often leads people to plant Roses under the shadow of overhanging buildings, or close to large deep-rooted trees, and then there is inquiry and wonderment why the plants are always covered with mildew; and why they do not blossom and grow as those in a neighbour's yard, where there are always beautiful Roses to be seen. There is much more in common, or should be, between animal and plant life than is practically acknowledged by most of those who strive to grow Roses. Both demand for their perfect development a sufficiency of nourishing food and drink,

a pure atmosphere, a temperature as equable as possible, and thorough cleanliness. Let every one who plants Roses bear this in mind and we shall find a wonderful improvement in the quality and quantity of the flowers. Some, having heard that a free circulation of air and abundance of sunshine are essential elements of success, select a spot which would be excellent for a windmill, observatory, beacon, or Martello tower; and there the poor Rose trees stand, or, more accurately speaking, wobble with their leaves, like King Lear's silver locks, rudely blown and drenched by the to-and-fro contending wind and rain. Others who have been told that "the Rose loves shelter, peace, and repose," have found "such a dear, snug little spot," not only surrounded by dense evergreen shrubs, but overshadowed by giant trees. Rest is there assuredly—rest for the Rose, when its harassed life is past, when it has nothing more for disease to prey upon, no buds for the caterpillar, no foliage for the aphid—the rest of a mausoleum! I was taken not long ago to a cemetery of this description which had been recently laid out, and there was such a confident expectation of praise in the pretty face of the lady who took me, that I was sorely puzzled how to express my feelings. I wished to be kind, I wished to be truthful; and the result was some such a dubious compliment as the Sultan paid to the French pianist. The Frenchman, you may remember, was a muscular artist, more remarkable for power than pathos; and he went at the instrument and shook and worried it as a terrier goes in at rats. His exertions were sudorific; and when he finished the struggle, with beads on his brow, the Sultan told him, 'that although he had heard the most renowned performers of the age, he had never met one who—perspired so freely!' Nor could I, with my heart as full of charity's milk as a Cheshire dairy of the cow's, think of any higher praise of the plot before me than that it was an admirable place for Ferns; and therefore, when my commentary was received with an expressive smile of genteel disgust, as though I had suggested that the allotment in question was the site of all others for a jail, or had said, as Carlyle said of the Royal Garden at Potsdam, that 'it was one of the finest fog preserves in Europe,' then, without further prevarication, I told the truth. And the truth is, that this boundless contiguity of shade is fatal, and every overhanging tree is fatal as an Upas tree to the Rose. The Rose in close proximity to a forest tree can never hope to thrive. In a twofold sense it takes umbrage; robbed above and robbed below, robbed by branches of sunshine and by roots of soil, it sickens, droops, and dies." * In connection with a choice of location, we must see that Roses are provided with a proper soil. They will do well in any ordinary garden soil that is free from standing water and well drained. When there is too much clay, the soil can be made sufficiently friable by the application of wood and coal ashes, lime, burnt earth, &c. When, on the other hand, a soil is sandy or too light, we need to bring clay, muck, leaf-mould, &c., to obtain sufficient body. This soil must, of course, be thoroughly manured and worked; frequent spading will do a great deal toward lessening the stiffness of a heavy soil. On no account attempt to make Roses grow in a wet spot; if there be such a place which it is desired to use, let the soil be thoroughly drained by sinking tiles to a depth of 4 feet, or provide in some other way for carrying off the water. Where it is impossible to find a position capable of being drained by tiles from the ground being too flat, the soil may be removed to a depth of a few feet and stones, bricks, debris of any kind thrown in; but whenever the water can be carried off in tiles it is better to do so.—ELLWANGER, on "The Rose."

Badly-shaped blooms of Niphetos Rose.—Niphetos mostly come well shaped in bud, but beyond that there is little to be said in favour of her form. But this is not what "E. M." means, I presume. If the greenhouse is a cool one, the coolness often more or less mars the forms of the

* Canon Hole's "A Book about Roses."

buds even. This is really a tender Rose, but for that matter 60° may be looked upon as the proper average temperature for the perfect blooming of Roses. We all know they will flower fairly well at much lower temperatures, and that a few of them, such as *Homère* and *Souvenir de la Malmaison*, come in better form in a cool rather than a warm temperature. That, however, is by no means the case with *Niphetos*, which frequently comes out of form in a temperature of from 40° to 45°. A good deal may at times be done to improve those malformed buds by relieving and rearranging the petals left. Such expedients are quite allowable for button-holes, and I have found it necessary at times to reduce the bulk and improve the form of a *Niphetos* bud before converting it into the centre of a button-hole, and fringing it round with a few *Marie Louise Violets* resting on their own leaves and a sprig of *Maiden-hair Fern*, the *Niphetos* having one of its own freshest leaves in the foreground of its blanched purity.—D. T. FISH.

BOOKS.

THE ROSARIAN'S YEAR BOOK FOR 1883*

Has just reached us. It contains photographs of Mr. G. Baker and Mr. E. R. Whitwell, winner of the Amateur Challenge Trophy, and the following useful articles, viz.: What is an Amateur? Tea Roses in the Perthshire Highlands; The Rose Weather of 1882; Tea Roses on Ridges; My Box of 24; The Rose Season of 1882; Shall we Manure our Roses? The best Roses for Exhibition; Rose Shows and Rose Judging; altogether a good shilling's-worth. From the article

On manuring Roses we extract the following: "The system of Rose culture," says the Rev. H. B. Biron, "must to a certain extent vary according to the accidents of soil, and I may say, too, the choice of stocks. In a rich, retentive loam Roses on the Brier will thrive upon light diet, while in a poor, hungry soil the same plants would die of exhaustion, unless abundantly supplied with meat and drink. I have known both these soils, and ere this is in print I hope to have commenced experience of a third, which promises to try patience if there is a spot in England that will do so, for it is situated on the top of a hill, with no shelter save the tower of Dungeness lighthouse between it and Demerara. But before manure is thought of even, there are other operations in Rose culture that are paramount. In the first place, it is a *sine qua non* that the soil must be perfectly drained, either naturally or artificially. Next, that it shall be deeply trenched—the deeper the better. Without these precautions all the manure in the world will have but little effect for good. On poor soil I say, without hesitation, that whatever be the stock used, abundance of good manure is necessary. Now how shall we administer it? Shall it be 'for outward application only,' or taken internally? Shall we dig it in or leave it on the top as a mulching? Personally I am inclined to the latter, as the rain will gradually wash the ammonia into the ground, where the little rootlets, like fledglings in their nest, are waiting open-mouthed for the expectant draught; or, should dry weather prevail, the mulching will keep the ground cool and preserve the Rose from that thirst which it so much dislikes. I think it is Anthony Trollope who, in his advice to the intending Nimrod, reminds him that 'it requires a pack of hounds to kill a fox.' Some so-called rosarians seem to need similar advice, viz., that roots are a necessary part of a Rose tree; and yet I must, though I do so in awe and trepidation, assert that they may have some grounds for supposing that Roses do not need roots, if they gain their experience from such club-ended specimens of standards as I have sometimes seen sent from the nursery. To have good flowers above, you must have abundant rootlets below; and as these require abundant nourishment, I hardly see how this is to be supplied, save by the use of manure. Some of my brother rosarians advocate

"Chemical stimulants, and they are very well in their way, but yet I fancy that a Rose which has known no other food will, towards the afternoon of a show, hang down its head in exhaustion, and look about as happy as did Mr. Verdant Green on the morning after Mr. Small's 'quiet party.' Chemicals are very well as stimulants, but a Rose can no more live entirely on them than can a rosarian thrive on nothing but gin and water. Still, I must allow the benefit of nitrate of soda, sulphate of ammonia, and other chemicals, but only as assistants to the farmyard manure, with which the Rose loves to be fed. I believe that nitrate of soda intensifies the colour of the Rose, and certainly adds to the beauty of the foliage. Amies' manure, the component parts of which I know not, I have seen used with great success, and this season I was well satisfied with the results of spent hops and malt-dust, the whole having previously passed through a bath in a liquid manure hole, but the smell was something 'too awful'; still, I think I was repaid, as never since I left the Wealden clay have my Teas been so good. I must here except *Maréchal Niel*, which has been very poor with me this year; indeed I do not remember being struck with it at any of the shows I witnessed, either early or late. Reynolds Hole, Xavier Olibo, Louis Van Houtte, and other dark Roses also failed with me, burning ere the sun had been on them half-an-hour—indeed, sometimes without any sun at all."

EUROPEAN BUTTERFLIES AND MOTHS.*

THIS work on the butterflies and moths of Europe will fill a place in our libraries which has not hitherto been occupied. A good book at a moderate price, giving coloured plates of British and Continental species, has long been wanted by collectors of Lepidoptera. Those already published being confined to the insects of some particular country, and all those relating exclusively to British species are now out of print and very expensive. To study any branch of natural history intelligently we must do more than confine our attention entirely to such species as are indigenous to some particular country. Every day the necessity of this is more apparent; greater facilities are afforded for travelling, and for obtaining specimens from other parts of the world. Mr. Kirby's work will be most useful to all collectors of butterflies and moths, and particularly to those who have opportunities of studying European forms. A description is given of every species found in Europe, with the exception of those belonging to the following groups of small moths (the micro-Lepidoptera)—Pyrales, Tortrices, Tineæ, Pterophori, and Alucitæ, which are passed over with six pages of letter-press and two plates. Speaking of these groups, the author says: "Although fully as beautiful, and in many respects at least as interesting as the macro-Lepidoptera, yet their small sizes, and the consequent difficulty in collecting and preparing them, cause them to be regarded with much less interest even by collectors than the larger species; it therefore becomes impracticable to describe the species in a popular work like the present, but not wishing to omit the micro-Lepidoptera altogether, we have figured a number of the more interesting species belonging to various families in our two concluding plates, as a considerable amount of information has already been given in our introduction."

European Lepidoptera is beautifully "got up." The paper and printing are everything one could wish, but the binding is too ornamental for a book of this description, which is scientific as well as popular. From an external point of view one would imagine it was only popular. Gilded butterflies are indigenous in fairy tales and transformation scenes, but nowhere else. This work is illustrated with sixty-two plates, sixty-one of which are coloured. Most of the figures are very

good, considering the price of the volume, but some are not so good as the others. For instance, the butterflies on plate 6, where the large and small tortoiseshell and the peacock butterflies are drawn from very badly set specimens, and the colouring of this plate and of some others is crude. Nearly all the British butterflies are figured, and a large proportion of the moths. There is an omission in this work of considerable importance, if the comfort of the student be taken into consideration, viz., there is no indication at the foot of the plate or on the opposite page of the names of the insects figured; consequently, anyone comparing a butterfly or moth they may have found with the plate must turn to the explanation of the plates at the beginning of the book or search in the letterpress before they can find the name or description of the insect under examination, both of which are troublesome operations. The numbers of the plates do not run in their proper sequence in every case. For instance, plate 3 is followed by plate 51, plate 12 by plate 52, and nine others are wrongly numbered; this is particularly inconvenient. Take, for example, plate 51, which faces page 6, and on which ten butterflies are figured; the letterpress describing them is on various pages from page 3 to 65. How is the reader of the descriptions to know where plate 51 is without consulting the list where the plates are placed even if the plate and figures were quoted? but they are not in all cases. In the description of the Brimstone butterfly (*Gonepteryx rhamni*) on page 10 the figure of the male (plate 4, fig. 9) is quoted, but no mention is made that the caterpillar and chrysalis are figured on plate 51. Again, on plate 52 butterflies are figured and no allusion is made in the letterpress to them, though other figures of the same insects on plate 14 are quoted. With plates 52 to 59 the same thing occurs; the figures or plates are not mentioned in the descriptions of the insects. All this shows a great want of care on the author's part. Having pointed out these mistakes, which can easily be remedied in a future edition, we revert with pleasure to

The introduction, which contains a vast amount of valuable information. It commences with a description of the formation of insects generally, then treats of the peculiarities of butterflies and moths, with a description of their organs. A plate is given showing their various parts very clearly, to render the letterpress more easily understood. The eggs, caterpillars, and chrysalides are then described with much interesting matter. "The habits and functions of Lepidoptera" are then discussed, but the author is unable to throw any light on the curious power that the males have of discovering the females which have not paired at a great distance, and when entirely hidden from their sight even in a collector's pocket. Probably the female makes some sound, which, though inaudible to our ears, is easily heard by the male. There is no reason for imagining, as so many do, that insects with few exceptions are mute. Our ears are only capable of hearing sounds caused by vibrations of a certain number per second, any vibrations above a certain number or below another per second being lost to us. Human ears differ in this respect; some are unable to hear the cry of a bat or chirp of a grasshopper. At page 23 is some interesting information on "Injurious Lepidoptera," which we wish, for the sake of horticulturists, had been fuller, but many destructive species are mentioned; few are injurious to man directly, but the hairs of some caterpillars have most annoying stinging qualities, being sharp and covered with very fine hooks. The author recommends rubbing with oil as the best antidote. Very full directions are given for

Collecting and preserving specimens, which are well worth studying. The plan of attracting moths by sugaring trees at night is well known to all collectors, but another, and in some respects a more convenient, way is that of using dried slices of Apples strung on a string, the method of preparing and using which is detailed, and will perhaps be new to some. The instructions for rearing caterpillars and chrysalides are very clear

* "European Butterflies and Moths." By W. F. Kirby, Assistant in the Zoological Department British Museum, and Secretary of the Entomological Society of London. Cassell, Pether & Galpin.

* London: Bemrose & Sons.

and practical. In his remarks on the arrangement and management of a collection, the author seems to prefer cabinets to boxes for keeping insects in; no doubt there is much to be said on both sides, but we are inclined to favour boxes which can be arranged on shelves like books, for the following reasons: as the collection increases it is much easier to introduce a fresh box where more room is required; if specimens are attacked by mites, &c., the presence of the enemy is at once detected, as their droppings fall to the bottom as dust, instead of underneath the specimen, where it is not noticed until the latter is moved. Drawers do not generally fit as tightly as boxes, unless very well made, when they are very expensive, whereas tight fitting boxes can be obtained very cheaply. The descriptions of the insects are necessarily very short; they include the caterpillars as well as the perfect insects, and give the time of year and the countries where they may be found. An asterisk is placed before the names of British species, so that the reader can at a glance distinguish which species are natives of this country and which are not. We recommend anyone who is in want of a book on butterflies and moths to obtain this work. Anyone who has a garden and takes any interest in the insects they see flying about in it will easily be able by means of it to name the butterflies, moths, and their caterpillars which they may find from it. S.

NOTES FROM A MARKET NURSERY.

ONE of the chief among the multitude of florists' nurseries from which the London markets derive their vast supplies of plants and flowers is that belonging to Mr. Maller, in Burnt Ash Lane, a few minutes' walk from Lee Station. A marked feature which almost every establishment of this kind exhibits is plenty of bustle and business, plenty of dirt in winter and very little time to spare, so that anyone desirous of a "look round" must make good use of the little time grudgingly allowed him. However, if the visitor makes good use of his eyes he will see much to interest him, and he must also keep his ears open, for he will find in the market florist not only a matter-of-fact individual, but also one who is able to impart a good deal of valuable information in a few words. As a rule, he seems to possess a keen discriminative instinct respecting the merits of plants and flowers. His opinion is wholly unmixed with sentiment, and he invariably regards the plant or flower in the light of its market value. Questions respecting plants one would expect to find in a market nursery are met by such curt answers as "it is not free enough," or "it wants too much doing," or, with regard to flowers, "they won't stand cutting," or "they haven't substance enough." Thus it may be seen that the market florist does not value a plant for its beauty or rarity, but simply for its adaptability for market purposes. When once a plant is proved to be a "good thing" it is taken in hand and "done" as only London market florists can do them. This accounts for the little batches of odds and ends one usually sees in nurseries of this kind. These, as a rule, have been "bought in" on the recommendation of someone, but no steps are taken to propagate them largely until they have been thoroughly tested. Though there is such a strong family likeness in most of the market florists' establishments, the majority of them have one, if not more, distinct specialities, that is, certain plants that are done better than others and receive the best share of attention. One may pretty well tell what this speciality is as soon as he is inside the nursery, and in the particular establishment now under notice one may at once see the chief feature is

Heath culture, and for his success in this Mr. Maller is now well known. Heaths everywhere occupy the greatest share of the crowds of houses, pits, and frames to be found here, and they may be seen in all stages from those in a marketable condition to tiny cutting plants. The present, however, is the very worst time of the year to see a Heath nursery, for the bulk of the flowering stock was cleared out for the Christmas

markets, and it is too early to see the succession stock "ranged" on the Heath ground. Pit after pit is filled to overflowing with plants struck last year, and now mostly in 3-inch and 4½-inch pots. The potting time for these has just commenced and will occupy some weeks, as many thousands of pots have to go through the potter's hands. The plants are mostly potted in 6-inch pots and replaced in the pits which they previously occupied there to remain until about April, when they will be removed to the Heath ground, where they are arranged in oblong beds consisting of some thousands of plants each on a good foundation of ashes. The best time to see the Heath ground is August, when the plants are well developed in vigorous health and dense masses of verdure. In September and October they are cleared out of the nursery if possible, generally by means of auction sales. Even now, however, a Heath collection possesses some interest, for several are in bloom. There are thousands of sturdy little plants of *E. gracilis* covered with myriads of tiny magenta coloured blossoms; *E. persoluta alba* and *C. caffra*, both pretty kinds, are likewise in bloom, and so is that most useful of all winter Heaths, viz., *E. hyemalis*, which largely preponderates. In looking over this vast assemblage one cannot help wondering where they all go to year after year. It is evident that they die, for of all popular market plants Heaths are the least understood by the general cultivator, who invariably kills them through excessive watering. It is doubtless the marvellously cheap price at which they are sold that keeps up the popular demand for them, and it is only when they are grown on such an extensive scale as here that their growth can be remunerative. There are about a dozen kinds which seem to predominate, viz., *E. cerinthoides coronata*, a beautiful autumn and winter kind, with large scarlet flowers; *E. hyemalis*, *ventricosa* and its varieties, *mammosa*, *gracilis*, *caffra*, *persoluta alba*, *arbuscula*, *colorans*, and *Wilmoreana*. Epacris are also grown here on a large scale, and amongst them we noticed the beautiful candidissima, with wreaths of snow-white blossoms now finely in flower. Amongst other plants are

Pelargoniums, which here, as in most florists' nurseries, occupy a good share of room. The decorative or market varieties are represented by a healthy stock, all in marketable condition. One called Madame Charles Koenig is a great favourite, and receives a good deal of attention. It has large pure white flowers, with petals of great substance, that is, they are firm and stand out well, and are produced in good sized trusses. What makes it valuable as a market variety is the fact that the blooms retain their petals and do not require gumming. The plant is also a free bloomer. Those who want a good winter flowerer cannot do better than make a note of this one. Zonal Pelargoniums do not seem to be grown largely, and what there are are confined mainly to one variety, viz., West Brighton Gem, a sort remarkable for its free and continuous flowering character and dwarf, compact growth. The flowers are glowing scarlet, produced numerously in big trusses, while the stems are invariably white or at least very pale. This rather new variety seems to be gaining favour wonderfully about London; we have met with it in various places, and it will probably supplant the old Vesuvius and others.

The old double white Primula forms, as it were the backbone of the cut flower trade here, at least as regards white flowers. A capacious span-roofed house is filled with it, and the plants flower without intermission for months together. The flowers, so pure white, last a long time in a cut state, and they are peculiarly well adapted for bouquets, wreaths, and the like. It has not been surpassed yet by any of the new double varieties that have been raised of recent years. There is also a purplish-pink kind in this nursery the exact counterpart of the Double White except in colour. It seems to be a valuable sort with which we do not remember meeting before. The Double White Bouvardia is found a very useful subject for cutting, and the new Double Pink sort, President Garfield, is being tried.

The Arum Lily (*Calla æthiopica*) is grown largely here, but we were assured that it is a profitless plant except during the Christmas and Easter season, when its ivory-white spathe are greatly in demand for church decoration. Therefore the great aim in the culture of these is to get a quantity of them in flower a week or so before Christmas, and to retard the others till Easter. A houseful of these plants, with their handsome foliage and ivory white spathe overtopping the leaves, is a pretty sight.

Fielder's white Azalea is the favourite sort here for supplying cut blooms. It is considered to be greatly superior to the old white variety, now scarcely grown at all. We saw the two side by side in flower, and the difference between them is remarkable. Fielder's white has larger flowers of firmer texture, more plentifully produced in bigger trusses; the foliage is larger, and the plant is altogether a more vigorous grower. Yet, for all that Fielder's white is still an obscure plant in private gardens, and is not as a rule enumerated in trade lists.

Variegated plants.—Among these the most prominent appeared to be the golden-striped leaved variety of *Ophiopogon Jaburan*, called *aureo-striatus*, an elegant and pretty plant having grassy foliage, produced in a tuft, and gracefully recurved on all sides. Being evergreen, it is a capital winter plant for the greenhouse. *Aspidistra lurida*, appropriately named the Parlour Palm, is a conspicuous plant here, and so is the variegated leaved form of it, though it seems the demand for it far exceeds the supply; indeed it is one of those plants that appears to be becoming very popular for room adornment, and unfortunately it is not one of the freest to propagate. A well-grown plant of it, with a dense tuft of broad foliage, strongly banded with creamy yellow on a green ground, is very striking. Another variegated plant worthy of note is *Eurya latifolia variegata*, a Japanese shrub with handsomely marked lanceolate foliage. It is an excellent plant for the greenhouse in winter, but apparently not much known. It is almost if not quite hardy, but it is one of those plants that are always grateful for glass protection. The variegated-leaved form of the African Lily (*Agapanthus umbellatus*) is likewise a noteworthy plant here, although somewhat scarce in gardens. A variegated form of *Anthericum comosum* is also grown numerously, and an elegant plant it makes.

Ferns are grown pretty largely, especially *Phlebodium aureum*, which always finds a ready sale on account of the distinct silvery look its fronds possess. Besides the popular Maiden-hair (*Adiantum cuneatum*) there are two or three others grown extensively, viz., *A. pubescens*, *hispidulum*, and *concinnum*, all elegant forms and very suitable for supplying a continuous demand for cut fronds. *Doryopteris nobilis*, *Onychium japonicum* are among others grown largely in this nursery.

Other plants which we saw worthy of note were the double Mignonette, the pretty variety so prominent at London exhibitions last year under the name of *Reseda odorata prolifera alba*. It is indisputably one of the finest sorts of Mignonette yet raised. Laurustinuses in pots make attractive little bushes when covered with clusters of white bloom. They are, we understand, imported from Belgian nurseries, where they are largely grown as pot plants. The little *Lithospermum prostratum* is grown, too, in pots, and extremely neat and pretty it looks, and are even now studded with its sky-blue flowers. Genistas are grown by the thousand, as are also such plants as *Grevillea robusta*, *Cyperus alternifolius*, both green and variegated; and *Gardenias*, both *intermedia* and *radicans*. *Centropogon Lucyanus* has just been taken in hand; it is one of the brightest of winter flowers, the colour being a vivid rose-magenta. The Fairy Rose is found to be extremely useful in the cut-flower trade, as it is so continuously in flower throughout the winter. Camellias, especially the old double white, Tuberoses, and a host of other things are likewise grown extensively for the large cut-flower trade done here. Besides

the market and cut-flower business, an important branch is hardy evergreen and deciduous shrubs and trees, Roses, &c., to which an extensive acreage is devoted. W. G.

TREES AND SHRUBS.

TREE PLANTING IN IRELAND.

A CORRESPONDENCE on this important subject continues to be carried on in the *Irish Farmers' Gazette*. Dr. Lyons, M.P., gives the following account of his visit to the Galtee ranges:—

I had the honour to telegraph to you this day from Cahir, at the foot of the Galtee ranges, the result of two days spent in exploring the plantations on those historic mountains, carried out by Captain Smith-Barry, Count Moore, M.P., Lord Lismore, Lady Margaret Charteris, Captain Massy Dawson, Mr. Murtagh, Mr. Buckley, and many others now celebrated as Irish foresters. Under the guidance of Mr. Hartland, of Cork, who in the third generation of practical foresters is now planting on these slopes, I was enabled to see the results over some 10,000 acres of forest in all shapes, from the mature woods of forty years and upwards, now ready for the woodman's axe, to the youngest plantations of yesterday, and I had further the happiness to see large gangs of planters actually at work hoeing, fencing, draining, and planting hardy three-year-old seedlings on the barest and otherwise most barren hillsides. I have seen probably some 10,000 acres planted from base to summit on a forest belt, which carefully protects and reserves every half or quarter acre of available oasis which will profitably grow a crop of Oats or Potatoes. Surely it was a healthful and cheery sign to see gangs of men who came two and three Irish miles to their work associated in reproductive labour of the most wholesome and manly kind. I could well have wished that my good and valued friends, Lord Spencer and George O. Trevelyan, had seen them at work, and learned by inquiry from those proprietors around, who had practical experience to guide them of 25 and 40 years, how infinitely better it was and more certainly profitable to the State to see them—men and boys, too—working zealously and healthily in every respect on the open hillside than shivering outside a workhouse. From the noblemen who blush to find themselves famous by their forest labours in the glens of Aberlow and the slopes of the Galtees, I appeal to those who hold the many hundreds of thousands of barren acres on the hillsides of Donegal and Mayo, Galway and Clare; to the Government I appeal for reproductive work to avert the impending crisis in Ireland, on the model of the works which, with unstinting hand, they are carrying out on the forests of India, on which, over a district of more than 60 millions of acres of forests, they now raise a revenue of more than £700,000 for the year 1881-82, which, after all expenses, leaves a nett profit to the State of more than a quarter of a million sterling per annum. As I have already fully explained in the House of Commons and on many other occasions, I ask no gratuitous boon at the hands of the Imperial Government. I ask only what we are fully entitled to as a right—an imperial guarantee, based on those revenues, to which we fully contribute our share, on all Irish loans made for State purposes in Ireland. Reafforesting will, as I have shown, after 40 years repay from £50 to £100 an acre on an outlay which may be stated as a maximum of £10. Let those who doubt my statement visit for themselves the Glen of Aberlow and the slopes of Galtemore. Mr. D. Sym Scott, Tipperary, addressed the following practical and suggestive letter to Dr. Lyons: "I cordially agree with you in your project of reafforesting Ireland. Timber once planted very soon becomes recuperative. Indeed, land planted with a crop of trees is like money laid out at compound interest, and is still ready money to lay hold of at any time. There are in this country immense tracts of land lying comparatively unproductive which would under a crop of trees, properly managed, become a terra felix from terra sterilis; a mine of wealth to the owner, and a source of happy employment to the rural labourers. It must not be inferred, how-

ever, that because the ground is waste any sort of plant will do to plant anywhere on any kind of soil. The great secret of success is the correct distribution of plants—adapting trees to soil, subsoil, rocky formation, and situation. The science of arboriculture is not simply planting *in situ* what may occur to the operator as timber. It is attained by planting the ground with a crop which will increase the value of the land occupied to the highest possible value at the least possible expense, and in the shortest period of time."

Mr. J. M'C. Meadows, in giving an account of work in the Glendalough plantation, says: "I take leave to say that the Glendalough plantations of the Mining Company of Ireland are a good example of what may be done with bleak mountain tracts, as advocated by Dr. Lyons. They have the advantage of being easily accessible, and if I limit myself to giving their history as narrated by the late Thomas Bewley, when chairman of that company in 1868, your readers will have materials for judging and gauging the merits of the question as a commercial one, on the authority of that gentleman. At the half-yearly meeting in July, 1868, Mr. Bewley gave the particulars as follows: There is a topic which, I believe, has never yet been alluded to, viz., the Glendalough estate. Those who were proprietors some seventeen or eighteen years ago will remember the great annoyance we received from the proprietors and farmers in the neighbourhood. We found it impossible to get the produce of our mines from the mine to the dressing floors in consequence of not being allowed a right of way through certain property. That ended in our purchasing up the whole of the property, about four miles in length. We have planted between five and six hundred acres of Larch and Scotch Fir. We commenced planting about twelve years ago. I think it has been a great success, and a more beautiful plantation I never beheld. From this time I expect we shall be receiving a moderate income from the sale of the timber. Up to the present we have planted about one million of trees, and we expect to plant 250 acres more, making altogether about 800 acres. We have an estimate made on the assumption that at the end of the twenty-fifth year the timber would be in a marketable condition, and the calculation is that at the end of the twenty-fifth year the thinnings will have realised about £18 an acre, and that the value of the timber standing will be from £22 to £24 an acre. This is done at a cost of £7 an acre, so that we will have been repaid the whole of the original outlay with interest up to the end of the twenty-fifth year, and there will then be standing on what would be otherwise worthless property timber to the value of £23 an acre. Of course, if we go to fifty years the value will be much increased, but, perhaps, for most of us fifty years would be rather too long a period to look to. It has been a most fortunate commercial speculation. Those who come after us will realise a very large advantage, whilst we in a short time will be getting the commencement of the benefit."

"In this instance we may find that the example set now twenty-five years ago by the Mining Company of Ireland upon mountain sides at the Seven Churches and its results may lead others to go and do likewise, when employment for those whose lot it is to ask leave to toil is so sorely needed."

THE HOLLY.

UNDER the form "holm," the name of the Holly enters into many of our early English place names, such as Holmwood, and no one has ever doubted the indigenous character of the species, which occurs from South Norway and the Highlands of Scotland to the Caucasus, and which is still represented by ancient trees in the oldest portions of our English forests. On the poor, sandy soil of the Millstone Grit in the old forest of Kingswood, now better known as the Bristol coal-field, the Hollies flourished so luxuriantly, that chatty old Aubrey suggests that they derive benefit "from the effluvia of that mineral." The Speech house in the centre of the Forest of Dean is surrounded by ancient Hollies, boughs cut from which used down

to within the last fifty years to take the place of the Testament in every oath sworn in the Verderer's court. In fact, Mr. Bellows has brought forward much evidence to show that the said Speech house is a most ancient rendezvous, and that the Holly was planted as a sacred tree round the villages of Kelts even on the bleak downs of Cornwall. The New Forest is also noted for its Hollies, and one of the largest in the kingdom is probably that at Claremont, 80 feet in height, which, considering the extremely slow growth of the tree, may be a relic of the primeval forest of North Surrey. The Holly will grow in any soil in which water is not absolutely stagnant, but it prefers a rather dry, sandy loam, and, whilst it not only "outdares cold winter's ire," but seems to flourish in the bleakest situations, it does not do well under the shade of other trees. It is generally from 10 feet to 40 feet in height, and not more than 2 feet or 3 feet in girth, but Hollies at Bleak Hill, Shropshire, are stated to attain a circumference of 14 feet. The slow-growing, even, and hard-grained wood is, except at the centre, as white as ivory, and is valued in turning and inlaying. It stains well, and is, therefore, used in place of ebony for the black handles of tea-pots, whilst for engraving it is, perhaps, second only to Boxwood. One of the great charms of the Holly is its silvery bark. Smooth on the old stems as in the Beech, and without the glossy sheen of the beautiful Birch, it yet affords a most pleasing contrast to the dark foliage. The young twigs are light green and slightly downy. It is the foliage, however, contrasting alike with the bright greens of surrounding trees in summer and with their leafless branches in winter, that gives the chief picturesque value to this "incomparable tree," as Evelyn terms this handsomest of our native evergreens. The glossy green leaves are associated in Shakespeare's lyric with the pleasures of forest life:—

Heigh-ho! the green Holly!

This life is most jolly.

Southey's well-known poem has popularised the fact that the leaves on the lower boughs are more spinous than those on the upper, suggesting a reason in accordance with that newer teleology which has been explained by the teaching of Darwin. The spines of the lower branches do, indeed, protect them from cattle, though not from deer; whilst a sort of innate tendency to spinousness must account for the one terminal point of the entire upper leaves. Still, besides deer, the Holly has enemies, a species of aphid (*Aphis ilicis*) living on the young shoots, and a fly (*Phytomyza ilicis*) burrowing in the larval stage under the epidermis of the leaves.

Holly berries.—From May to August the tree bears clusters of small, wax-like, white flowers, which seem peculiarly attractive to bees, and as the species is almost dioecious, that is, has on one tree flowers in nearly all of which the ovary is aborted, and on another those in which the four stamens bear hardly any pollen, it is by these insects that fertilisation is mainly effected. This is also, of course, the reason why certain trees, being male, never produce berries, though an opinion has been expressed that male Hollies become female with age, a point deserving further attention. Many of the variegated forms in cultivation produce little or no fruit, though one of these (*laurifolia*) bears a profusion of fragrant flowers. This absence of fruit argues a certain want of vigour, which is borne out by the fact that variegation is apparently produced by a deficiency of potash in the soil. Whether, as has been suggested, this ornamental partial "chlorosis," as it is technically termed, be or be not due to some internal parasitic alga, and whether, as Mr. Jenner Weir has suggested to me, it be contagious, are points yet to be decided. The berry is generally red, but sometimes yellow, white, or, without the aid of frost, black; but the four-chambered ovary with its four seeds are so distinct from the five-chambered berry of the Ivy, with the "ruminated" albumen of its seeds that the idea once suggested of hybridism or grafting between the two plants is, of course, ridiculous. The fruit, though eaten with impunity by birds, may be said to be poisonous to man, being

extremely emetic and cathartic in its effects; but, owing to a bitter principle, ilicin, which they contain, the leaves were formerly used in fever and rheumatism.

Holly hedges.—Though beautiful anywhere, it is as a hedge-forming tree that, since the days of Evelyn, the Holly has been most valued. "Is there under the heavens," he asks in his "Sylva," "any more glorious and refreshing object than an impregnable hedge of about 400 feet in length, 9 feet high, and 5 feet in diameter, which I can still show at any time of the year in my ruined garden at Sayes Court (thanks to the Czar of Muscovy), glittering with its armed and varnished leaves blushing with their natural corale? It mocks the rudest assaults of the weather, beasts, and hedge-breakers." For this purpose the variety known as Hodgen's Holly, or latifolia, is the best adapted, as it has fine, broad, and deep-coloured leaves, and a close, compact habit, without that tendency to become thin below and to run up into standards that marks some common varieties. Hollies can be readily raised from cuttings, which are preferably set in April or May; but, as Evelyn says, seedlings are better, especially natural and well-established ones from the woods. The berries for seed should be mixed with sandy loam for a twelvemonth, as they do not germinate till their second spring. The boughs of the Holly, like those of the Ash, are not unfrequently "fasciated," or grown together into broad, band-like masses. This is particularly common on the poor soil of Bagshot sand in the Wokingham district, and, though interesting, cannot be said to add to the beauty of the tree. Few objects on a lawn are more beautiful than a Holly bush or clump of Hollies, with red or yellow berries peeping from among the glossy leaves flecked with ivory-white, while a Brier Rose clambers with pink and white sprays among its boughs, or the autumnal glories of Virginian Creeper relieve the more sombre green.—*Journal of Forestry.*

FRUIT GARDEN.

ROOF PITCH FOR VINERIES.

MR. MACKIE (p. 546) has, I think, given excellent advice as regards the pitch of the roof of vineries, both as regards early and late houses. I would go even further, and say the pitch of a vinery roof should be equal in degrees to the latitude of the place in which it is situated. I am so convinced of the truth of this that I am about to erect two span-roofed houses 190 feet long at a pitch of 59°. These houses are intended for early pot culture. Of course 10° or 20° more or less do not make any appreciable difference in the number of rays of light admitted throughout the year. I am building at a steeper pitch than 52°, the latitude of Cambridge, to give me a little more rafter; my houses are 12 feet wide, with an 11-foot rafter.

According to Bouguer's table of the rays reflected from glass, of 1000, when the angle of incidence is—

1°, 25 rays are reflected	50°, 57 rays are reflected
10°, 25 " "	60°, 112 " "
20°, 25 " "	70°, 222 " "
30°, 27 " "	80°, 412 " "
40°, 34 " "	85°, 543 " "

From this it will be seen that at angles of incidence from 1° to 30° the number of rays reflected is nearly the same. The roof of a house may therefore be as much as 30° higher than that in which the sun's rays would fall perpendicularly without any important diminution in the light transmitted to the interior. In latitude 54° the angle of the roof may be as high as 74° or as low as 34° without the transmission of light being materially affected. Therefore, between these limits we may choose any angle. Houses such as those I am about to erect having no bottom ventilation must necessarily have a steep pitch to assist the circulation of the air. As regards houses for any one particular season of the year, the late Mr. Robert Thompson said, "It may be desirable to construct a house with a slope to which the sun's rays shall be perpendicular at any given period of

the year, say on August 15, at a place in latitude 54°. The rule given by the Rev. Thomas Wilkinson in the Transactions of the Horticultural Society is to make the angle contained between the back wall of the house and its roof equal to the complement of the latitude of the place, plus or minus the sun's declination for the day on which we wish his rays to strike perpendicularly. From the vernal to the autumnal equinox the declination is to be added; from the autumnal to the vernal it must be subtracted. Thus we have 90° - 54° = 36°, the complement of the latitude, and adding to this 14°, the sun's declination on August 15, we obtain 50° as the angle between the back wall and roof. It is true we have only to subtract this from 90° and we have the angle of elevation, 40°—the angle of elevation which a roof ought to have in order that the sun's rays may fall perpendicularly upon it on August 15, nearly eight weeks after the longest day; and it may be observed that they will do the same about April 28, or eight weeks before the longest day." As regards Grapes colouring better in a house with a steep roof on account of their receiving more light, it may be so, but I have always found Grapes to colour as well under the shade of the leaves of the Vine as they do in full sunlight. G. A. PASSINGHAM.

Milton, Cambs.

PEACHES IN DELAWARE.

TAKING a summer vacation, I went on board an Old Dominion line steamer at New York for Lewes, to spend a week among the Delaware orchards, about August 20. Of course, everywhere through Delaware Peaches were in profusion. Wherever I stopped evaporators were at work, each establishment using anywhere from 100 baskets upwards daily, and taking many which could not be shipped except at a loss, and by thus taking up the surplus, allowing better prices for those shipped. In the course of my trip I fell in with the Williams, Alden, Automatic, and Phillips evaporators, and, so far as I could judge from the finished article, there was no important difference, all doing good work. But my chief errand was to see the orchards, with their bending loads of fruit, and so I proceeded on, from point to point, everywhere meeting double-decked waggons loaded with Peaches and nothing else. In short, during my stay in Delaware outside the cities I hardly recollect meeting a team loaded with aught but Peaches. At Milford there were not less than twenty waggons at the station, either unloading or waiting for an opportunity to do so, and as fast as a half-dozen teams went away empty, as many more loaded came up behind.

There is an appearance of age, health, and maturity in most of the Delaware Peach orchards that would lead one to say, How is this? Well, first, the soil is well suited to the Peach. The surface in most of the peninsula is level, the soil only moderately fertile; but it is composed of coarse sand, mixed with clay and loam in such proportions as to make it very friable and easily worked; indeed, I think there is just enough calcareous and saline matter to make it a good soil for the Peach; and on just such a soil, anywhere from Georgia to Maine, I believe, with Delaware management, the Peach will succeed; and yet, in this soil of Delaware with bad management the Peach does sometimes fail. I saw large orchards well cultivated and managed, in which I failed to see a single diseased or unproductive tree. In one orchard—that of Mr. Phillips, of Milford—I found trees whose girth was 36 inches, 37 inches, 43 inches, 43½ inches, 44 inches, and having a proportional head, all loaded with beautiful, delicious fruit, a large proportion of which went to the owner's three evaporators which, like huge monsters, were using up Peaches as fast as they could be provided, and the finished article was almost equal in quality to the luscious fruit in his orchard which it left two hours before. Such wonderful speed in drying fruit would have been thought impossible ten years ago. In nearly every instance where I supposed I had found diseased

trees, I found, on examination, the borer at the base of the tree. This year's Peach crop, however, has injured many trees by breaking them down and exhausting their vitality; the orchards will need one or more years' rest, with good culture, to regain vitality sufficient to produce again. The best kinds this year were Mountain Rose, Crawford's Early, Crawford's Late, Oldmixon Free, Reeve's Favourite, Moore's Favourite, Ward's Late, Stump the World, and Smock. Mary's Choice I found all the way from very poor to best, according to circumstances. With good care and culture, and not too heavy a load for the tree, it is fine; when overloaded, like all others, it is poor. Where persons find Peaches shy of setting a crop, I should say try Mary's Choice, and thin out if necessary—a thing, however, that very few will ever do, though those who have done it admit it is a paying practice always, when needed. The Shakers at Enfield, Conn., last year thinned their Crawford's Early, so that 140 made a bushel, and received at their nearest market 8 dols. per bushel cash; when they have a crop they will try it again. Let all remember that fancy fruit brings fancy prices; it is the poor article that begs a market.

The Mountain Rose takes the place of the Early York now. The Oldmixon Free is regarded as having many good qualities, and can be raised probably more cheaply than almost any other Peach, and is excellent for canning, except that the fashion now runs to yellow-fleshed Peaches. Hence Reeves's Favourite, Crawford's Late, and Smock take first places for canning. Richardson & Robbins, of Dover, use these varieties largely for canning, and a look through their establishment from the receiving-room onwards would satisfy the most fastidious epicure. Richardson told me that the Susquehanna Peach would beat all others if it were only more productive. He who can raise fine Susquehanna Peaches may set his own price for them.—*Rural New Yorker.*

Marie Louise Pear.—We have an old tree of this, fan trained, which covers about 24 feet of west wall. Its roots are under a gravel walk; therefore, they get neither mulching nor artificial watering, and yet during the eleven seasons I have known this tree, the average annual crop has not been less than 3 bushels; once it was over 6 bushels. As regards quality, I may mention that its fruit was exhibited twice at Hereford and stood first in its class on both occasions. Would the cord-on system of training give equally good results?—A. G. BRIDGEMAN, *Marlton.*

Peach bloom and ants.—We are forcing Peaches, and on December 21 last the first blossom opened, which I watched closely. The following morning others opened, although the weather was dull and foggy. Next morning, the 23rd, I further examined the bloom, and found all the pistils eaten off and lying on the ground, but the petals were left, as though nothing had happened. On looking farther I soon discovered that they were infested with ants. I therefore got some warm water and thoroughly soaked the borders in all the driest places, and all round the pipes, back and front. I then got some treacle, put some in saucers round the tree, also some up the stems, and here and there all over the house. I find by so doing that the ants are not only trapped, but detained from going further up the trees; they stop and take their fill of the treacle, and return to hide and take rest. I have done this for nine consecutive days, and now I think I have quite overcome my would-be difficulty. I may add that I have had them on the fruit, and to get rid of them was a great difficulty, but it was overcome in the manner just described.—W. A. COOK, *The Cedars, East Sheen.*

Josephine de Malines Pear.—According to most manuals and catalogues this delicious Pear is ripe from February to May, but with us this year it is doing good service now, and has been doing so since the middle of November. I should like to know if any fruit grower has noticed this change of season, and why this fine Pear should be so much earlier this year than usual.—R. A. HOLME LACY.

PLANTS IN FLOWER.

FINELY-GROWN ARUM LILY.—Mr. Gumbleton informs us that he has a plant of *Calla æthiopica* in his conservatory at Belgrove, Queenstown, now carrying no fewer than fourteen fine spathes.

ANEMONES IN WINTER.—A bunch of *A. coronaria* in various colours is an uncommon occurrence in the first week of the year. It has been sent to us by Mr. Dean, of the Bedford Seed Grounds, Hounslow, who seems to make a speciality of these and other spring flowers.

EARLY PRIMROSES.—I send a bunch of common Primroses which I gathered this afternoon (18th January) from a bank facing due north to show you how early they are. Isolated flowers of them are common here and there along the hedgerows, but I never remember seeing such full and perfect-grown flowers so early.—A. DEWAR, *Hall Court, Botley, Hants.*

NARCISSUS MONOPHYLLUS.—Herewith I send you a flower of the charming white Hoop Petticoat Daffodil, and I am pleased to tell you that I have hit the way in which to manage it. In 1881 I had a quantity of roots from Algiers, and at once had them planted in my bottomless pans, plunged in a cold frame, and protected during severe weather. Now I am promised an abundant show of these beautiful flowers, judging by the appearance of numerous buds, some of which I will send you next week.—P. BARR.

HÆMANTHUS ALBUS MACULATUS is a singularly modest plant in point of colour, but one that may be used with good effect in winter floral decorations. From between a pair of large thick green leaves spotted copiously with white it produces a stout erect flower-stem some 6 inches or more high, ornamented by a dense cluster of white flowers with yellow-tipped stamens. It is a direct contrast in colour to the bright red *H. coccineus*, also flowering now. These are now in bloom in the rich bulb collection in the Pine-apple Nursery, Maida Vale.

KENNEDYA MARRYATTIANA—There are not many brighter greenhouse climbing plants that habitually flower at this season than this one, some beautiful flower-sprays of which have been sent to us by a correspondent. It is at once distinguished from other *Kennedya*s by the broad, roundish trifoliate leaves covered with a dense soft down on the under surfaces, and by its umbelled clusters of flowers about the size of Sweet Peas, of a bright, glowing red, with a conspicuous blotch on the dorsal petal. In a selection of greenhouse climbers we should always include this fine Australian plant.

NEW YEAR'S DAY FLOWERS.—I cut the following this morning from plants in the open, viz., African Marigolds, Chrysanthemums, Daisies, scarlet Pelargoniums, yellow Primroses, Polyanthuses, Pansies, *Pyrus japonica*, Roses (Gloire de Dijon, La France, and others), Brompton Stocks, Wallflowers, Veronicas, Violas, and Violets. I have never before had such a variety of bloom on New Year's Day. My garden is on the high ground of a river valley, facing the south and very much exposed to the north-west, from which quarter we here get most of our gales and cutting winds in ordinary winters.—E. W. SOUTHWOOD, *Heathlands, Fakenham, Norfolk.*

ECHVERIA RETUSA.—Some well flowered specimens of this succulent plant exhibited by Mr. Barron on Tuesday last, from the gardens at Chiswick, showed admirably what a useful winter plant this is. For greenhouse and conservatory decoration it is much superior to *E. secunda*, so much oftener met with. *E. retusa* has whitish powdery foliage and flower-stems some 6 inches or 9 inches high, producing numerous orange-red blossoms which continue in perfection for a long time. There are several varieties of it, and one of which we made a note some time ago, called *speciosa*, seem to be one of the best, but the original is nevertheless a beautiful plant.

CHRYSANTHEMUM MRS. C. CAREY.—This beautiful late flowering variety is as valuable at this season as Elaine is in October, and, singularly enough, both of these sorts resemble each other. It is of the Japanese section, having numerous long pure white florets loosely arranged in moderately large heads. The foliage, too, is bold and massive, and sets off the flowers admirably. Those who require one of the best late flowering Chrysanthemums should make a note of this one. Some excellent blooms of it have reached us from the garden at Nash Court, Faversham.

PAVONIA WIoT.—This plant, which is allied to the *Hibiscus* and *Abutilon*, has been now some years in gardens, but we never saw it well flowered till the other day, when we met with it in Mr. Maller's nursery at Lee, carrying a fine head of about a dozen blooms in an umbel-like cluster, and it had a strikingly bright appearance amongst the fine-foliated plants with which it was associated. Its chief beauty is the involucre bracts which immediately surround the flowers. These are very numerous, narrow, and erect, and of a bright magenta, while the corolla is a dull, heavy purple. Flowering as it does in winter, it is a valuable plant, and one quite out of the ordinary run of plants.

APHELANDRA NITENS AND AURANTIACA.—These two brilliantly flowered Acanthads are among the showiest plants in the stores at Messrs. Henderson's nursery, St. John's Wood, at the present time. The first is remarkable for its polished surfaced leaves of a bronzy hue and its glowing vermilion-scarlet blossoms, produced in a dense erect cluster some 4 inches or 5 inches in length. *A. aurantiaca* is a larger growing species, and the colour of the blossoms is more orange, but equally as showy as in the other. Both are valuable winter plants, flowering but when a few inches high. Here they are found extremely useful in floral decorations, for one or two are sufficient to light up a group of plants. *A. Roetzli*, a newer, but commoner kind, is likewise in flower and highly attractive.

EARLY OPEN-AIR FLOWERS.—Herewith I send Primroses of many hues, winter Aconites, Snowdrops (*Galanthus Imperati*)—always first here—an opening bud of *Sisyrinchium grandiflorum*, *Crocus vernus* and *Imperati*; Pansies, one or two; *Helleborus niger* *atrorubens*, *colchicus* and *odoratus*, the lovely milky cups of *Saxifraga Burseriana*; Cowslips, Hepaticas, single blue and double red; *Scilla sibirica*, and a spray of sweet-scented Jonquil; this from a cold house in pots, forced last year, grown on until ripe, and kept in a cold frame all the summer, until they started naturally in autumn, when they were taken to their present quarters, where they have been blooming since October, quietly throwing up spike after spike, and will continue to do so for some time to come.—T. SMITH, *Nerby.*

FLOWERS FROM CORNWALL.—I send you a box of flowers to-day (Jan. 8), most of which, in fact all but the Chrysanthemums, have been gathered out of doors. The Veronica sent is the prettiest and most floriferous with which I am acquainted, there being few months throughout the year in which we cannot gather quantities of its bright magenta coloured flowers. Of Primroses we have large quantities, especially the single red variety, which seems the earliest of all; some plants of this used for dinner table decoration each bear from 20 to 30 expanded blossoms. They look very pretty under artificial light, and appear quite at home in their new quarters. The Anemone *apennina* opened a few of its lovely sky blue blossoms in time to welcome the new year; it is even earlier with us than the Snowdrop. The *Aponogeton* blossoms sent are slightly discoloured owing to the few degrees of frost which we have lately had. The winter *Heliotrope* I am afraid I shall be obliged in the course of a year or two to term a nuisance, as it is finding its way towards the hardy flower border quite fast. Our Christmas Roses have seen the best of their days for this season; the clump from

which the two unexpanded blossoms sent were gathered has been especially fine, and I have gathered a great number of grand blossoms from it. The weather has been very mild and wet here for some time past, but now seems changed a little. The wind has set in from the eastward, and to-day is very biting. However, "its an ill wind that blows nobody good;" we can get on to-day with fork in hand to ground that has been like a "slough of despond" for months past.—JOHN C. TALLACK, *Prideaux Place, Padstow.* [The flowers sent with this were truly charming, especially the Primroses, four kinds of which (lilac, white, yellow, and red) were as clear in colour and as fine as if they had come from under glass. The Christmas Rose was also good, as was the Veronica, which we take to be *meldensis*. Such a fine collection at this time of the year serves to show how suitable the climate of Cornwall must be for the growth of outdoor flowers. From the open air at Highgate a correspondent has also sent us a Rose shoot nearly 4 inches long in full leaf, and a Pear blossom from a tree which a few days more of the same temperature would make a mass of white.]

DAHLIA ARBOREA.—The most remarkable exhibit at South Kensington on Tuesday last was some flowers of this Mexican Dahlia shown by Mr. Green from Sir George Macleay's garden at Pendell Court, Bletchingley. The plant somewhat resembles in growth the better-known *D. imperialis*, but is very different as regards the flowers. These are some 3 inches across. Normally the flowers have ray florets of a soft rose-pink and disk florets of bright yellow, but singularly enough Mr. Green's plant produced two kinds of flowers on the same plant; some are normal or single, the others with an outer row of narrow and flat ray florets, and the rest tubular or quilled. The double flowers are the showiest, and if the sport could be perpetuated it would be the most singular Dahlia we have, not excepting the Cactus Dahlia (*D. Jnarezi*). The Pendell Court plant is 9 feet in height, and even without the flowers handsome, as the foliage is so fine. In the same house with *D. arborea* Mr. Green has a plant in bloom of *D. imperialis* which is 23 feet high.

BILLBERGIA MORELI.—Among the numerous cultivated species of *Billbergia*, one of the most beautiful genera in Bromeliaceæ, none surpass in attractiveness the subject of this note, now finely in bloom in the Pine-apple Nursery, Maida Vale. The characteristic features of this fine plant are: a vasiform tuft of long recurved leaves, not marked in any way, but wholly of a bright green. From the centre of this tuft a long flower-spike is produced, and hangs over the side of the plant. The spike is furnished for fully half its length with long, pointed membranous bracts of the most brilliant carmine tint, and from the axils of these the flowers are produced. The blossoms are about 2 inches long, half yellow and half a deep bluish purple, and the calices being whitish, there is a strange association of colours. It is, indeed, a bright plant, particularly in mid-winter, at which season it habitually flowers. Unlike several of the *Billbergias*, this species flowers when in quite a small state—a desirable quality where space is a consideration. Having regard to the fact that the culture of Bromeliaceous plants is so very simple, it is not a little surprising that they remain in such obscurity as they now do, at least in this country.

Coleuses for winter decoration (p. 4).

—I do not think the reason why these are not oftener used than they are for the purpose is far to seek. Most of us have very little spare room in winter in houses in which these can be grown. Indeed, we think ourselves lucky if we are able to keep cuttings of them over winter. Then, again, they are not by any means so useful in winter as in summer, as they will not bear changes of temperature, and cannot be used for table-work or decoration in the house; this alone is very much against them.—JOHN C. TALLACK.

CACTI AND THEIR USES.

THE avenue of gigantic Cacti shown in our illustration is such as is not unfrequently met with along the Mediterranean coast lands, where these plants have long become naturalised, and where in some gardens they are cultivated with excellent effect among plants and trees of a more leafy nature. The whole of the Natural Order Cactaceæ belongs, with perhaps only two exceptions, to the New World, where, from California down to Chili especially, they are found in abundance. Opuntias, Cereus, Phyllocactus, and the dozen or so other genera constituting this Order all hail from this quarter, Mexico, perhaps, being the country where they are most abundant, although they are

or astonished by the unplantlike appearance of most of its inmates. From the small Selaginella-like Haworthia to the thick, post-like Cereus and Euphorbia, and from the Sea Anemone-like, foul smelling Stapelia to the large night-flowering Cactus there is much which to the general visitor appears highly interesting or amusingly ugly. Viewed for their forms alone, such plants are deserving of more favour than they meet with here, while if we add the beautiful, gigantic, or curious flowers borne by most of them, their claim is doubled at least. Such plants as the Phyllocactus and Epiphyllum are fairly well known and generally cultivated, but the mass of the plants of the Order are not much troubled about. In a collection of

the gardener to take the unwary in; the curious looking Opuntias, whose appearance is something like a number of green battledores placed one above the other, and so on all through the house. I have been told that American visitors almost invariably express high admiration for this collection, and two of them who are excellent plantsmen once told us that this house was worth coming from America to see. To most English plant cultivators this may seem hardly creditable, but we must not calculate taste in all countries to be as our own. Mr. Loder and several other correspondents of this paper have done much to awaken a love for some of the choicer Cacti, and it is to be hoped that their endeavours may pro-

Roadside vegetation in Mexico.

to be found now quite at home in various other parts of the globe. Some indeed, such as the Opuntias, on which the cochineal insect is cultivated, are grown in large numbers in Northern Africa, the Canary Islands, and the East Indies, as well as in Europe, where the manufacture of cochineal is conducted. The tree overhanging the Cereus in the right-hand corner of the illustration is apparently the Cochineal Opuntia. The Echinocactus is eaten by the mules of South America, after removing the spines with their feet, and the fruit of the Opuntia (Prickly Pear) is used in colour making, besides being relishable as a desert fruit. As contrasted with the grotesque form and singular appearance of most of the members of this family, their economic properties are insignificant, and it is as garden plants that we would draw attention to them here. The succulent house at Kew has always been one of the principal attractions of the place. Few people can walk through a house such as this without being amused

plants it certainly would seem proper to have represented the curious as well as the beautiful forms of vegetable life, and although a house of well bloomed Orchids will always find more admirers than a mountain side of Cacti, there seems no reason for excluding them altogether from our collections. In this, however, as in all other matters where taste is the pivot on which favour turns, there is little use in remonstrance; we must await the turn of fickle fortune. Meanwhile it is with great pleasure that we look through our fine national collection at Kew, and hear people acquainted with such matters say that it is the finest in the world. Here are the spiny dumpy Echinocactus, which looks like a Vegetable Marrow, thickly studded with rows of brown pins; the small Mammillarias covered with spines arranged in stars and looking like thousands of insects; the Turk's-cap Cactus (Melocactus communis), whose red crown is always viewed by juveniles with suspicion, as looking like a trick of

duce good results. There is much to be learned yet in regard to the cultivation of many of the species, the orthodox heat, sunshine, and lime rubbish system of growing them proving in a number of cases the reverse of successful. The Order has a wide geographical range, and therefore we must manage our plants so as to give them a temperature and treatment similar to what each enjoys naturally.

The climbing species of Cereus are remarkable for the size, colour, and fragrance of their flowers, and in some cases for their expanding only during night time. C. nycticalus, C. grandiflorus, and C. triangularis are large-flowered, sweet-scented, night-blooming kinds, well adapted for cultivation in a stove or warm greenhouse; C. Mallisoni, C. Napoleonis, and C. Macdonaldiae are smaller flowered, but very free day blooming kinds. A handsome species is the Rat's-tail Cactus, C. flagelliformis, of which there is a fine specimen in the succulent house at Kew. It is grafted on a climb-

ing species, and the long stems hang down from the rafter in a large cluster in a very graceful and striking manner. *C. speciosissima* is an old gorgeous flowered kind sometimes met with in old-fashioned collections, and where known very much admired. Like the *Phyllocacti*, it is a very easy plant to grow and flower, and along with the last-mentioned there are few plants which prove more satisfactory than these old Cacti. The great variety of form which distinguishes the Order *Cactaceæ* cannot be better exemplified than by selecting some of them, such, for instance, as *Rhipsalis*, *Epiphyllum*, *Pereskia*, *Disocactus*, the *Yucca*-like *Leuchtenbergia*, which do not bear the slightest resemblance in general appearance to the *Cereus*, *Echinocactus*, *Mammillaria*, &c. It is well known that most of the genera will graft one upon the other, the *Epiphyllum* on the *Pereskia* being perhaps the best known instance of this. We heard a day or two ago that *Epiphyllum* had been grafted on *Euphorbia splendens* and was found to do well. It seems highly improbable that such a thing should happen, and we shall be glad to hear from anyone who has tested this whether or not it could be practised with success. B.

FLOWER GARDEN.

THE GLADIOLUS FAILURE.

"DELTA" says (p. 570, Vol. XXII.), "I am able by taking care of the spawn to keep many varieties that I should otherwise have lost." Now, according to my experience, this statement contains the whole secret of success as regards *Gladiolus* culture. I cannot do much more with the old corms than "Delta." I plant to all appearance sound, healthy bulbs, and some arrive at the flowering stage and do well, while others die off both before and after flowering in a mysterious manner. Spawn and seedling plants are both much more encouraging, and, moreover, the *Gladiolus* failure is not so universal as "Delta" would make us believe. Not many miles from where I write there is a very successful amateur grower (Mr. Dobree, of Wellington), who not only grows the *Gladiolus* in perfection, but takes the highest prizes with it at all the shows in the West of England at which he exhibits, as well as at the Crystal Palace and other large exhibitions. This I think sufficient to prove that although "Delta" has been unsuccessful, it does not follow that failure is universal. "Delta's" most surprising statement is that one grower lost 50,000 bulbs in two years. Surely there must be some mistake as regards these figures. I write rather confidently on this subject, because I am an old grower, and since the 1st of November last have passed through my hands over 2000 bulbs that flowered last year. I mention this to show that at least I ought to know something about *Gladioli*. My course of management, both with young bulbs raised from spawn and seed, is as follows, and I will begin with

Soil. in the elaborate preparation of which I have no faith. A deep staple, not over drained, but at the same time not water-logged, will suit them, if not wholly of a peaty or sandy character; but it must be dug up at least 12 inches deep, and good down to that depth. If at all poor, it must be well manured in November with good farmyard manure, well rotted, and a good portion of the manure should be placed in the bottom of the trench as the digging goes on. This is indispensable, for the plants must be generously fed. I have found in practice that I get the best bulbs where their roots have found their way down to a lump of manure, and, further, a depth of 12 inches of good soil is necessary to have the bulbs a sufficient distance below the surface. It is my opinion that half the *Gladioli* planted in this country are not put deep enough; every bulb when planted should be at least 4 inches under the surface, and in light, well-drained soils 6 inches is not too much. I have in my time planted in all manner of expensive mixtures, but the results were no better than now when I plant in the ordinary soil of the garden. The only

difference is that I use considerably more manure than when I expended my strength on preparing a costly compost. By confining myself to young stock I have no reason to find fault with the results; but it is proper to remark that I often change the position of the beds, because I believe that a change of soil is good for them. This plan is adopted by Mr. Kelway, in the deep rich soil of whose nursery very little manure is used. There need not be a doubt that an early preparation of the soil in winter is beneficial to *Gladioli*. Our land, on which we hope to plant many hundreds in the spring, was heavily manured and dug up early in November. Before planting time this will be lightly forked over, and all large lumps broken to pieces with a fork.

Raising seedlings.—Perhaps it may be well to say that I write from the reputedly favoured county of Somerset, where no doubt the summers are longer than in more northern districts, a circumstance which may in some measure add to my success. For the most part, I save my own seed, and to insure its being of good quality, I fertilise the best flowers. I attribute a good deal of my success in raising seedlings to a proper selection and preparation of the soil. It is much more necessary to have it rich and fine in texture than when dealing with bulbs, and it must be understood that I sow my seed in open borders in the kitchen garden. I select a warm position, where the soil is both light and rich, and get the surface fine by raking it over rather deeply. About the middle of April I sow the seed in drills an inch in depth and 8 inches apart. The seed is covered with sifted sandy soil. To secure a good growth, the first year the seed must be sown very thinly, and then under ordinary circumstances, with no more care during the summer than that usually given to similar subjects, two-thirds of the bulbs will, if properly managed during autumn and winter, flower the next year. In our strong soil and in mild autumns they will keep growing until the middle of December, and unless severe frost sets in I do not usually lift seedling plants before that time. I think it may be accepted as a fact that the majority of *Gladioli* are lifted too early in autumn and kept out of the ground too long. I had last year more than 80 per cent. of my seedling bulbs in flower; that is to say, they flowered the next year after being sown. Young bulbs should always be cleaned and stored away in dry sand or earth, and not be allowed to lie about and get withered up by the air, thereby weakening them.

Raising bulbs from spawn.—When the large roots are taken up in autumn, a number of little bulblets will be found round the base of the large corm, and as some varieties produce more spawn than others, it is a good plan to mark those that it is desired to preserve, and then the inferior sorts may be destroyed if not wanted. In this matter the *Gladiolus* is an easy subject with which to deal. If a pure stock of first-rate kinds is desired, it is not much trouble to label them and keep each sort separate by placing them in small pots. Having secured the spawn, that of different sorts may be stored in the same way. Early in March prepare a place for them under the same conditions as I have advised for sowing the seed. Let the ground be dug deeply, heavily manured, and exposed to the winter's frost; in a word, treat them generously without any coddling, and I feel sure a sufficient reward waits those prepared to throw away their old bulbs and to confine themselves to young stock. A period of only two years is all that is required to place anyone in this position, and when once obtained there will be no difficulty in keeping up plenty of healthy corms. At the end of the first season's growth, lift the roots about the middle of December (unless severe frost sets in before that time) and store them away in the manner described. The cooler their quarters during winter the better, provided they are not exposed to actual frost. I omitted to mention in its proper place that it is desirable to have the drills for spawn deeper than for seed; a drill 2 inches deep is not too much. I merely sow the spawn thinly along the drill. I would emphasise the word thinly because, if the

young plants are crowded they will not get large enough for flowering the next year. It will not be much out of place here if I say that it would never surprise me to hear that some one had made the *Gladiolus* an annual plant, and flowered it from seed the first year. In our own garden the young bulblets come up quite promiscuously, and flower frequently the first year without any attention.

Treatment of the bulbs the second year.—If the seedling plants and young spawn have been liberally grown, the majority of the corms will flower the second year. But I must say here, and I wish to do so in the most explicit manner, that this course of management will not produce spikes fit for exhibition purposes. I am not an exhibitor, although an admirer of *Gladioli*; my business is to grow them for garden decoration only, and therefore I do not aim at producing large spikes of bloom; I grow them for the fine display they make. I select positions for them in any convenient places that do not interfere with the general scheme of decoration. I do not consider the *Gladiolus* a suitable plant to work in in a position where there is any attempt at harmony and effective arrangement. It is a very suitable subject for isolated beds and for clumps in mixed borders; but if *Gladioli* are to be grown successfully a properly prepared bed is the best place for them. Having selected the position and prepared the bed, choose the early part of the month of March for planting. The bulbs should be 6 inches apart all over the bed, and they should be planted in drills 4 inches deep, and if the largest corms are selected the majority of them will flower. The small ones may be planted in another situation to get larger for another year; but if any of them should push up a flower-spike it should be cut off without being allowed to open a bloom, for I feel sure after a bulb has once flowered there is no certainty as to its future behaviour. Someone may ask what is to become of the bulbs after they have once flowered. My advice is that if exhibition flowers are wanted they must be retained and cultivated in the best possible manner, chancing whether they will grow in a satisfactory manner or not. In a suitable soil I know no reason why a certain portion of them should not do well. But for garden decoration there need be no risk if the cultivator works in the way here indicated, and confines himself to young stock only. J. C. C.

NOTES FROM SCARBOROUGH.

SOME of our *Primulas*, both of seed I got from Huber's and some of our own saving, are turning out remarkably good, so good that I feel they should be in professional hands for propagation. One pure semi-double white with Fern leaves and fine pyramidal habit seems to me the prettiest thing I have seen. A curiosity has just bloomed with me — an *Anemone*-flowered *Dahlia*, like *imperialis* in growth, with flowers like *D. arborea*, but with quilled centre florets instead of stamens, and with good lilac guard petals. If its habit were better it would be an acquisition, but it is too tall and lanky for England. I got it from Nice. *Canna Ehemanni* is undistinguishable from *C. iridiflora* I brought from Nice last spring. It has bloomed freely lately with us. A fortnight ago we had one night with 11° of frost, which, alas, has killed *Gazania*s, *Nice Daisies*, and all such tender things, except where I was able to protect them for the nonce, but I hope I shall preserve a few old out-door friends for another season. One dwarf, shrubby *Veronica*, with rose-magenta blooms of the Blue Gem type, has proved hardier than other varieties, inasmuch as its flowers are quite untouched by that sharp frost, while other kinds are much paler in bloom, or have ceased to flower. It will be a distinct gain, and I must propagate it as much as possible; it has bloomed since you were here. I think I brought the cuttings from Marseilles. Under the glass copings there will be several nice *Tea Rosebuds* for the new year; *Marie Van Houtte*, *Wassilitchikoff*, *Falcot*, *Comtesse Riza du Parc*, and *Mdme. Lambard* still bravely struggling on against dark days and

wet, alternating with occasional hoar frosts and gleams of sunshine. We have, however, had some charming days lately, and things begin to peep up in quite a spring-like way. I send you a little box of winter Heliotrope, now in abundant blossom; it really scents the air these sunny mornings; also a specimen of what a simple glass coping will do for the Tea Rose. For January such a Rose bud is not to be despised outside. Also the two first blooms from the rockwork of *Crocus Imperati*, which are earlier than usual (in proportion), as no Snowdrop has yet put in an appearance above ground.

E. H. W.

A NEW DAFFODIL. (GERTRUDE JEKYLL.)

AMONGST the boldest and most beautiful of the

Aldborough Daffodils, this is one of the best, and I think the best of all those which I have actually seen. It was raised by the late Mr. J. G. Nelson, who sent me a fresh flower of it on March 20, 1882, a short time only before his death. Unfortunately for myself, I never saw Mr. Nelson, but his letters are treasured as those of a friend, and I cannot do better than quote what he said of the plant: "I send you one of my seedling Daffodils, of which I think you will approve; it is a chance seedling, but I think *N. cernuus* had something to do with it. It is to me a most pleasing flower and most distinct—a good substantial Daffodil, and of an uniform colour. Mr. Peter Barr calls it Gertrude Jekyll, he, good man, having got into a mess by naming one *Narcissus* after two ladies. I got him out of his trouble by giving him leave to name mine after one of them." Of all the new seedling Daffodils now known, this is one of the most pleasing in form, and it is unique in colour, and to certain minds it has another charm, being in point of fact as rare as it is beautiful. Even Mr. Barr does not as yet quote it in his newly-issued catalogue, in which Daffodil lovers may find one or two of their favourites priced as highly as half a guinea a bulb. What would dear old Parkinson say to this if he could only return to find the *Narcissus* he loved and wrote about so knowingly early in Charles I.'s reign of so much accounted value in this Victorian era? Our great-grandmothers, fond as they were of hardy flowers, rarely purchased them, but if perchance they did so, a silver groat did duty for the crowns and half guineas of our own times.

The Daffodil of which we now write, however, is so beautiful in form and its colour so delicately soft and pure, that one cannot but regret that it is so far unobtainable "either for love or money." As to its characteristics of distinctness and beauty, nothing short of a full study in colour by a good flower painter, say by Mrs. Duffield or Miss Nutrie, or by Mr. Muckley or Mr. Moon, could give an adequate idea of the plant as it opens its soft maize-coloured blossoms in defiance of all the winds of March. Our engraving shows the gracefully nodding flower, the cup-like manner in which the perianth segments cluster around the corona, and the relative length of the latter organ, which is peculiarly long and cylindrical, with a most elegantly frilled mouth.

As Mr. Nelson said, perhaps *N. cernuus* "had something to do with it." The graceful poise of the blossom on the stout scape is singularly suggestive of that species, but then the segments are of more substance and the whole flower larger, and the foliage also is stouter and broader, so that while looking at the blossom one must needs think of

Mr. Leed's seedling, yclept *N. bicolor sulphureus* (Barr), which in colour and size most nearly approaches our plant, and yet actual comparison enables us to note many differences in the nutant pose and in the form and colour of the two.

It is very interesting to know that Mr. Nelson's seedling *Narcissus* were not the result of actual manipulative hybridism, but simply, as he puts it, "chance seedlings," and yet but few of those who have raised Daffodils from seed have been so fortunate as was he in obtaining really distinct varieties.

F. W. B.

THE CARNATION AND PICOTEE.

Exhibiting.—Exhibitions are held by the National Carnation and Picotee Society every year in July, the secretary, from whom schedules may be obtained, being Mr. E. S. Dodwell, late of

this stretch some shading material, which will protect the flowers from the burning sun (half an hour of which would destroy every bloom for show purposes) and from the rain by acting as a sieve. The best flowers should be cut at 4 a.m. the day before the show (either six, twelve, or twenty-four; I should recommend amateurs to begin with two sixes—six Carnations and six Picotees). On this day they must be "dressed" for exhibition, and spend the night in a cool cellar, so as to reach the show next morning quite fresh. They are shown in boxes containing six, twelve, or twenty-four, the dimensions of which are given on the schedule published by the Society. Nature produces the flowers with the largest petals mixed with the smallest, with self-coloured or plain petals here and there, and the colours unevenly distributed; the florist's care is to

remove these imperfections, and so dispose the petals as to look their best. The points of the petals should be reversed with a pair of steel dressing tweezers, and any petals dead, mutilated, lacking colour, or ground must be pulled out, for if left in they would disqualify the entire stand. A white circular card with a hole in the middle, sold by Meek, Crane Court, Fleet Street, is then slipped over the bud so as to support the petals, and the largest are drawn with ivory tweezers to their fullest extent, and arranged in a circle on the card. The next largest are then arranged over them, and so on to the middle petals, which should just fill the centre of the flower nicely without crowding or confusion, the object of the operation being to 'distribute the colour evenly throughout the flower and hide any defects therein, so as to come as near as possible to the standard of perfection. The best flowers should be at the left hand top corner of the stand, and the smallest at the right hand bottom corner. The tweezers described may be had of Mr. B. Simonite, Rough Bank, Sheffield. The flowers should contrast as favourably as possible with one another, i.e., two crimson bizzarres or two purple flakes should never come together, nor two red edges or two scarlet in Picotees, &c. But a single lesson from anyone used to dress the blooms would be worth a volume on the art of "getting up" the flowers (I shall always be most happy to give any reader within calling distance the benefit of my experience, such as it is). When the flowers are on the plants it is a good plan to support them with Carnation pins, which are pins with ring heads (easily made by anyone handy), which take the bud, are fixed into the supporting stick, and prevent the flowers drooping or getting bruised by wind, rain, &c. The flowers after being dressed should never be touched by the hand or otherwise disturbed.

Propagation by seed.—The proper time to sow seed is about April or May. Prepare a little of the compost prescribed in last week's GARDEN (p. 7) with a little extra silver sand. Sift it fine; mix it well, and fill a quantity of 3-inch pots with it—as many as you have sorts of seed—to within an inch of the rim. Sprinkle each with a fine rose, flatten the surface, and put down each seed separately with the point of a knife, about half an inch apart; cover them very lightly with very finely-powdered compost, and put them in a cool frame or house out of danger of frost. When they have made three pairs of leaves, prick them out round the edges of 5-inch pots filled with the same compost, about 2 inches apart, and keep them still in the cool house till there is no longer serious fear of frost. When about 3 inches high, prick them out into beds about 4 inches apart. The beds might

Narcissus Gertrude Jekyll.

Chatham Terrace, Larkhall Rise, Clapham. If you grow for exhibition do not commence crossing for seed or layering till the show is over; it will take all your time guarding the blooms from insects, &c. As soon as the first bud shows colour spread an awning all over the plants. If your plants are, as recommended, under the shelter on the north of the south wall of your garden, the awning may be constructed as follows: Erect a little framework 4 inches high along the top of the wall, or let in two posts 6 feet high at the two south corners of the area, covered by the pots, with a cross-bar along the top. Erect two posts 8 feet above the surface soil at the two north corners, with a cross-bar between them. Connect the 6-foot frame and the 8-foot frame by rods with a 2-foot slope from the one to the other, and lay rafters from one to the other 4 feet apart; over

just be enriched with a little sand and manure if convenient. In the autumn they will be nice little plants, and may be put into beds. When they flower, which will be next year, keep and name as pot varieties anything really good in colour, form, &c. Throw away at once anything single. The rest, fancies and selfs, may either be given or thrown away, or put into the borders and beds for cutting from.

By pipings.—When the plants throw up too many shoots to layer, or the root is attacked by disease or other calamity occurs, the shoots may be taken off and piped as follows: Take hold of the shoot above the fourth or fifth joint from the top, and, with a sharp pull, draw it out from the socket formed by the next joint, which it will pull away with it. Make a little upward slit in the cutting just through the joint, and thrust it firmly into a pot filled with the compost prescribed above for seeds to within an inch of the top, and the rest with silver sand. Water the pot and plunge it in fibre under a hand-light for three or four weeks, when the pipings will be rooted. They may then be potted off singly or bedded like layers, and will flower next year. Remember plants struck like this are never so good as those propagated by layers, but to save a good sort or get up a stock it is a useful expedient.

By layers.—This is the best and most generally accepted method of propagating Carnations and Picotees. It should be set about immediately after the shows, or at latest the last week in July, and should be all finished by the second week in August, and is performed as follows: Having prepared the compost, having got it near to hand, get the pots up one after another on the potting table, and proceed as follows: First scrape out (I use an old broken table knife for the purpose) the earth to a depth of 2 inches, and replace it with the compost flush up to the brim; then strip each shoot up to the top three or four joints; go all round the pot, doing this before proceeding any further. Then, with a fine sharp knife (a surgeon's dissecting scalpel, with a pointed straight edge and long thin handle is the best), pierce through the shoot just above a joint, make a slanting cut down through the joint, bringing the knife out just below it; take a peg with a hook to it and thrust it into the fresh compost just above the tongue, so that it catches it as it comes down and pegs it into the earth. Then cover it with a little more compost, and the layer is finished, and so go on all round the pot, and so on from pot to pot till the entire stock is layered. The best pegs are those made of the fronds of the common Fern; but as these must necessarily be limited in quantity, hundreds may be made in a short time out of galvanised wire with a pair of pliers. In about a month the layers will be rooted, and by the second week in October all the young plants ought to be in their winter quarters. When the plants are in beds the procedure is exactly the same; the compost is spread round the plants 2 inches above the surface of the ground, and the shoots tongued and pegged into it.

Diseases.—Carnations are subject to three fatal diseases—canker, mildew, and gout. Canker is produced by damp, and the first symptom is either the grass turning colour or the non-formation or stoppage in the growth of the shoots. The roots will be found rotted through and decay creeping up the centres of the shoots, which should be taken off well above the affected part and piped. The only safeguard against it is to have the compost sweet and well mixed, and not to give too much water early in the year; and it should be here remarked that water should never be given unless, on stirring up the soil 2 inches below the surface with a sharp stick, it seems dry; mere surface drought should never be relied on. Mildew is of two sorts, the white and the black. White mildew appears like flour on the Grass, and should be sprinkled with water and dusted with sulphur one morning, and the sulphur carefully washed off the next morning. Black mildew appears as little black specks on the Grass, and means death. It is the Carnation grower's cholera. The instant it appears every shoot bearing the lightest spot

should be cut off and burnt with the root and earth, only the shoots quite untainted being piped and saved; if not, it will spread like wildfire and ruin the whole stock. Gout is generally the result of twisted stems and damp atmosphere. The soft wood just above the ground swells into a cavernous *goutre*. It does not seem to spoil the flowers, though a gouty plant can never be layered, so should have all the shoots cut off and piped. Damp is the greatest enemy of the Carnation, producing in the first instance all these ills, so must be very carefully guarded against, especially when the young plants are in the frame in winter. I have lost hundreds by a single injudicious watering in winter.

Insect pests have always been the most serious ill which (Carnation) flesh is heir to, because they cannot be guarded against. Lime spread under the pots or round the pedestals of the stages will keep off creeping evils, but not aerial ones. The chief ones are wireworm, earthworms, earwigs, thrips, and green fly. Red spider will attack them if kept too hot and dry, but not unless. Wireworm is the most deadly enemy of all; it is a copper-coloured worm, an inch long or less, hard and tough as wire, whence its name, which gets into the pots or soil and eats its way up the centre of the stem, showing no sign of its presence till the plant absolutely dies. All earth used for potting must be carefully searched before use. If in beds, slices of Carrot, Apple, or Potato thrust into the earth and taken up every morning will be found full of them. A skewer or piece of wire may be attached to them, by which they may be carefully sorted out of the potting earth; if they do get in a dose of lime water will drive them out; if the plants are on an ash bed, it must be thick enough for no worm to be able to get through; if infesting beds, frequent doses of lime water will generally rid you of them. Earwigs are a most persistent plague when the plants are in bloom; they eat their way through the pod into the seed vessel, which they destroy after eating away the roots of the petals. The best traps are pipe bowls, which, if inverted on the tops of the supporting sticks and searched every morning, will catch hundreds. Perseverance is the only guard against them. Thrips is a serious annoyance to the florist, being a tiny black insect only just visible, which eats into the bud and infests the expanded flowers, biting the colour out of them and spotting them with white in a most woeful manner. Green-fly plays the same game, and these must be searched for at the end of June and early July, and on the slightest trace being found, carefully washed off with Gishurst compound or some other good insecticide.

Running.—The most annoying and unavoidable freak of the Carnation and Picotee is that which is termed by florists "running." Without rhyme or reason, a plant which should be a flake or bizarre becomes a self, or a flake on a coloured ground. It has been so often asked what is the cause of this, that I cannot do better than give you a short extract from some voluminous notes on the subject from the *Florist* for 1876. This article relates the experiences of many good cultivators who produced good results in some cases with rich and in other cases with poor compost, and, again, bad results with either compost. But the whole goes to show that in the poorer composts were found the best results. As Mr. Dodwell says in that volume, "Sound, healthy life, whether in the animal or vegetable kingdom, is quite inconsistent with the habitual use of a highly stimulating diet." Your only chance is then to suit your compost to your situation, and have it thoroughly sweet and well mixed, using lumps of charcoal in it. It stands to reason that in unsuitable positions the plants will naturally want more stimulating diet than if natural causes were in their favour.

Weeds on lawns.—My lawn is infested with Daisies and Plantains. I should esteem it a great boon if any of your readers could inform me as to the best means of destroying them without lifting the Grass turf. Is the Daisy killer any good?—OLD SUBSCRIBER.

GARDEN FLORA.

PLATE CCCLXXI.

MARTAGON AND OTHER LILIES.

(WITH FIGURES OF L. MARTAGON ALBUM AND L. DALMATIUM.*)

THE accompanying plate represents two of the most distinct varieties of *Lilium Martagon*, the common Turk's-cap Lily, so named by Parkinson on account of the peculiar way in which the petals recurve. The Turk's-cap term is frequently applied to all the Lilies in which the petals reflex; thus we have the Canadian Turk's-cap, the scarlet Turk's-cap, and several others, but which do not belong strictly to the Martagon group. In some cases they are even called Martagons, but in speaking of the Martagon group proper I shall confine myself exclusively to the varieties of the common Martagon, which is one of the oldest Lilies in cultivation. The two varieties figured are the best and, I may say, two of the most distinct of the genus. It is a curious fact that the white Martagon, "which in the time of Parkinson (1650) was a common variety," should have become so scarce, as we usually find that plants or bulbs are pretty plentiful which take care of themselves, and, on the contrary, those that are particular as to soil or situation usually succumb sooner or later. Philip Miller, a century later than Parkinson, describes a number of varieties of Martagon Lilies, and among them a double white and double purple. The latter is still in cultivation, but the former I have never seen. *L. Martagon* is common throughout the centre of Europe, and is exceedingly variable, varying from pure white to deep purple, but not so dark as the Dalmatian form, which varies from dark maroon to almost black. As a rule they are all more or less spotted, the spots varying from minute specks up to large, irregular blotches, some of which have a peculiar appearance. I have seen a few varieties without any spots. I should consider this Lily as one of the most variable, as it would be an easy matter to make a collection of fifty varieties of it more or less distinct; for general cultivation, however, the black, white, purple, and double purple are the best. All the varieties will grow in any good sandy loam, moderately moist, not wet, and increase very freely by division of the roots, which ought to be done every three or four years to keep the bulbs healthy and vigorous. In some soils I have known them to stand for many years, and never disturbed, but I believe all Lilies should be moved occasionally, provided it is done at the proper time, viz., as soon as the stems begin to die off. They should be shifted and planted at once, dividing the large roots, taking off all the small bulbs and loose scales, and replanting the large bulbs in clumps, and the small ones in a bed by themselves until they are large enough to flower. By doing this you keep your bulbs healthy and increase your stock, and, as they take but little room, space could easily be found for them between shrubs, &c.

L. dalmaticum, herewith figured, differs from the common Martagon Lily principally in

* Prepared from plants in the Hale Farm Nursery, Tottenham, in June last.

Growers or introducers of new plants will oblige us much by early intimation of the flowering of new or rare species, with a view to their representation in our "Garden Flora," the aim of which is the illustration in colour, and in all cases where possible life size, of distinct plants of high value for our gardens.

THE WHITE AND BLACK MARTAGON LILIES

LILIUM MARTAGON ALBUM & L. MARTAGON NIGRUM

colour and growth. When established it grows from 5 feet to 6 feet high, with about thirty to fifty flowers on a stem, and varied slightly in shade, but the lightest in colour is much darker than the darkest form of the ordinary Martagon. There are numbers of other beautiful Lilies adapted for loamy soil, having a vigorous constitution, and easily grown in any ordinary well-drained border, and I will briefly enumerate a few of the most distinct, and such kinds as can be grown with a certainty of success in a rich, friable loam in any well-drained situation, provided they are planted early and are in good condition at the time of planting. When the soil is stiff and heavy, leaf mould, road sand, or Cocoa-nut fibre should be added to make it light and open. The bulbs of nearly all Lilies suffer from excessive moisture, and when the soil is wet and heavy the beds should be raised, so that the bulbs lie above the ordinary level of the ground, so as to be drier than when planted on the level; this is a very important point in Lily culture. When planted among shrubs you get these conditions, although in a different way, the roots of the shrubs absorbing what the Lilies do not want, and the foliage affording protection to the young growth in spring and partial shade in summer. To grow Lilies successfully the most important point is to plant early in autumn; whereas most persons plant in late autumn and spring, and then complain if they are not successful. I contend that most Lilies can be grown in any ordinary border without any elaborate preparation or expense, provided that they are planted at the right time and a judicious selection made.

L. bulbiferum.—A very free-flowering species, and one rarely met with. The flowers, which are not so large as in the varieties of *davuricum*, are of a crimson colour shading to orange, and with numerous bulblets in the axils of the leaves.

L. Browni.—One of the most chaste of all known Lilies; flowers 8 inches or 10 inches long, interior pure white, exterior brownish purple. This grows freely in light, sandy loam, but must be in a well-drained position.

L. candidum is too well known to need mention; one of the oldest, but still one of the best. The double variety is very effective in hot situations, flowers well with me in hot summers, and appears to want more heat than other varieties of this class. The variegated form is also very pretty during the autumn and spring, the leaves having a broad, heavy band of yellow on the edge.

L. carniolicum, though not so bright as some, is still worth growing, as it flowers very early.

L. giganteum, a majestic species, growing in suitable positions 8 ft. to 10 ft. high, has large leaves and long trumpet-shaped flowers, white inside, and striped with purple on the outside. This species must be planted early in the autumn, protected the first season from frost, and then left to take care of itself. Select a dry position, and one where the young foliage will get protected from the spring frosts.

L. chalcedonicum, commonly called the scarlet Turk's-cap, is a grand species. The colour is marvellous, of the most intense fiery scarlet; there are several varieties of this in cultivation, some flowering earlier, some spotted, while others have no spots, but all are beautiful and well worth cultivating, even though the garden is only a few feet square; this kind is particularly fond of a well drained position.

L. croceum, the old orange Lily, is as well known as candidum, and quite as effective, flowers early, very free blooming, and makes a garden look gay, even if there is nothing else in it.

L. davuricum (umbellatum and spectabile of some).—There are five or six good varieties of this and all worth growing; they are dwarf, take up but little room, produce an enormous quantity of bloom, very bright colours ranging through the various shades of scarlet, crimson, orange, &c., and increase very rapidly. Good clumps of these dotted about are very effective for about a month. They like a sandy loam and well drained.

L. longiflorum and all its varieties must not be omitted, although there is more difficulty with these than with any previously mentioned, but the difficulty is not so much with soil as with climate. They make a very precocious growth, which, if injured by frost, gets virtually spoiled for that season. The only way to get over this difficulty is to lift the bulbs in the autumn; keep them comparatively dry in silver sand, dry peat, or any other material which will keep the bulb from shrivelling, yet must not contain sufficient moisture to make it start, which it will do if not looked after. Plant the bulbs in January or February and you will flower them easily and increase your stock. This is the only Lily that I know of that should be treated in this way.

L. monadelphum var. szovitzianum (colchicum).—A species of great beauty, large and fragrant, early blooming, very variable in colour from primrose to golden yellow, and one of the easiest to grow. Select six of the finest Lilies and this must be one.

L. pardalinum, although usually considered a peat Lily, can be grown in light loamy soil, but planted in a damp, shady position. This should be planted among shrubs, as it usually grows 7 feet to 8 feet high. (Figured in THE GARDEN, Vol. XX., p. 528.)

L. pomponium verum.—In colour rivaling chalcedonicum, flowering about three weeks earlier; very graceful slender habit, foliage dark olive-green, reaching to the ground, and bearing from twelve to eighteen flowers on a stem. One of the best and most effective of Lilies. (Figured in THE GARDEN, Vol. XX., p. 420.)

L. pyrenaicum.—A small early-flowering species; flowers yellow, freely spotted; also a red variety, but neither can be very strongly recommended for their beauty.

L. speciosum (lancifolium).—This is a large group comprising about twenty varieties, all more or less distinct, and all flowering in the autumn, while all previously mentioned are summer flowering. I cannot attempt to describe them, but would refer anyone interested in autumn-flowering Lilies to peruse a catalogue of any good grower of this class of plants. If I were to make a selection of say six of the best I would select *Kratzeri*, *punctatum*, *Melpomene*, *multiflorum*, *rubrum verum*, or *purpureum*. There is no difficulty whatever with this group. All are easily grown; they like a good, rich, sandy loam, plenty of room, and to be every divided three or four years.

L. testaceum (excelsum or Isabellinum).—A stately plant, in general appearance claiming a close relationship with *L. candidum*, but having charming apricot-coloured blossoms. This will grow 6 feet high, and prefers a rich, sandy loam and moderately dry.

L. tigrinum and its varieties are autumn bloomers, stately in habit, brilliant in colour, very

profuse blooming, well fitted for terminating the procession of this gorgeous and lovely group. The best are splendens, jucundum, plenum tigrinum, or japonicum.

There are others I might enumerate in this list, but there are now quite sufficient for anyone to select from. They are all hardy, easily grown and increased, and very beautiful when in bloom, and with a little care in planting, selecting suitable positions, &c., there is no reason why every garden should not possess a few of this family. P.

THE CHRYSANTHEMUM AND ITS CULTURE.

The Chrysanthemum is, of all flowers, one of the most effective, and its many good qualities recommend it to cultivators of every grade. It is robust, hardy, easily increased by cuttings and seeds varied in form, colour, and even in fragrance, and it blooms naturally at a season when other flowers are proverbially scarce. So strikingly effective are its blooms, that they are equally well suited for exhibition stands or as cut flowers for the drawing-room, and so also the plant is amenable to severe and formal training into "specimen" shape; or it may be, as we think, more wisely allowed to assume its natural habit of growth, and so become especially well suited for greenhouse and conservatory, or even room and window decoration. During the past year or two especial attention has been paid to the culture and selection of the early summer blooming as also the very late blooming varieties of the Japanese and incurred types, so that now we may count on having Chrysanthemums in bloom from July until nearly the end of February, a period of at least seven months. We have but few other garden flowers so valuable for all purposes, and still fewer that may fairly be called an everybody's plant. It is as well fitted for the cottage garden, for a sunny corner beside the porch, as for the marble-floored conservatory. Every cottager, every artisan may grow it to perfection with but little trouble or expense. Oh! that you men of Lancashire, born gardeners and florists by nature as you are, would but take up the Chrysanthemum in the same earnest spirit as that which prompted you to take up the Auricula, the Onion, and Leek, the big Gooseberry, and the Celery as objects worthy of your cultural devotion and skill. Would that "merry Sherwood" men ("Nottingham lambs" if you like) could be induced to make the Chrysanthemum their winter queen, even as they have long enthroned fair Rosa as their summer one. We look to the artisans of Coventry—the city of art weaving—and to the flower-loving people of Norwich; these are the men into whose hands we would fain trust our favourite. Beautiful as the Chrysanthemum now is, there yet remains open a wide field for improvement. The summer blooming or early flowered section lacks size and form as yet, and vivid colour and fragrance may be still further increased even among the types which now possess these attributes in the highest degree. In some cases grafting weakly rooting kinds upon robust growers as stocks may be practised with advantage, and

The question of seed saving in our own climate is as yet far from being exhausted. Under good treatment the finest of home-saved seed may be produced in a properly constructed house fully exposed to spring and early summer sunshine, and heated with a flue, the latter being preferable in this case to hot-water pipes. Home growers have been too lethargic in the matter of seed saving, and yet no other cultivators could possibly beat them in this field if a beginning be once made on proper and well defined lines. If we once could but induce people to raise seedlings as well as grow beautiful blooms, we should be on a fair road towards enhancing colour and probably emphasising that fragrance which a few kinds possess. We must not be too restricted in our ideas as to what are and what are not good kinds. Instead of trying to limit varieties to one or two standards of perfection, our

object should rather be the extending of the boundary lines of variation. All tastes must be consulted. The florist or exhibition grower must have his incurved Anemone, Japanese, and Pompon varieties, but the artist also must have his bits of twisted fringe and glints of colour in tassel and frill of varied kinds. The botanist, too, must have structural peculiarities and forms of floret the most varied and distinct. Even the aesthetes must have their whims gratified with single or Daisy-like blooms, for it is not wise to restrict our admiration to those kinds in which reduplication of florets is the rule, and it is in the direction of single-flowered kinds that we are likely to gain most in vivid colouring, beautiful alike for artistic and decorative uses. I am firmly convinced that if raisers of seedlings will but widen their sympathies, and not throw away their single-flowered seedlings, as they hitherto have done, we shall soon be surprised at the immense variety of type and form and colour which raisers may produce. We have hitherto worked in narrow grooves, and the immense capacity for variation, of which the Chrysanthemum is possessed, has as yet been scarcely dreamed of, even by those of us who are most sanguine. As tending towards the desired increase in that direction, which in this, as in other cases, may become most charming, I most earnestly counsel all growers of the Chrysanthemum to raise a few seedlings every year, even if it be from imported seeds. The raising of seedlings is said to be the "poetry of gardening," and if this be so, then it was never more true than in the case of the popular flower now under notice. But the heyday of all that beauty and variety, of which the Chrysanthemum is by nature and art capable, will, I feel persuaded, only come to us as the result of patience and labour in the growth and culture of the produce of home-saved seeds—the results of our own ideas and desires rather than in the growth of plants from seeds saved abroad, as is now supposed to be best. Another important point as regards seed saving, and one on which too much stress cannot well be laid, is that cross-fertilisation has been but rarely resorted to, too much reliance having hitherto been placed upon inherent tendency towards natural variation.

History of the Chrysanthemum.—Of all flowers that which has been said to represent "cheerfulness under adversity"—the Chrysanthemum, or "Golden Flower" of the Greek—may fairly be called the "queen of autumn," six varieties of which were described by Breynius as being cultivated in Holland two centuries ago. Originally introduced to England from the Celestial Empire in 1764, it seems first to have been cultivated by that celebrated gardener, Miller, of Chelsea, but was soon afterwards lost by some unfortunate accident. Again introduced, this time by way of Marseilles in 1789, it reached London in 1795, and in Curtis's "Botanical Magazine" for 1796 we find a coloured figure of Chrysanthemum sinense (there described under the name of *C. indicum*)* the result of the second advent. Phillips, in his "Flora Historica," published in 1824, tells us that the new plant was sold at a high price soon after its introduction, but that it was not until the beginning of the nineteenth century that it attracted attention as a florist's flower. "Then," says he, "like the Roses of China, Chrysanthemums soon escaped from the conservatories of the curious, and as rapidly spread themselves over every part of the island, filling the windows of the cottagers and the parterres of the opulent with their autumnal beauties, that now vie with the China Aster in variety of colour glory."

Amongst other peculiar modes of culture resorted to by Chinese gardeners in Chrysanthemum culture is the engrafting of cuttings on to a strong-growing species of *Artemisia* (*A. indica*) as a stock.

* The figure in the "Botanical Magazine," vol. x., t. 327, represents a double bloom, with quilled florets of a maroon-purple colour inside, and of a silvery or rose-purple outside. Dr. Sharpe, a modern reflexed variety, very closely resembles this figure in all ways. It is in reality the Chinese Chrysanthemum (*C. sinense*), and not *C. indicum*, which is the type of the Pompon or small-flowered race.

The idea of grafting is suggestive, as some of the more delicate rooting kinds might be best grown by being grafted or inarched upon rooted cuttings or sucker stocks of a robust, strong-rooting character. Some may think this idea impracticable, but I know that Chinese gardeners rarely take any special trouble in plant culture without a sound reason for so doing, and cultivators at home will, I hope, leave "no stone unturned" in this respect. One reason why grafting might be useful is that by its means new sports might in all probability be obtained. Fortune tells us of the beauty of the Chrysanthemum in oriental gardens, and how banks of the gorgeous blooms are illuminated at night with lanterns, and how that even gigantic effigies are made up entirely of their lovely flowers.

Even when the Chinese emigrate to other lands, this their favourite flower is carried with them and affectionately cultivated. Here is an instance of this practice. I once went to see the late Consul Whampoa's garden at Singapore,* the entrance to which is a long bower of the most superb tropical flowers, waving crimson-stemmed Palms, and climbing plants of great beauty. Here the "Sacred Tree of Heaven," *Amherstia nobilis*, bends under the weight of umbrageous leafage and pendent wreaths of the most gorgeous crimson and golden blossoms. Every pool and stream, of which there are many in this garden, are filled with the rarest of Water Lilies and Lotus flowers. After our host had shown us all this—all the tropical treasures of Kew or Glasnevin in the open air and sunshine—he led us triumphantly to a little sheltered spot and showed us, with pleasure beaming from every wrinkle of his smoothly shaven face, not Orchids of curious structure, nor Water Lily of a loveliness divine—neither Palm nor Fern of filmy beauty—nothing more nor less than a bed of Chrysanthemums, the one flower of his heart, reminding him of home and country. That the artists and poets of China and Japan have lavished much of their finest and best thought and labour in representing this flower in all pleasant aspects to the senses is now a matter of history, attested by ceramic wares and textile fabrics of many kinds. The Japanese more especially possess voluminous illustrated works in which the Chrysanthemum, in all its phases of race and colour, is ably portrayed. The Rev. G. Henslow has well described how

The transformations in the corolla are brought about—the two principles of hypertrophy and atrophy both conspiring to effect the remarkable changes. Thus, while the corolla enlarges, to change from a five-toothed minute disk-floret into a broad, flat-petalled ray-floret, two petals are gradually dwarfed and finally disappear; while a corresponding atrophy takes place in the essential organs, for the stamens are totally arrested, and the pistil changes its form, the style-arms becoming much reduced in size. The tubular condition of the corolla may remain while the tube itself elongates without any or much splitting—hence the quilled and tasselled forms are arrived at, both representing a more or less arrested stage in the process of change into ray-florets. The ligulate petal may be broad—which gives rise to the incurved and recurved ball-like forms; or it may be greatly elongated and narrow—whence the Japanese linear-petalled forms; or it may be expanded at the mouth, and the teeth multiplied—which gives the trumpet-like so-called Dragon Chrysanthemum. Lastly, if the disk-florets enlarge, but remain more or less tubular while the ray retains its distinctive character, the Anemone form is secured.

The first Chrysanthemum that ever flowered in England flowered in Colville's nursery, in the King's Road, Chelsea, in 1795, the plant having been obtained originally from M. Cels, the celebrated nurseryman, of Paris. At this time, and for some little time afterwards, botanists had a contest as to its botanical position; some of them

* Mr. Whampoa was a Chinese trader, who early in life left China and settled in Singapore. He rose to affluence, and was a C. M. G.

contended that it was one of the *Camomiles* (*Anthemis*), whilst others declared that it was unmistakably a *Pyrethrum* or *Feverfew*, but at last it was decided that it should be called *Chrysanthemum*, from *chryso*, gold or golden, and *anthos*, a flower. Sabine, who was secretary to the Horticultural Society at the beginning of the present century, says, however, that Chrysanthemums had been grown and flowered in Holland nearly as far back as the year 1688; but, singular to say, in 1821 no gardener in Holland knew anything of them. In 1808 their cultivation had increased to some nine or ten varieties, and it went on increasing, many varieties being collected for the Royal Horticultural Society in China and Bengal in 1821 by Mr. Parks. At the end of 1825 the number of varieties seems to have been increased to 48, and in 1826 Sabine writes most cheerily concerning their rapid progress, and of an astoundingly large exhibition of them being held in the society's garden at Chiswick, in which were shown over 700 plants of them in pots.

The first sport from the original variety was noted in 1882, in which year Mr. Colville, of Chelsea, sent to Chiswick a pale pink variety, which had sprung from a sort called *Changeable Buff*. It is curious to note the names given to some of the varieties about this time. Let one or two be given for curiosity's sake: Early Blush, Park's Small Yellow, Blush Ranunculus, Curled Blush, Tasselled Yellow, Tasselled Lilac, Two Coloured Red, Double White Indian, Yellow Indian, Waratah, Quilled Pink, Pale Purple. These names, which in a sense give the characteristics of some of them, seem to indicate that in what are now called the show varieties, which are largely of the strain of *Chrysanthemum sinense*, there was the same special singularities as are to be seen now, only that now these idiosyncracies are positively classified. We often hear of incurved flowers, and recurved or reflexed flowers, of quilled flowers, of tasselled flowers, and of Anemone flowers, besides the Pompones and Japanese. Well, the incurved flowers are those whose flat florets curve or bend in towards the centre of the bloom; the recurved or reflexed bend backward from the centre (the recurved moderately, the reflexed more so); the quilled has the edges of their florets involute and coherent, so that they look like small pipes or tubes; the tasselled are the loose long and flat petalled flowers not coming under the other definitions; and the Anemone flowers are those kinds having a cushion-like centre of tubular disk-florets, surrounded by a ray of flat or strap-shaped florets of the usual kind.

Origin of the Pompones.—In 1845 the late Mr. Robert Fortune, who was sent to China in 1842 by the Royal Horticultural Society, brought home with him from Chusan (an island on the east coast of China) a semi-double reddish or light brown small Chrysanthemum, which was called the Chusan Daisy. The Horticultural Society propagated it, and sent it out amongst its members. From some of these members it was sent to M. Lebois, a perfect enthusiast in Chrysanthemum growing, in Paris. He seeded it, the autumns of France being more favourable to that operation than the cold foggy ones of England, and from this seed he raised a great many good varieties, which got into the hands of Mr. Salter, late of the Versailles Nurseries, Hammersmith, who in his day did more to popularise Chrysanthemums in England than any other man. Some of the best varieties, not only of Pompones, but of the other larger varieties, were introduced by him. He had a perfect knowledge of what was being done by the French growers, and generally secured their best seedlings. This is the generally received history of the Pompon varieties of Chrysanthemum, though we may infer from some of the names given to them as far back as 1821 and 1825, Park's Small Yellow, Blush Ranunculus, &c., for instance, that there were small varieties grown then; indeed, in the Horticultural Society's Transactions for February, 1821, there are coloured plates of small, many-petalled varieties, though they were not called Pompones until the French got hold of them in 1845—6. In 1846 a

new era commenced in the history of the Chrysanthemum, for at that time Mr. Fortune brought from China two small-flowering varieties, the "Chusan Daisy" just named and "Chinese minimum." Although Mr. Fortune admired them in Chusan, they were considered too small and insignificant for English taste. The French opinion of them was far different, for immediately upon their introduction, in 1847, into the already well-known collection at Versailles, the little "Chusan Daisy" became a favourite. From these two varieties have sprung all the Pompones now in cultivation. The French growers gave them this name, Pompones, from the resemblance of the flower to the tuft or pompon on the soldiers' caps.

Japanese kinds.—These were brought over by Mr. Fortune on a second visit to Japan about the year 1859 or 1860. The precise date is uncertain, but at least one variety was figured in the *Botanical Magazine* as somewhat of a novelty in 1863, so it must be about the time mentioned that they were introduced. The French and Guernsey growers soon got hold of them, and have improved them immensely. They are with some growers greater favourites than either of the other two older varieties. In 1862 Mr. Salter introduced several Japanese varieties, some of which were spotted and striped; others were of fantastic forms called Dragons, and one, *laciniatum*, was a beautifully fringed white flower, and invaluable for bouquets, having the appearance of a Japanese Pink rather than of a Chrysanthemum. One had petals like long thick hairs of a red colour, but tipped with yellow, looking like the fringe of a shawl or curtain; another had broad white petals striped with red, like a Carnation or Camellia, whilst others were remarkable for their great size and brilliant colouring.

Show Chrysanthemums.—In 1850 we find the Chrysanthemum taking rank as a winter exhibition plant at the meetings of the Caledonian Horticultural Society, which at that time held its shows in what is now the Royal Botanical Gardens, Inverleith. Here we are told that "Chrysanthemums were the principal flowers exhibited. The prizes for single clusters of twelve varieties were awarded to Mr. Young, gardener to Mrs. H. N. Ferguson, of Archerfield, who had *Minerva*, *Duc de Nemours*, *General Moreau*, *Salter's Annie*, *Queen of Yellows*, *Princess Maria*, *Clustered Yellow*, *Queen Victoria*, *Comte de Rantzen*, *Bicolor*, *Queen*, and *Marquis*; and to Mr. Mitchell, for *Temple of Solomon*, *Princess Marie*, *Antoinette*, *Celestial*, *Queen*, *Salter's Annie*, and others. For the most dwarf and finest-flowered plants, the prize was awarded to Mr. A. Sleight, gardener to the Lord Advocate, Lauriston Castle, the kinds being *Bicolor*, *Queen*, *Mirabile*, and *David*." I give the extract as it stands from the *Gardener's Magazine of Botany* (1850), as not only are the names of the varieties interesting, but also the custom which then was followed of showing the flowers in single clusters (*i.e.*, all the blossoms as produced on one stem) instead of single blossoms, as now.

British kinds.—So popular are the Chrysanthemums of China and Japan, that one almost forgets that there are other species. "Charity begins at home," and so we must not lose sight of the two Chrysanthemums of our own country commonly known as the Ox-eye Daisy (*C. leucanthemum*) and the Corn Marigold (*C. segetum*). Who can say what the Ox-eye of our meadows would produce in a few years if it were cultivated from seed with a little of that faith and persistence so characteristic of the Chinese gardeners? Even our golden Corn Marigold has been neglected, although in its native state it is one of the brightest and best of all annual Composites. Its Algerian relative (*C. coronarium*) has met a better fate, and we have now many varieties both single and double in our gardens. The same may be said of *C. carinatum*, which is likewise a very beautiful annual, although the Chinese use it as a pot-herb, just as their Japanese cousins eat up the succulent bulbs of *Lilium auratum*, thinking more of their use than of their beauty. *C. arcticum*, *C. speciosum*, *C. lacustre*, and *C. atratum* are all well-known hardy

species, the last named being a mere noble and stately edition of the Ox-eye of our meadows. Of all the late-blooming hardy herbaceous kinds, however, *C. (Pyrethrum) serotinum*, also known as *C. uliginosum*, is one of the most effective, producing its green-eyed stars in October or later, and continuing in beauty until cut down by the early frosts of November. The shrubby *C. frutescens*, better known as the Marguerite or the Paris Daisy, has of late years become almost as great a favourite in English gardens as it has long been in those of the Continent. There are several varieties, *C. tanacetifolium* being one of the best of the white-rayed kinds, and *C. Etoile d'Or*, a seedling from *C. Comte de Chambord*, is the best of the sulphur-rayed varieties. All are beautiful planted out in the open borders in May, or as grown in pots in a sunny greenhouse they bloom throughout the winter months, when their flowers are especially valuable. *C. coronarium*, *C. carinatum*, *C. Burridgeanum*, and other annual species are easily raised from seeds sown in spring like *Mignonette*, *Stocks*, or other hardy annuals. The herbaceous kinds, *C. lacustre* (syn., *C. maximum*), *C. uliginosum*, and others, are best increased by division in the spring or early summer months. *C. frutescens* and other allied 'sub-shrubby' kinds are easily propagated from cuttings. F. W. B.

KILLERTON.

FROM Silverton Station, on the Great Western Railway, to Killerton is about two miles, but the walk is a pleasant one, especially after one crosses the stone bridge which spans the river Clyst, for the road runs between high banks shaded by trees, Ferns being abundant on the banks, the Hart's-tongue predominating. Killerton is especially celebrated for its grand old trees, and their grouping has been done with rare taste and skill. There are no sharp, hard lines anywhere. The whole place is an illustration of the way in which art can help or mend Nature. Intending planters might learn useful lessons in bold grouping by studying the planting here. Much of it was done or altered by the late Sir Thomas Acland, in combination with the late Mr. Veitch, of Exeter. The soil is very fertile, overlying a stratum of rock called honeycomb rock, which is of volcanic origin. In many places the rock is deeply covered; in others it crops up near the surface, but in such cases it cracks into fissures, and the roots of the trees penetrate to a great depth. A curious instance of this was pointed out to me on the Beech Mount, in the deer park. Here a shifting of the surface on the edge of a ravine showed the fissures in the rock as if upheaved by a subterranean force; the roots of the trees had gone down, and from their luxuriant development they were evidently enjoying the feeding ground provided for them below. In the grounds surrounding the private chapel, built by the late Sir Thomas in 1841 with stones dug on the spot, are many handsome trees. Several of the common Larch are very fine. One I measured was 12 feet in circumference at 3 feet from the ground, and had an altitude of not less than 130 feet. Here also were several handsome Cedars of Lebanon, transplanted some years ago when they were more than 40 feet high. They are now about 65 feet, and suffered but little check from their removal, having been heavily mulched as soon as the work was done. Near here is a very fine scarlet Oak, and a short distance away in an opening stands a handsome specimen of the Lucombe Oak girthing 17 feet 6 inches. In and around the open glade in front of the chapel are many fine trees, although some of them are comparatively youthful specimens. For instance, here is a Spanish Chestnut planted by the late Mr. Veitch seventy-two years ago which girths 13 feet at 5 feet from the ground. The upright Cypress, *C. sempervirens*, and *C. torulosa* are in duplicate 50 feet high; and near the chapel-yard is a hedge of *Berberis asiatica*, and another of common Box. These I notice just to say how elegant they look growing in a free and open manner, without shearing, the only attention given being to nip off long ends with the knife

once a year or so. Standing in front of the mansion and looking southwards across the park, the views are very fine, extending for many miles.

The park is of considerable extent and well timbered; handsome specimens of English Elm abound. To the left of the mansion, and some 300 yards or 400 yards away from it, is a group consisting of the finest specimens of evergreen Oak in the country. One of the largest measures 13 feet round the trunk, and has a spread of branches of 81 feet, and scattered about in this part of the park are many handsome Thorns. A small formal flower garden fills a sort of recess on the east side of the house, and this is the only bit of really formal gardening I saw at Killerton. But the handsome trees and their picturesque grouping are worth going a journey of many miles to see. The mansion is a square building, suggestive of comfort rather than architectural beauty. In a glass colonnade is the usual assortment of flowering plants adapted to such structures; also such plants as *Bougainvillea glabra*, *Acacia Riccaua*, *Luculia Pinceana*, *Heliotropes*, and *Abutilon*. *Boule de Neige*, trained on the wall and roof. The latter plant makes an excellent climber, its white flowers being so useful, and produced most abundantly and continuously when planted in a light position. The walls of the mansion are clothed with climbing plants, among which are *Magnolias* and the *Judas tree*, which reaches up to the roof; *Chimonanthus fragrans*, *Banksian* *Roses*, *Akebia quinata* (quite hardy and flowering freely); and last, but not least, there is the old pink monthly Rose. In the flower garden are a pair of nice plants of the hardy Palm, *Chamaerops Fortunei*, and to the west of the mansion and only a few yards from it standing on the open lawn is one of the finest Tulip trees in the country. It measures 17 feet round the bole 5 feet from the ground, and must be at least 100 feet high, and of handsome proportions. There are several acres of dressed ground on the west side of the mansion. Its surface rises upwards like an amphitheatre, and it is embellished with trees and shrubs of the most varied and interesting character. Handsome groups of trees, wide stretches of closely shaven velvet turf, deep glades running far back up the hillside with an unseen, unknown termination, are evidences of taste on the part of a bygone generation. Away far back, many feet above our standpoint is a large, bold group of common Beech, which thrives amazingly here, intermixed with the wild Cherry, which also forms a timber tree, and must be especially ornamental when in flower in spring amid the delicate tints of unfolding foliage. In front of the deciduous trees are masses equally bold of *Wellingtonias*, *Taxodiums*, *Cupressus Lawsoniana* and *C. macrocarpa*, with the funeral Cypress jutting out into the foreground, and variegated Hollies and lighter tinted low-growing shrubs in front. *Rhododendrons* also abound, as do many other flowering and evergreen shrubs, which lack of space compels me to pass over. In a secluded spot with an open space of turf in front is the conservatory, chiefly filled with handsome specimen Camellias, some being as much as 15 feet high and well furnished. East of the conservatory is a small enclosed garden devoted to hardy herbaceous plants called Miss Acland's garden, and a most interesting spot it is. As we ascend the hillside we come upon a handsome specimen of *Thujaopsis dolabrata*, the best furnished example I have yet seen; it is 17 feet high and of proportionate diameter. Then we come upon a Scotch Fir with a straight and massive trunk 33 feet to the first branch, though the branches are drooping to the ground. The bole is 12 feet in circumference and as straight as an arrow; next a *Picea cephalonica* in cone, a handsome specimen. But the grandest feature in this part of the grounds is the group of *Cedrus atlantica*, at least 90 feet high, furnished down to the ground, and showing the beautiful silver tint for which this Cedar, when well grown, is remarkable. *Pinus insignis*, many years old, was green as a young plant, and a fine *Araucaria*, 54 feet in height, healthier and better coloured than usual, feeling the benefit of the warm sea air.

One of the features of the grounds at Killerton, and a very pleasing one it is, is the mixed groups of climbing Roses, Honeysuckles, Thorns, and other shrubs which mingle in a wild, graceful manner. The outlook from a rustic summer-house, which occupies a retired spot on the side of the hill, is a most delightful one. Dartmoor, some 25 miles away, is distinctly visible, looming up dark and drear. To the left is the break in the chain of hills called Sidmouth Gap, through which the sea is visible. Westward are the wood-crowned Woodbury Hills and Woodbury Castle, whilst we have a foreground that cannot be surpassed in the tastefully-planted park. We leave the dressed grounds, and ascend higher up the hill, and come upon a rockery formed principally from the natural rock, and wild and bold with steep banks and ravines planted with Bamboos, Azaleas, Ferns, and other appropriate plants. Far up 40 feet above is also a large natural self-sown bed of the Evening Primrose (*Oenothera biennis*), which here seeds and grows abundantly, giving a bright and pleasant character to the place. Foxgloves might be added to keep them company with advantage. Further on we emerge upon an open space where there is a rustic seat, in front of which is a monument erected to the memory of the late Sir Thomas Acland by a few of his friends. It is in the shape of a Maltese cross, and occupies a pleasant site amid leafy glades, and commanding a charming view up the Exe valley. The Fern glen is an exceedingly pretty and interesting spot. It is a ravine or deep glen, shaded by trees and spanned by a rustic bridge, and is full of very fine specimens of hardy Ferns. We pass onwards through a Beech avenue noting some extremely fine Chestnuts and a group of *Cupressus Goeniana*, and grand examples of *Taxodium* and *Cryptomeria japonica*, through a wilderness of natural beauty called the Druids, where we find a plant of *Rhododendron Blandfordianum* 10 feet high, one of *R. Thomsoni* 10 feet high and as much through. We pass up through the Beech wood which crowns the summit of the hill, taking note of the fine herd of deer in the park below, through the Deodar glen which contains a handsome healthy lot of trees, the undergrowth consisting of *Rhododendrons*. We turn to the left across a wide, open, breezy hill covered with Bracken with Thorns planted thinly among it from which the views are magnificent. The shades of evening were descending as we entered the kitchen garden, but enough light remained to show that there was an abundance of fruit and vegetables. The pyramid Pears were especially well managed and full of fruit. The walls also were well furnished with healthy trees. The Vines, both the Muscats and others, were producing plenty of fine Grapes, and several other ranges of glass were occupied with healthy collections of Orchids, Ferns, and flowering plants. Mr. Garland grows all his Potatoes and coarser vegetables in the open field, and I saw two acres planted with Regents and Champions looking at the time of my visit remarkably well, and in an adjoining field another acre planted with Onions, Carrots, &c. The Potatoes are planted 3 feet apart in the rows, and never earthened up. Turnips (Orange Jelly and Red Globe) being sown between the rows for autumn and winter use. This system of growing the main crop of roots, Cabbages, &c., in the open field, and leaving the enclosed, sheltered garden for the early crops and things that are benefited by shelter, or which, such as Celery, require to be near the water supply, is a step in the right direction. E. HORDAY.

their silky appearance and extreme whiteness?—J. H. W. T. [They are bleached, we believe, by means of chloride of lime.]

FIRES IN MANSIONS.

THE directors of the Law Fire Insurance Society, viewing the severe fires which have lately occurred in mansions and private houses, request the attention of their customers to what appear to be the most frequent causes of these fires: Timber built into or near fireplaces and flues. Hot-air apparatus of every description. Stoves introduced into rooms previously unprovided with them without professional advice. Workmen allowed to carry out repairs and alterations without proper superintendence; fires being lit without fenders or guards, and candles used without candlesticks. Plumbers lighting fires upon the roof to melt their lead have caused the destruction of many noble mansions. Fires lit in grates not previously used, or disused for a long period, the flues not having been first examined. Chimneys not being

the inmates of mansions, and, indeed, of all dwelling-houses, that in case of fire each person should immediately run for water, and continue to fetch it by any means, so long as there is hope of arresting the flames; but at the same time all doors and windows must be closely shut. When water is not available a fire may be extinguished with rugs, carpets, blankets, or other such materials. When all hope of stopping the fire is at an end, excluding the air must be relied on. A fire may thus be confined to one room, giving time for the arrival of the engines.—*Architect.*

INDOOR GARDEN.

PELARGONIUM COMTESSE DE TANNBERG.

A DECIDED break among the now very numerous varieties of zonal Pelargonium has lately been made on the Continent. The accompanying woodcut admirably shows one of the varieties of this new type now in flower in Messrs. Cannell's nursery at Swanley. It is said never to exceed 6

Pelargonium Comtesse de Tannberg.

thoroughly swept. This should be done at fixed periods, and especially before the return of the family after a long absence. Gas within the house; danger may be avoided if the service pipes are provided with taps, so that the gas may be turned off at night by some person specially appointed to that duty from those rooms where it is known to be not required. Mineral oil lamps are a fertile cause of fire, and demand the greatest caution in their use. Such lamps should have a heavy flat base to prevent their being easily upset. The oil should always be stored outside the dwelling-house. Lucifer matches have caused immense loss of property and of life. Lying about the house they are trodden upon, and by this and other means they are ignited. Only matches which can be ignited by friction upon the box should be permitted. Clothes hanging before the fire. Overheated flues. Wood left on the kitchen range to dry for lighting fires in the morning. Reading in bed. These and similar acts of carelessness and causes of mischief can only be guarded against by an inspection of the house by a trustworthy person after the family have retired to rest. It is necessary to give immediate notice of the intention to introduce these or similar additional risks. The fire office will then give advice as to the precautions required to avert danger. It cannot be too strongly impressed upon

inches or 7 inches in height. It is compact and vigorous in growth, and produces an abundance of flower-spikes, terminated by large, dense clusters of semi-double flowers which just overtop the foliage. The colour of the flowers is a mottled salmon-pink, shaded with soft purple. It is a seedling from the variety *Souvenir de Carpeaux*. Another variety of this new class is also in bloom at Messrs. Cannell's nursery. It is named *Princess Stephanie*, and resembles the preceding in habit of growth, but the colour is a beautiful lilac-pink. It is, like the other, extremely floriferous, and bears very large heads of flowers. This section, as we before remarked, forms quite a new feature, and no doubt it will be "worked" upon largely in order to obtain numerous varieties and a diversity of colours. A third variety of a similar stamp is *Archduke Rudolph*, but not being in flower at the time of our visit we cannot describe it. Among other new Pelargoniums we took note of at the Swanley Nursery there were two just received from the Continent bearing the largest flowers we had ever seen on a zonal Pelargonium. One called *Aurore Boreale* had flowers fully 2½ inches across borne in a huge truss, and of a bright cherry-crimson colour. The other, named *Gloire Lyonnaise*, had similarly large flowers, but of a darker shade. In these varieties the characteristics of the Ivy-leaved section

Pampas Grass plumes.—Kindly tell me if the beautiful white plumes of Pampas Grass now to be seen in the fruiterers' and flower shops are artificially bleached, and if so, how they are done. At a fruiterer's here (Hastings) they told me the plumes came from Canada; and as they are, of course, grown there under glass (one ordinary winter in the open would be fatal to them), would this protection alone account for

is traceable, and it is very apparent in the foliage. We shall no doubt hear more of these fine sorts during the coming season. Konigin Olga von Wurtemberg, F. Kauffer, Masterpiece, Kate Greenaway, and a host of other beautiful new Pelargoniums may likewise be seen in the Swanley Nursery.

FINE FOLIAGED PLANTS FROM SEED.

WHERE sub-tropical gardening is largely carried out, it is a great advantage to utilise as far as possible plants that can be readily raised from seed, for although many beautiful plants used for such purposes are of a permanent character, and others are increased by cuttings, there yet remains a large class that can easily be increased by means of seeds. Sow in heat in January, so as to allow time to get up really fine plants by the end of May, as if deferred until March there is not sufficient time to get them properly established in good sized pots, and above all gradually hardened off in cool houses preparatory to planting in the open air. Carefully prepared plants soon grow on and form effective beds or groups, while late sown ones hurried up to the required size languish or make but little progress until the summer is too far advanced for them to have much effect. I would, therefore, advise immediate sowing of the following valuable aids, not only to those who have a good stock of Palms, New Zealand Flaxes, Tree Ferns, &c., to form their most striking effects, but also in the case of those whose limited amount of glass structures render it impossible for them to winter many of the most suitable plants under glass, and who must of necessity rely on plants that can be increased by means of seeds. After trying most of the varieties in cultivation, I can strongly recommend the following as sure to give satisfaction:—

Acacia lophantha.—Seeds of this if sown at once in pots or pans of light soil and placed in a temperature of from 60° to 70° will germinate quickly; pot the young plants off singly in 3-inch pots, and after they are well rooted transfer them to 6-inch pots, keeping them on shelves near the glass, to insure a sturdy, well developed habit of growth; thus treated, they will be graceful, thrifty plants by the 1st of May, when they should be placed in cool quarters, such as pits that have been cleared of hardier plants, and if exposed as much as possible to sun and air on all favourable occasions, will by the end of the month be fit to take their place in the flower garden, where, if planted thinly so that each plant stands out singly on a ground-work of dwarf carpeting plants, they will hold their own in point of effect with many far more costly subjects.

Acanthus latifolius and **A. mollis** are indispensable in what are called foliage gardens, and, if treated as above described, make excellent material for purposes of decoration, and not the least of their many good qualities is the fact that they may be lifted and potted when the beauty of the summer garden begins to wane, and will be found equally useful for indoor decoration in winter, their deep green and elegantly formed leaves having a fine effect in large vases under artificial light.

Beet—Chilian or Brazilian—forms a very effective edging plant for large beds, the midribs of the leaves being brilliantly coloured in many various shades, from creamy white to crimson. If the seed is sown in pans or boxes in heat, and gradually hardened off in a cool house or frame, the young plants may be planted out in April so as to get well advanced in growth before subjects of a more tender character can be safely trusted out of doors. In their earlier stages of growth they are not very effective, but as they attain full dimensions of leaf growth, the midribs assume very beautiful shades of colour, and as edgings to plants of stately habit of growth they are very valuable.

Cannas in great variety are readily increased by seed, called Indian Shot, from the fact of its being round like large shot and very hard. If

kept for any length of time, so as to become very dry, it takes a long time to germinate. I find soaking it for a couple of days before sowing a great help, or if the hard skin is slightly cut with a sharp file it has the same effect; otherwise the seeds, although perfectly sound, may lie dormant for months. If the young plants are potted off singly and grown on in a stove temperature, gradually inuring them to open air treatment in May, good sized plants may be had the first season, but they will not attain the dimensions of those from older roots. It is, therefore, advisable to either lift and preserve the roots, or protect them by external coverings in the open ground.

Centaureas, such as *candidissima*, *Clementi*, and *gymnocarpa*, with their beautiful silvery foliage, are readily increased by seed. If sown in January they make good edging plants by May, and, being of a half-hardy character, may be planted early. They form most effective contrasts with *Coleus* or *Amarantus melancholicus*. *Chamæpuce Cassabonæ* and *C. diacantha* are very beautiful Thistle-like plants with spiny foliage. If treated like the preceding as regards sowing and general routine of culture they will be found most effective as central or dot plants in carpet beds, or as edgings to fine foliage plants of a more robust habit of growth. *Cineraria maritima* is another excellent silvery-leaved plant which requires the same treatment as the *Centaureas*.

Echeveria metallica and *E. m. glauca* so useful for edgings, are readily increased from seed. Care in sowing is required, the seeds being very minute. The best plan is to press the soil very firm, and cover it slightly with silver sand; then spread the seeds evenly on it, water with a very fine rose, and cover the mouth of the pots or pans with a sheet of glass to prevent too rapid evaporation until the seeds germinate, when air must be given.

Eucalyptus globulus, the Blue Gum tree, is very effective as a fine-foliaged plant, the bluish grey tint being quite unique. It is a plant of very rapid growth; seeds of it sown in January will produce good plants by the end of May. The young plants naturally run up tall and erect, and are, therefore, well suited for planting at wide intervals in large beds with an undergrowth of plants of more spreading habit.

Ferdinanda eminens is a very fine plant, and one well suited for planting in groups or as single specimens. If sown at once good plants of it may be had by the first week in June.

Melianthus major has handsome leaves of silvery hue, and produces a good effect either as single specimens in a large state or as an undergrowth to tall plants in its young state. If sown early good plants of it for the latter purpose will be produced by the end of May, and if planted in pots the work of lifting them in autumn will be more safely performed.

Ferula communis and *F. gigantea* produce very elegant deep green foliage, and if sown at once and treated as above make very handsome plants. These are very difficult plants to propagate otherwise than by seeds.

Castor-oils treated as annuals are amongst the finest plants that can be grown. The seed is large, like Beans, and should be sown in pots in light, sandy soil in a brisk heat. As soon as large enough to handle the young plants should be potted off singly into 3-inch pots, from which they may be transferred to 5-inch ones in March and to 8-inch ones in April, so as to have large plants by the end of May. If planted in rich deep soil they will attain a height of from 10 feet to 12 feet in one season, with leaves measuring nearly a yard across. There are many fine varieties, and especially useful is the one called *Ricinus Gibsoni*. It has deep bronzy foliage, is of medium growth, and excellent for forming edgings to the larger kinds.

Solanums of the ornamental foliaged kinds are very effective. Sow them at once, and pot off as required. They mostly have large spiny foliage, of various shades of colour. They are of easy culture; the best I have proved to be *S. giganteum*,

S. laciniatum, *S. macrocarpum*, *S. marginatum*, *S. robustum*, and *S. Warscewiczii*.

Wigandia caracasana and *W. urens* are noble foliaged plants of a spiny, stinging character. If sown and treated as the above they form very fine subjects for beds or groups.

Zea japonica variegata, *Z. Cuzco*, and *Z. Cuzko*, ornamental varieties of Maize or Indian Corn, are very effective in the flower garden. Being of rapid growth, they need not be sown so early as the preceding, the end of February being a good time to sow them, and also that elegant plant, *Cannabis gigantea*, or Giant Hemp, that runs up to a great height, and forms a good background for borders; the foliage is excellent. The main point

To ensure success with the above is, as I have said, early sowing, attention to successional repotting or shifting into larger pots before the roots get pot-bound, and gradual hardening off, or inuring to the outer air when removed from heated structures. A cool orchard house, with plenty of space in which to develop themselves without crowding is the only way to ensure success with plants that need to be large enough to make an immediate effect when transferred to the flower garden; and with a good stock of the above the work of furnishing the sub-tropical garden will be rendered comparatively easy without drawing too heavily on the stock of plants of a more permanent character. JAMES GROOM.

Seafeld, Gosport.

SELECT CHRYSANTHEMUMS.

HAVING lately written out a catalogue of autumn flowering Chrysanthemums, the names of which I have selected from the trade lists of three of the principal growers of this now fashionable flower, I find myself in a difficulty as to how to make a selection of the best of them. I find that there are six hundred and sixty-eight varieties, most of which have some special quality to recommend them. Now, I am afraid many of them are very inferior, and as I can only grow about a hundred and fifty at the most, I should be glad—as doubtless would many more of your readers—of some assistance in this matter. What I wish to propose is this: Will some of your Chrysanthemum-growing readers give us the names of those they think best worth growing? By doing this, and comparing notes, we may get a kind of election of the best kinds independently of trade lists. I shall be glad to send the names of those I like best. The names of four sorts which I have finely in blossom now are Baron de Prailly (pink), Regina (yellow), Dr. Masters (bronze), and Meg Merrilies (sulphur white). Of these the first is, I think, the best late Chrysanthemum I ever saw. Meg Merrilies is also a good late kind, though I should not expect very good blooms of it if I stopped the plants till the middle of August, as recommended by a writer in THE GARDEN a few weeks back. Regina I never saw, till this year; it is very late and very dwarf, being only about 18 inches high, with remarkably stout shoots and large foliage. Dr. Masters is a well-known good variety. I have had Chrysanthemums in bloom ever since the last week in September, the first to open being White Travenna. JOHN C. TALLACK.

Prideaux Place, Padstow.

Callicarpa purpurea.—In the Birmingham Botanic Garden there are some very handsome specimens of this old, but rare stove plant. Mr. Latham, recognising its usefulness at a time of year when flowers are scarce, grows a number of plants of it every year. As a stove shrub, which may be grown in a greenhouse during the summer and brought into warmth in the autumn, so that its handsome bright purple berries may be well coloured by winter, it proves itself most valuable. *Callicarpa* means “beautiful fruit,” and certainly the plant is well named, for there are few berries brighter coloured than those of this plant. It grows to a good size in a season, old plants cut back and encouraged to make long

shoots being the most desirable. The berries are produced in clusters in the axils of the hairy, lanceolate leaves, and remain on the plant for a considerable time, retaining their bright colour until the end. A branch well berried is very ornamental associated with flowers. The plant reproduces itself freely from seeds, and it may also be raised from cuttings. Liberal treatment during the growing season seems to be what is necessary for the production of long, well berried, gracefully curved branches.—B.

CLEANING GLASS-HOUSES.

ALL glass-houses should have one thorough clean out at least once a year, and now, or during the early spring months, is the best time to do it. Stoves and greenhouses may be done when the plants are potted, but many fruit-houses are now empty, or at rest, and the cleaning of these should not therefore be delayed. First clean every inch of the woodwork and glass with hot water in which a good quantity of soft soap has been dissolved, and when dry, if the wood is at all bare of paint, one or two coats of white lead should be given. Any part decaying should be removed and made good, as work of this kind can never be done without danger of injuring growing crops. A water-tight roof should be secured under all circumstances. Some paint their houses to preserve the wood only; others do this annually to give them a clean appearance, but in no case should paint be put on unless the wood is thoroughly clean and as dry as possible, or it will not give satisfaction. Stone or brick walls should also be carefully cleaned and lime-washed, the lime being worked well into the crevices, and applied both hot and strong so that it may adhere to the wall and kill all insects with which it may come in contact. All flues should be opened here and there, and every particle of anything that would impede the free circulation of the smoke should be removed, and in mending them up again no small holes must be left to permit the slightest escape of smoke. Surface soil which may contain insects or their eggs should be removed, and new sweet material substituted. It may take a good deal of labour to do all this, but it will not be thrown away as its good effects will be felt and observed throughout the season; everything will work satisfactorily afterwards, and insects will have received a check from which they will not recover for a long time to come. CAMBRIAN.

Boiler setting.—In the case of a saddle boiler which I have had set, the space between the back end of the boiler and the wall is 6 inches, so that instead of the flame striking the boiler, it seems to hit the back wall. What I would like to know is, Is not 3 inches enough space for draught, and, if so, would not a course of brick at the back be the means of stopping the flame and throwing it more on to the boiler?—C. C.

Gutta-percha pads.—Colonel Anstruther Thompson, of the Fife hounds, hunts, according to a contemporary, when the snow is deep on the ground, as it is for long periods in that county. The colonel uses cobs and ponies on these occasions. He takes a sheet of gutta-percha about a quarter of an inch thick, cuts out a set of plates a little larger than the hoof inside the shoe, softens them in hot water, and moulds them inside the shoe over the frog, so that a face of gutta-percha touches the ice and snow, and balling with snow is impossible. These plates remain until the end of the hard weather; and the colonel has had famous runs. This excellent method may be adopted by gardeners instead of the cumbrous and costly lawn boots used for horses and ponies when mowing or rolling. A set of boots cost from 20s. to 30s. They are constantly out of repair, and are objectionable because of over-heating which they cause to the hoof. Holes may be pierced in the uppers for ventilation, but this is only a partial remedy for the evil. Gutta-percha pads will be found equally effective in preventing marks on either the lawn or walks; they are easily

adjusted, more comfortable to wear, and much more economical.—T. C. W.

ECONOMIC AND MEDICINAL PLANTS

Cultivated under glass in the Royal Gardens, Kew.

Abrus precatorius, L., Crabs' Eyes; India.
Acacia arabica, Willd., Gum Arabic; Arabia, &c.
Catechu, Willd., Catechu; India.
Farnesiana, Willd., Cassie; W. Indies.
Achras Sapota, L., Sapodilla Plum; Trop. America.
Adansonia digitata, L., Baobab; W. Africa.
Adenanthera pavonina, L., Barricari Seeds; India.
Egle Marmelos, Corr., Bael of India; E. Indies.
Agave americana, L., American Aloe; Trop. America.
Aleurites triloba, Forst., Candle Nut; Polynesia.
Alcaecia indica, Schott., "Taro"; India.
Aloe ferox, Mill., Cape Aloes; Cape.
succotrina, Cape Aloes; Lam.; Cape.
Perryi, Baker, Socotra Aloes; Socotra.
vulgaris, Lam., Barbadoes Aloes; Medit. and Trop. Asia.
Alpinia officinarum, Hance., Galangal; China.
Alstonia scholaris, R. Br., Dita Bark; E. Indies.
Amomum masticatum, Thunb., Ceylon.
Melegueta, Roxb., Grains of Paradise; Trop. Africa.
Anacardium occidentale, L., Cashew Nut; India.
Anamirta paniculata, Colebr., Cocculus indicus; India.
Andira inermis, Kth., Bastard Cabbage Bark; Trop. America and Africa.
Andropogon citratus, D. C., Indian Lemon Grass.
Nardus, L., Citronella; India.
muricatus, Retz., Cuscuta; India.
Schoenanthus, L., Rnsa Oil; India.
Anona cherimolia, Mill., Cherimoyer; Bolivia, Peru.
muricata, L., Sourp; Trop. America.
palustris, L., Alligator Apple; Trop. America.
reticulata, L., Custard Apple; Tropics, cult.
Antiaris saccharina, Dalz., Sack Tree; India.
toxicaria, Lesch., Upas tree; Java.

New Garden Report.

every case. I cut the bark of the tree in the shape of a V, raised the tongue of bark, and put the seed underneath. This I did both upon Apple and Mountain Ash. I did not tie down the cut bark, and I found that it curled up.—J. McD.

SEASONABLE WORK.

FLORAL DECORATIONS.

An effective arrangement may be made with the following subjects to be had now, selecting as the receptacle for them a moderate-sized trumpet vase. Cut three or more of the showy heads of Poinsettia and five or six spikes of Calanthe vestita rosea; intersperse freely with the former fronds of Maiden-hair Fern; then let the spikes of the Calanthe be inserted sufficiently long in the stem to stand well above the showy bracts of the Poinsettia. To an arrangement of this kind we once added a few blooms of a bright scarlet seedling perpetual Carnation, and perchance a single one (even these are not to be despised), and one bloom only of the Amazonian Lily, and a pleasing change for the dull days of winter was the result. Neither the Poinsettia nor the Calanthe would have lasted much longer on the plants; therefore advantage was taken to make the most of them. For another rather small vase of the same form we selected developed trusses of Early Roman and Paper-white Narcissi, and three or four spikes of the white Roman Hyacinth, each with their own foliage, taking care to have a good length of stem, so that when arranged they should not look crowded. This gave another distinct grouping. In a somewhat shallow vase or bowl a few trusses of the single forms of Chinese Primrose will look well, using two or three distinct colours and their own foliage. A vernal tinge to this may be given if desired by adding a few Snowdrops or Violets. In my opinion the single forms of Primula sinensis are far better and more effective in a cut state than the double ones. The latter, however, may perhaps be a trifle more durable, which in packing flowers to send a distance is certainly a consideration. For specimen glasses for the dinner-table Camellias will now be extremely useful. We generally contrive to cut these with sufficient stem to hold them safely in the glass. In this way they last a good time. Sometimes they are disposed to drop from the stem; when this is the case a little gum arabic in solution will hold them together. This is preferable to wire, which soon leaves a deposit on the glass. When from any cause glass vases happen to become discoloured or furred, a weak solution of hydrochloric acid will easily remove the stain, a better plan than undue rubbing, thereby endangering the glass.

FLOWER GARDEN.

Abutilons.—Amongst these the best bedders are Duc de Malakoff, which has very large flowers, in colour like those of the old striatum; Boule de Neige, white; Lemoine, sulphur-yellow; and the variegated kinds Darwini variegatum and Thomsoni variegatum. The two last are effective as "dot" plants in large masses of Pelargoniums or dark-leaved plants used for the sake of their foliage, and they are almost equally well suited for massing by themselves, but still better for planting thinly over entire beds, and using either Violas, Verbena venosa, or Verbena Purple King in the interstices, the whole forming one of the finest "shot-silk" bed arrangements that can be conceived. The preceding kinds are the most effective when used singly either as centres or equi-distant over large beds of naturally dumphy-growing bedding plants. All the kinds are best propagated in autumn; they strike readily in a frame if afforded a bottom heat of 65°. As soon as struck they should be taken out and wintered in store pots in a cool house or pit, and at the beginning of February be potted of singly in good loam, and be grown on sturdily till planting out time at the end of May or early in June.

Shrubberies.—We are now at work among these, cleaning out all leaves that would be likely to blow out and cause untidiness; where possible

Mistletoe.—I would be very glad if any of your readers would record in THE GARDEN their experience in regard to Mistletoe growing. Last March I tried a good many berries, but failed in

without injuring the roots, preference is given to forking them in, but before doing this the plants are regulated as to space, either by thinning out and replanting them in other positions, or else by cutting out straggling growths, so as to keep each plant from injuring its neighbour. The margins of turf are then cut, and any vacant ground in front furnished either with hardy bulbs or spring flowering plants, such as Wallflowers, Forget-me-nots, Polyanthus, Primroses, and similar plants. In forming new beds for shrub planting the ground should be trenched as deeply as the nature of the soil will allow; plenty of decayed manure should be worked into it, and for those beds that are intended for what are generally termed American plants, *i.e.*, Azaleas, Rhododendrons, Kalmias, &c., peat soil is desirable, but by no means essential, as they do almost equally well in pure loam, provided it is not too heavy and is free from chalk, which seems to be rank poison to American shrubs and Conifers, and their growth should never be attempted in soil of this character. See that the plants are not buried deeper than they were previous to removal, and also that the soil is well worked in and consolidated about the roots. These precautions may seem of little moment, but they make all the difference between the bad or well-doing of the plants.

General work.—High keeping is certainly most desirable at this dull season of the year; therefore lawns should be kept clear of leaves and worm-casts by frequent rolling and sweeping; walks should be cleared of Moss and weeds by turning, and, where necessary, regravelling. The best of all walk preservers is the roller; when this is used freely, weeds and Moss have a hard time of it, and firm walks are the result. In the event of frosty weather setting in, plenty of work may be found in carting out soils and manures to spots where they are required, throwing together leaf heaps, and burning up prunings or other rubbish, the ashes of which form a valuable manure for any crop.

FRUIT.

Orchard house.—If the roots of the early trees were in a satisfactory condition when forcing was commenced, the blossom-buds will now be swelling fast, and the earliest kinds will be ready to expand. When this stage has been attained fumigate the house to destroy any green-fly which the gentle warmth may have brought into existence, otherwise it will prove extremely troublesome, and do serious mischief to the crop before the later kinds have set their fruit. Pay particular attention to watering and syringing with tepid water until the blossoms begin to expand, and avoid wetting the trees during the time they are in flower, but on no account allow the roots to suffer from want of water. Allow the temperature to range from 50° to 55° on mild nights, with a little air, to 60° or 65° on fine days, with an increased circulation, and impregnate the flowers with a camel's-hair pencil about noon when the house has reached the maximum and the atmosphere is dry.

Later houses.—Where the trees have been removed to the open air to make room for other subjects, preparations must now be made for replacing them under glass, as, owing to the mildness of the season, the buds on many of the Peaches, Plums, and Cherries are now getting forward, and unless they are protected with nets or carefully watched small birds in wooded districts will soon destroy the most prominent and of course the most valuable flowers. If cleansing and painting has been delayed, get it done at once; examine each tree as it is drawn out of the plunging material, wash the shoots with strong soapy water to free them from scale, scrub the pots, and see that the drainage is satisfactory. If space is limited Pears may be left out till next month. In the final arrangement of the trees, Peaches, Nectarines, and Figs should occupy the warmest part of the house, Plums, Cherries, and Pears the coldest; but choice kinds of the latter will be im-

proved by removal to a warm, airy situation when the fruit is swelling and ripening. If pot Strawberries are grown in orchard houses, they should be placed on shelves near the glass, where they can be well syringed and have the full benefit of light and solar heat.

Cherries.—Where only one house is devoted to Cherries the end of the old year or the beginning of January is a good time to begin forcing, if forcing it can be called, as owing to the excitable nature of the trees, the great art of growing house Cherries successfully consists in the maintenance of a low temperature, ranging a few degrees higher than the external air when the weather is temperate, and as low as 40° at night when very severe. Like all stone fruit trees which are liable to be affected by aphids, cleanliness is very important, and no trouble should be spared in preparing for a good start. When this has been done, soft-wooded plants like Geraniums, Cinerarias, or other subjects liable to carry green-fly should be excluded, and the everlasting pot Strawberry should be dipped in a strong insecticide before it is allowed to have a place. Assuming that the borders are inside, see that they are well mulched with manure and watered with water at a temperature of 70° to 80°. Syringe daily, warm the pipes every morning with air, ventilate freely at 55°, and shut off fire-heat when the house is closed on mild afternoons. Early houses started at the end of November will be getting well advanced, and the blossoms on some of the trees will soon be open. When this charming picture begins to unfold, syringing must be discontinued, otherwise the petals of the flowers will damp before the fruit is properly set. Keep up a circulation of air unless the weather becomes very severe. Let the temperature range from 45° at night to 56° by day when fire-heat is needed, and a few degrees higher under gleams of sunshine. Fumigate before the blossoms open, and fertilise with a brush when the pollen becomes free.

Melons.—Where early Melons are required and a light, efficiently heated pit is at command, a few seeds of some free-bearing early kind may be sown at once in small pots and plunged in a bottom heat of 80°, which can be kept up by the aid of hot-water pipes running beneath the bed. The great drawback to Melons at this early season is want of light, a difficulty which may be met by keeping the young plants close to the glass, which must be clean, and by covering with bell-glasses in preference to mats on severe nights. Immediately after the seeds are sown, set about the preparation of suitable materials for making up the plunging bed in which the plants are to grow and ripen their fruit. For this purpose well-worked tan gives least trouble, but in wooded districts sound Oak leaves produce better results, as the moist heat from decaying vegetable matter is more favourable to a clean healthy growth of vine and foliage. Another important item in successful Melon culture is a good supply of strong loam from an old pasture, which should be cut some months before it is wanted for use, and tacked in an open, airy shed or in long narrow ridges out-of-doors, with some kind of covering for throwing off heavy rain and snow. If this is not at hand, lose no time in securing enough for the season, and expose it to the atmosphere, as wet crude soil is sure to lead to disappointment if not to complete failure.

Pines.—With the exception of plants which are swelling off fruit, and the early batch of Queens recently plunged in strong bottom-heat, the general stock of Pines may be kept very quiet until the end of the month, when with increasing length of days and brighter weather they will soon start into vigorous growth, and make better plants than if kept in a state of excitement through the dead months of December and January. Queens, Rothschilds, and Cayennes rest and winter well in a bottom-heat of 70° to 75°; but in the event of the old material in which the Queens are plunged sinking much below the above figures, it will be advisable to open the valves for a short time, and water the bed with hot water at a temperature of 90°, care being

taken that it does not pass over the sides of the pots to excite a portion of the roots before the proper time arrives for starting them into fruit. Keep a close watch upon plants now about starting and increase the supply of stimulating liquid to the roots as soon as the fruits can be seen, also atmospheric moisture by damping all available spaces between and around the plants, but avoid wetting the fruit till well above the foliage and the flowering period is over.

Successions.—Examine these once a week, and see that the plants in small pots, placed in near proximity to the bottom-heat pipes, do not want for water. Where this danger does not exist but little water will be needed for the present. Give a little air on fine days to prevent the plants from becoming drawn, and cover up at night to economise fire-heat. Prepare crocks, pots, and soil for use next month. If the latter, good turfy loam, is not in suitable condition, break it up with the hand and expose it to the atmosphere, where it will become dry and warm before the time arrives for potting.

INDOOR PLANTS.

Forced hardy shrubs.—There is much difference in the result which follows the forcing of hardy shrubs consequent on the more or less matured condition of the preceding season's growth, and in this a good deal depends on the soil and position in which the plants to be forced have been grown. Where much of this kind of stock is required it is well to select a place wherein to grow them that is best calculated to insure the requisite conditions, and if the natural soil is not of a character such as to suit them, it should be prepared. Heavy tenacious land, where the roots of plants grown in it are usually deficient in quantity, and of a long straggling description, is not well adapted for the preparation of shrubs for this purpose, as they take up badly; whereas if the soil is moderately light and free, most of the roots can be preserved, and in addition the plants in soil of this character are generally much more compact and better furnished with bloom-buds. In most gardens suitable material for the purpose can be found in the old potting soil ordinarily consisting of a mixture of loam, peat, and vegetable mould with sufficient sand, and if an open position facing the south exposed to the full sun is available, a stock of such things as Viburnums, Azalea mollis, A. anæna, double-flowered Plums, Lilacs, Deutzias, Andromedas, Laurustinus, Rhododendrons, and Kalmia latifolia may be grown. In parts of the kingdom where this last-named shrub flowers it is one of the most beautiful of all hardy plants. Where a sufficiently large piece of ground devoted to this purpose exists, so that the plants can be prepared by frequent transplanting, the effect of which is to induce a close, compact habit with a disposition to form plenty of bloom, it will be found a great assistance in providing the means for a continuous supply of forced flowers through the winter and spring. There is no better time of the year than the present for the formation and planting of a reserve plot of this description, and to no better purpose can the annual accumulation of old potting materials I have mentioned be turned. All that is further needed is to see that the plants are not placed too close, to keep them slightly pruned into shape by the reduction of straggling shoots, and the yearly addition of sufficient successional small plants to take the place of those that in time get too large for potting. The advantage of taking the little trouble thus required to have at hand small compact, profusely flowered examples of this kind of stock is apparent in the Continental grown Lilacs, Azalea mollis, and Laurustinus, which, by judicious treatment, are prepared in a way that enables their yielding a profusion of blooms from plants that are so small as to take up little room, and are much more sightly than the rough, often untidy examples dug out of the shrubbery for forcing. Continue to introduce once a fortnight enough plants of the above description to meet the demand, being careful not to hurry them by too much heat, or the flowers will not last long, and be of little use for cutting.

Gardenias.—There are few, if any, flowers held in greater estimation or that are more difficult to produce during the depth of winter than Gardenias, for even where there is a large stock that have been especially prepared for blooming at this season, and with plenty of heat at command, they open very slowly without sun. The best means in order to have these flowers in winter is to get the crop of buds well forward in autumn, to keep the plants with their heads close up to the glass in a light house where there is a good supply of heat at command, being careful not to give too much water at the roots, or to keep over much moisture in the atmosphere, and not to use bottom-heat, as any of these conditions are sure to cause the buds to fall off a little before they should open. *G. citriodora* deserves a place wherever delicately-scented flowers are liked; small and in appearance unlike others of the family, it is much easier to have it in bloom through the winter months where there is sufficient heat to induce the flowers to open; it takes up very little room and is a profuse bloomer.

Bougainvillea glabra.—This, the freest flowering and most easily managed of the Bougainvilleas, can be had in bloom early if plants with well ripened wood are at hand. Where they have been dried off so as to cause the leaves in a great measure to fall the plants may be cut in, removing the small shoots that are too weak to produce flowering growths, and shortening to a convenient length the strongest; after this if the ball of earth is very dry it will be best to soak it for several hours in a vessel of tepid water large enough to admit of the ball being covered. This *Bougainvillea* requires plenty of root room; if too much confined the quantity of flowers will be proportionately limited; consequently if larger pots are needed they should be given before the plants are started, but in this case there must not be any disturbance of the roots. Where no potting is required manure water should be given as soon as growth has fairly commenced. A brisk heat is necessary to get it to move freely at this early season, but with 65° in the night and a rise by day proportionate with the weather it will be in flower in about ten weeks, and when started at this time and kept going in a temperature as above indicated it will bloom three times before the season for again resting it will have arrived.

Allamandas.—The earliest rested of these may also be started. It is best to cut them well in, removing all the shoots that have not been fully ripened up. In the case of young examples in comparatively small pots they should have more room at once, seeing that the balls are thoroughly soaked through beforehand, otherwise difficulty will be found in getting the soil moistened afterwards; if the specimens are old and the soil in the pots is exhausted, they should be half shaken out and potted in good loam well enriched with rotten manure; at the same time the plants ought to be cut well in, and if they are to be grown on trellises these should be fastened to the pots at once, and the plants trained to them.

Cyperus alternifolius.—The variegated form of this plant is usually liked the best, but the green kind is also worth growing, although not so showy. Both are most useful when in small pots—6 in. or 7 in. in diameter. The present is a good time for dividing any that have got too large, turning them out of the pots, separating them so as to leave two or three crowns to each. The variegated sort generally keeps its colour best when grown in loam. The plants as soon as they begin to grow should be kept well up to the light, as this also tends to preserve the variegation and keeps them stouter.

Amarylids.—Where a sufficient stock of these is cultivated, and their growth was completed early so as to admit of their being put to rest in good time, a portion may now be started, as by regulating the period of growth and rest, they may be had in at almost any time. They will bear a brisk heat, and if the bulbs are strong they will seldom fail to flower. Give the soil a good

soaking. This is earlier than it would be advisable to start the main stock, but if a few be put in heat at a time they will give a succession, and the earliest flowered portion will come in when flowers are not too plentiful.

ORCHIDS.

East Indian house.—Let the ventilators in this house be closed early on sunny days so as to diminish the amount of fire-heat and thus benefit the plants. In all Orchid houses it is well to have ventilators in the walls just opposite the hot-water pipes, and these should be open every night in mild weather, and even on frosty nights if the air is calm. The air gets heated as it passes over the pipes, and thus circulates amongst the plants night and day. If the temperature is up to 65° at daybreak in the morning, the top ventilators should be opened at once if the weather is mild, but only to the smallest extent; so much as to cause the temperature to fall would be too much. If there is a sharp frost, better not admit air until the sun rises sufficiently to raise the temperature a few degrees. No time should now be lost in getting all the repotting of *Saccolabiums*, *Angraecums*, and other plants of that character done. The pots should be half full of drainage, and the potting material should be clean Sphagnum. We use well dried material in which to pot the roots, mixing it with crocks and charcoal, finishing off the tops with live, clean Sphagnum cut up with a knife. The small growing *Angraecums* succeed better in pans or baskets than in pots. Than these winter-flowering Madagascar Orchids there are few more desirable. All the large growing species, such as *A. eburneum* and *A. sesquipedale*, succeed best in pots, and large plants of them form noble ornaments to this house in winter. The first named is not so much grown as it ought to be, but large specimens in bloom cannot fail to please. The pretty little *A. citratum* is most floriferous when suspended from the rafters, and cultivated either in shallow pans or baskets, as are also *A. Ellisii* and the form of it called *A. articulatum*. These do best suspended in quite the warmest part of the house. With the exception of *A. falcatum*, all of them require plenty of heat. We do not put any water in the evaporating troughs until a month or six weeks later than this; we rather depend for moisture from water sprinkled on paths or stages. The evaporating troughs filled with water form an important aid to culture when the plants are in full growth.

Cattleya house.—As regards the best time to repot certain occupants of this house, a very successful Orchid grower told me the other day that his plan was to begin as soon as he could after the new year with the East India house, and that he was usually forward enough to pot the plants in the *Cattleya* house in February. Some *Aerides* in this house as well as *Vandas* are, I find, now beginning to make new roots, and that being the case no time should be lost in repotting them if they need it. All the *Vanda tricolor* section require to be potted now, and *Aerides Fieldingi*, *A. Lindleyanum*, *A. crispum*, &c., require similar treatment. I do not pot any of these annually unless it is seen that the potting material about the roots is rotten and requires removing. Another very successful grower repots every year. In repotting take care not to injure the roots. In arranging the plants see that those that have a tendency to be shy bloomers are placed in the lightest part of the house and as near the glass as possible. Some are better in the warmest end; others prefer a cool position. We would place *Cattleya gigas*, *Dowiana*, *lobata*, &c., at the warmest end and near the glass, while such plants as *Lelia majalis*, *acuminata*, *autumnalis*, &c., should be placed in the coolest parts—the first named near the glass, and well exposed to the sun. *Dendrobiums* of the tall-growing type, such as *D. Dalhousianum*, *nobile*, *thyrsiflorum*, &c., and also *Vandas* and *Anguloas*, may be further from the glass; the smaller-growing *Dendrobiums* may be suspended in baskets or in pans

from the roof; *D. crassinode*, *Wardianum*, and all the pendulous growing species succeed best and look best in that way, while the dwarf growing upright section, of which *D. Bensoniae*, *Parishi*, *albo-sanguineum*, and others are examples, make the best and most sturdy growths in that position. Of course, when in flower they may be arranged on the stage nearer the eye, and there, too, the flowers last longer than near the glass. One of the best of Mexican Orchids is the charming *Odontoglossum citrosimum*; this should still be kept as dry as possible at the roots, so much so as to cause the back bulbs to shrivel. Thus treated it makes strong, healthy growth next season. On the other hand, *O. Phalaenopsis* must not be allowed to become so dry; plants of this are now making their growth, and must not suffer from want of water at the roots. Watch carefully now for slugs, &c., as the spikes of many Orchids are showing, and a stray marauder may blight the best prospects of a twelvemonth's labour and anxiety. They seem to have a preference for *Odontoglossum hastilabium*, *Oncidium crispum*, and *O. Marshallianum*.

Cool houses.—It may not be out of place to make a few remarks on the construction of a cool Orchid house, as the culture of these beautiful flowers seems to increase more and more, and a house may be constructed for them in a position where the other sections of Orchids would not succeed. Some of the best grown plants ever seen were in a lean-to facing the north. A house in the form of a lean-to, say from 9 feet to 12 feet wide, against a north wall, and high enough to allow a tall man to walk down the centre of it with comfort, will answer as well as any other form. Span-roofed houses, too, seem equally well adapted for them, judging by results; the plants not only grow well in them, but their flowers last long in good condition after they open. The advantages possessed by a lean-to against a north wall are, first, the least cost in construction compared with a span-roofed house, less cost for fuel, and very much less attention as to watering, shading, and ventilating. In all cases there should be ventilation in the front walls, and in the case of lean-to houses also in the back wall near the top, in order to secure ventilation in wet weather. The stages should also be built so that some material, such as gravel, spar, or fine coal, may be used on which to stand the plants. The stages ought not to be so wide that the plants cannot be searched every night for slugs and snails. We have required very little artificial heat in our house this winter, except during short spells of frost on three or four occasions. The temperature has seldom fallen below 50° without any heat in the pipes.

KITCHEN GARDEN.

ALL Ashtops and early varieties of Potatoes should now be exposed to the light. The main object is to keep them back; long white growths not only weaken the tubers themselves, but have a tendency to invite disease. The more robust and wood-like stems our Potatoes have, the less we have to fear from disease. Later varieties will also be greatly benefited by exposure and turning over, that is, the stock for next season's planting; those used for food should never be subjected to light. Look over quarters of Snow's Broccoli, cutting close to the surface of the ground all heads that are showing, and stack them up close together in a shed. In this way they last for a very long time in the best possible condition at this season. It is a fact that cannot be too widely known that 4° of frost on Broccoli or Cauliflowers not only spoils their colour, but also their flavour; therefore be not caught napping. Digging and trenching all land as it becomes vacant should be proceeded with, and at this season, when families assemble together, give the garden an extra clean up. The weather being still mild, supplies in the forcing department are abundant without much trouble. Our winter Tomatoes are looking well, and we get from 10 pounds to 12 pounds a week of very good fruit—a valuable addition to our esculents. Cucumbers

are doing well. Keep the shoots thin, the house shut and not too damp, and success is sure to follow. The same range of temperature as advised last week will do well. Of Asparagus, Seakale, and Rhubarb keep up plentiful supplies, as formerly directed, and at the same time use your own discretion in the matter. Mustard and Cress, Tarragon, and Chervil all now want attention. These things, though small, are of great importance; so keep up good stocks of all by sowing and replanting.

KITCHEN GARDEN.

NOTES ON MUSHROOM CULTURE.

FOR some time past Mushroom growing has received a good deal of attention here, and as the beds were formed in various atmospheres and positions, notes on the results may be useful. The place we call a Mushroom house is a lean-to shed facing northwards. There is space for beds on each side, with a lattice footpath up the centre, underneath which is a flue, which begins at one end and terminates in a chimney at the other. In mild weather this keeps the temperature up to 60° or so, but when the cold is unusual it is a difficult matter to work it properly, and then the temperature fluctuates a good deal. Rhubarb and Seakale have been forced successfully in this house, especially when the roots were placed in fermenting material, but for some reason or other Mushrooms have not been invariably satisfactory. We never fancied the place as a Mushroom house, and the results did not increase our affection for it; therefore other places were tried with better results. In one day we made up four different beds. One was in the house just referred to, the second in a flower-pot bin in the potting shed, the third under the stage in the Cucumber pit, and the fourth in the Orange house, a large unheated structure 330 feet long, 30 feet wide, and 20 feet high. The bed in the Mushroom house should have been bearing six weeks or more ago, but it has never produced a Mushroom yet. The potting shed bed is only a small one, about 5 feet square and 18 inches deep. It was formed early in September. The first Mushrooms were gathered from it on October 20, and they are still coming up strong and healthy. The temperature here is not much higher than that out in the open, as there is a door at each end of the shed, and many cold draughts blow when the doors are open, but it is dry overhead—a great advantage. This bed, like all the others, was soiled over with loam and covered with a layer of hay about 6 inches in thickness from the time it was spawned. The hay is turned over to one side when the Mushrooms are being gathered, and thrown over again afterwards. Probably, through the weather being humid, that portion of the hay which rests next to the soil becomes rather moist after it has been on for a few days, and to prevent this from doing any harm to the Mushrooms or chilling the bed the damp hay is taken off and dry material substituted about once a week. The hay taken off is not thrown away, but shaken out and dried, and put back again in its turn. The bed in the Cucumber house has been very satisfactory. This structure is a lean-to one, 12 feet wide, and there is a Cucumber bed in front, a pathway along the centre, and a plant stage at the back. It is heated with a flue, which goes all round and keeps the temperature from 55° to 60°. The beds have been formed underneath the back stage and resting on the ground. The one which was made up first is 3 yards long and 3 feet wide. It is about 1 foot deep at the back and 6 inches in front, and the surface is inclined from back to front. We have hardly ever had a Mushroom bed with less bulk of material in it, but it is not far from the fine, and this appears to keep it at a bearing temperature. Here the Mushrooms were ready for gathering in five weeks after spawning. We have now been gathering from it for nine weeks, and I am sure if all the Mushrooms we have had from it were spread out on the surface of the bed they would cover every inch of it twice over. Owing to the heat they spring up quicker and grow faster

than in the cool shed, but otherways they show no superiority. This bed receives more light than any of the others, but this is no disadvantage. The bed in the Orange house is made up against the back wall, and is 2 feet deep at the back, 3 feet wide, and 1 foot high at the front; the length is 12 feet, and it has done as well as any of the others. The first Mushrooms from it came well in to time, and it has now been bearing over two months, but here they did not come so evenly over the whole surface as in the heated pit. The greatest quantities have come in masses together, some of the clusters being composed of as many as thirty, and as these are constantly breaking out in fresh spots it is proving a most profitable bed. The temperature here is never above 50°, and sometimes as low as 40°, and having no means of driving the moisture out, the atmosphere is rather humid at times. The bed here has been treated like the one in the potting shed; a good covering of hay has been constantly over it, and this has given place to dry material as the old covering became damp and cold. In very cold weather some mats were thrown over the surface of the hay, but as these retain too much moisture, they are not kept on always.

As to positions, I prefer the beds in the cool houses. They are the least expensive to keep up and no less fertile than those in artificial heat, and the cool-grown produce is certainly equal to that of any of the others as regards size and flavour. Now, I would never lament the want of a properly constructed and heated Mushroom house. I have indeed no doubt about obtaining all I want from any shed. Eighteen months ago we had a most fertile Mushroom bed in the shed in which we store Potatoes in winter, and some recently made ones are showing signs of following the example of their neighbours in cool sheds. Abundance of superior Mushrooms can never, however, be produced from inferior spawn; unless that is right, disappointment will follow. Old spawn is said to be as good as any provided it has been kept dry, but I do not like old spawn in any condition, the newest and best being preferred. Before making any beds we have to collect the droppings at the stables for a fortnight or more, and then it may not amount to more than two or three cartloads. To this we add about one quarter of rough loam and a few leaves, the whole being well mixed together before being made up. We are not particular about gathering all the straws from amongst the droppings; on the contrary, we like them best when they contain about half their bulk of short straw, as that generates heat and retains it for a long time. In drying the material has not every particle of moisture taken out of it; on the contrary, it is made up in almost a semi-moist state. The beds cannot be too firm when finished, and when this is done properly cases of little Mushrooms forming and dying away before they are ready for use will seldom occur. We attach much importance to covering the beds up with hay, and in this way keeping their surfaces comfortable and sweet.

Outdoor beds.—Respecting Mushrooms in the open air, I have nothing of importance to add. It may be said that those who can grow Mushrooms under cover may grow them in the open too, but this has not been the case with us. Had we been depending on our outside bed for a supply at this time, we would have had no Mushrooms, but as long as we can have plenty of them in any of our sheds their failure in the open is of no consequence. There is certainly an advantage in having them under cover during frost, snow, or rain, as the beds are prevented from becoming damp or mouldy. It is gratifying to know that some are able to make up Mushroom beds from 50 yards to 100 yards in length, and containing from twenty to thirty cart-loads of material, as such heaps must retain the heat for a long time, but how would makers of such beds get on in the open air if they had to deal with only one cart-load at a time? Then I fear they would not do more than private cultivators do who have seldom more than that quantity with which to form a bed. Some, perhaps, manage to grow Mushrooms better

out-of-doors than under cover, but if there are sheds one need have no desire to grow them more simply or successfully. J. MUIR.

Margam Park, S. Wales.

THE SAVOY AND ITS CULTURE.

THIS variety requires about the same treatment as Cabbage, but may be easily distinguished from Cabbage by the rugosity of its leaves. The Savoy comes into use in October and lasts till spring. It is one of the most esteemed of winter vegetables, turning in earlier than the Borecoles. The Savoy is very hardy, withstanding a good deal of frost after being hearted without injury. The dwarf-growing kinds are best for small gardens, and as a rule withstand intense frost better than those that grow to a large size, and they will also be found to be better flavoured when cooked.

The soil most suitable for the growth of this esculent is a light mould well enriched with rotten stable manure. It should be trenched 2 feet deep, working into it plenty of the manure just named as the trenching proceeds, or if only deeply dug bury in it plenty of manure as deeply as possible to encourage the roots to run downwards, where they will find sufficient moisture to sustain them should the weather be hot and dry in summer. In order to ensure a good supply during winter two sowings should be made, the first early in April, the other the last week in the same month or first week in May. Sow the seeds upon a piece of well-prepared ground, by digging it deeply and manuring it with rotten stable manure, which is better than manure from the farm-yard; by using the latter the young plants will often be found to club. Sow upon beds 4 feet in width, leaving alleys 12 inches wide between them, or sow in rows 3 inches apart and an inch deep, covering the seeds carefully with an iron rake. If possible choose a piece of ground free from shade, so as to induce the plants to grow short and stocky; whereas if in a shady position they will draw up thin and leggy. As soon as the seedlings appear above ground or just when they come into rough leaf, mix some slaked lime and soot together in the proportion of about two parts lime to one of soot, and give the beds a good dressing of the compost, which will be found to be a good preventive of club, and means of killing grubs, if any, in the hearts of the plants; few will be found to go what is termed blind in the hearts after using this compost. As soon as the plants have four leaves, prepare a piece of ground, into which the seedlings may be pricked out 4 inches apart, and give them another dressing of soot and lime, which not only obviates club, but keeps slugs from eating their young leaves; besides, the roots derive benefit from the soot and lime, which induce them to make strong fibres. When carefully raised with a digging fork, before being planted, they soon get re-established, growing strongly and vigorously and forming good hearts before winter. Plant for autumn use in the third or fourth week in May, selecting for the purpose large growing sorts. They should be set 18 inches apart row from row, and 15 inches asunder in the row. The Dwarf Ulm and small varieties should stand 12 inches apart in the rows and 12 inches plant from plant. This plantation will be fit for use some time in October, when a good supply may be had from it till after Christmas. Another plantation made late in June will carry us on till late in the spring, when other green crops will be getting plentiful. Choose a showery day for planting if possible. Hoe frequently between the rows both to keep down weeds and to stir the surface soil, an operation which will be found beneficial to the growth of the young plants. When well established sow some artificial manure between the rows, hoeing it deeply into the ground, or liquid manure may be used with equal success. When the plants have become large enough draw some soil up to their stems to keep them steady, when they will require little more attention until ready for use.

Varieties.—The Dwarf Green Curled is one of the best for a general crop, forming as it does close, compact heads. The Drumhead is a large growing sort of good quality, suitable for large gardens. The Golden Globe is a good useful yellow kind, hardy in constitution; Early Dwarf Ulm is the best dwarf variety; its flavour is good and it is very hardy, standing even severe frosts well. Tom Thumb, a small variety, is crisp and very hardy. W. C.

JERUSALEM ARTICHOKE.

THIS, when under good cultivation, often grows to a height of from 12 feet to 14 feet. It flowers occasionally in this country, but not often, except the weather in September and October is very warm, and even then it never ripens seed. It is propagated by means of its tubers, which somewhat resemble those of the Potato, but grow in clusters, often numbering from 20 to 30 large tubers to each root. Any ordinary soil will suit this Artichoke, but the finest crops are produced in good loamy soil.

Preparation of the ground.—This should be trenched 2 feet deep during autumn or early in winter, ridging it as the trenching proceeds so as to expose a large surface to the action of frost. Plenty of rotten manure, if at hand, should be worked into the soil at the same time, as well as any decayed vegetable matter or half-rotten leaves, all of which will be found to be beneficial as manure. The tubers grow larger and are of better quality in ground of a rich, loose character than in poor, stiff land. If trenched in autumn, fork it over early in the new year, or some time before planting the tubers, an operation which enables the ground to get dry and in what is termed good working order.

The planting should be done in February or March, provided the weather is favourable, but it is always advisable to wait until the ground is sufficiently dry to prevent it from sticking to the feet. Dibble in the sets with a large dibber or open a drill with a draw hoe 9 inches deep; then stretch a garden line, and plant in rows 2 feet apart and from 9 inches to 12 inches set from set. Procure some tubers of a medium size, which may be planted whole, but if large cut them in half, and if extra large cut them into sets, leaving several eyes to each. When planted cover them over and rake the ground level. Hoe frequently between the rows to keep down weeds until the stems are tall enough to cover the ground. Draw some mould up to them when from 12 inches to 18 inches in height. As soon in autumn as the stems become yellow cut them down, when the tubers may be dug up and stored in a dry shed or cellar, or, if more convenient, in a pit in the ground, covering them with straw and covering the pit 18 inches thick with soil, which will preserve the tubers during the winter. When required for use a few may be taken out of the pit at a time, but care must be taken to re-cover the pit carefully each time. If thought fit, the tubers may be left in the ground where they grew, and a few dug up from time to time as may be required, the whole being lifted in time for other spring crops. Be careful when digging up the crop to leave as few in the ground as possible, as every small piece grows and becomes a source of trouble when small seed is sown upon the ground. Artichokes will be found to yield the best crops when the tubers are planted upon a different piece of ground each year, preparing it as previously recommended.

As food the tubers may be used in a variety of ways. They are both wholesome and nutritious boiled and mashed with butter. They are also largely used for making soups. When made into pies they will be found to have an excellent flavour, and by some are highly appreciated. Cottagers will find this Artichoke a profitable crop, not being liable to any disease either when growing or after being harvested. Small tubers may be boiled and used as poultry food mixed with Barley meal, a kind of food which will be found to suit both young or old poultry. If more are grown

than are required they may be used in a raw state for feeding pheasants. WM. CHRISTISON.

MARKET GARDEN NOTES.

CONSIDERABLE activity is being already shown in the market gardens in clearing off winter crops, manuring the ground, and breaking it up in readiness for the earliest sowings of Peas and Beans. Fortunate indeed are those growers who have soil that is not stiff and wet, for in such case early working would do more harm than good; still farther, very early sowings in wet land result in very doubtful advantages. The winter has so far proved very acceptable to the market men, as except on exceptionally wet days or when a little frost has prevailed there has been nothing to hinder actual work. On the other hand, there has been little to hinder growth, and all hardy crops have for the season been unusually active. Green stuff everywhere might have been abundant but for so much having suffered from the grower's greatest torment—club. Still, the market fields have all the winter been green, and many breadths of Brussels Sprouts, white and purple Broccoli, Cabbages, Turnips, Spinach, &c., look as fresh and green now as in the month of October. Turnips have found it to be a remarkable season, as growth has never been checked, and the latest sown breadths have bulbed more or less, but far beyond expectation. If the open weather continues, the growth in an upward direction will soon push, and the season of Turnip-tops prove a short and early one. Broccoli have had no rest, and the majority, unless materially checked, must turn in early. Should such be the case, a dearth of late Broccoli must not only be looked for, but there will very probably be a general dearth of green material in the later spring months until summer Peas and Cauliflowers turn in. Market growers are not generally large growers of

Cauliflowers, except of the famous Autumn Giant, the most popular of all the late kinds, and I was indeed surprised to note in an adjoining market garden truly handsome white heads of this variety on late plants on New Year's Day. These I was assured were worth 3d. each in the market, and certainly if it were possible to ensure through late planting a good supply of this fine vegetable in midwinter at the profitable price of 3s. per dozen, the growing of them would be a veritable Golconda. It is worthy of mention that these excellent late heads were found beneath the overhanging branches of trees. Now, as a rule growers plant bushes, flowers, and various roots beneath trees, but few vegetables. It is well worth consideration whether a good breadth of the Giant Autumn Cauliflower planted beneath the boughs of trees might not prove a good speculation. But the possibility that we may have a dearth of green stuff about May should encourage growers to push on large quantities of early Cauliflowers at once if none has been sown in the autumn. A good sowing of the Snowball or Early Dwarf Erfurt made now in frames and pushed along with gentle manure heat would give a strong lot of plants to go out at the end of March, and if planted in rich soil and in warm positions would turn in very early indeed. The trade knows little of the Snowball, the very earliest of all the dwarf varieties, but in time we may expect to find a sowing under glass in January for the production of several thousands of plants, one of the most important of winter duties in market gardens. Such famous Cauliflower growers as Messrs. Beach, Bopart, &c., stick to their old strains of the Early London, and this kind, under their high culture, produces huge solid heads that, but for the time of year, would render it difficult to tell them from the Autumn Giant. These must, however, be sown at the end of August or early in September, and be put out under hand-lights or cloches for the winter. On the other hand, a sowing of the Snowball made in January will give plants heading in almost as early, and, if smaller, at least three can be grown where one of the large heads are found. Cauliflower seed is always of uncertain quality, as so

very much depends upon the season. In 1881 I got but a few ounces from a large breadth. Last year from one-half the breadth of plants I got as many pounds. Still, it is evident that the same good fortune has not been universal, as in Germany, from whence so much seed is obtained, the very same variety is offered wholesale from £8 to £12 per pound, a marvellous price to charge for Cauliflower seed. Still, few gardeners must wonder if for choice first early kinds that must ripen their seed in the autumn seed can be got only in half-crown packets.

Flowers.—Wallflowers have been furnishing bloom all the winter; indeed, from the middle of October till the present time there has scarcely been cessation in the cutting. If the bunches are few, they secure at this time of the year a good price, and every little that can be obtained for market means something useful towards the heavy and inevitable expenses. Violets, too, have bloomed freely, but it must be admitted that around London these assumed very hardy plants are suffering considerably from the effects of fog. I have a large breadth of the fine Victoria regina that in November was one mass of leafage and the plants blooming freely. The fogs of December, however, have destroyed almost every leaf, and similar damage has been widely done. It would, indeed, be a great misfortune were Violet culture about the metropolis to become impossible through fog. That the fog will from time to time be often with us there is too much reason to fear, for in spite of all the talk we hear about smoke abatement and curative measures there is too much reason to fear that as it begun so will it end—in smoke. A mild winter has been good for the flower-root trade, for open weather both promotes sale and growth. The public, however, seem to be tiring of many common things. Daisies, blue Pansies, single Carnations, &c., seem to hang on hand somewhat, whilst large blotched Pansies, Hollyhocks, Clove Carnations, Primroses, and similar good things find a good market. Blue King Pansy is grown about the West Middlesex district in immense quantities, even cottagers having patches of thousands in their gardens. It is an early blooming, free growing kind, and is very easily propagated. A year or two since it was in great demand, but now it has become too abundant. Good yellows and whites are more fancied, but none are so robust and free as Blue King. The general public who patronise plant hawkers care little for the small-flowered tribe, however free and early they may be. The larger Pansy blooms are the greater the demand for the plants that carry them. It is very gratifying to learn that "Jacks," as the single-flowered Carnations are vulgarly called, are giving place to double seedling varieties. I have urged upon local growers the benefit to them which would result from the growth of double-flowered strains, seed of which, warranted to produce from 70 to 80 per cent. of double flowers, can be purchased at 8s. per ounce. If purchasers of plants got but half of them bearing double flowers they would be satisfied, but a good strain will give them more, and the grower may well ask, and doubtless obtain, a higher figure than he gets for his single kinds, which deceive and disgust all who purchase them. A. D.

SHORT NOTES.—KITCHEN.

Johnston's St. Martin's Rhubarb.—We gathered our first dish from this very early variety on the 5th Dec. Well ripened crowns were taken and placed in the Mushroom house, in which there was a temperature ranging from 50° to 55° at night, and from 55° to 60° in the daytime. Here they produced Rhubarb fit for use in three weeks; other kinds taken up at the same time and under exactly the same treatment were a fortnight later.—J. CLARKE, Brynkinallt.

John Harrison Bean.—This is said to be a very fine new early long-podded garden Bean, extremely fertile, of hardy constitution, growing about 2 feet high, and of branching habit; pods numerous, large and well-filled, each containing six to eight beans. It is one of Mr Laxton's seedlings.—J. S.

ORCHIDS.

Lælia autumnalis grandiflora.—The very fine variety of this *Lælia* named *atrubens* is now pretty well known, but not so the variety under notice. It differs from the type in having much larger flowers, yet they are not of such a deep colour as those of the *atrubens* variety now in bloom in Messrs. Henderson's nursery, Maida Vale.

Dendrobium Dearei.—Mr. Lee informs us that this new species, which has not yet flowered in cultivation, is in a flowering state in his collection at Downside, Leatherhead. It is one of the nigro-hirsute section allied to *D. infundibulum*, and has white blossoms produced very freely, at least judging by the clusters of dried flower-stalks on imported plants.

Oncidium juncifolium.—Under this name there are some plants in flower in the Pine-apple Nursery, Maida Vale, of a very singular character. The leaves are about a foot long and cylindrical, as they are in some of the *Brassavolas* and *Vandas*. It produces long slender flower-stems from the base of the leaves. The blossoms are small, bright yellow and chocolate-brown. It is only remarkable for curious growth.

Stenorrhynchus speciosus.—At Kew this plant is now flowering freely, and is really attractive even when placed among some of the most popular of Orchids. It is a terrestrial kind not unlike some of the British Orchises in habit. Another handsome species which does not appear to be in cultivation is *S. orchioides*, a native of Jamaica and Barbadoes. It was introduced into this country from the latter island in 1806.—B.

Limatodes rosea.—The popularity of the beautiful *Calanthe Veitchi* has almost obscured one of its parents, the old *Limatodes rosea*, with which we were pleased to meet in bloom in the Pine-apple Nursery, Maida Vale. It has flowers much resembling those of *C. Veitchi*, but somewhat smaller, and the spike is not so high and does not produce so many flowers. The centre of the blossom is pure white, which adds to its beauty considerably. Its culture is much the same as that of the *Calanthe*.

White Vanda teres.—A flower of this extremely rare Orchid comes from Colonel Charlton's garden, Douglas, Isle of Man. It is a lovely Orchid, in size and form differing in no way from the original except instead of being rose coloured it is pure white with only a very slight suffusion of lilac and a little yellow at the base of the labellum. Colonel Charlton received it from Burmah, and though he has flowered many plants of *Vanda teres*, he has never had a white one before. He is fortunate to possess such a treasure.

Masdevallia towarensis.—In Messrs. Low's nursery at Clapton there is now a mass of some thousands of this chaste little Orchid in bloom, which more resembles a sheet of Snowdrops in a wood than anything else to which we can liken it. Every plant is carrying several spikes, each with from one to three and even four pure white blossoms. A few years ago this species was a rarity, but now it bids fair to become one of the commonest of Orchids, and a very useful one too, as it flowers throughout the winter. In Messrs. Henderson's nursery a mass of flowers of it may also be seen, though on a smaller scale.

Spiranthes euphlebius.—At p. 11 we stated that this plant was in flower in Messrs. Shuttleworth & Carder's nursery at Clapham. It appears, however, that the plant we saw was a variety of *Stenorrhynchus speciosus* with spotted foliage. Plants of *Spiranthes euphlebius* were lately imported by this firm, of which one was presented to Kew Gardens. This plant has recently flowered and proved to be a new species. It is a whitish flowered species with a few brown streaks along the sepals and petals. The scales at the base of each flower are also brown and covered with short tomentum. It is a distinct and pretty plant worthy of being grown along with the old

and handsome *Stenorrhynchus speciosus*, which is closely allied, although placed by Professor Reichenbach in another genus.

Angræcum citratum.—In a short time there will be the finest display of bloom of this charming little Orchid in the Clapton Nursery that has ever been seen since it was introduced. In one house there is a group of some hundreds of plants, each carrying one or more long spikes thickly set with buds, which, when expanded, will be a fine sight. The flowers, about half an inch across, are ivory white, except the centre, which has a spot of delicate mauve; the foliage, being broad and of an unusually deep shining green, makes a charming contrast. Other *Angræcums* in this nursery which are either in the flowering or in the bud state are *A. sesquipedale*, *A. Ellisi*, and an unnamed species which appears to be *A. Kotschy*.

Odontoglossum baphicanthum.—This scarce and rather new variety is now flowering freely in Messrs. Low's nursery at Clapton. It appears to be a natural hybrid between *O. crispum* and *O. gloriosum*, as its flowers combine the peculiarities of these two in a striking degree. The sepals are narrow and remarkably long, as is also the labellum, which reflexes at the tip. The colour is a creamy white, with one or two spots of cinnabar-red on the sepals, while the labellum possesses a conspicuous blotch of the same colour. Other noteworthy *Odontoglossums* in flower among the vast assemblages of the genus in this nursery are *O. Andersonianum*, a particularly fine form; *O. cariniferum*, a neglected species; the ever beautiful *O. Roezli album*, and the miniature *O. Erstedii*, which has a peculiar charm of its own.

Angræcum eburneum.—I see in his "Notes on Orchids" on December 30 Mr. Douglas omits to mention this grand species in his remarks on its congeners. As it is now in our collection it is a beautiful sight, carrying a spike of eleven blooms with lips 2 inches across, of the purest white equal to driven snow. Its purity is enhanced by the two greenish marks, one each side of the keel on the base of the lip. The sepals and petals in this Orchid are always curiously deflexed, the grand lip being erect like a standard, the spur projecting downward below the petals forming a perfect tail to a flower, as much like a green grasshopper flying away with a white dish in its mouth as Nature could make it. Were it not for the large habit of growth it would be more grown, but where the room can be afforded a specimen plant it is always a handsome object.—D. B. C.

Three rare Dendrochilums are now in bloom in the Clapton Nursery. They are *D. Cobbianum*, *D. uncatum*, and *D. arachnites*. The first is a neat and elegant little plant in the way of the better-known *D. glumaceum*. The flower-spikes produced from the new bulbs are slender, and vary from 6 inches to 9 inches in length. The upper half is furnished with two rows of tiny blossoms about a quarter of an inch across. The sepals are of a transparent white, the lip a soft yellow. The weight of the blossoms on the thread-like spike causes it to droop gracefully. *D. uncatum* is similar, but smaller in every part, and the flowers are more open and not subtended by such conspicuous scales. *D. arachnites* was not sufficiently expanded to describe. These elegant little Orchids have been lately donned with the new generic name *Platyclinis*, though it will be some time probably before cultivators will use it.

Cattleya labiata Percivallana.—At length this much criticised Orchid is showing itself in its true character, and proves not a whit less beautiful than its introducers said it was. On Tuesday last two plants of it were exhibited in flower at South Kensington, one from Mr. B. S. Williams' nursery, Upper Holloway, the other by Mr. Salter, from Mr. Southgate's collection at Selborne, Streatham. Both plants seemed to have been from the same importation, as they were similar in size and growth. Each bore a flower on moderate sized bulbs, not, however, half so large as we may eventually see them. In both cases they were quite a third smaller than those

of an ordinary form of *C. Mossiæ*, but it is indisputably a beautiful Orchid and a most valuable one if it should prove to habitually flower in mid-winter, when few if any large flowering *Cattleyas* are in bloom. The plant shown by Mr. Williams was obviously a much finer form than the other, the colours being brighter and richer. The sepals were of a uniform lilac-purple, very soft and pleasing. Its great beauty lies in the labellum; the throat is of the richest golden orange, pencilled and netted with deep markings; then comes a zone of the richest velvety maroon, then one of a beautiful amaranth, while the crisped edging is pale lilac. It is beyond doubt one of the most valuable Orchids that has been introduced of late years provided it continues to bloom at mid-winter. The committee at South Kensington did not see fit to award it a certificate, probably because neither of the plants were thoroughly established.

—This new *Cattleya* is now in bloom here. The flowers are 5 inches across, the sepals and petals are a light purple, the lip is splendidly fringed at the margin and of a deep velvety purple, with golden yellow throat.—D. DOWDESWELL, *Nash Court, Faversham*.

Dendrobium Hughii is a pretty addition to the already long list of *Dendrobes*, and is moreover distinct from any other with which we are acquainted. The stems, or rather pseudo-bulbs, are very slender and of moderate length. The flowers are produced on the leafless growths. They are an inch or more in diameter, pure white, except a tiny circle of purple round the tip of the column. It is strongly and peculiarly scented, resembling that of *Stephanotis*. We saw it in flower a few days since in Messrs. Low's nursery at Clapton, where also that dainty little species *D. hedyosmum* was in flower; it has likewise very sweetly scented blossoms, the perfume resembling a mixture of Violets, Primroses, and Wallflowers. The flowers are not very attractive, being only an inch or so across with white sepals and a greenish and yellowish lip, but its delightful fragrance alone should be sufficient to recommend it to cultivators. It is one of the black-haired or nigro-hirsute section of the genus, and is not one of the easiest to grow well, but it well repays a little extra trouble. *D. Boxalli* and the almost perpetual flowering *D. philippinense* are also in bloom in this nursery.

Lady's Slippers.—What striking objects these are at this dull time of the year in an ordinary greenhouse, and so easily grown, too, not requiring any more care than that usually given to the general run of greenhouse plants; they are free flowering, and scarcely ever troubled with insect pests. I have had a number of them in bloom here for several weeks, and they are still looking as fresh as ever. I counted forty fine flowers the other day on a plant in an 8-inch pot. The mode of cultivation I adopt is as follows: After they have done flowering in the greenhouse they are removed to a low pit, round which runs a 2-inch pipe; they remain there in just a little warmth till they have made and ripened their growth, when they are taken to the greenhouse to flower. This usually takes place in the end of August, and they remain in the greenhouse till, say, February, as a rule. If they require dividing or re-potting this is done at that time before they commence their growth. The compost I use is potsherds, broken small, mixed with a little chopped Sphagnum and fibry peat, a mixture in which the plants seem to revel, and being so porous there is little danger of over-watering.—R. LLOYD.

Phalænopsis at Clapton.—It is very unfortunate that these lovely Orchids, above all others, should be so susceptible to injury from fogs that generally occur about their flowering season. Before the recent spell of foggy weather set in we saw the capacious *Phalænopsis* house in Messrs. Low's nursery, and thought we never saw such a fair promise for an abundant crop of bloom as there was then, every one of the thousands of plants being furnished with flower-spikes. But fogs came, and in a few hours destroyed nine-tenths of the buds, thus considerably marring the prospect of a fine display. There is, however, a beautiful show

of bloom even now, for the latest buds which escaped the fogs have at last expanded. The flowers of *P. amabilis* and of *Schilleriana*, of which the bulk of the plants consists, are beautiful in the extreme, for they combine such elegance of growth with the most delicate colouring. Among the rarer kinds in bloom are *P. leucorrhoda*, a species or variety intermediate with *P. amabilis* and *Schilleriana*, the characters of both of which may be seen in the flowers. The lovely *P. Stuartiana* is likewise in bloom.—W. G.

Calanthe Sylvatica.—In a recent number Mr. J. Douglas says, "I do not hear of anyone being successful in flowering *Calanthe sylvatica*." In October, 1881, I purchased half-a-dozen bulbs of it in Mr. Stevens' rooms from the importation sent home from Madagascar by Mr. Humbolt. They were planted in fibrous peat and loam, with a little leaf-mould, and in the following spring four of them made their appearance. Of these only one flowered; the spike was about 1 foot high, and was certainly one of the most disappointing things to me which I have come across yet in the way of Orchids. The flowers, of which there were not many, were of a dullish green colour, with a slight tinge of purple in the lip, and only about an inch across; in fact, it was so insignificant that I concluded it could not be *Calanthe sylvatica*, but something else which must have been collected for it by mistake, as the fact of its having been recently imported would scarcely account for such defect in shape and colour. I wonder whether any other of your readers have had a similar experience. The foliage and growth of the bulbs which did not flower were the same as that which did, so it did not seem to be one particular exception.—C. R. SCRASE DICKINS, *Coolhurst, Horsham*.

Dendrobium heterocarpum philippinense.—Can Mr. Douglas or someone else tell us anything about this Dendrobe, which was imported in large quantities by Messrs. Low, of Clapton, in the autumn of 1881. I had a couple of plants from them which were in flower at the time; both made growth last spring, but neither have flowered; they were kept moderately dry after the leaves withered, but one of them after a short time, though to all appearances plump enough, I found to be quite hollow inside, and it has since died off. It would seem that this Orchid requires a slightly different treatment from the ordinary *Dendrobium*, as most of the other Orchids from its native home delight in heat and moisture. No doubt another year they will improve in their captive state, but a nurseryman told me the other day that "they are brutes to manage," so I hope I may benefit others as well as myself in asking for a hint as to its treatment from anyone who has succeeded with it. May we not call it *D. philippinense* without the *heterocarpum*, as the former name is quite long enough by itself, and sufficiently distinguishing, whereas *D. heterocarpum* might tend to confusion?—C. R. SCRASE DICKINS.

Vanda teres.—In reference to the question raised by "F. W. B." in his notes on *Vanda Hookeriana* in the last issue of THE GARDEN, allow me to say that the treatment of *Vanda teres* at Grimston Park was very simple. The plants were grown in the East Indian house on the centre stage, and were never moved to another house at any time. They were not dried off (called by some "resting"); they were syringed twice a day in summer and once a day in winter, and when in flower the bottom portions of the plants were sprinkled every day. I do not now remember the number of flowers each plant had, but the last time they were exhibited at South Kensington, the largest plant (Anderson's variety) had twenty-three spikes on it, two spikes on some growths and many spikes with seven flowers. Mr. Denning was justified in being proud of them, and those who advocate the resting system have yet to learn the culture of *Vanda teres*. The moving of Orchids when in bloom to a colder house hastens the decay of nearly all Orchid flowers.—F. B.

NOTES OF THE WEEK.

LINNEAN SOCIETY OF LONDON.—On Thursday, Jan 18, papers will be read "On the Fall of Branchlets in the Aspen" (Mr. S. G. Shattock), and on "The Internal Hard Parts of the Fungidae," by Professor P. M. Duncan.

LES PLANTES POTAGERES.—We have just received this excellent book by Messrs. Vilmorin, Andrieux et Cie., of Paris, and have only time to announce it. We hope to notice it at some length at an early date. Many will be glad to know that a book so useful and so much wanted is at last obtainable.

VEITCH MEMORIAL PRIZES.—Three of these prizes will this year be competed for at the shows held by the Royal Horticultural Society of Ireland. Each consists of a prize of five sovereigns and the Veitch memorial medal. One is offered at the May show for the best specimen Orchid in flower, selected from any of the plant classes. The second at the summer show for the best specimen stove or greenhouse plant in flower, selected in the same way; and the third at the autumn show for the best three bunches of Grapes (one variety), selected from the fruit classes. These prizes are open only to *bona fide* gentlemen's gardeners.

THE THAMES EMBANKMENT.—A writer in the *Pall Mall Gazette* warns the public of the barbarities shortly to be perpetrated on the Thames Embankment. "Some time ago," he says, "the Savoy Theatre commenced the work of destruction by erecting an engine-house, which on summer evenings does its best to convert the gardens into a pandemonium. The Metropolitan Board of Works determined on building another in the very gardens themselves. The Board has rooted up a young plantation which was doing its best to hide the advertisements of the District Station, and planted on the spot a piece of red-brick barbarism unparalleled in the story of metropolitan mismanagement. When the scheme is completed, John Stuart Mill will gaze into a column of foul gas, and have ample opportunity of reflecting on utilitarian principles; Brunel will be usually enveloped in a cloud of engine smoke; while Outram has been obviously placed on a pedestal in order to be seen by the District engine-drivers."

SPECIAL PRIZES.—We are asked by Messrs. Carter to state that they intend offering the following prizes during the ensuing year at South Kensington: On May 22 and 23, for the best brace of Carter's Blenheim Orange and Emerald Melons, first prize, £2 2s.; second, £1 10s.; third, 15s.; fourth, 10s. 6d.; fifth, 7s. 6d. On July 3, for the best four dishes of Peas (50 pods each) of Carter's Stratagem, Telephone, and Pride of the Market, Culverwell's Telegraph: First prize, £5; second, £3; third, £2; fourth, £1; fifth, 10s. 6d. July 24, for the best 6 dishes of Tomatoes, to include Carter's Dedham Favourite and Green Gage and Vick's Criterion: First, 63s.; second, 42s.; third, 21s.; fourth, 10s. 6d. Dec. 11, for the best 12 dishes of vegetables, to comprise, Onions—Golden Queen, Silver Ball, Golden Globe; Parsnips, Cauliflowers, Celery, Brussels Sprouts, Potatoes, Carrots, Parsnips, red Beets, Leeks: First prize, £5; second, £3; third, £1 10s.; fourth, £1; fifth, 10s.; sixth, 7s. 6d.

Lima Beans.—I have never found any variety of Bean so prolific as the small Lima. We have a plot of them in the garden, from which we have been using through the summer, and have saved a gallon to the square rod of dry Beans from them, which is at the rate of twenty bushels to the acre, and they are now loaded with mature Beans, but not dry. I have no doubt that from fifty to eighty bushels per acre could be grown of them. We do not plant the large Lima, for we find these fully equal to them in flavour, doubly prolific, three weeks earlier, and much easier to shell. We grow also the Drier's Improved Lima, and find it much better than the old sort.—*New York Tribune*.

SOCIETIES.

ROYAL HORTICULTURAL.
JANUARY 9.

HAVING regard to the bitterly cold weather on Tuesday last it could scarcely be expected that any tender plants would be exhibited, but there was nevertheless a goodly show of Chinese Primulas from various exhibitors, and Cyclamens, besides a few new plants.

First-class certificates were awarded to the following:—

ODONTOGLOSSUM MADRENSE GIGANTEUM.—An extremely fine variety, having flowers fully twice the ordinary size. The long narrow sepals were creamy, heavily blotched at their bases with deep vinous purple, while the labellum was marked with the brightest yellow. The spike shown bore seven of these large flowers, thereby indicating skilful culture. Mr. Vanner, Camden Wood, Chislehurst.

AZALEA DUCHESS OF ALBANY.—A new hybrid variety remarkable for the profusion of its pure white blossoms, which are about 1½ inches across. It is said to be excellent for forcing. It was certificated "as a decorative variety." Mr. Todman, gardener to Mr. Connell, Tooting.

Cyclamens were numerous. A fine group of some half a hundred plants, large and profusely flowered, came from Messrs. Veitch, for which they were awarded a silver medal. The flowers represented a wide variation in colour, from snow white to deep crimson. A larger group of Mr. B. S. Williams' "improved superb strain" of Cyclamen made a bright display. This "strain" is remarkable for the distinct and brilliant colours of the deep tinted sorts and the refined purity of the light ones. The snow-white variety is in striking contrast with the intensely deep coloured sort called Brilliant. A silver medal was also awarded to Mr. Williams.

Chinese Primulas were in great profusion. Messrs. Carter exhibited a large collection including several new, distinct, and beautiful varieties. There were about twenty sorts shown, eight of which were represented by basketfuls of some half-a-dozen plants, which arrangement showed the plants off to advantage. The names of the sorts were Covent Garden Favourite, with massive trusses of large carmine-purple blossoms; Mauve Queen, with Fern-like foliage and mauve-tinted flowers; Salmon Queen, of a peculiarly bright shade of rich salmon-rose, very fine; Vermilion Queen, of an intensely bright carmine; White Queen, the largest and finest white yet raised, being simply lovely in every way; Holborn Gem, the nearest approach to blue that has yet been obtained—the colour is a purplish blue, and the flowers are large and produced in fine trusses (it was shown better on this occasion than it has been before); Florence Rose, in the way of Salmon Queen, but paler; Rosy Morn, similar to Covent Garden Perfection; Mont Blanc, with large white flowers shaded with pink; Elaine, a very prolific flowerer and pure white; its Ferny foliage adds greatly to its beauty. Other beautiful sorts were Vermilion Queen Improved, Rosy Morn, Magenta Queen Improved (a lovely sort, with blossoms 2 inches across, of the brightest magenta shaded with purple), and Golden Leaf, with yellowish green foliage and purplish pink flowers. These two last-named sorts are very fine, and the committee wish to see them at a future meeting. The Golden Leaf variety is quite distinct from any we have seen, and if constant will be a pretty and valuable decorative plant. A new variety named *hederifolia* had singularly palmate-shaped foliage, very much resembling some kinds of Ivy. It is unlike anything we have hitherto seen among Primulas. A bronze medal was deservedly awarded to Messrs. Carter for this fine collection. Messrs. Cannell & Sons, Swanley, sent a choice group of single Primulas. A dozen plants of a sort called Princess of Wales was the loveliest sight we have seen for a long time among Primulas. It is a vigorous and free grower, of a compact habit of growth. The flowers are 1½ inches across

borne in large trusses well above the foliage, and the petals beautifully crisped and fringed. The colour varies from a warm rose-pink to a delicate blush-pink—tints which render the flowers very charming. Other varieties shown by Messrs. Cannell were Swanley White and Swanley Red, two splendid sorts which have a well-merited reputation; The Queen, a beautiful variety remarkable for its very large crisped petaled flowers of a delicate blush, and Marchioness of Lorne, somewhat similar to the preceding, and equally as beautiful. With these came Wallflowers, Primroses, and Cineraria cruenta, a neat plant with its elegant sprays of starry magenta blossoms.

Mr. E. H. Woodall, St. Nicholas House, Scarborough, sent large, well-grown plants of five new and distinct varieties; one had Fern-like foliage and semi-double blossoms of a delicate blush, and was altogether a beautiful variety. Another was similar to the popular old double white, but more vigorous, floriferous, and better in every way. Among the others was one with semi-double blossoms, having a conspicuous greenish yellow centre; another with very large blooms of a bright carmine-crimson; while the fifth had white blooms, freckled and striped with purple. It was, moreover, extremely floriferous. A cultural commendation was awarded to Mr. King, seed grower, Rowsham, Aylesbury, for some plants of a beautiful new Primula, named Mont Blanc, a variety of sturdy growth, producing fine trusses of large white flowers of good substance. Another lovely white Primula came from Mr. B. S. Williams, called *P. sinensis fimbriata alba*, now proved to be one of the best white sorts in cultivation. It is remarkable for its floriferousness, and its large trusses of pure white fringed flowers.

A collection of about a dozen sorts of Primula was sent by Mr. Barron, from the Society's garden at Chiswick. These included, besides several unnamed seedlings, such beautiful sorts as lilacina, fimbriata alba, rubro-violacea, Chiswick Rose, and Chiswick Red. Of the latter there was an improved form shown, having even deeper carmine-tinted flowers than the original.

As a harbinger of the coming spring, Mr. G. F. Wilson brought some bunches of really fine Primroses of the beautiful varieties he grows so well in his garden at Heatherbank, Weybridge. Another welcome exhibit was a bunch of the winter Heliotrope (*Tussilago fragrans*), brought by Mr. Green, Sir George Macleay's gardener at Pendell Court, Bletchingley, who also exhibited the fine *Dahlia arborea* alluded to in another column. A glorious wreath of flowers of *Bougainvillea spectabilis* was sent by Mr. Miller, Northdown, Margate. It is brighter and richer in colour than the well-known *B. glabra*, and is a much more difficult plant to flower, and particularly so finely as Mr. Miller showed it.

Fruit and vegetables.—A cultural commendation was accorded to Mr. Miles, gardener to Lord Carington, Wycombe Abbey, High Wycombe, for a fine pair of Pine-apple Lord Carington, a rather new sort of a handsome conical shape. Cultural commendations were also awarded to Mr. Stevens, gardener to the Duke of Sutherland, Trentham, for some excellent bunches of Black Hamburg Grapes, which were as plump as usually seen in autumn. He received the same recognition for fine bunches of Duke of Buccleuch Grape, which showed the variety to perfection as regards size of berry and flavour. Mr. Allis, gardener to Mr. Shuttleworth, Old Warden, Biggleswade, exhibited three very fine bunches of Black Alicante Grape, for which he received a cultural commendation. The bunches were large, finely shaped, and the berries were all that could be desired at this season. The new Grape named John Downie by two exhibitors. A bunch was sent by Messrs. Downie & Laird, Edinburgh, and another by Mr. Dunn from the Duke of Buccleuch's garden at Dalkeith, but the committee considered that the two bunches represented different varieties. The Grape is in the way of Gros Colmar, but it is claimed to possess all the good qualities of that variety and none of its bad ones. Mr. Ford, Leonardslee, Horsham, sent examples of Alicante Grape, grafted

on Raisin de Calabre; Mrs. Pince, grafted on Royal Vineyard; Gros Colmar, grafted on Alicante and Black Prince, but in all cases the committee did not discern any appreciable difference in flavour.

A very fine dish of Doyenné d'Hiver or Easter Beurré Pears was sent by M. Cauchois, Orleans. The fruits were large and handsome, and as fine as we have ever seen them. Three of them weighed 19 oz. each. It is a remarkable fact that the trees from which these were gathered were cut to the ground by frost in the winter of 1879 and 1880. A cultural commendation was awarded. A similar award was given to Mr. Stevens, Trentham, for some wonderfully fine fruits of Calville Blanche Apple, large and handsome, and of a bright golden yellow. Mr. Ford also showed a dish of Josephine de Malines Pear of a size and quality not often seen. A small Melon, William Tillery, produced by the aid of the electric light, was exhibited by Mr. Buchanan, gardener to Dr. Siemens, Sherwood, Tunbridge Wells, but the fruit was in no way remarkable.

A collection of Celery came from the Society's garden at Chiswick. The varieties Early Rose and Leicester Red the committee considered not sufficiently distinct to justify distinct names.

The members of the committees present on this occasion were—

Fruit.—Mr. H. Veitch (chairman); Messrs. P. Crowley, J. Burnett, J. Woodbridge, A. Sutton, G. Bunyard, G. Goldsmith, S. Ford, Z. Stevens, J. Lane, J. Willard, and H. Weir.

Floral.—Mr. G. F. Wilson (chairman), Rev. G. Henslow, Messrs. T. Moore, J. Laing, H. Bennett, W. Bealby, S. Hibberd, J. Douglas, H. N. Ridley, G. Duffield, W. B. Kellock, H. Cannell, J. Dromy, J. Hudson, C. Green, J. James, H. Ballantine, and J. Wills.

Lecture.—The Rev. G. Henslow called attention to various Primulas exhibited which showed different types of foliage as well as of blossoms. The typical form of leaf is palmate, resembling the palm of the hand. Of this Mr. Carter exhibited a golden-leaved variety which is now permanent, having originated as a single seedling from Vesuvius. A second variety is the Ivy-leaved form, which appeared suddenly in different gardens, a peculiar form, having no minor indentations in the margin. A third variety is the crisped-edged leaf. This form, like curled Cabbage and Parsley, is due to a kind of hypertrophy or excess of growth. It is interesting to note that this is accompanied by very poor flowers. But after a few years the curled plant will doubtless become fixed, when the blossoms can be improved by crossing if it has not already been done. Another remarkable fact connected with this sport, as with some others, is its sudden appearance simultaneously in different localities and without a common origin. It was observed several years ago that double Petunias appeared on the Continent and in England for the first time simultaneously. What the meteorological conditions may be to give rise to this curious coincidence are as yet unknown.

The second type of foliage is the Fern-leaved, in which the apex has grown out so that the form is elongated. These two types of foliage run through other plants besides Primulas, and give rise to the corresponding types of "compound" leaves, such as the digitate leaves of the Horse Chestnut and Lupine, and the pinnate ones of the Ash. Similarly, Palms are mainly divisible into the fan-leaved and feather-leaved kinds, according as the midrib is arrested or elongated. With regard to the flowers, the diversity in the tints of red is almost infinite, but curious results follow from crossing. Thus two whites may give rise to a deep red. A mauve (the so-called blue Holborn Gem) when self-fertilised gave half its seedling white, the other half mauve. Similar diversities are well known in other plants besides Primroses. Thus Mr. Veitch found that an orange-flowered *Rhododendron* crossed by a white one gave a white, a pink, and a yellow-flowered seedling. The same thing occurred in *Abutilons*.

Scientific committee.—Mr. G. F. Wilson in the chair.

Rhododendrons.—Mr. Mangles exhibited a three-year-old seedling of *R. nobile*, a form of *R. arboreum*, from an elevation of only 6000 feet, in Ceylon, and which lately withstood 19° of frost, while *R. arboreum* (proper), a hybrid of the last, *R. setosum*, from 13,000 feet to 16,000 feet, and *R. anthopogon* were all more or less injured, although coming from a much higher elevation.

Magnolia Campbellii.—He mentioned, on the authority of Mr. Gumbleton, that this species had flowered in Europe, as well as that the tree of Mr. Crawford's garden, near Cork, has at the present moment thirty buds upon it.

Ocotea auricomum.—Dr. Masters exhibited a specimen of this fungus from a Sycamore. Mr. W. G. Smith remarked that he had observed the same fungus on wood in a cellar.

Dahlia arborea.—Mr. Green forwarded a branch bearing single as well as Anemone-flowered forms. There appeared to be some doubt as to its specific identity, as it has never been known to flower before. It was referred to Dr. Masters to report on.

Pines.—Dr. Masters also showed specimens of *Pinus contorta*, remarkable for its twisted branches, P. Bolanderi, and P. Murrayana, all three from California, and supposed to be the same, but the hypodermic cells clearly show that they are specifically distinct.

Melon grown under the electric light.—A small, smooth-skinned green Melon was sent from Dr. Siemen's gardens. It proved to be very watery and sugarless. Dr. Masters will inquire and report on the exact conditions of its growth.

Mycelium on alum.—Mr. W. G. Smith exhibited a solution of alum in which a fungus was growing. On transferring it to a syrup it proved to be the Vinegar Plant, or *Penicillium crustaceum*.

Lupageria rosea.—Mr. Boscawen has sent a fine spray of this plant, which was grown out of doors in Cornwall, as well as flowers of a species of *Colchicum* from Cyprus.

"Journal of Botany."—The editor of this periodical, Mr. J. Britten, informs us that "Peregrine" is mistaken in stating that this monthly has ceased to exist. On the contrary, Mr. Britten hopes to make it yet succeed. The January number contains, among others, an interesting synopsis of the genus *Selaginella* by Mr. J. G. Baker, of the Kew Herbarium.

Drying plants (Amateur).—See an article on this subject in last week's GARDEN (p. 4).

Resting Calanthes.—Can I safely rest my *Calanthe Veitchi* and *vestita* in a warm room—not in the greenhouse? If some of your Orchid-growing readers will kindly answer this question I shall feel greatly obliged.—S. N.

Self help.—"Peregrine's" friend's suggestion in reference to this matter is good. I should be delighted to join such a society as is proposed, and to do my best to get others to join it if it could be set on foot. Will not some of your influential readers take the subject up?—JOHN C. TALLACK, *Prideaux Place, Padstow*.

Names of plants.—*R. Green*.—1, *Justicia calytricha*; 2, *Tradescantia repens*; 3, *Euphorbia jacquiniiflora*; 4, *Centradenia floribunda*.—*W. Hills*.—*Convolvulus hispida*.—*S. A. M.*—*Hemanthus coccineus*.—*G. C.*—*Triteleia uniflora*.—*W. W.*—*Dendrobium chrysanthum*.—*G. Cooper*.—*Selaginella caesia arborea*. Send the Orchid and other plant when in flower.—*H. D. Thickthorne*.—Varieties of *Begonia Rex*, but cannot name the sorts without more material.—*R. Lloyd*.—*Cypripedium insigne* and variety *punctatum violaceum*, *C. venustum*.—*D. D.*—1, *Acacia longifolia* variety; 2, *Kennedyia Marryattiana*; 3, *Erica melanthera*. The *Angreum eburneum* represents a very fine variety.—*A. C.*—*Vanda teres candida*; other is apparently *Cologneya ochracea*.—*J. M. L. H.*—1, *Epidendrum ciliare*; 2, probably *Oncidium scarodes*, but cannot be certain without more material.

Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FRUIT GARDEN.

GRAPE GROWING FOR MARKET.

AMONGST those who have long held a first place as a London market fruit grower must be included Mr. Rochford. Succeeding Mr. Davies at Oak Hill, East Barnet, so celebrated for the Grapes, Pines, and other fruits there produced, he kept up the well-earned reputation which that garden so long had. Mr. Rochford has now been established at Tottenham some twenty years. Pines were with him at first there a leading feature; forced Peaches also were one of his specialities, but both of these have been given up. The great reduction in the value of Pines, through the advent in recent years of the immense numbers of Smooth Cayennes imported, has made their cultivation in this country unprofitable. Until comparatively recently Mr. Rochford used to be one of the earliest in the market with forced Grapes; his Muscats especially were exceptionally early; but with Grapes, as with Pines, a great change has of late years taken place. The immense quantities that now come early from the Channel Islands, and the home cultivation in large quantities of sorts that will keep if need be until long after new Grapes are in, have reduced the price of early forced fruit to not more than a third of what it used to fetch. Mr. Rochford, along with many others, has now confined his practice to late black varieties and Muscats, treated so as have the latter as well as the former as late as they can be kept. He has five houses with the crop yet untouched, consisting of Gros Colmar and Black Alicante, the cutting of which will not be commenced until February. Three of these, two occupied by Gros Colmar and one Black Alicante, each 80 feet long, with one similar of Muscat of Alexandria, were built and planted two years ago last spring, and of these special remark should be made. In

Private gardens it is no unusual occurrence to see Vines retained for years when the fruit they produce is anything but satisfactory, either through exhaustion, indifferent condition of the roots, or the various ills which Vines are heir to. The reluctance to clear them out and replant arises from the mistaken idea that it takes a considerable length of time to get new ones into bearing. If evidence were needed as to the mistake in this matter, Mr. Rochford's young Vines would afford it; the strongest of the Alicantes were allowed to carry three bunches to a cane in 1881; the past summer the whole of both the black kinds have been permitted to bear an average of eight bunches to a rod, all having two canes each; the greater portion of the bunches run from two to three pounds, and highly finished; the canes are as thick and strong as usually seen at double their age, and have evidently been in no way distressed by the crop they have borne. The corresponding house of Muscats carried five good bunches each in 1881. During the past season they were allowed to bear about eight bunches to a rod, big clusters, well finished. Nothing less would have enabled them to realise the high prices they have made. This year the whole of these young Vines will be cropped their full length. Mr. Rochford is no believer in the doctrine of growing Muscats and late-keeping black Grapes with little fire heat, knowing, as he and other leading market growers do, that although fuel is an expensive item near London, still its unstinted use in the case of Muscats and late black Grapes means the difference between obtaining the top price in the market and having to put up with a low figure vastly out of proportion to any apparent saving effected by pinching the fuel. The houses are kept comparatively close in the

spring, and as soon as there is any inclination of movement in the Vines the heat is laid on and kept going freely without any intermission until the Grapes are ripe. The roots are necessarily all inside, on account of the houses standing close together side by side, but as they are supported by piers, they have an unlimited run. In addition to those mentioned a number of other houses are devoted to late Grapes. A roomy, well-arranged

Grape room has been built with hollow walls and a double-boarded ceiling, with a hot-water pipe running round just above the floor, which is boarded. With warmth that can be regulated according to the weather, and ventilating arrangements, there is little trouble in keeping the fruit. The bottles used are made especially for the purpose, with wide necks. Mr. Rochford has tried a Vine or two of Alnwick Seedling amongst the young Alicantes; it finished up well, being almost blue in colour, but it is evidently not destined to be much of a keeper, as the berries were shrivelling considerably at the end of the year. This is to be regretted, as there is scarcely another black Grape with such a beautiful appearance when well managed.

T. B.

APPLES IN THE UNITED STATES.

It is with much interest that I have just read Mr. Strong's paper in a recent number of THE GARDEN on the culture of these fruits in this country, reproduced from the Proceedings of the Massachusetts Horticultural Society. Many of his suggestions are pertinent and timely, and the subject embraces a very wide field of thought and inquiry to every intelligent fruit grower in the States who is willing to step out of the rut of his ancestors long enough to investigate the failures and realise the necessities of to-day. Beyond all question the Apple is the most useful and valuable fruit we have in the temperate zones, and has been perhaps since the world began. No other fruit is so widely adapted to our wants, and none will grow over such a wide extent of territory, and thrive under the diversifying influences of soil and climate by which it is thus surrounded. We could more easily spare any other fruit on the whole list, but the Apple would be a sad loss indeed. Now in view of these facts what are we doing to keep up a supply of this wholesome fruit for the people, to maintain or improve its quality, to battle with its insect enemies? Not very much, as it appears to me. The young trees are purchased where they can be got the cheapest, usually with little regard to root or top, and of such varieties innumerable as the shrewd nurseryman chooses to recommend without a question as to location, soil, or special market. They are planted about as carefully as the average hired man is apt to do when undirected by an intelligent oversight. "Sure, and did I not bury the roots well, and place the tender sprigs in line? and what more would ye have?" exclaims Pat. Thus the orchard is planted, and Nature is usually relied upon for the rest. The soil is cultivated and cropped for a time, but this is soon found inconvenient, and the orchard is finally seeded to grass and the trees are consigned to turf which, of course, is expected to perpetuate itself without manure. The little trees are now becoming discouraged in the race for existence. Their growth has been small and immature, they find nothing to feed upon, and small inducement to keep up the fight. It is about this time that insects commence their operations. The cultivator looks at the green leaves above and suspects nothing below; but he wonders why the trees don't begin to bear. He thinks they are old enough, and soon becomes thoroughly convinced that Apple growing is a mistake and does not pay. Such an outline is a picture which must be familiar to thousands of fruit growers in all localities, and yet we continue to hear of the obstacles and failures in Apple-growing, the slow and inadequate returns, and the business is looked upon with disfavour. Now, in my estimation, there is in this country an obstacle to profitable Apple growing. But it is in no way indicated by

the results of any slipshod culture, as before alluded to. As is well known, the Apple tree of America bears an abundant crop only in alternate years, and few, if any, the odd year, it being the common belief that the tree exhausts itself beyond the power of recuperation until two years from bearing. The effect of this upon the grower is obvious. The bearing year he has a heavy crop of Apples, but the market is overstocked, and he can scarcely sell them at any price. As an instance of this abundance, I may state that in 1880

The Apple crop of the States was estimated at nearly 200,000,000 barrels. Thousands upon thousand of barrels were allowed to rot in the orchards for the want of consumers. The odd year the trees are about barren of fruit; Apples bring a high price, but the grower has little or none to sell. And thus it is he murmurs at the poor returns of his Apple orchard after he has waited long years for it to come into bearing. This, as I view it, is one of the great problems which confronts the fruit growers to-day. How shall we teach the Apple tree moderation? How convince it of that periodical and consummate folly which makes it an invalid for a year to come, and disgusts the grower who gives it ground room? This is a legitimate obstacle to successful Apple growing, and it must be met in some way if the renewal and increase of Apple orchards is to go on. The cultivator raises Apples to make money, just as the manufacturer shapes his wares for the same purpose, and although there is a charming interest about the business of fruit-growing to every lover of Nature and her wonderful processes, there must also be money in it, or the grower cannot afford to devote his land, his money, or his time to it. Now, what shall be done? Our Apple orchards are declining; old orchards are passing away, new ones are planted sparingly and with misgivings, for the reason indicated above. Other fruits bring quicker and larger profits. Our stay upon earth is short at best, and bread is of all things the hardest to wait for beyond certain specified limits. Mr. Strong says you can stand under an Apple tree and pick the fruit by the barrel, and I agree with him; every two or three years this is so. But he does not tell us where we can sell the fruit at such times for a price that will cover the cost of picking, rent of the ground, care of the tree, and leave any margin of profit to the grower. This is the practical side of the question to be met. The season following the bearing year is a blank in the Apple orchard, and the grower must live on the profits of the previous year. His returns at least are only biennial in their recurrence; and now the experience of the year just closed has thrown us all at sea and invested the whole subject with new complications. It was

Our Apple year, this 1882, and everybody looked with confidence for the usual abundant yield. The trees blossomed copiously, and our vast orchards were as redolent and beautiful as ever before; but the succeeding months brought disappointment, and the autumn did not begin to fill our baskets. The yield was scarcely more than in off years, and at this time a fine barrel of Apples is really quite a luxury in most localities. Various theories for this freak have been assigned by pomologists and others which I cannot now stop to discuss. But surely everybody is now looking forward to the product of next year with the greatest interest and anxiety. Has the bearing year only been changed? Have the trees been brought into a condition for moderate annual crops? Or what will be the effect of this innovation? Such are the questions that now agitate our fruit growers. But it is meanwhile an additional season of loss for the Apple grower, as will be observed. Now, I am the very last man to discourage Apple growing. We have immense Apple orchards in America, splendid orchards, grandly beautiful in their luxuriant foliage, their charming blossoms, and their red and golden fruitage. I am proud of them. Not far from my residence is

An orchard of 25,000 Apple trees, perhaps the largest in the world, and we have other

very large orchards in New York State which I could name; and there are doubtless to-day over 150,000,000 Apple trees growing in the United States, and yet I say, plant more; don't give it up. There must be some way to make it pay, and the first desideratum is to get a crop every year. I don't know how to do this, but I believe it is practically impossible to secure such a result by thinning the blossoms or young fruit in the bearing year, as has been advocated. The labour is too great and success too uncertain. Who will give us the remedy? The large and increasing demand for foreign shipment of late years has in some degree favoured the producer. Better prices have prevailed for certain varieties, and this demand is likely to increase still further in the near future. This, at least, is an encouraging feature. Let us keep on planting Apple trees; our population is rapidly increasing, and every year we want thousands of barrels more than ever before. But get the very best and most vigorous trees to be had, no matter about the price, and then give them the best care possible. There is no time to waste in this business. Confine your orchard to a few established leading varieties. Experimenting with new sorts is a pleasant amusement, full of interest to those who can afford it, but there is little money in it. Mr. Strong says the Apple makes a

Homely tree. It always seems beautiful to me when well formed, as it invariably will be unless mutilated and deformed by some person who uses a pruning saw without brains behind it. If there is a handsomer object in the orchards of America than a grand, old Apple tree bending beneath its luscious load, and stretching out its fruitful arms to the cultivator on every side, I have yet to see it.

H. HENDRICKS.

Kingston, N.Y.

THE GRAPE ROOM.

NOTWITHSTANDING the excessive rainfall which we had during the autumn months, and the oft-recurring heavy showers that we are experiencing even now, our late Grapes are keeping unusually well this season. We have had them cut from the Vines about a week, and removed to a dry, commodious room in which the temperature is pretty equable, ranging now from 45° to 50°. Should it fall below 40°, we light a fire in a charcoal stove, and when this has burnt clear we place it in our Grape room to slightly raise the temperature. We find this to answer very well, though we would much prefer a room heated by means of hot-water pipes. The room in which we find Grapes to keep best is one that was formerly used as a fruit (Apple and Pear) store, but being over the young men's room, and a chimney likewise contiguous, the temperature ranged too high to keep the fruit in a satisfactory manner. For Grapes we like to see the temperature average 45°, and this we can generally maintain without artificial means. When cutting them from the Vines, we secure as good a length of wood as possible below the bunches, so that when inserted in the receptacles set apart for them, the shoot dips a good distance into the water. If perchance a fair length of stem below the bunch cannot well be secured, the natural order of things may be reversed, and that part of the wood extending beyond the bunch inserted in the water instead. We are now doing this in the case of some Gros Colmars, and we expect them to keep just as well as the rest. We use champagne bottles for our late Grapes, filling them fairly well up with rain water, and placing in each bottle a few small knobs of charcoal. As these bottles hold a considerable amount of water, frequent renewals or additions thereto are not so necessary as in the case of smaller bottles, which at one time we used, but found them to be somewhat inconvenient. In order to preserve the bloom as perfect as possible, we prefer carrying the bunches from the Vines to the room in our hands to that of laying them down in a basket or box, and the sooner they are in the water after being cut the better. For our present uses we are supplying the dessert with the Muscat of Alexandria and Black Alicante, both of which are still in

good condition. After these are used up, we shall take to the Gros Colmar, a Grape which is giving us greater satisfaction this season in point of flavour than it ever has done before, though the colour is not quite what we would like. When these are finished we will have recourse to Lady Downes, the backbone of the supply, till new Grapes are fit to use. We think this variety improves in flavour during the next two months. It is undoubtedly the best of Grapes for latest use. Good bunches of this kind well preserved form an attractive feature on the dessert table during March and April.

JAMES HUDSON.

Gunnersbury House, Acton.

NOTES ON GRAPES.

THE controversy last autumn about the good or bad qualities of Duke of Buccleuch Grape brought out such interesting details as to the conditions under which it succeeded, that I send you some notes on the behaviour of a few modern raised Grapes in our garden, in the hope that they may be useful to some, and draw wise experience from others. First, let me say, while thanking Mr. Fish for his pleasant account of the Clovenfords vineries, that his recommendation of a dry, airy atmosphere for Duke of Buccleuch, combined with the praises of some lady friends of mine who saw and tasted that Grape there last autumn, has made me purchase a cane wherewith to experiment. When one sees the fine Muscat and other Grapes grown out-of-doors in private gardens in Australia, Italy, or the south of France, it has often struck me as a matter for surprise how well such Grapes succeed in the damp, steamy atmosphere of an English warm vinery; some sorts surely must suffer, either in skin or flavour, under conditions so widely different from the dry air and bright sun of those climates. We all know that heavy syringing and constant moisture will keep down insect plagues and swell out the berries to a large size, but where Vines are clean to begin with, an airy, wholesome atmosphere will cause such strong growth and stout textured leaves, as to defy such pests, and give a flavour and colour to the Grapes that will repay any extra care. If, too, by such means, a thin-skinned variety is sufficiently solidified to withstand the recurring damps of an English climate, it is a gain in every respect. Being strongly impressed myself from various Continental experiences of the advantage of free ventilation and plenty of fire heat in growing really fine Grapes, we built, some three years ago, a range of glass in the most open and airy (not to say windy) situation that can well be imagined; and as a proof of success in growing one variety commonly thought intractable, I may mention that Canon Hall Muscat has with us set its berries so evenly and so thickly as to require thinning, and its magnificent bunches of berries became in due time of the amber colour we all admire, while its flavour and hanging powers turned out remarkable.

Of newer or modern Grapes we planted Golden Queen, Mrs. Pearson, and Dr. Hogg among white Grapes, and Royal Ascot and Madresfield Court of black varieties. As far as our own experience goes, I must say that Golden Queen is not worth growing in a private garden where vigour and appearance do not compensate for peculiar flatness of taste and absence of all particular flavour. On the other hand, Mrs. Pearson, a Grape by the same raiser, has shown itself of such great excellence in every way that we are pulling up several canes of other varieties in order to plant it more largely. It is a matter of surprise that so little has been said about this excellent kind in the gardening journals, where so often a new comer is at first unduly praised and recommended. That it should rarely have been shown is not so surprising, as Mrs. Pearson is of Frontignan origin, and consequently its berries are not of the largest size; they are, however, much bigger than any other Frontignan variety, and have the deliciously fresh and piquant flavour of the old and excellent white Frontignan. For vigour of growth, freedom of bearing, and shape and size of bunch, this white

Grape is in a cool house unsurpassed even by such a useful variety as Foster's Seedling; while as to excellent flavour and clear golden colour, combined with high keeping qualities, it puts it in the shade altogether. In a cool span-roofed vinery, where the Grapes ripened in the end of August, the bunches of this variety hung until the new year, although the damp caused by bedding plants and Chrysanthemums crowded in under the Vines in autumn must have been very prejudicial; and I believe I am literally correct in saying that not six berries ever required to be cut out from first to last during the four months the Grapes remained on the vine. It is quite evident that in a Grape room or dry vinery this Grape will keep as late as Black Alicante, and prove a most admirable contrast to that old variety. With so many excellencies there must be some defect, if only a small one, and with us it is this, that the bloom is thin, and the berries in a young state rust very easily with any handling or moisture condensing on them. A cane that was planted in the Muscat house was quite disappointing from this cause, as the greater heat and moisture so rusted the berries in early stages as to destroy its appearance entirely. Curiously enough, in this warm house the berries never became golden or nearly as well flavoured as those in the cool house. It is hardly possible that one grower could succeed in raising many distinct and good kinds where already there are so many, and Dr. Hogg, another Grape by the same raiser, is an exception to the rule. Being much of the same Frontignan origin, and with high Frontignan flavour and extremely large but loose bunches, it is to be recommended as a summer Grape, and is useful where Frontignan Grapes are grown and liked. Royal Ascot, grown in a very airy house, is very remarkable for its oval Muscat-shaped berries and fine flavour, but its bunches are so small as to make it a poor cropper, unless two be left on a shoot. As its keeping powers are very limited, it is hardly a Grape for everybody.

Of all black Grapes, new or old, Madresfield Court has been with us the most admired; it has grown and fruited splendidly, so as to justify, with us, its reputation in many places of being the finest black Grape in cultivation. For size of bunch and berry, and high Muscat flavour, this has certainly been first of all, and quite puts Muscat Hamburgh into the shade. Gros Colmar, in an airy, but warm house, has acquired a brisk agreeable flavour, and though not equal to Lady Downes, is so handsome and good as to be much liked at table as well as on the Vine. A seedling Vine of great promise as a black and late Grape, that has been raised in this neighbourhood, is being tried, and, from its foliage, should be distinct. What it may turn out to be time will tell.

ED. H. WOODALL.

Cordon-trained Pear trees.—Mr. Bridgeman seems to think that fan-trained trees are superior to cordon-trained ones; but in this I may be allowed to differ from him. I have here ample proof that cordon-trained trees on the Quince stock bear better fruit not only as regards size, but quality and smoothness of skin, than those not so treated, and the bearing properties are greater, taking as a rule space and weight of fruit into account. I have three trees fan-trained on the Pear stock, all on a west wall, and where their roots are is a mystery; but the border in which they are supposed to be receives no dressing except that which is necessary for a crop of vegetables, yet these trees bear good crops, and some fine fruit of all sizes and shapes. Adjoining this wall at right angles I have the same kind as cordons on a south wall, and the difference between the two is so much marked that a casual observer would not hesitate to pronounce them to be different sorts. No doubt out of some six bushels of fruit or so it would be an easy matter to pick out a single dish fit to take a prize at Hereford, but this is poor proof in favour of fan-trained trees, as I know that out of a full crop it is seldom one can get many good single dishes,

owing to the fruits being so variable in size. In the case of cordon trees this is reversed, and it is characteristic of the system that the fruits are even in size, at least that is my experience here.—R. A. HOLME LACY.

Huyeh's Prince Consort Pear has proved itself to be so good in every way here for several seasons, that I consider it worthy of a place in the front rank with our best varieties. It is comparatively new, and for that reason not so well known or extensively planted as it deserves to be. The tree which we have of it is growing against a south wall; it bears well, so much so, that the crop has to be generally thinned—a good fault. It is not a very handsome Pear, as when ripe it has a green skin and is brown and russety on the side exposed to the sun. It resembles a well-grown fruit of Beurré Rance, and is quite equal to a Winter Nelis or a Doyenné du Comice in flavour. It comes into use about the same time as the last named sort, viz., November. Those who are dubious about planting new kinds of Pear trees may safely add this variety to their collections.—WM. ALLAN, *Guntton*.

NOTES.

IN writing in my own modest way a few little notes for THE GARDEN at the request of one who has ever been a staunch and faithful friend to me, I will begin them now, and shall continue them from time to time as opportunity will allow me. Of necessity these notes will not please all alike, and the honest criticism of those who disagree with me is invited rather than deprecated, but this much only, on the sole condition that I must be allowed to be excused from making any reply whatever. The readers of THE GARDEN must be our judges.

Crocuses.—Amongst the species of these now in bloom none are more pleasing than *C. Imperati* with its dark striped buds of soft fawn colour and purple-lined perianth. In pots in a cold house it is now most lovely. Flowering with it for company are other hardy gems, such as *C. Sieberi*, lilac-purple; the vivid golden-orange *C. Olivieri*, and two or three others less showy, but none the less beautiful. How eagerly cultivators of these hardy little earth stars must be to see that beautiful monograph which Mr. Maw has in hand, and no flowers better deserved or stood more in need of a beautifully illustrated history than do these dainty little flowers which long ago won the heart of good Dean Herbert, to which love his notes and beautiful original drawings in the Royal Horticultural Society's library bear ample testimony.

Half-hardy Primroses.—One at least of those now in flower is worthy of note. I allude to *P. erosa*, an Indian species of the farinose section. Its mealy scapes rise from a rosette of deep green roughly serrated leaves, bearing a whorl of delicate lilac blossoms and mealy buds nestling together in sweet companionship. This plant and the mealy-leaved *P. verticillata* (*P. abyssinica*) are well worth special culture as pot plants for blooming in the greenhouse during the earliest spring months. With them *P. mollis* also deserves a place, although it flowers, as a rule, later in the year.

The great white Christmas Rose (*Helleborus niger angustifolius*) is a rare plant, with flowers as large and as white as the *Eucharis Lily*. It must not be confounded with *H. altifolius* (figured in THE GARDEN), which bears similarly large flowers, but shaded with rose colour, with red stalks to the flowers and foliage quite different in outline from *H. niger*, so different that, with the late Miss Hope (who grew and distributed it), I hold it is a true species, distinct from all the half-dozen or more varieties of *H. niger*, or common Christmas Rose. This *H. altifolius* comes true from seed. What I call the true *H. niger angustifolius* is a beautiful variety, having its fresh, glossy, green leaflets born aloft on pale green scapes a foot in height, so that the leaves themselves form a canopy above the big snowy flowers.

Nine people out of ten would pass the plant without observing that it was in blossom, but if the leaves are drawn aside, a snowdrift-like mass of white blossoms, unsoiled by wind or rain-splashing, rewards the discoverer. Some very good cultivators of hardy flowers who have seen the plant in bloom know nothing of it or its history. I have promised our great authority on garden Hellebores, Mr. Barr, flowers and foliage of this swan-like beauty, which is a real *H. niger maximus* as far as leafage and flower are concerned, but totally distinct from *H. altifolius*, which is the *H. niger maximus* of most gardens.

The late frost.—Of things erratic perhaps climate is most so of all. Thus friends tell me that during the recent hard weather 12° below freezing was all the frost registered at Cambridge, while at Clovenfords on the same morning the thermometer stood at 11° below zero, and even in Dublin, quite near to the sea, and where the climate is proverbially mild and genial as a rule during the winter months, even there we are told as many as 22° of frost (*i.e.*, 22° below freezing point) was experienced. A comparison of the temperatures registered at any given hour in say a hundred localities in England would give some curious and perplexing results. Of course, properly tested instruments would be necessary, and the questions of altitude, subsoil, proximity to the sea, wind, and other influences must needs be added to the readings. Topographical knowledge of this kind would be of great advantage to good gardeners, and is well worth attention, perhaps quite as much so as reports on fruit crops or on the Potato harvest. A special report prepared every winter on these lines would be of great interest.

Of hardy fine foliaged plants beautiful in winter we have a goodly store. Yet how seldom do we see their effect developed and made more impressive by good, to say nought of artistic, arrangement. Of things habitually neglected, even if not otherwise badly treated in a positive way, are Ives, Hollies, Yuccas, Smilax, and Aucubas, and yet we have here material for a good winter garden in the open air, with the one addition of green Grass, for all defy frosts, wind, and rain even under the worst phases of garden culture.

Ivy.—The capabilities of our common green-leaved Ivy with its varieties, and the different uses to which it may be put, have never yet been exhausted; as low edgings on Grass, as garniture for mossy stones, as drapery on bare walls, as pyramids, beds, or borders, or used as a clothing of glossy leaves for tree trunks, living or dead, we have no other plant so permanently fresh and fair as the different kinds of Ivy. Among its forms there is variety almost infinite, so that there is no need to cover a wall or bare gable, or many individual tree trunks with one and the same kind. *Rægneriana*, *algeriensis*, *pedata*, *palmata*, *hastata*, *canariensis*, and its golden forms are all alike distinct and beautiful.

Hollies.—The variable beauty of these is like "a soft sweet song" to all who have an eye for leaf form and colour in the wintry landscape. The "Hollies at Shawdon" sounds almost as classical as the "Bells of Shandon," and then there is that wonderful collection at the old College Gardens, Dublin, many being unique examples of red, orange, and golden-fruited kinds, raised there from seeds during the palmy days when Mackay and Bain were in their prime. Even now their past labours cast a halo over the sheltered nooks and corners within its quaint old stone walls. No effects of climate, however erratic or severe, affect the life or beauty of our native Holly and its innumerable varieties. Its leaves are ever clean and fresh, and their berries shine bright and cheery even when all is decay and blackened gloom around. After all no South Sea Croton was ever so effective under a glass roof as the old Milkmaid or a Golden Queen, as seen glistening above the snow and illumined by wintry sunshine. Every shower washes the Holly and adds to its beauty, and so of all hardy shrubs it is the one

for town gardens, beautiful alike as a hedge, or in its natural bush shape rising from the fresh green turf.

Different kinds of Smilax.—When the "cold house" idea develops itself—and it is making headway more and more—we may expect that justice will be done to the different half-hardy forms of Smilax. All are fresh and beautiful—mostly evergreen—and their elegant sprays of piquant leafage endure fresh and fair for weeks after being cut from the plants. *S. tamnoides* (recently figured in THE GARDEN) is one of the best, but all the seedling forms of *S. aspera* are likewise beautiful evergreens. *S. laurifolia* and *S. latifolia* are both effective; the last, in fact, is one of the most distinct of all half-hardy climbing plants, and there is a still larger variety with variegated foliage, but it is not hardy. *S. China* and *S. mauritanica* are familiar enough by name, but I am not at all certain what special plants they are supposed to represent. In Devon, Cornwall, Scilly Islands, and in some parts of Ireland nearly all the species are hardy—*S. aspera* and *S. latifolia* especially so if planted beneath the shelter of walls on which the morning sunshine does not fall too early after hard frost. Even if cut down by winters the most severe they spring up afresh from the old crowns, and so regain their beauty before midsummer. Smilax, Ruscus, and some species of Asparagus are fine foliaged plants of the very best kinds for planting out in cool houses.

Orchids and their culture.—One by one the "frightful old bogies and hobgoblins" of Orchid culture are being "laid," and the best of success attends those who treat them as if they were ordinary plants, and not as if they were mysterious "creations" of the natural habits of which nothing was known. It took some time before we could believe that the Andean Orchids were not "fire-worshippers," as once were the human inhabitants of the mountains whence they came to us. Then we "shaded" whole shiploads of these valuable plants to death, and "drying off" and "resting" were answerable for the exodus of many others from our collections. But now all is changed. Dr. Paterson and other cultivators have demonstrated the possibility of growing the majority of tropical Orchids in a warm, moist greenhouse temperature of from 50° to 60°, with abundance of air and water during growth. Some of Dr. Paterson's plants are unique in health and vigour, and even professional Orchid growers had nothing but praise for the plants he recently disposed of in Edinburgh.

Shading Orchids.—Such great changes have taken place in Orchid culture of late years, that all the works hitherto published on this branch of culture are well-nigh obsolete. We have unlearned so much that nothing less than a new departure will satisfy those who are abreast of modern practice. The old plan of growing Orchids in heavily shaded hothouses, a plan which necessitated drying off and resting, is quite superseded. Orchids like the sunshine, and wind, and rain abroad, and here at home make the stoutest and most robust growth in light, airy houses, being protected from actual sun scorching only by a slight muffing of turpentine and white lead, or by the thinnest of textile fabrics. Growing Orchids in gloomy glass-roofed tunnels gave us weak, sappy growths, which had to be ripened up in order to obtain flowers. Now the ripening and growing processes go on together in our plant houses as naturally as they do at home in the Tropics.

Orchid growing epitomised.—If I were asked to epitomise our modern knowledge of Orchid growing into a few words I should say small pots, three parts drainage and one-fourth compost, light, sunny houses, ample ventilation (especially at night), a large watering-pot with a strong arm, a clear head, and a real love of plants behind it; all small-growing plants to be grown in shallow suspension pans, and absolute cleanliness to be observed in all things; a careful use of the syringe, no fumigation, and no insecticides. There

are many details in any special culture, of course, but the above guiding lines ought to be in every young Orchid grower's mind. A compost of brown peat fibre only and Sphagnum Moss, charcoal nodules, and crocks the size of Peas will suit most things, but only use a layer of from 1 inch to 3 inches thick above the drainage in the pots. Too great a body of compost is the stumbling-block of most beginners. This is proved by the general success which attends shallow pan culture. If you are troubled because any particular plant does not bloom in a pot on the stage suspend it near to the roof for a season, and ten to one the growth so made will bloom.

Orchids injured by frost.—In relation to this question of Orchid culture, I quote the following from a letter just received: "At the beginning of the last frost our big boiler gave way—at least the flow-pipe burst at 9 inches from the boiler itself. We repaired it on Thursday, which was here the coldest day of all. We began to fill the pipes at 4 o'clock p.m., and the thermometer outside then showed 18° of frost. We had 6000 gallons of cold water in the pipes, and were a little afraid of its freezing ere we could get the repairs finished and the fire started. All the pipes were nicely warm by 6 o'clock, however (outside temperature 22° below freezing), but frost had obtained a footing in all the houses, and our poor plants have suffered much in consequence, but I am thankful to say that it might have been worse. Of all our stove plants I think the Orchids have come through the ordeal the best." I do not believe that any tropical or inter-tropical plants are benefited by frost. No doubt whatever exists that it is injurious, even if not actually fatal to them; but I am thoroughly persuaded that a mean temperature of 55° to 65° is sufficient for the good culture of all known Orchids.

Combinations of scented flowers.—The agreeable blending of floral perfumes when fragrant flowers are used indoors is not often mentioned, but perhaps is as worthy of attention as colour arrangement. Here are a few combinations which we think very pleasant. Heliotrope and Rosemary, Violets and Mignonette, Lilac and Tussilago fragrans, Lilac and Narcissus papyraceus, leaves of Eucalyptus oitriodrus and Vanda furva, Violets and Tussilago, Rosemary and double Roman Narcissus, Chimonanthe fragrans and lemon-scented Verbena, or Chrysanthemum Progne, and Lemon Grass. A single flower or spray of each in separate glasses does not please us so much as when two are grouped in this way. To enjoy perfume, it is necessary to be very chary in its use, one or two of the above groups are ample in any ordinary room. The result is a subtle odour of which one longs for just a little more—not a "fragrant stink," suggestive of a perfumery shop. To use large quantities of Lilies, Roses, Narcissus, and Violets, and other strong-scented blossoms in a room is as offensive to delicate taste as wall paper of purple and yellow or green or scarlet.

Impatiens Sultani.—One of the prettiest little stove plants of modern introduction is this Balsam (recently figured in THE GARDEN). Cuttings 3 inches or 4 inches in height flower freely, and rival Calanthe Veitchi in the bright rosiness of their blossoms. Quite small plants of it, grouped along with Isoplepis pygmaea or the small variety of Pellea muscosa, are most effective for indoor decorative uses.

Cuscuta reflexa.—Can anyone tell me where this may be obtained? It is an Indian Dodder with slender twining stems and sweet white Lily of the Valley-like flowers, and being a parasite it grows well on zonal Pelargoniums, Crasulads, Ivy, Willows, Forsythia, and other shrubs. It is so distinct and interesting even when not in bloom, that surely some of our nurserymen must have it in stock.

VERONICA.

Diseased Camellias (A. B.).—It is impossible from an examination of the leaves only to say what is wrong with your plant. No doubt there is

or has been something wrong in the general culture, but you give us no clue to this. A few spores of the fungus named Pestalozia Guepini (peculiar to Camellias) were on the black spots and patches, but this fungus we look upon as a result rather than a cause of disease.—W. G. S.

ROSE GARDEN.

TEA ROSES ON RAISED BEDS.

FOR some time past, in designing Rose gardens, says Mr. George Paul, I have more than once suggested a bed in the centre raised above the surrounding level, to be filled with Tea Roses; but it was more with the idea of slightly breaking the monotony of the flat beds prevalent in Rose gardens than with any cultural purpose. I found, however, the Tea Roses in some of these raised beds doing exceedingly well, and the thought occurred to me that the lifting the plants up from the moist level ground and the more efficient drainage they thus had might be the cause of this happier growth, better ripening, and escape in greater proportionate numbers from the effects of winter frosts. The difficulties of growing Tea Roses have been always greater in low-lying valleys, with heavy soils, than on the light sandy hill grounds. There was some analogy also in this more successful growth of the Tea Roses on raised beds, with the method of growing Hyacinths in Holland, in garden soil, reclaimed but perhaps a year or two from the Dutch marshes; and our first bed was a copy of a Dutch Hyacinth bed. A piece of our ordinary good alluvial soil was trenched up, and some beds, 6 feet across, were marked out. These were dressed with road sand and manure, and a board was fixed at each end of the bed, to show the level they were to be made up to. The earth was then thrown from the paths on to the beds, which, when sunk, were and are about 8 inches above the level of the main paths at the end and between the beds. This was done during the winter; owing to busy times, the dwarf Teas—some on own roots, some on Manetti, some on seedling Briers—were only planted, after the soil had been just pricked over again with a fork, about the first week in March. They were put in 18 inches apart all ways; but such was their growth during this not too favourable summer, that the more vigorous of the dwarf Teas, such as Marie Van Houtte, have made almost impenetrable thickets. The plants were by no means selected, being those left over after the sale of the whole winter; but they gave such good flowers, that in the Tea classes we fairly held our own at the several shows.

The kinds chosen were confined to the moderate-growing Teas, excluding all of the Gloire de Dijon race, but allowing Bourbon Souvenir de la Malmaison a place. The kinds are—

* Anna Olivier.
Alba rosea (a little weak).
Amazona.
Catherine Mermet.
Comtesse Riza du Parc.
David Pradel.
Devoniensis.
Duchess of Edinburgh.
Innocenta Pirola.
Jean Ducher.
Jean Pernet.
Mad. Angele Jacquier.
" Charles.
" Falcot.

* Mad. Hippolyte Jamain.
" Lambard (magnificent).
" Margottin.
" Villermoz.
Welch.
Marie Guillot.
Marie Van Houtte.
* Perle des Jardins.
Perle de Lyon.
Perfection de Monplaisir.
Reubens.
Safraout.
Sombreuil.
Souvenir d'un Ami.

* Those asterisked were the most even in growth and freest flowered varieties. La Boule d'Or, Niphotos, and Souvenir d'Elise were not tried as dwarfs, but as standards alone on raised beds.

The culture, continued the summer through, was simply keeping the beds hoed, and the plants, in the very hottest time of summer, had a little rotted manure by way of mulch; but they were not watered, nor did they seem to need special moisture, owing, probably, to the roots being pushed well down into the deeply-moved soil. They made a vigorous autumn growth, giving flowers abundantly, and of fine quality. With December 1 came the protecting process. They were on that day ridged up with the surrounding

earth with a hoe, much as one would mould up Potatoes. The effect is that the plant is left high and dry, with an open hollow dyke to carry away all moisture to the large open drains formed by the paths between the beds. The wood is thoroughly protected, as far as the bottom eyes are concerned; and these eyes will lie dry and dormant until the earth is removed in the spring, when they can be pruned in closely, and all injured upper wood be dispensed with, though that has also been slightly protected with litter. I need hardly say that, accepting any width for your bed that seems desirable, such beds may take any form—say a long S or an oval—and be ornamentally placed on grass, the sides being sloped up and turfed. The idea is quite simple, not particularly original, but having been found effective for Tea Roses, and seeming to me to simplify their culture, I have ventured to describe the practical application of the idea under the title at the head of this brief article.—*Rosarian's Year Book.*

BUDDING ROSES.

"R. H." is not alone in his failures with lean buds. All that is possible should be done to convert them into fat ones. Some sorts of Roses will have lean buds, feed or treat them as we may. Something may, however, be done to fill them by stopping the current year's wood before it flowers. What a sacrifice, I fear; but at times we must sacrifice beauty for utility, and a harvest of bloom is often of far less moment to a rosarian than a fine crop of plump buds. The buds under such treatment plump up from the heads of the shoots downwards. The process of filling must be carefully watched, and so soon as one bud gets fairly filled remove it and wait patiently till another plumps up, and so on till all are fit. It is seldom that all will fill of these lean-budded kinds; but if one, two, or three are thus developed to the growing point that is something gained. Then there is another way of forcing these lean buds to grow. About a week after insertion cut the stocks back to within an eye or two of the inserted bud. So soon as this eye threatens to break rub it off, and thus force the whole strength of the stock into the lean bud. Sometimes this will drown or flood the lean bud off; at others it will stimulate it to immediate and successful growth. There is yet another way of treating these lean buds. Get as long and hard a piece of bark as possible. This will occasionally assist the first year, and if not, give them more strength to live through the winter and break into growth the following spring. Finally, instead of budding with bark in the usual way, take a small slice of cambium or young wood with the bud and insert it in the usual way. Almost the thinner the slice of wood the better, provided that the roots of the bud are preserved intact; and it is well to bear in mind in this connection that the leaner the bud the deeper its roots; in fact, like the preacher whose sermons were reputed to be all sound, the lean bud is pretty well all roots, and hence the vital importance of conserving them, even by the addition of a section of wood. If "R. H." cannot succeed by either of these methods, then he must never propagate his lean-budded Roses in this way.

D. T. FISH.

Mice and Aponogeton distachyon.

That mice destroy the tubers of this plant I had actual proof during the late severe frost. From a pond covered with it here a portion had to be removed, as it was choking other things. I observed in the cleared part that the bottom was frequently disturbed; and, knowing that the fish were not on the move, I was curious to ascertain the cause, and kept a close watch. It was not long before I perceived a mouse emerge from a hole near the edge, plunge into the water, and dive a distance of 5 feet. I could clearly see its progress through the water, which is about 2 feet deep. After wriggling itself among the debris at the bottom and finding a suitable root, one about the size of a Pea, it

returned under water, straight to the hole and ate it. The process was then repeated, indeed, several times in succession. It was one of the long-tailed species, but which I could not determine. Is it not strange that these warmth-loving animals should thus boldly take the water at such an inclement time? *En passant*, Aponogeton was finely in bloom up to the time of the sharp frost, which of course destroyed the flowers. The mild weather we have since had has again brought it into blossom, and in a few days if unchecked it will be as gay as before the frost.—J. M., *Charmouth, Dorset*.

TREES AND SHRUBS.

TREES IN THE STREETS OF WASHINGTON.

By F. L. OLMSTED.

WASHINGTON has gained more in outward appearance during the last half-dozen years than it had before in half a century. It now has forty miles of better pavement than can be found in any other American town, and which compares favourably with any in Europe. This has made thorough street-sweeping practicable at small cost, and it results that, though the city is but poorly supplied with water, it is little afflicted with dust and is beginning to have a refreshingly clean aspect. But your readers will be more interested to know that on lines bordering these streets there now stand, fairly started, upwards of 100,000 well-formed nursery-grown trees. Maples of several species are the more common, but there are representatives (by the hundred) of at least six different genera. They are at present but club-headed saplings, hardly recovered from the shock of transplantation, or fairly settled in their new homes, and show none of the characteristic mature beauty of their several families. They have as yet, therefore, little value except as promissory notes, their growth to be discounted. Nevertheless, seen as they constantly are, in long perspectives of uniform mass and colour, their effect on the city is absolutely transforming, and, if all goes well with them, Washington will in a few years be a new and glorified city; a capital that Americans may be proud of; supreme at least in its street beauty, whatever monstrosities in building fate may have in store for it. It can hardly fail in April and May to become a great pleasure resort.

But more than this is to be said. The streets of Washington ("if all goes well") will become a national tree school, providing a standard, a stimulus, and an incentive for the improvement of every village and hamlet in the land, and it may be well to add that if those able, as your readers must generally be, to foresee the future value of this work, will but let their intelligent applause be heard by members of Congress, it will prevent the occurrence of such a catastrophe, as under our present political customs, is always hanging over every beneficent enterprise as soon as it is well started. The commission of thoroughly competent experts (Smith, Saunders, and Saul) should be very warmly and effectively sustained at every pertinent opportunity. They have yet a vast barrier of indifference, ignorance, and active prejudice to overcome—not against their object or the results of their work, but against the essential conditions of lasting success. Any one who has watched the various processes by which nine-tenths of all the street trees planted throughout the country are killed, stunted, distorted, mangled, and hardly one in a thousand suffered to attain its full, natural beauty, will understand what they mean.

But in spite of what has been gained in the two particulars named, in a rapid development of gardening decoration, and in a large addition of private dwellings of a more or less elegant character, the greater part of Washington, outside the lines of its public plantations, yet retains much of its old character. Two offences to good taste are at this time particularly conspicuous, and all the more so because of the neat, trim, and genuine

quality of most of the new brick, tile, and stonework. The first results from efforts at cheap, tawdry, and garish display in the embellishment of door-yards and lawns; the second from the necessity which has resulted in the recent grading down of streets, of leaving miles of formal earthworks between them and the houses fronting on them.

The fields about Washington are turfless, and good turf is only to be had by a tedious process, with great care and labour, and through the heat of summer only by a profuse command of water. There will soon be thousands of houses here, planted on banks from 4 feet to 10 feet above the sidewalk, with flat, formal, steep slopes, such as even in the climate of England, and with the best of soil and gardening skill, it is hardly possible to maintain turf upon suitable to carry the eye up to a house of refined materials and workmanship. The soil upon these slopes in Washington is such as one sees in going there from Baltimore in the railway cuttings—a cracking, brick clay and gravel, bearing naturally almost nothing but stunted "Broom Sedge." But were it much better, proper turf in such a situation in the climate of Washington would be out of the question, and nothing more incongruous with the cut stone and plate glass which often appears behind it, or more positively dreary and forlorn than what now generally stands upon them for turf, can be imagined. It compares with true turf as a ragged and dirty doormat compares with a table napkin. As the arrangement has been forced upon the people, and such banks cannot, in many cases, be now avoided except at great expense, and as miles of them must be brought prominently into view to all visiting a city in which every American has a responsibility, the question of any generally available, tidy treatment of them is one upon which good advice is greatly needed.

Nearly always it would be better, as far as practicable, to break art of rigidly mathematical forms; to obtain everywhere curving faces and especially to destroy angular crests. Next, a much more liberal use of shrubbery is desirable; not alone for decorative purposes, but for beautifully screening or throwing into background retirement banks of dead and ragged Grass. Even screens in the form of low, closely-trimmed hedges might be used. As Washington should appear well in winter, they should be of evergreens; the best if one had patience, probably of Tree Box or American Holly; but it may be observed that after an exceptionally severe winter and a fearfully trying summer both Yews and Retinosporas of all species and varieties are looking very well in Washington.

After all that can be done in this way, however, should not the chief resort be to creepers? In Europe such banks are sometimes seen covered very perfectly and yet very snugly and daintily with Ivy. They may be seen also dressed with Periwinkle, but it is rarely in good order. Evergreen Honeysuckle would almost surely succeed, but might look too riotous. Has the evergreen Euonymus had a fair trial as a carpet, carefully spread and pegged? Could anything be done with creeping Junipers? Perhaps in some cases it would do to make a facing of rough stone, to be generally overrun with Honeysuckle and Clematis, but with breaks and niches supporting Sedums and other dry rock plants, and with outbursts of Yuccas and drought-enduring shrubs, as the smaller Sumachs and Mahonias. Suitable stone is to be easily obtained about Washington.

Still another expedient that might be admissible in some situations would be a trellis set at the base of the bank and of sufficient height to obscure it without obstructing the view toward the house; the trellis to be covered, of course, with creepers. Wire netting stretched on iron frames, with the simplest possible supports of iron, would be best. But one of Cedar or Sassafraz poles might better be used than leave the banks in their present repulsive prominence. Such material is easily obtained anywhere about Washington, and it can be easily morticed and wire-bound together, and perfectly clothed with evergreen drapery in a single year.—*Gardener's Monthly*.

THE RUSSIAN MULBERRY IN NEBRASKA.

MR. G. F. CLARK, Gage Co., Nebraska, who lives near a colony of the Mennonites, gives the *American Agriculturist* this account of their Mulberry tree planting:—

The Russian Mulberry was introduced into their European colonies by the Russian Government for the purpose of silk culture and to shade and improve the land. The landowners were compelled to buy these trees from the Government, each being obliged to plant a certain number. After cultivating them until they found out their value, they voluntarily planted the trees very extensively, and learnt that silk culture was not the only object in raising them. They found the timber very valuable for fence posts, outlasting any other Russian timber. It was also found profitable for cabinet work, and one of the most desirable trees for fuel; besides it bore edible fruit, which was marketable in Russia. When the Mennonites came to this country they brought the seeds of this tree with them, together with those of several other trees, but planted these more extensively than all others combined. The Russian Mulberry is a very rapid grower. Trees, the seed of which was planted by the Mennonites, are now 20 feet high and large enough for fence posts. They grow very large and bear abundant crops. The fruit resembles the Blackberry in appearance, a large share being black, marked with reddish white. They vary in flavour from acid to sweet. The growth of this tree is like that of the Apple tree. Many of the leaves have the margin with from 5 lobes to 12 lobes. The Mennonites use it as an ornamental hedge plant; it makes a beautiful fence, and will stand shearing as well as any tree. By some this tree is regarded as the most hardy Mulberry, and the best suited for silk culture in northern localities. The Mennonites have interested themselves in the silk business to some extent since they have been in this country, and raised some cocoons for sale.

SIBERIAN CONIFERS.

So far as I can ascertain there are in Northern Siberia five trees belonging to the Pine group. They are as follows:—

Larch.—This well-known tree extends further north than any of the others, it is abundant, though small, as far north as lat. 69½°. Further south it attains large dimensions. At Yen-e-saïsk' a Larch pole, suitable for the mast of a ship, 36 inches in diameter at the base, and 18 inches in diameter at the point, and 60 feet long, may be bought for a sovereign. This hard dark wood looks well for the walls and ceilings of the peasants' rooms.

Spruce Fir (*Picea obovata*).—This elegant tree, with branches growing out of the trunk down almost to the root and trailing on the ground, extends nearly as far north as the Larch, say to lat. 69°. It is a very important tree for commercial purposes. Its wood is white, of very small specific gravity, extremely elastic, and is said not to lose its elasticity by age. It makes the best masts for ships, and is for oars the best substitute for Ash. Snow-shoes are generally made of this wood. The quality is good down to the roots, and it makes the best "knees" for ship building—knees which do not require to be cut out of the solid, or artificially bent. It is, however, subject to very hard knots, and care must be taken not to blunt the edge of the axe.

Siberian Spruce Fir (*Picea sibirica*).—This tree differs from the common Spruce (*Picea obovata*) in having a smooth bark of an ash-grey colour; its leaves are also of a much darker blue-green. We did not meet with it further north than lat. 63°. It has little commercial value, being soft, and apt to crack and decay. The ease with which it is split causes it to be used for firewood and for roofing. The well-known Pine or Scotch Fir tree scarcely extended so far north even as the preceding, say to lat. 62½°.

Cedar (*Pinus Cembra*) is very similar in appearance to the Scotch Fir, but its timber is said

to have a much higher marketable value. It is dark, but not so dark as Larch, and there is very little of the white inferior wood next to the bark. If stacked too long in the forest it is liable to be attacked by worms, but for furniture and indoor use it is the best timber to be found in Siberia. It is reputed never to rot, shrink, warp, or crack. Soft and easy to work, it has nevertheless a fine grain, and is almost free from knots. The Ost-yaks build their ships of it. They hew down a trunk 2 feet or 3 feet in diameter, split it, and of each half make a wide thin board; the rest is wasted, for the axe is an extravagant tool. This tree is found up to lat. $67\frac{1}{2}^{\circ}$.

We found the common Birch up to lat. $69\frac{1}{2}^{\circ}$, and in various places we noticed that where a Pine forest had been burnt or cut down it appeared to be immediately replaced by a luxuriant growth of Birch. The creeping Birch and two or three sorts of Willow were common in suitable localities on the Tundra as far north as we went—i.e., lat. $71\frac{1}{2}^{\circ}$.

The Alder was abundant at $69\frac{1}{2}^{\circ}$, and the Juniper at 69° .

I did not observe the Poplar at the Koo-ray'-i-ka, in lat. $66\frac{1}{2}^{\circ}$, but it was abundant at Sil-o-vah'-noff, in lat. 66° . The Ost-yaks hollow their canoes out of the trunk of this tree.—“*Siberia in Asia*,” by Henry Seebohm.

Rhus cotinoides.—In April, 1842, at the beginning of a botanical tour through the Southern Alleghenies, I found this rare tree about twelve miles from Huntsville, Ala., on the road to Winchester, Tenn. A few years later I urged the importance of introducing this Rhus into cultivation. Its fruit-bearing panicles, with their long, hairy pedicels, have a strong resemblance to the Rhus Cotinus, or Venetian Sumach, so extensively cultivated both in Europe and America. But our Rhus attains the dimensions of a tree 8 inches to 12 inches in diameter, with a height of more than 30 feet. It has large, bright green leaves, 4 inches to 6 inches in length, which joined with its conspicuous feathery fruit-bearing panicles, 8 inches to 12 inches long, would render it a striking and beautiful object in any landscape. There is no other tree like it in cultivation in the United States. Nuttall first discovered it as a large shrub on the banks of the Grand River, a branch of the Arkansas in the Indian Territory, in 1819. It grows in a limestone soil on the sides of mountains 800 feet to 1000 feet high. It may be known in the winter by its light grey and furrowed bark. Its wood is yellow, variegated with shades of yellowish brown. Its branches are brittle.—S. B. BUCKLEY, in *Country Gentleman*.

Fungus on evergreens (Indigo).—The name of the fungus which causes the thick sooty-looking coating on your evergreens is Capnodium Footi. Judging from the frequency with which examples of it are now sent to us, this fungus appears to get commoner every year. It is also grown on the foliage of some deciduous trees and herbaceous plants. It is very frequently accompanied by scale insects. This fact has caused some (including one of our American correspondents) to say the scale insect is the cause of the fungus. The fungus undoubtedly grows with greater luxuriance where the excretions of scale insects are present, but it is quite able to hold its own without them. We advise the destruction of the infected leaves as far as possible, the destruction of scale where present, and good clean gardening.—W. G. S.

SHORT NOTES.—TREES AND SHRUBS.

Wellingtonias.—In Vol. VI., 1874, of THE GARDEN (p. 262) I read of a large Wellingtonia then growing at Cecil, Co. Tyrone, said to be the largest in the United Kingdom. It would be interesting to know the height of this tree now. Will anyone kindly furnish it?—E. W. G.

—I have just heard of a very tall Wellingtonia at Inchrya, Glencarse, in Perthshire, said to be 84 feet high but I doubt the statement, till from actual observation I can verify it.—R. IL

ORCHIDS.

Orchids in bloom in the Royal Exotic Nursery, Chelsea, comprise some exceptionally beautiful species and varieties. Of *Lælias* there is a fine display of *L. anceps*, including its finest varieties, such as *Barkeri*, *Dawsoni*, and *rosea*, all extremely beautiful. The charming little *L. albidula* is represented by some fine flowering specimens with as many as seven or eight blooms on one spike. It is a sweet little winter Orchid indispensable to a good collection. The variety *bella*, also very fine here, differs from the type in having the labellum strongly marked with rose-pink. *Cattleyas* include the beautiful *C. Dodgsoni*, noticed some weeks ago, and the charming *Lælia Veitchi*, a hybrid between *Cattleya crispata* and *C. labiata*. It is quite intermediate between these two, and combines their peculiar characteristics in colour in a remarkable degree. It is indisputably one of the fin of hybrid Orchids. The numerous varieties of *C. Trianae* are beginning to expand their blossoms, and one we notice named *Aspasia* was uncommonly handsome; *C. Percivaliana* is likewise in bloom. In the *Phalaenopsis* house there are crowds of *P. Schelleriana* and others of the better known type, together with such novelties as *P. Stuartiana*, which is the admiration of every one. *Dendrobiums* include the exquisitely beautiful *D. Ainsworthi*, a hybrid between *D. nobile* and *heterocarpum*, and preserves to itself the delicious perfume of the latter in a remarkable degree. *D. moniliforme* *alias* *C. Linawianum* and Hutton's variety of *D. macrophyllum* must be included among the most noteworthy. *Angræcum sesquipedale*, that most remarkable of all Orchids from Tropical Africa, may be seen represented by flowering plants not more than 6 inches high; yet sometimes we hear that it cannot be induced to flower until it attains a foot or two in height. Here are plants of all sizes in bloom, each bearing from one to half a dozen flowers, and fine ones too. *A. Chaillanum*, and *A. eburneum*, and others are also in flower. There is a host of *Cypripediums* in flower, chiefly those of hybrid origin, such as *C. euryandrum*, *macrochilum*, *selligerum majus*, and *Sedeni*, of which, by the way, there is the deepest coloured variety we ever saw. Cool Orchids abound in profusion, and rarely have we seen a finer display than is here of *Odontoglossum crispum*, and varieties of other cool house kinds. Among other *Odontoglossums* is the dainty little *O. blandum*, a species—a miniature, so to speak—of *O. nævium*, but even more charmingly spotted and with a broader labellum. It does not grow more than half a dozen inches high, and its flowers are crowded, many together in short spikes. *Masdevallias* in flower include the dull-looking and vile-smelling *M. velifera*, a species only remarkable because of its rarity.

Temperature for Vandas.—Of late much has been said as to the temperature suitable for these lovely Orchids. When at Elvetham Park recently I observed how healthy some *Vandas* looked. I asked Mr. Jones, the gardener, what temperature he kept them at in winter. He told me 55° , and he assured me they always blossomed grandly; they are in a mixed collection, and the house is a lean-to facing the west.—J. CROOK.

Odontoglossum Coradinei.—This, a rare variety, apparently intermediate between *O. luteo-purpureum* and *Lindleyanum*, is represented by a fine flowering example in Mr. Bull's nursery, Chelsea. The flowers are about the size of those of an ordinary *O. crispum*. The ground colour is creamy white, blotched and spotted with pale brown. The habit of growth is similar to that of others of the *O. luteo-purpureum* section, the flowers being borne in long two-rowed spikes.

Marked distinction in Orchid bulbs. In referring to THE GARDEN of Sept. 29, 1882, p. 85, I happened to notice a query by “R. C.” in regard to the “marked distinction except that of colour of flower.” I may say that it is exceedingly hard to make the decision certain, for, as to two plants in our collection, I can quote of one that

one of the best judges in the land pronounced it *C. Mossiae*, and I thought it *exoniensis*—it bloomed *C. Trianae alba*. Of another plant, as yet unbloomed, reputed to be a new species, I have taken the opinions of all who see it, and the result of three first-rate judges is, “they one and all differ.” One said *C. Mendelli*, another *C. Mossiae*, and a third *C. Trianae*.—D. B. C.

Promenæa xanthina.—This rare species is somewhat similar in style of growth and size of flowers to *P. citrina*. The flowers are borne singly from the base of the bulbs, and are about an inch across, of a pale primrose-yellow, deeper towards the centre, while the side lobes of the labellum are profusely spotted. It is in flower in an intermediate house in the Royal Exotic Nursery, Chelsea.

January Orchids in flower from Dr. Paterson, Fernfield, Bridge of Allan, include a twin-flowered spike of *Lycaste Skinneri*, a somewhat uncommon occurrence; the flowers are larger than usual, and of a rich deep colour. Other flowers of this Orchid also represent very fine varieties. Among other Orchids sent are the rare and handsome *Vanda Cathcarti*, with large flowers and chocolate-brown sepals transversely barred with a paler hue; *V. furva*, more uncommon than beautiful; a very fine form of *Lælia anceps*, apparently *Barkeri*; a large-flowered variety of *Masdevallia ignea*, and *Vanda lamellata Boxalli*.

Angræcum sesquipedale.—I see on reference to Mr. Douglas's article on Orchids in THE GARDEN, of March 11, 1882, that he mentions this plant having “tails 18 inches long.” I should much like him to measure the tails of his plants this season, and tell me the maximum length of the spurs, and say what corresponding size the flower is and the size of the plant. I do not remember having measured a spur longer than 15 inches. I should like all owners to write their present experience, as I have heard it said and seen it in print that up to last season the spur had not established its claim to the word “sesquipedale.”—D. B. C.

Masdevallia ignea Massangeana.—The ordinary form of this *Masdevallia* is beautiful, and there are few better or brighter winter flowering Orchids, but this variety is superior to it, inasmuch as the blossoms are larger, more oval in outline, and brighter in colour, the tint being of a peculiarly bright orange-scarlet, marked with vermilion in longitudinal streaks. It is as free or even freer in growth than the type, is equally floriferous, and like it remains in perfection for weeks and even months together. It is now one of the most prominent among the numbers of beautiful cool Orchids in bloom in Mr. Bull's nursery at Chelsea.

Cattleya Backhousiana.—A grand specimen of this splendid new *Cattleya*, a variety of *C. Trianae*, is at the present time one of the chief attractions of Messrs. Backhouse's nursery, at York, where it originally flowered last year. The plant in question has no fewer than ten flowering leads, several of which are carrying three flowers. It differs from all other forms of *C. Trianae* in having very broad petals of firm texture and of a delicate lilac tint, heavily blotched and streaked with rich carmine, while the ample labellum is exquisitely fringed at the margin and of an intensely rich carmine-purple. All Orchid lovers will welcome this beautiful plant to their collections, and we hear that Messrs. Backhouse are so fortunate as to possess a few small plants of it beside their original specimen.

Spathoglottis Lobbi.—This charming and elegant terrestrial Orchid is now in flower in Mr. Bull's nursery, where it attracts a deal of attention on account of its distinct appearance, so unlike that of the majority of Orchids. It may be best described as possessing the habit of growth of a *Bletia*, and with flowers much resembling in shape those of some of the *Phalaenopsids*, but the whole flower is of a clear and bright yellow, traversed here and there by chocolate lines. The flowers are borne on a tall slender stem, which adds considerably to their beauty. Some of the species of *Spathoglottis* and allied genera are

mere betanical curiosities, but this is not; indeed, it would be difficult to name a more attractive and graceful Orchid. It is of easy culture if treated like a *Bletia* in the East Indian compartment of an Orchid house.

Cattleya Trianae alba.—The flowering season of *Trianae* *Cattleya* and its numerous race of beautiful varieties has just commenced, and for some time to come wealthy Orchid collections will be enlivened by their gorgeous blossoms. Some noteworthy varieties of it are now in flower in Mr. Bull's nursery, and amongst these none are so lovely as the true *alba* form, which has snow-white blossoms only marked with a faint dash of yellow on the labellum. Of this rare variety there is a grand specimen plant nearly a yard across, and carrying fully a dozen of its chaste blossoms all expanded at one time. Another form of *C. Trianae* named *maxima* is likewise a beautiful variety remarkable for its unusually large flowers with broad sepals and an ample lip richly coloured and exquisitely crisped at the margin. *C. chocoensis* and *C. Warscewiczii* *delicata* are also flowering. Both are lovely plants. The first is a somewhat scarce variety, easily recognised by its lean pseudobulbs. The flowers, about the size of an ordinary *C. Trianae*, are of a delicate blush pink with a blotch of yellow on the labellum. They are delightfully scented with a rich balsamic odour quite unlike that of any other *Cattleya*. A great drawback in the case of this variety is the fact that its flowers hardly ever open more than half way. *C. Warscewiczii* *delicata* is a superb Orchid, indispensable in every good collection. It is rightly named *delicata*, for its blossoms are of a soft, delicate shade of pink rarely met with even amongst its congeners.—W. G.

PLANTS IN FLOWER.

CAMELLIAS IN THE OPEN AIR.—Many of your readers having stated the various flowers they have in bloom out of doors, allow me to say that I have several double *Camellias* in full bloom in a south warm corner of my garden.—H. J. BUCHAN, *Wilton House, Southampton*.

EARLY PRIMROSES.—I send you bunches of *Primroses* of which we have had in the nursery at Grove an abundance throughout the winter; the colour seems much brighter than that of the ordinary wild ones.—W. CAUDWELL, *Wantage*. [*Primroses* are now plentiful in the London markets.]

LUCULIA GRATISSIMA IN SMALL POTS.—This is most useful when it can be had in small pots for filling vases in the house, being valuable on account of its scent. In this state I noticed some recently at Elvetham. The plants in question were in 6-inch pots, and each carried from four to six of its beautiful *Hydrangea*-like trusses of blossoms.—J. CROOK.

CRASSULA SEPTAS is a singularly neat little plant—quite an alpine. In a cool house at Kew there is a plant of it in flower, the whole being not more than 2 inches or 3 inches high. The roundish leaves are gathered in a cluster, after the manner of some of the *Saxifragas*. The flowers, about as big as a threepenny piece, are borne in an umbellate cluster on slender stalks. The petals are pure white, and the flowers are peculiar in structure for those of *Crassula*.

CYCLAMEN COUM VERNUM.—This charming little harbinger of returning spring is now very beautiful in one of the numerous nooks in the rock garden at the York Nurseries. The colour of the blossoms is so intensely brilliant, that there is nothing to vie with them at this early season. Another recommendation in favour of this *Cyclamen* is that it is so easily managed if planted in a sheltered corner in ordinary loam. In order to make a good display, several plants should be placed together, so as to form a tuft.—R. P.

CENTROPOGON³ LUCYANUS is evidently grown finely at Farnborough Grange judging by the specimens which Mr. Crook sends cut from plants

grown in a temperature varying from 40° to 50° by night, a much lower temperature than in which the plant is grown as a rule. He also sends flowers of the yellow *Flax* (*Linum trigynum*) from plants in a house the temperature of which ranges from 38° to 45° at night. The specimens are not inferior to those grown in a warmer temperature, and probably the plants are altogether the better for cool culture.

HIBBERTIA CUNNINGHAMII.—Flowers of this old-fashioned greenhouse plant have been sent to us by Mr. Crook, gardener at Farnborough Grange, who considers it by far the best of the cultivated species; it is bright in colour, a profuse flowerer, and is scarcely ever out of bloom. It is a dense and very twiggy shrub with narrow, toothed leaves, among which are produced numerous bright yellow blossoms an inch or so across. *H. dentata*, a slender twining species with large yellow blossoms, is now prettily in flower in the temperate house at Kew, and produces quite a cheerful look at this season.

BELLADONNA LILY.—It is very refreshing to see flowers of the lovely *Amaryllis Belladonna* in the dead of winter, for as a rule it does not unfold its bloom till summer or the autumn. In one of the stoves at Kew we saw the other day a beautiful flowering plant, with blossoms finer and of a deeper rose-pink hue than usual—probably a variety. The bulbs, we understand, were received from South Africa, and were started as soon as received, hence the result. It would be well worth the trouble if bulbs were treated with the express view of getting them to flower in midwinter, as they are so beautiful.

SERICOGRAPHIS GHIESBREGHTIANA.—Of this bright winter flowering stove plant, some excellent sprays have been sent to us by Mr. Crook from the garden at Farnborough Grange. Some of the sprays are a foot or more in length, and from the axils of each leaf a long elegant spike of rich scarlet flowers is produced, which in contrast with the large shining green leaves is very striking. In another column Mr. Crook gives an account of his method of growing this plant, which at Farnborough Grange may be seen a yard or more high and as much through.

NEPENTHES SANGUINEA.—This fine species of Pitcher plant, says the *Irish Farmers' Gazette*, is at present in flower at Glasnevin, a rare occurrence; at least, we remember the late Dr. Moore stating that he had never been able to get it to flower. At present the plant is bearing a fine bold spike; being the pollen bearing or male form, it is to be regretted that some other members of the family with which it might be desirable to effect a cross are not in flower just now. Doubtless, however, Mr. Moore will take measures to preserve some of the pollen, or share it with those who may happen to have seed-bearing forms of some of the species in flower.

FLOWER NOTES FROM DUBLIN.—I see the *Snowdrops* peeping up here and there, and at Straffan the other day they dangled like clusters of pearls above the purple-brown leaves of *Anemone pennina* in a very pretty way. In the pearl bud stage they are most lovely. *Narcissus maximus* is spearing up apace now that the weather is mild, and the *Crocuses* are racing the *Aconite* buds closer than usual. I wish "E. H. W." could see the luxuriant way in which *Tussilago fragrans* grows and blooms here now, carpeting the ditches and roadsides and canal banks, and perfuming the air, at night especially, just as *Orchids* do abroad. *Orchis longicalcarata* (Algiers), white, with a rich claret-coloured lip and a long spur, is one of the gems at Straffan just now flowering in a cold frame. *Vanda furva* (V. Roxburghii unicolor) is distinct, having cinnamon-brown flowers and a delicious odour of *Cowslips*. Speaking of hardy winter blossoms, there is now a plant of *Helleborus altifolius* (*H. niger maximus* of gardens) at Straffan, inside the old orangery square, a yard across, and it bears at this moment fully 200 flowers and buds. I never saw a specimen half so good before, each flower being perfect and clean. The common *H. niger* is a poor thing as

seen growing beside it; in fact, comparatively speaking, not worth soil and care. Frames full of *Marie Louise Violets* on a sunny border are now giving little lilac-purple rosettes of the sweetest. Mr. Bedford, the gardener at Straffan, grows them remarkably well. Some patches of *Anemone coronaria*, raised from seed sown in May last, are now yielding fresh buds and flowers quite plentifully, and seemingly these *Windflowers* are not much disconcerted by 24° of frost. Cut in the bud stage, they endure fresh and bright for two or three weeks in fresh water. The only difficulty is to be sure of obtaining seed from a good strain. On sunny walls the *Japan Allspice* displays its golden buds, and its waxy flowers dangle prettily from the soft grey twigs, and are sweet enough to tempt the wintry flies and stray bees drawn out from their shelter by the warm sunshine. *Golden Jasmine* is a good companion for it, more showy, but less fragrant.—F. W. B.

WHITE DOUBLE EPACRIS.—This plant, which is the double-flowered variety of *E. onosmaeflora*, is now one of the most attractive plants in bloom in Mr. Bull's nursery at Chelsea, by whom it was introduced some years ago. It is a vigorous little bush, each tiny branch being wreathed with clusters of tiny rosette-like blossoms of snowy whiteness for some inches in length. In growth it resembles other *Epacris*, but is very dissimilar as regards the flowers. It is, we believe, the only double *Epacris* known. It was exhibited and certificated about seven years ago, but as yet it has not been distributed, as it is not one of the easiest plants to propagate in quantity. When it is put in commerce, it will doubtless be much sought after, as it is such an admirable greenhouse winter-flowering plant, and one that could be relied on for remaining in flower for an unusually long time. The flowers being white, they will be valued for cutting from for bouquets, wreaths, and a variety of uses.

LONICERA FRAGRANTISSIMA.—This sweet-scented *Honeysuckle* is now crowded with blossoms, the odour of which quite pervades the air, especially in the case of plants under glass, a circumstance which proves how valuable it is at this dead season when there are not many plants in flower, and what are in blossom are mostly tender kinds, whereas this *Honeysuckle* is so hardy as to brave all cold and frosts and keep on blooming nearly the whole of the winter out in the open. To have it at its best there it requires, and deserves, the shelter of a wall with a southern aspect and a sheltered corner. If so favoured, it is surprising what an amount of flower may be got from it. Although naturally bushy, it may soon be made to cover quite a large space by encouraging and training up the leading shoots, and from these breastwood is formed. It is from this twiggy wood the blossoms come, and, therefore, in pruning, or rather in stopping and pinching during the summer, the object should be to have as much of this shrubby growth as possible, and the shorter and riper it is the better will it bloom. It may be readily propagated by means of cuttings or layers; the latter root freely if the branches are pegged down and covered with sharp, sandy soil, as do also cuttings made either of the ripe or green shoots inserted in a border, under a hand-glass, and if some are put in now they will form nice little plants by next autumn.—S. D.

CHINESE PRIMULAS.—Of these there is in Messrs. Carter's Crystal Palace Nursery, Forest Hill, one of the finest collections we know of, being of considerable extent in point of numbers, and the varieties represented are particularly fine. All the varieties we enumerated in our report of the meeting at South Kensington may be seen here and hosts of others, named and unnamed, two or three capacious houses being entirely filled with them. Under glass the colours show themselves off to much greater advantage than in the dull, secluded light of the council room at South Kensington, and thus an adequate idea can be formed of their glowing brilliancy. For example, the *Holborn Gem* is more decidedly blue under glass than elsewhere. It seems to us that it greatly improves year by year, so that by constant

selection an undisputably blue *Primula* will eventually be obtained. The variety Golden Leaf, with foliage of a primrose-yellow, is very distinct, and associates admirably with the other sorts. The brilliancy of such fine varieties as Magenta Queen Improved, Vermilion Queen Improved, and other high-coloured kinds is here fully brought out, while in contrast with these are the delicate and pure hues of the white and lighter-tinted sorts. Such a rich collection as this is worth seeing, and we understand that it will be on view until the end of the present month, when it will undergo preparation for seed saving. It is, we believe, necessary that intending visitors should obtain a card of admission at Messrs. Carter's offices, 237, High Holborn, before going to their Forest Hill nursery.

INDOOR GARDEN.

SERICOGRAPHIS GHIESBREGHTIANA.

THIS ranks amongst the most useful of autumn and winter blooming plants. It is very showy, the long spikes of flowers being bright scarlet. Many grow this plant, but few grow it well. Often one sees an old cut-back plant with the leaves quite yellow, plainly denoting the condition it is in. Such plants produce only short spikes and small flowers, and these even are sparsely produced. This is to be regretted, seeing the many good qualities this plant possesses. It is highly ornamental; the spikes, which are produced from the axils of the leaves, are, on well-grown plants, from 6 inches to 8 inches long. It is highly valuable on account of its blooming during the duller months of the year, from October to February. It is very accommodating, too, adapting itself to warm conservatory treatment during the blooming period, or it may be treated as a stove plant, although here it is a shorter time in bloom; and, lastly, it is easily grown.

Culture.—Its propagation is a simple matter. Take off the tops of the shoots and insert them three in a $\frac{1}{2}$ -inch pot filled with the usual propagating soil. Plunging them in a good bottom heat, such as that in a Cucumber pit or in a stove, they may be rooted without bottom heat, but not so quickly. In three or four weeks they will be nicely rooted, when they may be gradually exposed to more air, and in a week or two they will be ready for potting off; then the old plants should be at once placed in a strong heat in a light place to furnish another batch of cuttings. The soil for this plant should consist of two parts loam, one of leaf mould or peat, one of rotten manure, and a little sand to keep it open. The first potting should be in 3-inch pots, then into $\frac{1}{2}$ -inch, and last into 6-inch or $\frac{3}{4}$ -inch, potting firmly. It is a good plan to stop them two or three times, when it will be found that they will make good plants. But the stopping must be regulated according to the time when the cuttings are rooted; they should not be stopped after midsummer. To get them well ripened should be the main object to keep in view. The best place in which to grow them is a heated pit furnished with fermenting material. During the early stages of growth they should be plunged in it close to the glass: under such circumstances they will grow fast and require no cleaning and but little syringing, the humidity from the fermenting material being highly beneficial to them. They may be kept in such a place till the beginning of August, when a cold pit kept close will suit them perfectly, as they can get abundance of light. They need but little shade, and air can be given them according to the state of the weather. By the end of September their shoots will be ripened, when the plants should be placed in a pit or house where fire-heat can be given on cold nights. They may be kept here till they come into bloom, which will be in the end of October, when they will be large plants if well managed. Much of the success depends on judiciously applying liquid manure during the growing season, as the *Sericographis* is a strong rooting subject. When the pots are well filled with roots the plants should be watered with liquid manure every alternate watering. They

are not particular what sort; we use soot water guano, or farmyard manure water; I find any of them good, but it must not be used too strong. When they come into bloom it is discontinued.

Insects are troublesome, especially when the plants are grown in the stove, but by treating them as just described they will probably escape. Scale and mealy bug are troublesome to them, also green fly when it gets established; but it will be found by laying them on their side and syringing them with paraffin in the way usually recommended it will keep them clear. For green fly we syringe with soapy water, which gives them a bright, glossy appearance.

If large specimens are wanted, when the plants have finished blooming they should be kept a little colder and somewhat dry for a week or two. When they go out of flower the shoots should be cut down to five or six good joints and then placed in a moist house or pit, giving but little water till active growth begins, which should be about the end of March or beginning of April; the soil should then be shaken from their roots, placing the plants in the same sized pots as previously and in the soil alluded to above for the last potting of young plants, not over watering till they are established; when full of roots give them their last shift, which should be the beginning of June. Treating them from this as young plants, except they will need only one stopping, which should be before the last shift, these will make grand plants. Excellent young small plants may be had by placing four or five cuttings round a $\frac{1}{2}$ -inch pot in the end of April, and growing on without stopping and not shifting into larger pots. Many of our plants were from 3 feet to 4 feet high and as much through. The temperature of the conservatory here ranges from 40° to 45° at night with 5° rise by day. It has often occurred to me that this plant would meet with a ready sale if taken in hand by market growers, as everyone who happens to see them here always admires them and asks the name of the plant.

Farnborough Grange.

JOHN CROOK.

Double white Mignonette.—This appears to bloom as well in winter as the single kinds, judging by some plants of it which I saw in the end of December at Elvetham. They were in $\frac{3}{4}$ -inch pots, full of flower, deliciously sweet, and perfectly white and double. Mr. Jones has succeeded in striking it from cuttings, which root well in the autumn.—J. CROOK.

Freesias.—Seeing a note on these in last week's issue of THE GARDEN, I may say that I find refracta alba very easy to grow. Left in pots during the summer, it comes up again in renewed strength in the autumn; or if turned out and dried after dying down it does equally well on being repotted. Its perfume is so exquisite, I wonder it is not more grown than it is.—H. STUART-WORTLEY (Colonel).

Auricula Col. Champneys.—"M. R." in writing the other day about Auriculas, mentioned this as one of the best grey edges grown. In that opinion he differs widely, I fancy, from all other Auricula growers, for it has not in my opinion one of the properties of a good Auricula. It is cup-shaped instead of flat; it has a pale watery eye; the body colour is rich, but there is too much of it, and it runs continually into the edge. "M. R." will never find it staged (unless people are very hard up) on a prize stand, nor especially amongst single specimens.—DELTA.

Coleuses for winter decoration.—Cuttings of these for this purpose should be put in in the end of July, and when rooted shifted into 3-inch pots, using pure loam with plenty of sand in it. They should be grown on in their natural form, for then they produce larger foliage than when stopped, keeping them close up to the glass and fully exposed to light. Get their pots well filled with roots before winter, for in this lies the secret of colouring them well; the more pot-bound they are the more concentrated the colours will be, and if good varieties are used few

plants are better calculated than Coleuses are to brighten up our stoves in winter.—JAMES KING, *Rowsham, Aylesbury.*

Boiler setting.—In reply to "C. C." (p. 38,) I should say that his boiler, like many others, has been badly set. The only object which some boiler-setters appear to have in view is to make the fire roar away and burn as much fuel as possible. I have no doubt that "C. C." will find 3 inches of space between the back end of the boiler and the wall quite enough, but it will be useless to put a course of brick at the back if the rest of the boiler is not properly set. If the side flues are too wide the flame will spread and only half do the work which it should do. They should not be wider than 3 inches for a boiler 30 inches long, and the cover should not be more than 4 inches from the top of the boiler.—H. PARKER.

Spiraea Thunbergi forced.—This is one of the easiest of shrubs to force into flower, and although as a rule the blossoms do not remain long on the plant, yet if the latter be taken out of the forcing house as soon as the first flowers commence to expand they will then last some time. It is a small slender-growing species, the branches of which, clothed with small bright green linear-shaped leaves, curve over in a very graceful manner. But little preparation for forcing is necessary; the roots form a dense mass of fibres, so that the plants may be taken up, put into pots, and introduced by degrees into the forcing house without any danger of failure. The blossoms are white and bear considerable resemblance to those of the Hawthorn, but much smaller, and being thickly set on the branches are very pretty.—ALPHA.

Seedling Freesias.—Two years ago I stated in THE GARDEN that I had got possession of a quantity of Freesia bulbs direct from Capetown. These flowered with me very freely during the summer of that year and ripened a good deal of seed, which was sown in a 6-inch pot at the end of February, 1882, and placed in the stove. To my surprise almost every seed germinated, which was more than I anticipated, and my pot was crammed full of seedlings. In order to give more room I shifted about half of them into other pots, but those transplanted afterwards grew but very little, whereas those left undisturbed grew very well during last summer, and part of them flowered in the end of November and beginning of December last. More vexing still have the old bulbs behaved. After their first flowering they dried off quite naturally in autumn, and were kept dry till the end of February last, when they were potted off; then they were placed in the greenhouse. There they did not grow, and in May I removed them into a cold frame, where they stood all summer with their Grass-like growth just peeping through the soil. Since September I have kept them in a house, the temperature of which ranges from 55° to 60°. Here they soon began to push, and made Grass from 8 inches to 10 inches long, but only produced three weak flower-spikes. I noticed that Freesias enjoy sunshine, of which we had but little last autumn, and that they dislike being kept too moist until they are in full growth. This year I intend to make the growing season as long as possible, keep them at rest in their present pots, and not pot them again.—E. H.

Complete Index to "The Garden."—The general index, embracing the whole of the volumes from the commencement to the end of the twentieth, is now ready. It has been compiled, printed, and bound with much care, and will be very useful in making more accessible to all who possess the volumes the immense mass of practical gardening matter, plates, and woodcuts embodied in its pages. Those who intimated their willingness to subscribe for it will be supplied at the subscriber's price of 10s. 6d. per copy. As its production has been more expensive than was anticipated, the price has to be fixed at 12s. 6d. per copy. There will be no free copies, and no reduction to the trade on the published price.

NOTES ON HOYAS.

The usefulness of Hoyas both as flowering plants and for clothing damp, dark walls or rafters, is well illustrated by the many ways in which the old *Hoya carnosa* is employed. This plant thrives and flowers freely in almost any position in a warm house, and generally the more neglectful the treatment the greater the yield of flowers. The waxy-looking blooms, tipped with honey drops, are always admired and much in demand for bouquets and button-holes, &c. *Hoya imperialis*, of which the annexed is a representation, is the largest flowered of the genus, and where room can be afforded it proves a glorious stove climber. It is a strong grower, with large thick leathery foliage, in the axils of which the umbels of purplish flowers are produced. A rafter or a pillar in the stove is what it delights to run along, wood or stone being most suitable, as on such substances numbers of roots are soon produced, which cling to them as the roots of Ivy would. These stem or aerial roots play some part in the nourishment of the plant, and would, if it were severed from the soil, be found to sustain the plant in full vigour if there was sufficient moisture in the atmosphere. Along with the other species *H. imperialis* is much more satisfactory grown in a pot than when planted out, as the resting this species requires during the winter months can be better managed under the former treatment. Although a strong grower, *H. imperialis* does not require much root room, though during summer it will be found a good plan to supply some liquid manure at the roots. Although not by any means a new plant, this fine Hoya is not often met with. It flowered at Glasnevin last year, and from specimens sent by Mr. Moore the annexed illustration was prepared.

A delicate and very attractive flowered kind is *H. campanulata*, of which a small figure was printed in THE GARDEN two years ago. It is a thin, papery-leaved species, graceful even in habit, and a really excellent plant for pot culture. The flowers are cream coloured, with a few rosy dots on the corona, and, as has been before remarked, "look as if a breath of warm air would melt them." A plant of this species is grown in one of the stoves at Kew, and is nearly always in flower during the summer months. The pretty kinds *Hoya bella* and *H. Paxtoni* are not very different from each other, though, perhaps, distinct enough for garden purposes. Grown in pots or baskets suspended from the roof of the stove, these plants prove very attractive, and generally thrive under such treatment. A frequent cause of failure with these kinds is too much root space and too much moisture. A sandy peat soil, with a little charcoal mixed with it, is the best mixture for these plants, and for water, sufficient to keep moist, not more, is all they require. *Hoya globulosa* is one of the Cranston Nursery Company's new introductions, and a handsome species it is. The leaves are leathery and about the size and shape of the common Laurel leaf. The large globular heads of pale yellow flowers, which are freely produced from the axils of the leaves, are likely to prove useful in bouquet and button-hole making. Some of these Hoyas make handsome specimens when trained on a balloon

trellis. They are, however, so amenable to culture, that one can use them in a variety of ways, and always find them satisfactory. For the production of flowers abundance of atmospheric moisture is necessary during the summer season when these plants bloom. During winter a long rest is advisable, and any long, straggling shoots may be cut away, which will induce the plants to break freely, and on these young growths the bulk of the flowers are produced. B.

Flower and leaf of *Hoya imperialis*.

DISROOTING HARD-WOODED PLANTS.

This operation has been occasionally noticed during recent years in different gardening papers, but the practice, like many others not generally adopted, appears to be followed by only a very few cultivators. In using the term disrooting, I do not allude to a partial reduction of the roots of hard-wooded plants at the time of potting such as is usually carried out with many soft-wooded subjects—for instance, Pelargoniums at their annual potting when they have broken subsequent to cutting back after the blooming is over. Neither do I mean an interference with the young roots that at the time of potting in healthy, thriving young stock, or young specimens of hard-wooded plants are usually found encircling the ball of earth they already occupy, and which at one time it was thought necessary to disentangle and

spread out in the new soil in the way practised with free-rooting soft-wooded plants. By this operation quantities of the best and most important feeding fibres are bruised and mutilated to an extent that is the direct cause of death to a considerable percentage of the plants so treated, and leaves others for weeks or months struggling to repair the loss they have suffered, so that the summer is frequently half over before the roots are in a condition to sustain top

growth to the extent requisite. What is understood amongst gardeners as disrooting, when applied to hard-wooded plants, is a considerable reduction of the balls of those that have attained a large size, and have to such an extent filled with their roots the soil already within their reach as to need more, and which addition can only be effected by giving them larger pots, or removing a portion of the soil they already possess and replacing it with new. The latter course is frequently preferable, particularly when the pots occupied are large, or it is deemed advisable to restrict both the roots and heads of the plants within certain limits. When this object was to be attained, the course that generally used to be followed was to work away a good portion of the outsides of the balls with a pointed stick, skewer, or something of a like description, the operation thus performed necessarily leaving the remaining portion of the roots in a jagged, bruised state, the effect of which is that many of them die back for a considerable distance, frequently some of the strongest up to the collar from whence they spring, hence the injurious effects often amounting to destruction in plants so treated.

The removal of a good portion of roots from any plant cannot fail to have an effect more or less according to the strength and vigour natural to the plant and its ability to form new feeding fibres to supply the place of those of which it has been deprived; and it is found that if such portion of the ball and roots as have to be removed are cut clean away there is much less liability in the remaining portion to die back in the way described, and also that new fibres are much more freely formed from roots that have been shortened by a clean cut than others which are torn asunder. This accords with the accepted theory bearing upon root severance generally, and is supported by results following the practice as here described. The best implement I have found for the work is a piece of old scythe blade with the back rim removed, giving it an edge by rubbing up frequently with an ordinary scythe-stone, so that it will shave off clean as much of the soil and roots as are deemed necessary; the extent to which I have found it safe to reduce the soil and roots of such plants as under consideration is from one-fourth to a third. Cape Heaths are looked upon as amongst the most delicate-rooted subjects in cultivation, and correctly so; yet if the operation is carried out at the right time and the after treatment is right, even when the plants have reached a large specimen size, few will fail to get well over it; whereas if the work was done by the taring process, probably not one in a score would survive. Few plants bear being thus treated better than Azaleas, and there are not many things which it is often so convenient to thus treat, as they frequently live and grow on until the pot room required makes them cumbersome to move about. Acacias, Cytisus,

Cassia corymbosa, *Clanthus puniceus*, *Habrothamnus elegans*, *Correas*, *Kennedias*, *Statice*, *Neriums*, *Myrtles*, *Swainsonias*, and others of similar character amongst those usually grown as decorative plants, and in such as are less generally cultivated, *Pimeleas*, *Croweas*, *Pleromas*, *Polygalas*, the red varieties of *Leschenaultia*, *Hoveas*, *Eriostemons*, *Chorozemas*, and *Adenandras* will bear their roots cutting back in this way. There is

One thing of vital importance connected with the matter which is that the operation is carried out at the right time. Anyone conversant with plant cultivation will easily understand that if the roots of such things as the above-named were interfered with to the extent here detailed at a season when they would not at once commence the recuperative process, they would be all but sure to die; consequently the time to carry out the operation is just when active growth is about to commence, and immediately the work is done the plants should be placed in a house or pit, kept close, with a slightly moist atmosphere, and if the time of the year or the weather is not such as to afford an intermediate temperature, it should be raised to this by fire-heat. In addition to this shade ought to be used when the sun is bright, as if air is given to any considerable extent for some four or five weeks, or until so long as it takes to admit of new feeding fibres being formed, the drying influences cannot fail to be such as to endanger their flagging, the result of which at the least would be some loss of leaves, or not unlikely the destruction of the plants. It is also necessary to see that plants which are to be subjected to this treatment have the soil within the pots they already occupy sufficiently moistened before the operation is carried out, so that as much time as possible may be allowed afterwards before it is necessary to water them beyond sprinkling overhead daily with the syringe. In other matters they simply require treating in a similar way as if they had been ordinarily potted, gradually allowing them more air when enough time has elapsed for the production of new roots. Those who have not tried this method of renewing the roots of such hard-wooded plants as I have named would be surprised at the vigorous growth they make, particularly the second season. T. B.

SOIL FOR EUCHARIS AMAZONICA.

IF "J. W." will try good fibrous loam and leaf soil, three parts of the former to one of the latter, and add to it a fair proportion of silver sand, he ought not to experience any difficulty in flowering this plant, other things being equal. In cases where the loam is not of a fibrous character it is a good plan to reduce the quantity by one quarter, and substitute good peat, and I may say that plants of this kind do not object to a bit of rotten manure being mixed with the compost, although they will grow well without it. Referring to "J. W.'s" other statements, I should say his plants do not want repotting, and if they have been growing for the last four months in a regular stove temperature, they will be more likely to flower sooner if placed in another structure where the temperature ranges from 45° at night to 55° by day and the supply of water considerably reduced, but he must not err on the side of giving them too little water; just enough to keep the leaves from flagging is all they require whilst at rest. If this treatment is continued from eight to ten weeks, and the plants taken to the stove again and plunged in bottom heat, they will most likely flower. If they do not flower by the end of April, they should be shaken out of the old soil, the bulbs divided into two sizes, large and small, and then each size potted separately, as it is the largest which will flower first. Every bulb must be well grown and matured and of a reasonable size before it has strength enough to flower. I find in dealing with this plant that it is desirable to change the soil in which it grows once a year. In order to do this we set apart two or three plants to be repotted at different times during the early spring and summer; every bit of the old soil is

shaken away from the roots, which are then repotted in two sizes. They are at once plunged in bottom heat, and as the roots increase the amount of water is more liberally supplied. Under this treatment most of our large bulbs flower twice a year. J. C. C.

FLOWER GARDEN.

HYBRIDS OF GLADIOLUS GANDAVENSIS.

As regards these hybrids, I prefer the word failure to disease, as I am not at all certain when a corm fails, or rots, or does neither, but simply remains sound in the ground for some time without showing that there is disease at all. I have very few failures to record, and these were, I agree with your correspondent, among the most "highly bred," and, as a consequence, the most expensive. However, I found a remedy in all but two cases of those "certificated seedlings," and this is what I did. My rare and expensive corms are generally separately planted, and receive special attention. When I did not see foliage bursting upwards as usual, I examined at once, and very soon ascertained that Sir Stafford Northcote was not disposed to move. After a further trial I took up the corm, potted it in a small-sized pot, and put it on the shelf of a plant pit. Here, after some hesitation, it commenced growing, and now promises to give me a bloom—of a novelty too—when I shall be thinking of planting my ordinary stock. I tried another of Mr. Kelway's (*Agrilus*) in the same way, and with equally satisfactory results. I beg to commend this remedy for valuable Gladioli that you do not want to lose in such a case. That I have had failures, inexplicable failures, I freely confess. I have lost several *Shakespeares*, but generally get enough to keep up the stock from spawn. I am afraid I have finally lost *Armide*, *Madame Desporte*, and indeed, with some exceptions, white-tinted seem with me unusually liable to get lost, I can hardly say decayed. But what of a fractional loss of this kind? My stock increases from year to year without, as a rule, waiting for increase from either seed or spawn. No doubt there are some old ones parted from with regret, and that if I had time and patience I might be inclined to nurse the spawn of or save seed from, a thing not always possible by the most careful fertilisation, but there are thousands of seedlings raised every year many as a rule superior to anything gone before, and though the finer kinds, especially "certificated seedlings," are somewhat expensive at first, the humblest can add to their stock by purchase from year to year. But, "what," I may be asked, "if there is a general failure, like Mr. Banks, of Shelden Lodge, near Deal, losing 50,000 in two years?" At first this seems to stun the ordinary grower, especially the inference drawn by "Delta." He says, "if Mr. Banks got a good seedling"—alluding probably to Mr. Douglas's advice to increase, and perpetuate your stock by raising seedlings—"he could not keep it; therefore the recommendation to grow seedlings is worth very little." This conclusion is not of course at all warranted.

Success last year.—Time prevented my reaching as far as Langport, Somerset, last autumn, so I cannot personally speak of Mr. Kelway's 20 acres of Gladioli, but I have a letter before me now from a gentleman who saw them, and speaks in unqualified glowing terms of last year's success there. That firm may, through your columns, be able to contrast last year with previous years. As to what I have myself seen it would be hard to imagine anything finer than the brilliant stands shown at the autumn Royal Horticultural Show in Dublin. The spikes, especially in the prize stands, were unusually large and gorgeously coloured. Lastly, as to my own experience, my losses were unimportant comparatively, while the blooms gave me immense satisfaction. The editor favourably noticed a box I sent to THE GARDEN, and if this catches the eye of the curator of Trinity College Gardens, Dublin, he will possibly remember similarly the pleasure he also expressed at seeing my blooms. Those

who grow the Gladiolus never know when to stop when referring to it, so as the season to think of growing it is coming round—I commence putting in some of the hardier kinds always in February—I may fitly conclude by briefly recapitulating how I manage to attain fair success and enjoy much real satisfaction with my limited collection. I must, however, at once premise, as with that fascinating flower, the *Auricula*, there are "rocks and dangers of many kinds in the way," and if there were not, to my mind, Gladiolus culture would lose half its charm.

Storing the corms.—This is a matter of consideration at present, so I take it first. My stock is divided into named and unnamed. The first is situated on a board floor, in a back dry room, where the temperature has not fallen below 40° Fahr., standing upright, with their stems attached, exactly as they left the ground last October and November. Some that had flowered early were taken up in September. I never let the stem rot off—one of the reasons is that the rot may continue downwards to the corm; but a better reason, for my convenience, is that to each corm—and in many cases one becomes three—with its attached spawn I closely tie the wooden labels. I could not tie them to the stems if I allowed them to wither and rot off. This tying and labelling and partial drying on a sunny day being done in the late autumn, my stock is placed as indicated, each corm resting separately on the boards, on which a layer of moist river sand has been previously strewed. Then the whole are covered all around and above with this same sand. They gradually and slowly dry out here; and I am satisfied, from close observation, that it is in this manner the fulfilment or finishing of the summer's—perhaps sunless—maturation is completed. I never lose one during winter by this method, and they turn out as clean and as hard as bullets at planting time or whenever examined. I do not agree with those who cut off the stems, or, what is worse, wring them off at storing. But I must not go further into details of storing now.

Soil, manure, and planting.—Mr. Douglas suggests preparation of the soil and manuring in autumn. Our climate is so moist that the heavy rains would possibly carry the greater portion of the soluble organic feeding material long beyond the reach of the young fibrous roots when they want it most—on commencing to grow—if this system was followed, with perhaps the single exception of retentive clay, on which I should not like to try the Gladiolus at all. However, the borders where I grow my limited stock are full of bulbs and perennials, which I could not think of disturbing, so I manure and prepare in this way: I dig a large hole, say 18 inches deep or more, and put in it a quantity of good rotten stable manure (that from a plant pit mixed with leaves of twelve months before is desirable), but whenever I had not this I tried fresh stable short manure or old cow manure without any injurious results. But this must be remembered, I never put the corm on the manure; that is, covered with clay or 6 inches of mould, and then two handfuls of sand under the corm, and two more over it. I have much faith in the silicates absorbed by the young rootlets to give firmness and stamina to both foliage and corms. If I plant early I plant nearly 6 inches from the surface, to prevent injury from late frosts, but I lean to planting near the surface. I would plant on the surface of the soil for the sake of the ripening and maturation, but that the wind would ruin them. I believe one of the secrets of failure is deep planting and want of proper ripening of the foliage, and consequent non-ripening of the corms. I give them plenty of liquid manure, and have had twenty-two flowers to one spike, often three spikes on one stem. As to varieties, improvements are made every year; and as to soil, with the exception made, any will deserve trial.

Clonmel.

W. J. M.

Chrysanthemum pollen.—Can any correspondent inform me whether it is possible to procure pollen from the Incurved or Japanese *Chrysanthemums* in this country?—T. K.

BEDDING FORMS OF TAGETES.

THE pretty dwarf Tagetes, of which the annexed is an illustration, is a new variety that owes its existence to that unceasing care in selection which characterises the management of Messrs. Carter's extensive seed farms at Dedham, where it has been largely grown. There is nothing specially striking in the individual flowers, which are small and insignificant, but the decorative charm or effect of the variety is found not only in its dwarfness, but in the wondrous abundance with which the flowers are produced. The colour, too—a bright orange—gives a hue that is singularly striking either in lines or in masses, and, allied to the ease and cheapness with which the plants can be raised, renders it at once one of the most popular and effective of bedding plants. It is the glory of all the tender Marigolds, all members of the Tagetes family, that once beginning to flower, cease not to produce bloom incessantly until frost finally destroys it. It is this feature which makes the single-flowered forms of Tagetes pumila so effective. They are certain

New Marigold, Golden Ring.

from the first to bloom continuously, and, if of a well-selected strain, to preserve the much desired uniformity of height. In spite of this well known flowering quality, however, we find some of the dwarfier Tagetes used with admirable effect as foliage plants, the pretty and elegantly-cut leafage proving useful in furnishing green carpets for taller plants. Rich soil helps to produce an excess of leafage, because the Tagetes, and indeed all the Marigold family, prefer soil that is poor rather than rich, as that is conducive to bloom. Of the double-flowered varieties patula nana is perhaps the best, and it is grown largely in northern districts, where outdoor tender flowers are necessarily short-lived. In common parlance all the best known of the Tagetes family are called Marigolds, and thus we hear of Africans, tall and giant flowered, and of French kinds, dwarf and variously flowered, but none know them ordinarily by their botanical appellations. It would be hardly fair to these fine double varieties to class them with the single if abundantly flowered bedding Tagetes, because the Marigold is a florist's flower, and displays in a very marked degree the improvement which the florists have made on what, like the bedding Tagetes of the illustration, must once have been very poor single flowers. This feature is in no flower perhaps more marked than in the huge yellow and orange African varieties, as in these the petals are indeed wonderfully dense and al-

most countless. As the finest double strains still, and probably always will, give us some single flowers, we can, without leaving it to the imagination, gain a pretty exact idea of what is the difference between a single and double flower of the African Marigold. Probably no plant grown shows this difference more forcibly. Further still, perhaps no double flower presents a more marked contrast to the single form, which is by reason of the comparison rendered weedy and insignificant. Let the rage for single flowers become ever so furious, we shall never see single African Marigold blooms preferred to the grand double ones, and which all who see them, especially in the cool autumn, so much admire. Probably few gardeners, even though ever so enthusiastic for the gaudy yellow hue, have yet planted a big bed of African Marigolds. It is worth a trial, especially if in a position where the wind does not play too fiercely. The effect of a big mass of glorious yellows in diverse shades seen in the dull autumn evenings amidst a setting of heavy greens, would be such as to make the æsthetic re-

joice, and the gardener who was so bold to determine to go and try again. The striped French Marigold has furnished the most popular of the family for the florist, and it must be admitted that of double flowers few can excel a really good specimen in form, fulness, or in perfection of markings. From the best strain ever grown there will not always come perfectly marked flowers, for the striping is always somewhat erratic; but some flowers will be as finely striped as possibly can be, and will be of good double form. The florist still prefers for the production of his exhibition flowers the tall and most rambling habited strain, but for all general purposes, and specially for pot culture or bedding or for ordinary decorative uses, the dwarf or compact-habited varieties are best, and of these some produce handsomely striped, others rich chestnut, others clear yellow or orange flowers, and so on, and the amount of variety very much enhances the beauty found in plants that are so wondrously floriferous. A. D.

Lawn weeds.—In reply to the query (p. 32) as to the eradication of Daisies and Plantains on lawns, allow me to say that my gardener has adopted the following with great success, but as a matter of course the means adopted cause much trouble, yet I consider the good done amply repays him. A man in the first place stretches a line across the lawn, and then goes over the inter-

mediate space with a sharp knife, cutting off the top of each plant until the white root shows itself; he has then placed in his hand a lemonade bottle with a wire fixed round the top to hold it by, and into the bottle, having previously placed in it some oil of vitriol or sulphuric acid, he dips a stout piece of wire and draws out two or three drops of the vitriol, which he places on the top of the root and kills it; it never comes up again, neither does it break out in any way from the bottom. I have tried the lawn sand, which is very effective, but it leaves a large bare patch of earth which takes some months to recover itself. The operation should be performed in the early spring when the ground is hard and dry.—H. J. BUCHAN, *Wilton House, Southampton.*

SINGLE ANEMONES.

A CORRESPONDENT, I observe, states that these Anemones prefer light, sandy soil. Now, I have a large bed containing several hundreds of these plants in full growth and flowering freely even in the winter, and yet they are in quite a stiff loam; in fact, at this time of the year so tight and sticky is it that it more fully merits the designation of clay. I very much doubt whether the plants could do better in any soil however light or sandy it may be; and, indeed, other roots in another part of the ground, where it is both warm and the soil is light and gritty, are not nearly so early, scarce showing a single flower. I think a fact like this is worth mentioning, because many may be deterred from growing one of the most beautiful of hardy spring flowers because their soil is stiff, and they fear the plants would not thrive in it. If I could cover up the whole of my bed with glass I could have at any time a beautiful lot of bloom, but when we get heavy fogs and white frosts, alternating with rain, it is difficult for any out-door flowers to look fresh and pleasing. Still the determined way in which these Anemone blooms come up even in bad weather is remarkable. Nothing but really hard frost seems to check them, and as soon as that is past and the air becomes soft and mild the rebound is great, and the blooms again expand rapidly. I lifted a few roots a week since and put them under glass. All had flowers in the bud state, and I have just been enabled to gather a handful of lovely expanded blooms of the most brilliant colours, all of which will keep well in a cool room for a couple of weeks, for being once expanded they do not, when cut, again close. In the open air there is no fear that they will open too rapidly, but if placed in a house or frame which has a south aspect, the blooms will often, when the sun shines out, open rather more rapidly than is desirable; in fact broadly expand before they are fully developed. To have the blooms in winter at their best, however, it is advisable to plant in a low frame, and in good rich soil that will nourish not only fine blooms, but large handsome leafage. This latter feature of the Anemone is worthy of special notice, because it is so handsomely cut, and only just inferior to Fern fronds for the dressing of flowers in vases. Dry roots should be purchased early and planted at once, as the drying of the roots no doubt gives material check; there is absolutely no reason why the roots should be lifted and dried, provided during the hot summer months they are sheltered with either a dressing of Cocoa fibre refuse, leaf soil, or well rotted manure. I, however, have given my bed no such protection; in fact the roots simply shifted for themselves during the summer, being only kept free from weeds. I prefer transplanting at the end of September, when some growth has been made to doing so earlier, as not only are the roots the more easily found, but, being full of growth, they the sooner root into the new soil and become established. Raising Anemones from seed is simple, and may be done with perfect success by the merest tyro. April, if under glass, and May, if out-doors, are the best months in which to sow seed. If under glass, then sow in shallow pans or boxes and in light sandy soil, first rubbing up and disintegrating the seed with

sand. Just bury the seed, water freely, and shade lightly from sunshine until it has grown. In the open ground sow in very fine sandy soil, cover thinly, pat it down gently with a spade, and water, then shade for a week or two with calico or newspaper till the seedlings are well up. A. D.

ARRANGING HERBACEOUS PLANTS.

"PEREGRINE" has not caught my meaning as regards herbaceous plants. Tall plants can rarely be planted so that their flowers come in 'solid masses close together, and so long as their flowers appear as patches of bright colour on a neutral or broken background, and do not touch each other, it does not matter whether the colours of the flowers harmonise or not. We can also have a long line of Phloxes, or of Carnations, or of Roses, or groups of these which will all harmonise, because they are all of related shades; even the yellows will not discord if we plant them beside white or the very dark crimsons. But the case is quite otherwise when we come to dwarf plants which produce their flowers in masses. Irids, Anemones, blue Gentianellas, and yellow Alyssums are just as discordant as red Pelargoniums, blue Lobelias, and yellow Calceolarias. We can avoid discords by separating our flowering plants by those out of bloom, but then we avoid harmonies as well, and there is no better reason why our gardens should consist of a series of solos than our music. We can have solos if we choose, but we can also have beautiful harmonies, and ones which will change with the seasons instead of being always the same, as with bedding plants. We must bear in mind, however, that the arrangement of the colours in a garden presents no real difficulty; what people who can colour have to do is to place those colours together which look well together; even where a doubt exists, the fact of the colours improving each other when placed together will settle the matter in a moment. That is how everybody who has to deal with colour from artists downwards proceeds. If you think two colours will look well together, try them; if they do not look well, try something else. All that even the best colourist can do is to name a few combinations which do harmonise and others which do not. Those who do not enjoy colour should leave the matter to those who do. Rules are only useful to those who have gone wrong and do not know how to get right again. Even for these it is only necessary to keep rid of the discordant combinations already indicated and follow the rules of good colour art, and they will soon learn to arrange their colours properly. What we grow brightly coloured flowers for is their colour, and surely any trouble is well taken which will enable us to arrange these colours so that they will improve instead of injure each other. For arrangements of cut flowers a knowledge of colour harmony can scarcely be dispensed with.—J. D.

Lilium pomponium (verum).—"P." (p. 33) speaks of this as a Lily easily grown and increased. This is not my experience of it; for though it generally flowers well the first year and fairly the second after importation, still it goes "all one way," as they say in Cheshire, and disappears in three or four years. "P.'s" descriptions are so correct that I do not suspect him, as I have done others who mention this Lily, of mistaking *L. pyrenaicum rubrum* for it; but if he or anyone else in England has grown it continuously in the same spot for ten years, I should be interested to know what are the soil and situation. *L. pomponium* was cultivated in the last century, but had nearly disappeared when Mr. G. Maw re-introduced it from the Maritime Alps, its chief habitat, about twenty years ago. Since that time it has been imported in considerable numbers every year; but those with whom I have compared notes have for the most part found it difficult to establish permanently and to increase. This is to be regretted, as it is the brightest scarlet in colour of any of the Lilies, and is less liable to have its flowering injured by late frosts than *L. chalcedonicum*, though, as stated by "P.," it flowers earlier. I have had fine bulbs of the true pom-

ponium several times from Mr. Ware, and one flowering is worth the price paid; but I should like to be told how the bulb could be persuaded to increase, and I may say the same of *L. Browni*.—C. WOLLEY DOD, *Edge Hall*.

GARDEN FLORA.

PLATE CCCLXXII.

HYBRID LADY'S SLIPPERS.

(With coloured plate of *Cypripedium Morganæ*.)
OF all Orchids none have lent themselves so kindly to the hybridiser's influence as the *Cypripediums*; of all hybrid Orchids their growth is most rapid and robust, and the result is that we now scarcely note their advent, albeit that every year brings us many novelties in this way. At the present time we have possibly fifty hybrids in cultivation, and three times that number are at the present moment existing as unbloomed seedlings in our gardens. The annexed plate represents one of the best of recent varieties, which has been named in compliment to Mrs. Charles Morgan, of New York, a lady amateur especially fond of plants and their culture, and the present plant and Mr. Taplin's hybrid *Nepenthes Morganæ* will long serve to commemorate her name in European gardens. Mr. Moon's beautiful plate renders a merely wordy description of *C. Morganæ* quite unnecessary, except so far as the facts of its parentage are concerned. *Cypripedium Morganæ* was raised by John Seden, at the Royal Exotic Nursery of Messrs. Veitch & Son, at Chelsea, a year or two ago, its parents being *C. Veitchii* (superbiens) and *C. Stonei*. After all one need not feel much surprise that two such noble parents should have produced so beautiful a hybrid, one of the best of the series to which it belongs. Ever since Mr. Dominy raised *Cypripedium Harrisianum* scarcely a year has passed without one or more seedlings making their appearance from the Chelsea Nursery, and of late years Mr. Seden has been most industrious in adding variety after variety to the already long list of novelties in this way. Other cultivators have also been successful in the same field. Thus Mr. Cross, when gardener at Melchet Court, gave us *C. Ashburtoniæ* and *C. Crossianum*. Both varieties came from the same seed-pod, and *C. Ashburtoniæ* especially shows much variety in leafage and some little variation in blossom also, so that I infer that many individuals of it were raised. *C. Ainsworthi* came as a reward to the hybridisation experiments of Mr. Mitchell, who has long had charge of Dr. Ainsworth's collection at Cliffe Point, Lower Broughton, near Manchester, whose *Dendrobium Ainsworthi* is one of the finest of all the hybrid Dendrobies, and remarkable as having been reproduced or nearly so both by Mr. Seden (*D. splendidissimum*) and Mr. Swan (*D. Leachianum*), its parents being *D. nobile* and *D. heterocarpum*. Again, Mr. Swan, of Fallowfield, near Manchester, raised *C. Swanianum* as the result of a cross between *C. barbatum* and *C. Dayanum*; and Mr. J. C. Bowring, of the Forest Farm, Windsor Forest, produced at least three hybrid variations of the genus, known as *C. conchiferum*, *C. gemmiferum*, and *C. stenophyllum*.

* Drawn from a plant in Messrs. Veitch's nursery, Chelsea, in July last.

Growers or introducers of new plants will oblige us much by early intimation of the flowering of new or rare species, with a view to their representation in our "Garden Flora," the aim of which is the illustration in colour, and in all cases where possible life size, of distinct plants of high value for our gardens.

Of the parentage of the last named I find no record, although I came across an interesting note as to its branched flower-spike showing the remains of thirty flowers.

Mr. K. Warner has raised also quite a series of hybrid Lady's Slippers, and it is a great misfortune that their parentage is hidden in obscurity. Judging from their foliage, however, *C. venustum* would appear in some cases to have been one of the parent species employed. On glancing through my "Cypripedium" notes I find that there are about sixty known species, most of them being in cultivation, so that of species and hybrids we have over a hundred kinds at present in our gardens. Who has a full collection of them? What a fine monograph a complete collection of Slipper plants would make if one could find a publisher, even if it were executed a little less sumptuously than the "Orchids of Mexico and Guatemala," or the "Monograph of *Odontoglossum*." I heard some whisper once of an amateur's intention to form a full collection of "all the *Cypripediums*," with the intention of publishing a monograph. If this should catch his eye, and he has a more complete collection than, for example, let us say, that of Mr. Harry J. Veitch, at Chelsea, I shall hope one fine day to receive an invitation to go and see his plants, and he may expect to see me arrive with an armful of MS. papers and sketches and lists of *Cypripedes*, all in a state of chaos; but if the whisper be a true one, I venture to think that they will have more of interest for him than anyone else whom I know at present. What a boon to posterity it would be if amateurs, while growing a little of everything such as pleases them, would but grow all of the genus they love best, and leave us, or those who come after us, a record, pictorial and descriptive, of their favourite flowers. For full information as to the species of *Cypripedium*, with references to culture, propagation, native countries, and figures, see *THE GARDEN*, Vol. VI., pp. 43 and 67; also *THE GARDEN*, Vol. IX., p. 524. The following list of all the hybrid Lady's Slippers of which I can find records to hand at present may be of interest and even of use to those fond of these plants:—

HYBRID AND SEEDLING LADY'S SLIPPERS.

Hybrids.	Parent species
1 Domini	Pearcei × caudatum
2 Harrisianum*	barbatum × villosum
3 vexillarium	barbatum × Fairbairnium
4 calophyllum	barbatum × venustum
5 Sedeni	Schlimi × longifolium
6 patens	barbatum × Hookeri
7 selligerum	barbatum × levigatum
8 euryandrum	barbatum × Stonei
9 major	barbatum × levigatum
10 microchillum	neivum × Druryi
11 ananthum	Harrisianum × insigne Maulei
12 superciliale	barbatum × Veitchii
13 marmorophyllum	Hookeri × barbatum
14 alhopurpureum	Schlimi × Domini
15 porphyreum	Roezli × Schlimi
16 calanthum	barbatum var. biflorum × Lowi
17 pycnopterum	barbatum × Lowi
18 Morganæ	Veitchii × Stonei
19 calurum	longifolium × Sedeni
20 lucidum	villosum × Lowi
21 grande	Roezli × caudatum
22 Ashburtoniæ	barbatum × insigne
23 Crossianum	barbatum × insigne
24 Ainsworthi	Sedeni × Roezli
25 Swanianum	Dayanum × barbatum
26 conchiferum	Pearcei × Roezli
27 gemmiferum	Hookeri × purpuratum
28 stenophyllum	
29 discolor	
30 Williamsianum	
31 melixra	
32 chloroneurum	
33 polium	
34 melanophthalmum	

* *C. Harrisianum* is interesting, as being named in compliment to Dr. Harris, of Exeter, the gentleman who first inspired Mr. Dominy with a desire to accomplish the hybridisation of orchidaceous plants.

These six varieties are seedlings raised by Mr. Warner, but their parentage is not definitely known; evidences of *C. venustum* are shown.

CYPRIPEDIUM MORGANIAE

This list of thirty-four varieties is not offered as a complete catalogue of all the hybrid *Cypripediums* known, but simply as showing approximately their number and parentage. When I try to recollect, it is simply astonishing to find how few of these magnificent hybrids have been figured in colour; and in the present state of our knowledge I need not say that mere descriptions in words do not conjure up before the mind's eye any true likeness of the plants themselves. Lindley's test-proof of a good botanical description was that from it an artist should be able to pourtray the plant described. Alas! one might count on the fingers of one hand the artists who can with any degree of exactness draw a plant, even if it be placed before them.

It is interesting to find that some of these hybrids enumerated above are fertile even in the second generation. Of those which have been proved in this way are *C. Harrisianum*, *C. Domini*, and *C. Sedeni*, all of which have been made to intermarry again with pure species—*C. Ainsworthi*, *C. calurum*, and *C. alboburpureum* being the resulting offspring.

It would be very interesting to know what the self-fertilised seeds of some of these hybrids would produce if tested, a point which, so far as I know, has never been experimented upon. Again, I should like Baron Schröder, or his gardener, to raise us a few hybrids from his wonderful variety of *C. Stonei*, yeleft *platytænium*. "But who would be so ridiculous as to risk such a valuable plant?" whispers a cautious friend. No; I had thought of all that also. I would not suggest that *C. platytænium* be utilised as the seed parent, but no possible harm could come to the plant by its pollen being used to fertilise a less valuable species as a seed-bearer. Nearly all our evidence points to the prepotence of the male parents in hybridising, and this seems to me a good opening for a "new departure," so far as long-petalled *Cypripedes* are concerned. These hybrid *Cypripedes* open up a wide field of thought. Thus Mr. Seden told me long ago that when he crossed *C. Schlimi* and *C. longifolium* he also reversed the cross, thus making both parents alike pollen and seed parents, and yet the seeds gathered from either parent gave as results two batches of *C. Sedeni*, which to all appearance were identical. Now and then some variety appears among a batch of seedlings, but so far as I can learn this is not so common among *Lady's Slippers* as among plants of other genera. For example, take the five varieties of *Cattleya Fausa*, all from the same seed-pod. Yet we chroniclers may not know everything; perhaps it is better we should not. At any rate I have no doubt that Mr. Harry Veitch could open our eyes a little, for when one considers the quality of all the hybrids which come from Chelsea there arises a question as to whether some judicious selection is not practised. Be this as it may, these Chelsea hybrids are certainly among the most marvellous floral productions of our time.

F. W. BURBIDGE.

Dutch bulbs.—Last year I had my bulbs from a firm in Holland. They appeared very fine ones. I put the *Hyacinths* and *Narcissi* in pots, and they have filled them with good roots, but that is all. There does not appear to be any flower in them; such a miserable lot I never saw, and there are no signs of improvement. Can any of your readers tell me the cause? I have given them the best of cultivation.—J. S.

NEW PLANTS OF 1882.

THE year which has just been brought to a close must rank amongst the most fertile in the production of meritorious novelties; some of them have been imported at great risk and expense from distant parts of the world, but a great many of them are the results of successful hybridism. Whichever way we look there are signs of unmistakable improvement having been made in all classes of florist's flowers, as, for instance, in the once neglected, yet beautiful

Auricula, of which no fewer than eighteen received first honours last year. They are mostly due to the exertions of Messrs. Douglas, Turner, and Horner, who well deserve the congratulations of all interested in the regeneration of that attractive family for bringing out such a beautiful variety as *A. Agamemnon*, whose flowers are edged with bright green, with a slight beading of meal on the margin; body colour dark and well defined, dense white solid paste and golden tube, with very fine pip and truss; the delightful *A. Amazon*, with bright golden centre, and a maroon base to the marginal colour, edged with bright rosy cerise; or the equally pretty *A. Bluebell*, which, besides bearing very attractive flowers of a bright violet-purple colour, good paste, large pips, and excellent truss, possesses also a very handsome mealed foliage. Quite as remarkable is *A. Jumbo*, with edge clear, distinct, and of a lively green, body colour claret-black, good white paste and medium tube; and, finally, in *A. Brunette* we have a strong grower, with handsome mealed foliage and superb flower, having a broad and well defined black margin, good paste, and pale tube—indeed, a totally distinct and meritorious new variety.

In *Azalea pontica narcisiflora* we have also an exceedingly handsome variety having double flowers like those of some of the *Narcissi*, pure rich yellow and delightfully scented; whilst *A. rubiflora* fl.-pl., an introduction from Japan, has proved an attractive shrub which produces a profusion of double rosette-like blossoms some 3 inches across of a deep rose-pink colour. Hybrid *Azaleas* are not numerous, but the quality in *Azalea* Mr. F. Cobert makes up for any deficiency in quantity. This beautiful variety produces medium-sized flowers which are borne profusely on small plants; they are semi-double and of a glowing carmine crimson colour. The richly coloured

Begonias, although of comparatively recent introduction, have been already and are still being so vastly improved, that it is very difficult to say where we are likely to stop, as the new generations, the outcome of the imported plants, are so very unlike their parents, that they do not bear any resemblance to them; for instance, where is there any family likeness between the old-fashioned, although much, respected *B. boliviensis* of fifteen years ago and the truly gorgeous double-flowered varieties of the present day, which only a few years since used to be compared with enthusiastic pride by their raisers to *Gardenia* flowers for size as well as for perfection of shape? Now those are considered poor, small specimens when by the side of the last Continental acquisitions, specially the varieties brought out by Mons. Crousse, of Nancy, which may be fairly compared and without exaggeration as to size or form with good *Camellia* flowers, whilst in colours they are much more prolific than even that favourite and popular class of plants, as amongst those double flowered *Begonias* are to be found not only all the intermediate tints between pure white and the most intense deep crimson, but also all the shades between the pale sulphur colour and the darkest orange. But the newcomers amongst the single-flowered section raised here and exhibited mostly by Messrs. Laing are not to be despised; far from it. For instance, *Begonia* Arthur G. Soames, one of the finest among the singles, has perfect flowers of large size, fine form, very good substance, and of an intensely deep crimson. The charming *Begonia* Ball of Fire is a remarkably fine variety, producing its large

finely-shaped flowers of a vivid scarlet-velvet colour plentifully on small plants. In *Begonia* Madame Stella we have one of the finest of new single sorts with large and finely-shaped flowers of a glowing rich scarlet; while among the several very meritorious forms raised at Chiswick we may particularly mention the very distinct and showy variety Thomas Moore, free in growth and flowering, producing flowers of medium size of very fine rounded form and pale rosy scarlet colour, and also the vigorous habited and highly decorative *Begonia* A. F. Barron, whose perfectly formed flowers are very large and of a brilliant vermilion-crimson.

The Carnation, also a plant which had been rather neglected of late, and towards which much more sympathy is shown now, equally comes in for its share of novelties, the best of them being *C. Charles Page*, a perpetual flowering variety, remarkable for its profusion of blossoms, which form rosettes of the richest deep crimson; a very free bloomer of the tree section, named William Howard, having large flowers of a globular form, and of a brilliant cherry colour. *C. Mary Morris* proves a border variety of vigorous growth, highly recommendable, for its flowers are large and full, the petals being of good substance, and of a very pure bright, lovely rose-pink. Finally, *C. Florence*, with its large and perfect flowers of a nankeen-yellow colour, a peculiar tint even among *Carnations*, will keep its place as an excellent bedding variety. Half-a-dozen or so of new *Chrysanthemums* have also made their appearance; prominent among them is *C. la Petite Marie*, whose flowers, produced in great abundance, are about 1½ inches across, and pure white. It is one of the early or summer-flowering race, and is remarkable principally for its extremely dwarf growth and free-flowering habit; then comes *C. Crimson King*, which is a very fine, distinct, large-flowered variety of the reflexed class, with globose flowers of a rich chocolate-crimson. Of the Japanese section, *C. M. Desbreaux* is a very fine variety, with unusually large flowers; the florets, which are long and narrow, are peculiarly twisted; the colour is a rich yellowish brown. Several new

Clematises have also been brought out by Mr. Noble, the most striking among them being *C. Princess Beatrice*, an exceedingly handsome variety, whose large and finely-shaped violet blossoms are produced in great profusion. A steady and gradual improvement is also going on in that handsome and highly useful class the *Cyclamens*, as was shown by the interest manifested by the public as well as by the horticulturist, when on March 14 last Mr. Little exhibited at Kensington, and on March 29 at Regent's Park his unrivalled forms, for which his collection is so justly famous, including his *Cyclamen* *Crimson Gem*, with large and beautiful blossoms of an intensely rich deep crimson; *Cyclamen* *Rose Queen*, a beautiful variety, with large flowers of uniform deep rose, produced on short stalks in a compact head; and *Cyclamen* *White Gem*, a lovely variety, whose flowers are large, the petals broad, of great substance, and of pure whiteness. Of

Dahlias and Pelargoniums, to which an aggregate number of seventy-seven certificates have been awarded, being thirty for the former and forty-seven for the latter, both a very decorative and exceedingly useful class of plants, nothing too much could be said in their praise, although too numerous to warrant an attempt at description being impartially made. It will be sufficient to notice that in both cases the favourite raisers whose names have long been connected with the welfare of these very ornamental flowers, Messrs. Turner, Lemoine, Keynes, Ware, Cannell, and Pearson, have really surpassed anything that had been offered by them to the public previously. The already existing collection of *Gloxinias* has been enriched by the addition of several first-class varieties, foremost amongst them being *Gloxinia* *Garibaldi*, an abundant flowerer and vigorous representative of the erect-flowered type, with large blossoms, whose rim is of a fiery vermilion; the tube is white and copiously spotted. *Gloxinia* *Robin Hood*, with its large flowers of a rich deep

crimson, bordered with a lighter hue, will also prove an excellent novelty; whilst in *Gloxinia Cordelia* we have a magnificent form of the upright-flowered section, having unusually large blossoms of a beautiful violet-purple, copiously freckled and spotted in the throat. These very fine acquisitions come from Messrs. J. Veitch & Sons, who have also contributed some improved forms of Hyacinths, such as *H. Challenger*, bearing a massive and dense spike of beautiful single flowers of a reddish purple hue, with a deeper stripe running through the centre of each petal; *H. delicatus*, whose flowers of over 1 inch across are also borne on a massive spike; they are single; the colour is creamy white, flushed in the centre of each petal with a reddish buff tint, and *H. Duke of Albany* produces a close spike bearing semi-double flowers of a lively pinkish red of a pale shade with stripes of red. Mr. Robert Veitch has produced a fine

New climbing Rose named *R. Marie Henriette*. It has large full blossoms of a fine globular shape in the half-expanded state, and is of a rich crimson-lake in colour. Other excellent Roses have also been brought out by Messrs. Bennett, Paul, and Noble, the place of honour being held by *R. Her Majesty*, a beautiful hybrid partaking of the character of the Tea varieties as regards foliage. The flowers are large, full, and massive, and the colour a lovely rose-pink, delicately shading off to lighter hue towards the edges. *R. Duchess of Connaught* is a remarkably free flowerer, and will prove one of the best of bedding varieties; the colour is of a beautiful deep crimson. Finally, *R. Earl of Pembroke* may be given here as an extremely fine variety, being large and full, good in substance, and of a rich, solid tone of crimson of various depths spread over the whole flower. Foremost among the genera which have benefited by the works of the hybridiser must be noted the

Greenhouse Rhododendrons of the *jasminiflorum* types. For several years past special attention had been paid to these by Messrs. J. Veitch & Sons, and the well-known *R. Princess Royal*, *Princess Alexandra*, *Taylori*, *Duchess of Teck*, *Maiden's Blush*, and others bear testimony to the amount of skill as well as patience which that class of plants has received at their hands. Their results, no doubt, proved both scientifically grand and remunerative, but it was given to the untiring exertions of their present *chef*, Mr. J. Heal, to produce, besides single flowers of irreproachable forms and admirable colours, some magnificent double-flowered varieties which are not mere monstrosities, but handsome and decorative plants, having, like all other double flowers, excellent lasting qualities. Amongst the new single flowered productions of last season we note first *R. Monarch*, a beautiful hybrid raised between *R. Princess Alexandra* and *Duchess of Edinburgh*. Its individual flowers, which measure 2 inches across, are borne on a dense and compact head 5 inches in diameter; they are of a delicate orange-red colour. *R. Queen Victoria* is a very handsome hybrid variety, the flowers being orange-red, shaded with a deeper hue; it is a vigorous grower and free bloomer. *R. Favourite*, also an hybrid of the Japanese group, has large dense trusses of flowers of a lovely rose-pink. In *R. Sir Beauchamp Seymour* we have a magnificent variety, with large flowers of a pale yellow, suffused with red and with projecting stamens of a bright red, making a pleasing contrast. It is perfect as regards form of flower, but the most gorgeous of all the single flowered varieties is certainly the one called *R. Sir Garnet Wolseley*. It bears a large truss of blooms terminating the stem and surrounded by foliage. The individual flowers, which are over 3 inches across, are symmetrical in outline, and of a soft, pale orange-red hue, suffused with a deeper tone. The double kinds have been produced in three distinct colours; they are named—*R. balsamiflorum*, a perfectly double flower of a flesh-pink colour. *R. balsamiflorum album*, a very handsome variety, having perfectly double pure white flowers produced in dense terminal trusses. The flowers in this form equal in size those of a good double *Tuberose*. Lastly, *R.*

balsamiflorum aureum has bright yellow flowers, large and full, produced in great terminal heads.

Amaryllises.—We have in *A. Duchess of Connaught* a variety with finely formed flowers of a pure white without any markings whatever; they are of a long and elegant funnel-shape, and in *A. Dr. Masters* is found the very opposite in colour to the one just described, as it is the intense brilliancy of colour, combined with the fine form of flower, which are its principal characteristics. *A. Duke of Albany* is also a very valuable addition, being a magnificent variety with flowers 5 inches across, of a vivid scarlet-vermilion, with a broad central band running half way up each division. *A. The Giant* is, as its name implies, a robust grower, producing large flowers of fine massive form; colour crimson, feathered and pencilled with white; but one of the most attractive forms on account specially of belonging to the many-flowered section is *A. Baron Schroeder*, which bears intensely deep crimson blossoms of large size and irreproachable form. In that family the last season has also produced the forerunner of a new race which we think will prove very valuable. It is certainly a most striking example of success obtained by the intercrossing of *Amaryllises*. The plant which we refer to is a lovely hybrid between the well-known autumn flowering *A. reticulata* and one of the large-flowered varieties of the *Hippeastrum* section. The flowers are large, well formed, of a pale rosy pink, beautifully chequered with a pink of a deeper shade. The foliage bears the characteristic white mid-ribs of *A. reticulata*, but less pronounced. The new hybrid also flowers at the same time as its variegated parent, viz., December and January, and will be on that account much sought after.

Fine foliated plants.—If these have not been so numerous introduced during last year as formerly, it is no doubt due to the increasing difficulty of producing subjects in any way superior to those which we already possess. Some such genera as *Croton* and *Dracena* are so rich in colour and form, that it is almost impossible to add to their numerous lists anything likely to supplant any of the old sorts. We have nevertheless witnessed the triumph of *Croton Thomsoni*, which is indeed a very handsome variety, with foliage a foot or so in length and some 3 inches or 4 inches wide. The leaves are of a golden yellow hue, broadly margined and spotted with rich green and suffused with crimson tints. Moreover, it possesses the desirable quality of colouring highly even in a small state. *C. Eyrei* is an extremely elegant hybrid between *C. majesticus* and *C. Johannis*. The leaves are long and narrow, variegated with green and bright yellow, and recurve in a very graceful way. In *C. Dayspring* we have also a handsome novelty; its oblong elliptic leaves are orange-yellow, edged with dark green, the yellow parts becoming tinged with red in the older leaves; the variegation is highly effective. Another very distinct and decorative new variety is *C. aureo-marmoratus*, whose leaves are upwards of a foot in length, rather broader than usual, and of a bright yellow colour, beautifully mottled with various shades of green. Of *Dracenas*, only two really good acquisitions made their appearance during last season—*D. fragrans* variegata with broad recurving foliage, banded longitudinally with greenish yellow, and *D. Thomsoniana*, from the west coast of Africa. It is a fine, bold, erect-growing stove plant with the habit of *Cordyline*, having a head of long bright green leaves. Among the miscellaneous list of fine foliated plants are to be found half-a-dozen new forms of Japanese Maples, the most conspicuous being *Acer japonicum aureum*, a variety with broad palmate leaves of a uniform pale golden hue, forming a very pretty contrast with the green kinds; and *A. polymorphum linearilobum*, a very elegant variety whose leaves are divided into very narrow leaflets. Then there is *Asparagus plumosus nanus*, which is a most elegant South African plant of dwarf growth, with feathery foliage of a bright green hue. It is of rapid growth and will prove invaluable as a decorative plant, the more so that it lasts fresh for a very long time when cut. *Begonia gogoensis*, a new species from

Sumatra, is one that will also keep its rank; its handsome leaves, which are shield-like, almost circular, measure about 9 inches across. The colour is a deep metallic green on the upper surface, traversed with veins of bright emerald green, while the under surface is red. From Borneo we have a very gorgeously attired new-comer, the *Leea amabilis*, with pinnate leaves, having two pairs of leaflets and an odd one from 4 inches to 6 inches long by 2 inches in breadth, coarsely toothed at the margin. The upper surface is glossy, metallic green, with a bright silvery band running down the centre of each leaflet; the under surface of the leaves is a vinous purple. Two very meritorious *Nepenthes* have also been added to the already numerous collection of these wonderful plants. *N. madagascariensis*, a recently introduced new species from Madagascar, is of rather small growth, and the pitchers are of a bright red colour, and produced plentifully; it is one of the most distinct of the new Pitcher plants. In *N. Mastersiana* we have a very handsome hybrid between *N. distillatoria* and the gorgeous *N. sanguinea*. It produces pitchers very freely, and they often attain 10 inches in length, of the shape of those of *N. sanguinea*, elegant in form and of a deep sanguineous red.

New Ferns have been introduced which will no doubt prove real acquisitions, especially the lovely *Osmunda japonica corymbifera*, which is a remarkably handsome form of the Japanese Royal Fern, having every frond terminated by a broad crest, which renders the plant very elegant in appearance. The stalks are of a beautiful claret colour, and the foliage of a pretty pale green. Its growth is dwarf and dense, and it will flourish well in a cool greenhouse. Next comes the very elegant *Davallia tenuifolia Veitchiana*. This light variety of Hare's-foot Fern from Penang has no creeping rhizomes; its beautiful finely divided fronds are produced from an underground rhizome; they grow from 1½ feet to 2 feet in length, are very finely divided, and of a pale green tint; the slender stalks are of a beautiful pink colour. *D. fijiensis plumosa* is another elegant—indeed one of the handsomest of stove Ferns; its long, finely cut fronds are produced on outside running rhizomes; they are heavily tasselled at the tips, and are gracefully arching. The robust growing *Polypodium ornatum* is also a new species likely to hold its ground among the best introductions of late years. It is a very handsome Fern, with large, widely-spreading fronds, finely divided and pale green, rising from a short, thick caudex, forming a little stem in the course of time; the stalks are of a glaucous hue. From Java we have also a Fern of very peculiar appearance, the *Pleopeltis fossa*, of dwarf-growing habit, with thick, leathery fronds, deeply pinnatifid and arranged in a low, spreading tuft. Among the hardy Ferns the most prominent is, no doubt, *Polypodium cornubiense* Fowleri, a most elegant variety of the common *Polypody*, and one which can only be compared to *Trichomanes radicans*, for it is more like it than any other. A very grand *Selaginella* called *grandis* has also been brought out. It is, no doubt, the handsomest of the whole genus in cultivation; its gracefully-arching fronds are of a deep green, and measure about 15 inches in height. S.

COCOA-NUT REFUSE AND ITS USES.

This substance has been at one time or another recommended for all kinds of horticultural purposes. Its use for potting has been recommended either by itself or mixed with soil, also as a medium in which to strike cuttings, as a plunging material, for top-dressing, and, lastly, as a manure. When incorporated with potting soil instead of peat or leaf-mould care should be exercised as to the subjects for which it is employed; in the case of most plants I should certainly prefer either peat or leaf-mould to it. I have grown Ferns in a compost of which this refuse formed a part with very satisfactory results, but with all other subjects on which I have tried it in this way the results have not been such as to warrant its continuance. When employed for potting the particles of refuse often become affected with a white fungoid

growth, and when such happens the roots make no headway even if they do not die altogether. Even if no fungus makes its appearance when it is used in the case of a general collection of plants, their roots will not as a rule be so healthy as where none is employed after they have all stood, say, six months. For one purpose it may be and often is used with advantage, and that is for mixing in the proportion of about one-fourth with soils used for potting off all kinds of quick-growing cuttings. As these remain in their pots only a short time, all that is required is a rooting medium, and one that will hold a certain amount of moisture without becoming clammy, a

A bottom heat bed in this way proves very useful for striking a great variety of things. As a substance in which to plunge pots to protect the roots from extreme changes either in or out of doors this fibre undoubtedly stands in the first rank owing to its lightness and cleanliness, and the readiness with which it may be worked; moreover, the various insect pests do not appear to much relish the idea of making their homes in it. It generates but little heat even when in a good sized heap; therefore it must not be used for forcing, but solely as a plunging material. For small bottom heat cases in which stove propagation is carried on, this fibre should

the latter, when mixed with potting soil, tends to make it clammy instead of keeping it open, while for indoor beds it has not the fresh, stimulating smell of the new fibre; and for resisting frost 1 inch of the latter in a moderately dry condition will keep out as much frost as 3 inches of the old material when in that decayed and saturated state in which it becomes after long usage.

Mulching.—Where plants are growing in exposed places a coating of this refuse on the surface of the soil is of great service in maintaining moisture about the roots during hot weather, and in protecting them from frost in winter, but its use is advocated simply as a protective agent, and not

Adiantum speciosum. (See p. 63.)

purpose which the fibre helps to fulfil, but even then I should certainly prefer well-decayed leaf-mould.

For striking cuttings it is undoubtedly a material of high value, as it seems conducive to the formation of roots, but in that case the cuttings must not be allowed to remain too long in it, as when used alone the roots soon decay. For all kinds of soft-wooded or quick-striking subjects I use the fibre alone, with the exception of a little sand mixed with it. Into this the cuttings are inserted, and when sufficiently rooted potted off without delay. Rather more care is needed during this operation than when the roots are made in ordinary soil, as when in fibre they are more succulent and brittle, and therefore liable to be broken. Again, when employed as a plunging material, as it often is in the stove, cuttings of different kinds may be struck in it, and being sheltered by the plants overhead require scarcely any attention until rooted.

be often renewed, as in such a close, steamy atmosphere it soon gets saturated with moisture, besides which the effluvia which it gives off when fresh seems to arrest decay amongst the cuttings. Where pots are plunged out of doors during summer, this refuse will tend greatly to keep them in a uniform state as to moisture and prevent them from becoming baked; and if in winter any dormant subjects are covered with 3 inches or 4 inches of this fibre in a new or unused condition, no ordinary frosts will touch them, especially if the fibre can be prevented from becoming too wet. For covering all kinds of bulbs after they are potted till taken indoors for forcing this refuse possesses a great advantage, inasmuch as it does not harbour insects, and is easily removed without breaking the young growths, even if they are an inch or two in height. For all purposes the fresh material is greatly to be preferred to that which is partially decayed, as

from any stimulating properties possessed by it. Judging by the way in which it is often used in villa gardens, i.e., sprinkled over the ground in homoeopathic doses, it would appear to be considered a powerful manure; but such is not the case, although it is of service to mix with the soil in order to lighten it when too heavy. For lightening soils it may be worked in when too much decayed to be retained any longer in the houses, but it should be spread out to sweeten beforehand, as it is apt to turn somewhat sour through the continual waterings necessary in hot-houses. In the case of Lily bulbs received during the winter I much prefer laying them out and covering them with this fibre for a little time to potting them at once, as some of the scales are generally injured in transit and the absorbent qualities of this material tend to arrest decay, while when taken up for potting any bad parts can be removed which would not have been

perceived had the bulbs been potted at once. Of course they are not allowed to remain long enough for the roots to attain any length, otherwise much damage might accrue, as from their brittle nature they are easily broken. The best time to pot the bulbs is as soon as the new roots appear around the base.

ALPHA.

FERNS.

ADIANTUMS.

(Continued from p. 10.)

A. lunulatum.—A very distinct and handsome species from the East Indies. It has a

the handsomest and most distinct of the whole genus. The fronds, which rise from an underground creeping rhizome, are pinnate, and grow from 12 inches to 20 inches high; the pinnae are very large and irregular in shape, sometimes deeply serrated, while in some cases their edges are almost smooth, both forms being generally found on the same plant. When young they are of a delicate pink or red, changing to bright green with age; they are produced in great abundance, and have their stalks stout and shining black. It requires to be well supplied with water at the roots, or it will have a wretched appearance, its beautiful fronds becoming spotted. Stove.

lobes, which are again more or less divided. It is deciduous, but should not be allowed to get dry. Stove. Some idea of its appearance may be gleaned from the annexed illustration, for which we are indebted to Messrs. Veitch.

A. pedatum.—This highly ornamental and thoroughly deciduous North American species, although perfectly hardy and most suitable for the out-of-door fernery, makes a very fine specimen for the greenhouse, where, in fact, it shows itself to better advantage, as it being of rather a fragile substance, it is seldom seen in perfection outside unless it be in a very sheltered situation. The fronds, which are produced from an underground

Adiantum palmatum.

very slender, pendulous habit, and is prolific at the apex; so much so, that it is not rare to see produced from the ends of the fronds three generations of plants; the fronds are pinnate, with pinnae alternate and lunulate, bright green in colour, and about 15 inches long, sometimes more; the stalks are of a beautiful shining black. On account of its pendulous habit and of its rapid growth, it is considered one of the best basket Ferns by all who grow it. The fact of its being deciduous accounts for its loss in many cases, as care must be taken in the winter that it does not become thoroughly dry, or it will not start again. I have always found it to do much the best if kept moist at the roots all the year round; by that means it does not die down altogether, and perhaps does not get quite as much rest as if treated as a deciduous species. Stove.

A. macrophyllum.—This beautiful erect-growing species, from the West Indies, is one of

A. Neo-guineense.—A charming species with fronds growing to about 18 inches long and very gracefully arched; they are tripinnate, the pinnae set rather far apart, and the pinnules, which are of a dark green, reminding one as regards colour of *A. Capillus-veneris*, are deeply cut, and being loosely set, give the plant a very elegant appearance. Stove.

A. palmatum (digitatum).—A very beautiful Fern with fronds of an indefinitely elongated form, produced from a stout creeping rhizome, and very well adapted for basket culture. Grown in that way it soon makes a handsome specimen, as the fronds, which are light green in colour, attain a considerable size. A very noticeable feature in the plant is the flexuose or zigzag character of the rachis, most marked towards the terminal end of the frond. The pinnules are distant and distinctly stalked, from 1 inch to 1½ inches in breadth; they are deeply cut down into from three to five large

thick rhizome, grow to 18 inches or more in length, are of a delicate green colour, pedate or bird's-foot shaped, and smooth; they are supported upon black shining stems. Greenhouse.

A. pentadactylon.—This fine ornamental Brazilian species has fronds from 2 feet to 3 feet in height, produced from a thick, fleshy decumbent rhizome; they are tripinnate, of very bold appearance, and borne upon jet black stalks; the pinnules, rhomboid in shape, are soft green in colour, except when very young and in undeveloped state, for they are then of a fine metallic or bronzy hue. It is, when properly grown, a very grand plant, and requires all the year round a good supply of water at the roots. Stove.

A. peruvianum.—This species, native of Peru, is undoubtedly one of the very finest of the large-growing Maiden-hair Ferns; its stout black, polished stalks rise to about 15 inches, supporting the ample and gracefully pendent fronds, which

grow to a length of from 2 feet to 3 feet, and are almost triangular in outline. They are produced from a thick decumbent rhizome, and are beautifully arched; they are compound, and made up of large pinnules, trapeziform, but having their basilar angles rounded and of a beautiful dark green when mature, and of a soft metallic hue in a young state. The sori are large, produced along the whole of the anterior margins of the pinnules, somewhat varying in length, but generally oblong. Stove.

A. princeps.—Not only does this splendid Maiden-hair from New Grenada possess a degree of boldness of character on account of the size of the fronds and the pinnules, but the plants are also remarkably graceful from their fulness of development and the arching and pendent position which they assume. The fronds, which are produced from a thick underground rhizome, are broadest at the base, the lower pinnae being about a foot in length, with the lower pinnules bipinnate, so that the frond itself becomes quadripinnate; the pinnules are large, the base margin and inner side is entire, while the anterior margin is cut into broadish shallow lobes, but the sterile pinnules are minutely serrulate. The whole of the plant is of a delightful light green. Stove.

A. pulverulentum.—This very handsome evergreen species from Tropical America produces bipinnate fronds, about 20 inches high, with rachis and stalks covered with close rufous hairs; it grows into a compact plant, all its fronds rising from a thick-set rhizome; when young they are of a brilliant metallic hue, and of a rich glossy green colour when mature. Stove.

A. reniforme.—An evergreen Fern from Madeira, looking as little as possible like an Adiantum; this great distinctness alone is sufficient to give it a right to be in every collection. The fronds are produced in great abundance from a crown, are kidney shaped, of a bright shining green colour, from 1 inch to 3 inches in width, and from 5 inches to 8 inches high; they are borne on slender dark polished stalks. This beautiful species is generally considered difficult to manage, but it is only on account of its being kept in too warm a place, and often from being potted in too loamy a mixture; it only requires cool treatment; and as to its compost, it does best in a mixture of two parts peat and one part coarse sand. No loam is required. Greenhouse.

A. rubellum.—A very pretty Peruvian species of dwarf habit. The fronds are produced in a close tuft from a crown; they attain the height of 9 inches or 10 inches, and are bipinnate and triangular in outline, whilst the pinnae are wedge-shaped and incised. They are produced in great profusion, the young ones being on their first appearance of a beautiful purplish crimson tint, changing to light green with age, but even then tinged with pink, so that a good specimen is always more or less enlivened by a roseate hue. Stove.

A. Sanctæ-Catherinæ.—The fronds of this truly ornamental Brazilian species are from 1 foot to 2 feet in height and decomposed; they are freely produced from an underground thick rhizome; the stalks and rachis are wiry and jet black; the pinnules, rather far apart, are obliquely rhomboid, dark green and coarsely toothed. It requires little light. Stove.

A. scabrum (Silver Maiden-hair).—A very compact-growing and beautiful species from Chili, very seldom met with in cultivation; the fronds, which are produced in great quantity, seldom attain more than 9 inches high; they are decomposed and formed of roundish pinnae, dusted on both sides with a white farinose powder. It is generally considered a difficult plant to grow, but it is only on account of its being kept in too great heat and with too much moisture round it. I have seen it grown best, indeed to perfection, on a dry shelf with Cacti, and a very little allowance of water during winter in a greenhouse.

A. scutum, or more accurately *A. Ghiesbreghtii*, under which name, however, it is very

little known, is a beautiful plant which has sprung up in our gardens without anyone being able at present to say from whence it has come, or if it is merely an altered and improved form of some species already in cultivation. Anyhow, it has the power of reproducing itself freely from spores, as may be seen by the immense quantities yearly grown for market. It is a fine large-growing kind with somewhat the habit of *A. farleyense*, but less dense, and makes one of the finest Maiden-hairs for decoration or exhibition purposes. Its beautiful fronds are tripinnate, somewhat ovate, from 18 inches to 24 inches in length, and produced from a thick crown; the pinnae, large, slightly crenate on the margins, are of a bright green colour; the stalks and rachis are black and shining. Stove.

A. Seemanni.—This handsome and rare Fern from Central America is of a very peculiar growth, inasmuch as in a young state the plant only produces simple fronds of extraordinary dimensions; these are heart-shaped with an elongated point, and often measure as much as 3 inches in breadth; but as the plant assumes its mature form they become pinnate, the pinnules being ovate, acuminate, unequal-sided, and drooping at right angles from the rachis. The fronds, which are produced in clusters from a thick underground rhizome, are, when unfolding, tinged with a bronzy colour, turning with age to a deep glossy green above, while their under surface is of a very pretty glaucous colour. They attain about 18 inches in height, very leathery, and are borne on deep black, shining, stout stalks. Stove.

A. setulosum.—A beautiful dwarf-growing species from Norfolk Island and the Fijis. Its fronds, which seldom grow to more than 10 inches high, are produced in great abundance from slender underground creeping rhizomes having the peculiarity of forming young plants on all their parts, thus making very compact little specimens or agglomeration of bright green bi or tripinnate fronds, whose pinnules, closely set, have a few black hairs upon their upper side. It is of very easy culture and very useful for cutting, lasting well when severed from the plant. Greenhouse.

A. speciosum.—This very elegant Fern from New Grenada resembles a Maiden-hair, but very little in general appearance, as it is of a semi-scandent habit with large tripinnate fronds borne on fleshy stalks; they frequently attain a length of 36 inches with a width of 22 inches, and their pinnules, which are very symmetrically set, often measure $1\frac{1}{2}$ inches across, their lobes cuneate and soriferous at their apex. The whole of the pinnules are covered with dense short hairs, giving the foliage a woolly feeling when touched. Altogether it is a very distinct and ornamental Fern, as will be seen by the annexed illustration (p. 61) from Messrs. Vietch. Stove.

A. sulphureum.—This beautiful dwarf evergreen species from Chili, a fit companion for the pretty little *A. scabrum*, is always regarded as a difficult subject to manage; it is, however, well deserving any extra trouble it may cause, but will succeed well under the same treatment as *A. scabrum*, viz., on a dry shelf in a cool house, with little water during the winter months. The fronds, which seldom attain more than 8 inches in height, are produced from a crown; they are tripinnate, with small pinnules, roundish when barren, but slightly incised on their edges when fertile, and covered on their underside with a more or less bright golden farinose powder. Greenhouse.

A. tenerum.—This very fine evergreen species from the West Indies is a general favourite wherever Ferns are in requisition for decoration, where it is found most useful, as its beautiful fronds, which are produced from a decumbent rhizome, grow from 3 feet to 4 feet in length, and are possessed of a very elegant character, bold, with their charming polished black stems standing upright, and the weight of the numberless broad, semi-circular pinnules causing them to curve over very gracefully; they are tripinnate, and of a pleasing light green. It also makes a grand specimen for exhibition purposes where sufficient room is allowed it. Stove.

A. tetraphyllum gracile.—A comparatively new species introduced from the United States of Columbia. It is specially remarkable for the beautiful reddish hue assumed by its fronds when first developed, and which continues until they are fully expanded. It is a close grower of moderate stature. Its fronds, which are produced in great numbers from a thick underground rhizome, are pinnate, borne on slender black stalks; they are elegantly arching over at the top, and dividing into from four to six linear pinnae. It is a very striking and distinct species. Stove.

A. tinctorum.—This pretty dwarf-growing little species from Tropical America is not very often met with now, although it is a gem which should be in every collection. Its fronds, which rise from a compact crown, are produced in profusion; they seldom attain more than 8 inches in height; they are pinnate in form and of a rosy red in their young state, changing to bright green with age. It is about the dwarfiest of the coloured Adiantums. Stove.

A. trapeziforme.—A well-known and much appreciated bold-growing species from the West Indies. It is evergreen and makes a grand exhibition plant, its thick underground rhizomes producing fronds of a bright rich green, from 3 feet to 4 feet in length with very large pinnules of a peculiar shape. It is also a very free grower, which quality no doubt accounts for its popularity. Stove.

A. Veitchi.—No doubt the most highly coloured as well as the largest foliageed of the tinted Adiantums after *A. macrophyllum* is this very elegant Peruvian species. The fronds, which reach some 18 inches high, are produced in abundance from slender underground rhizomes; they are tripinnate, very symmetrical, and borne on stout black polished stalks, and affect an erect position; the pinnules are closely set, of a bright red in their young state, and with age change to a pale green; they are also thicker and of better texture than most Adiantums. Stove.

A. velutinum.—A fine, tall, bold-growing species from Columbia; its fronds are very large and almost erect; the pinnae are somewhat falcate and acuminate, broad, and of a dull green colour; the stalks and the rachis are densely clothed with dull brown silky scales, giving the plant a very distinct appearance. Stove.

A. venustum.—This very distinct Himalayan species is very rare in cultivation; although discovered many years ago by Dr. Hooker, it has never become plentiful. There is quite another plant which is generally known under this specific name, and found in a great many collections as well as in most catalogues under that name, but which is only a dwarf form of *A. aethiopicum*, with stems slender and brittle, of a purplish black, and round pinnules of a very light green. This variety is most prolific, provided with slender underground rhizomes, from which spring a quantity of young growths. The true *A. venustum* also produces its numerous fronds from a creeping rhizome, but their stalks are ebony black and not brittle; the colour of the upper surface of the fronds is of a bright green, while the under-surface is quite glaucous. They are tripinnate and the pinnules of two very different shapes, the fertile ones being wedge-shaped and with nearly smooth margins; whereas in the barren ones the cuneate form is not so definite, they being much more rounded and beautifully serrated all round the edges. The whole of the foliage is very coriaceous and quite distinct from the spurious form. Greenhouse.

A. villosum (varium).—This beautiful evergreen species from Tropical America is a very ornamental plant. Its fronds rise from an underground rhizome, and are of a bright colour, about 18 inches high, bipinnate, with bright shining pinnae. It is most peculiar in having the sori in a continuous, unbroken marginal line, and its rachis very heavy. Stove.

A. Williamsi.—A very handsome species from Peru, where it is found at a great elevation.

It is probably a form of *A. æthiopicum*, and has somewhat the aspect of *A. chilense*, although the growth is not so dense. This plant is also of a more free and more vigorous constitution; its beautiful fronds, of a bright light green and very elegantly arched, often reach 2 feet long, and are supported by stalks 6 inches to 8 inches high, golden at the base, and a rachis in zigzag about 12 inches long. The pinnules are about half an inch broad, and attached by pedicels about a quarter of an inch long, so that the parts are nowhere crowded; they are membranous and of a semi-circular form. It is especially as a basket plant that this species is most valuable and as such that it is seen to its best advantage, and the more useful, as it is one of the few *Adiantums* which really make a good, effective basket for a greenhouse.

PELLEA.

SEASONABLE WORK.

FLORAL DECORATIONS.

ORNAMENTAL Grasses impart to an arrangement a lightness and distinctive character which Fern fronds, handsome as they are, fail to give. Moreover, it is difficult to keep up the needful amount of cut Ferns without disfiguring the plants; therefore, we should grow ornamental Grasses for the purpose, thus sparing many Fern fronds. Most of the useful sorts are easily grown from seeds. We sow them in March in the open border in well prepared soil—the earlier in the month the better if the weather is favourable. We have found the following six kinds to be amongst the most useful, viz., *Agrostis nebulosa* and *pulchella*. These come into flower early, and are about the very lightest that can be grown; they are also often sown in pots, and in this manner are useful for furnishing purposes. *Briza maxima* and *gracilis* are two of the best of the Quaking Grasses. We find the former to be especially valuable, and to arrange well with Water Lilies and similar subjects. This sort is also one of the best for cutting and drying for later use. If cut while the deep green tint is in it, it retains its colour better than if left till it has assumed a brownish tinge. *Lagurus ovatus* (the Turk's-head Grass) is one of the most distinct kinds, as well as one of the best for keeping purposes if treated as just advised in the case of the *Briza*. For bold arrangements in association with large flowers this is an excellent kind. Another valuable Grass is *Eragrostis elegans*; this is a later kind than those previously named, and comes in useful for cut purposes up to the time when the early frosts spoil its colour. It is a somewhat stronger sort than the others; when well grown it attains a height of from 2 feet to 2½ feet high. It should, therefore, be allowed more room than the others in which to develop itself. The following sorts are all useful and distinct, viz., *Anthoxanthum gracile*, *Brizopyrum siculum*, *Bromus briziformis* and *giganteus*, *Hordeum jubatum*, and *Paspalum elegans*. Two new kinds have recently been brought forward, viz., *Briza spicata* and *Bromus patulus nanus*, both of which will doubtless prove useful. These Grasses, taken collectively, are about the best that can be annually raised from seed. *Stipa pennata* and *elegantissima* may be increased by division, perhaps, with more certain results than from seeds. These ornamental Grasses are all valuable in their seasons and for preserving for use afterwards, not, however, after they have been disfigured by drying. When those raised from seed are well above the soil it will be well to thin out any kind that has come up too thickly. This will throw more stamina into those that are left, rendering them more durable. The following annuals are all useful associated with Grasses, viz., *Campanula Loreyi* and its white variety, *Catananche coerulea*, *Sweet Sultan* (yellow), *Rhodanthes*, *Linum grandiflorum coccineum*, the Corn Flowers in various colours, dwarf Poppies, single Dahlias, which have a future before them, and last, but not least, *Gypsophila elegans* and its variety *rosea*. Many more annuals might be named, but these are among the best for decorative arrangements and for using in conjunction with

Grasses. One of the hardy perennials that may be raised from seed is *Chelone barbata coccinea*; this when in flower yields good spikes for trumpet vases.

INDOOR PLANTS.

Conservatory.—After the clearing out of *Chrysanthemums* from conservatories there is often some falling off in the display. This should be remedied by having ready to take their places such plants as come into bloom, either naturally at that time, or with a little forcing. For this purpose there are few things better than the different varieties of winter flowering *Salvias*, such as those named a few weeks back. These, combined with *Camellias*, forced *Lilacs*, *Hyacinths*, *Tulips*, *Narcissi*, *Cyclamens*, *Primulas*, double and single, early sown *Cinerarias*, pot *Mignonette*, *Epacris*, *Correas*, *Genistas*, and *Azaleas*, will, if grown in sufficient quantities, keep up a display little inferior to that which may be looked for later on. It is well, in particular, to urge the claims of *Azaleas* for conservatory decoration in the two dull months, December and January, during which time there is no more difficulty in having them in good blooming condition than there is later on provided the plants have been properly prepared by having their growth made early and their buds set, but this cannot be done by turning the plants out-of-doors to set their buds when the growth was partially made the summer previous. To have them in good blooming order in winter they must be kept tolerably warm under glass through the summer, so that their buds are plump and big, looking as if they were ready to burst by the middle of September. Managed thus, there will be no difficulty experienced in getting the flowers to open freely in a moderate heat in November. In this way there is no forcing in reality required, such as would cause the blooms to come soft in texture, making them of little use for cutting. Medium-sized plants are best for the purpose, and they should never be stopped, but allowed to grow, as they will do if kept clear from insects and vigorous, a little loose, which admits of half the flowers they produce being cut with a fair length of wood attached to them, a way in which they are of much more use than when the growth is stumpy and short. It often happens that the climbing subjects employed to cover an end wall of a conservatory, or to furnish the roof, are the least satisfactory of its occupants. This is especially the case when the plants chosen are naturally of too strong and vigorous a habit. In this case they either smother everything else in the house or have to be so severely cut in as to interfere with their flowering, and, what is even more detrimental to their well-being, they generally exhaust the limited quantity of soil that can be afforded them to grow in to an extent that does not admit of its fertility being kept up by additions or manuring. Where such a state of matters exists it is much the best to remove the old plants and replace them with others of a less rampant habit; this will give an opportunity for completely removing the soil. This is essential, as with permanent plants of this kind comparatively little can be done in the way of removal without destroying the roots to an extent that would be injurious. With the same object in view those plants that will thrive in loam should have soil of that description given them in preference to peat. Whatever is to be done in the way of cleaning conservatory climbers from the worst kinds of insects that affect them, such as mealy bug and scale, should now be carried out whilst the plants are comparatively at rest, as during this time the work can be done much more effectually as well as with less injury. As I have often urged, a sustained effort should be made to completely eradicate these pests, for where nothing is done beyond periodically freeing the plants from a portion of them, the work has to be repeated indefinitely, the result being a continuous expenditure of labour, with more or less injury to the plants.

Browallia elata.—This free-flowering little plant is very useful for decorative purposes, com-

ing into bloom in a comparatively short time from seed. If some are raised in this way two or three times in the course of the year, a continuous succession will be kept up; if a little seed is now put in and stood in moderate warmth, it will at once vegetate. As soon as the seedlings are up they should be placed on the shelf near the glass and allowed to remain until large enough to handle, when they must be pricked off into small pots.

Camellias.—Where these have not yet had their annual cleaning by sponging the leaves and removing any scale insects that may exist on the shoots, it should at once be attended to. In the neighbourhood of towns, where the atmosphere is charged with soot, they are greatly benefited by having their leaves sponged two or three times a year. If the plants are turned out in beds—and still more so when grown in pots or tubs in conservatories, where some warmth is kept up during the winter—especial care must be taken that the atmosphere, as well as the soil, is not allowed to get dry, or the buds are sure to drop; this is particularly the case with the white varieties, which are more easily affected in this way than the others. Where any large plants of inferior kinds exist that it is intended to graft with better sorts, they may now be headed down and grafted. Many of the numerous ways in which grafting is performed will answer, but if the plants are large and the stems a considerable length before branching out, they may be cut down 8 inches or 10 inches above the collar and cleft grafted, putting in four or six, binding the stock round so as to keep the scions in their places, surrounding the whole with ordinary grafting clay, after which they may be placed in a house or pit where a little extra warmth is kept up. I have found *Camellias* to succeed best when grafted thus early, before the sap is about to rise, as if the work is deferred too long the flow of sap is such as to often prevent the grafts taking.

Fuchsias.—Young plants struck from cuttings at the latter end of summer and that have been kept on growing slowly in an intermediate temperature will now require larger pots, for if ever they are allowed to become at all cramped for want of pot room, they will not move freely afterwards. Such as have occupied 5-inch or 6-inch pots may be moved into others 2 inches or 3 inches larger, using good turfy loam with a little leaf-mould, some thoroughly rotten manure, and sand in proportion to the greater or less quantity which the loam naturally contains; but *Fuchsias* do not require the soil to be quite so open as some other quick-growing plants do. Pot moderately firm, but not so much so as in the case of some things of a more permanent character; pinch out the points of the shoots to induce a close, well-furnished condition. Some varieties require less attention in this respect than others, being naturally disposed to branch out without stopping. A well-grown *Fuchsia* should, when in bloom, present a dense mass of pendent shoots drooping from a single stem, each clothed with healthy foliage and flowers. This state can be secured in these autumn-struck plants in a way that it is difficult to accomplish with old specimens or with later spring-struck stock, although the latter make nice small examples, but for large conservatories where size is an object with a considerable portion of the occupants autumn-struck plants are the best.

FRUIT.

Vines.—So far a mild winter has favoured early forcing, and now days are increasing in length, time apparently lost through the dark month of December may be redeemed by taking advantage of bright days for running up the temperature of the house after it is closed, and by making frequent additions of warm leaves to the internal ridges and linings which have been at work ever since the house was closed. A continuance of mild weather will lend an inducement to the maintenance of a high night temperature, but a period of rest being absolutely necessary to successful culture, a mean of 60° must not

be exceeded during the hours of darkness. Run up to 70° on bright mornings with a chink of air at the apex, and close early to insure a rise to 75° for a short time with plenty of atmospheric moisture. Continue direct syringing until the bunches are well formed and increase the fire heat if they show signs of running to tendril and drawing up towards the glass. Many growers leave off syringing as soon as the Vines break, but whenever early forcing is carried on against Nature, a good syringe in skilful hands plays a very important part in keeping the Vines clean, healthy, and vigorous through the early stages of growth. If pruning and cleansing in late houses be still in arrears, lose no time in bringing this work to a close. Avoid the barbarous practice of depriving the rods of their natural protection by scraping off the bark, but wash them well with strong soap water, and keep the ventilators open until the time arrives for starting the Vines. Prepare Muscat houses for shutting up at the end of the month by giving repeated waterings to inside borders, and have a good body of well-worked fermenting material ready for use as an economiser of fire heat as well as to produce a mild soft atmosphere, so essential to the proper filling and bursting of the buds. By taking time by the forelock, and bringing Muscats on steadily, they will break evenly, and set their fruit better than if placed under high pressure before they come into flower; moreover, having the whole of the summer before them, the fruit will become thoroughly ripe by the end of August, the Vines will have a long season of rest, and the Grapes, being finished under bright sun-heat, will be in the best possible condition for keeping after removal to the Grape room. A mid-season house containing mixed kinds may now be started in the usual way, and pot Vines which have been rested and cut down for growing into fruiting canes may be brought forward by being placed on the fermenting material. Give water sparingly, shake out, and pot when they have made growths 2 inches in length, and plunge in a bottom heat of 70°. Put in the remainder of the "eyes," using small pots firmly filled with sandy loam, and have a good bottom heat in a close pit ready for their reception by the first week in February. If grafting is contemplated, perhaps the best time is the rising of the sap in the Vines selected for working.

Pot Vines.—Fruiting Vines may be kept at a temperature of 60° to 65° by night, and 10° higher through the day; give air at 70°, and run up a few degrees after closing. Having selected the bunches for the crop, stop the shoots at the third joint, and allow the first set of laterals to extend until every part of the trellis is covered, but not crowded with foliage. Feed well with tepid liquid, and keep the roots well covered with fresh surface-dressing as often as the soil is washed away from them. Guard against sudden checks by the admission of cold draughts of air, or by allowing the bottom-heat to fall below 70° before it is renovated with fresh leaves in a fermenting state. If the pots are standing on pedestals, the whole mass may be turned to the bottom of the pit without disturbing the roots, which must be kept progressing, otherwise the Grapes will not set well.

Peaches.—Where numbers of houses are forced a busy time is close upon us, and in order to keep pace with daily details in this and other departments no time must be lost in getting late trees tied in and ready for starting or retarding as the case may be. In the management of late Peaches, which it is usual to retard in the spring, all pruning should be performed as soon as the fruit is gathered, when the application of fire-heat for a few weeks will bring up the blossom buds and ripen the wood to the tips. This important point having been secured, vigorous young trees may be tied in full length; but should there exist a doubt as to their ripeness the strongest shoots may be cut back to a triple bud which always contains a shoot-producing bud in the centre. If the trees have not been attacked by insects dis-
pense with paints and strong dressings, which fre-

quently do more harm than good, and wash well with warm soapy water, or a weak solution of Gishurst Compound, 4 oz. to the gallon of water. Largetrees which produce an abundance of blossom may be top-dressed with good rotten manure as soon as they are tied in. Young ones will set their fruit best without the manure; but in each case the roots must be well supplied with water from the tanks, as the buds are now swelling and a short supply of water will prove fatal to the crop. Give an abundance of air by night and day, and to counteract the influence of this mild weather, run off all portable lights when the external air stands above 40°. In cold gardens where the open air Peach crop is uncertain, large span-roofed houses of the most simple and inexpensive character, if judiciously planted with the best late kinds, will soon clear their cost, as the demand for late house fruit is considerably on the increase, and, like late Grapes, pays better than early forcing. For this house such varieties as Barrington, Walburton Late Admirable, Gregory's Late, Prince of Wales, Sea Eagle, a fine free bearing kind which keeps a long time after it is gathered, the Nectarine Peach and a few of the high-coloured mid-season sorts, including Bellegarde, Royal George, and Dymond. Nectarines, being less valuable, a good yellow, like Pitmaston or Pine-apple, Stanwick Elrige, and Albert Victor might suffice. If the houses are built lofty and planted with trained standards, Bays, Aloes, and a host of half-hardy subjects may be kept in them through the winter months.

Early houses.—By this time many early houses will be in flower, and former directions having been followed, the blossoms will be strong, free from aphids, and capable of bearing a free circulation of air—a very important item in the fertilisation of all kinds of stone fruit. On fine days the temperature may rise to 70° with free ventilation, and it may descend to 50° on mild nights, or 10° lower when very severe. Fertilise the blossoms with a camel's-hair pencil; when the pollen becomes buoyant, discontinue direct syringing, but keep the atmosphere soft by damping all available spaces as usual on fine days.

Cucumbers.—A few seeds of Telegraph may now be sown in small pots filled with light, rich soil, and placed near the glass in a light, well-heated pit. Cuttings of a good strain may also be struck in a sharp bottom-heat, provided they can be taken from healthy plants which are free from insects. To ensure success, select firm, short-jointed shoots, insert them singly in small pots filled with fibry turf, previously warmed to a temperature of 80°, plunge under bell-glasses, and treat as seedlings after they are well rooted. Where Cucumber houses are divided into sections, now is a good time to take one in hand and divest the plants of all the fruit and a portion of the old foliage which may have become infested with spider or mildew—two of the worst enemies we have to contend with in winter culture. Cleanse the house and glass, syringe with a mild insecticide and top-dress the beds or pots with fresh virgin loam and horse manure. If worms have found their way into the beds or pots, warm clarified lime water will soon dislodge them. See that houses in full bearing are not over-cropped, feed well with warm liquid manure and guano water alternately, fill the evaporating pans with the same, and top-dress the roots with fresh maiden loam little and often. With increasing length of days syringing may be more frequent, provided it can be done without raising a scalding steam from the pipes when they are hot. Many houses of winter Cucumbers are ruined by scalding steam from highly heated pipes, and it generally happens that the mischief is not discovered until it is too late to seek a remedy. Amateurs and others who grow their Cucumbers upon the old-fashioned principle and depend upon their own seed beds for plants, should now set about getting the materials ready for making up a bed sufficiently large to receive a one-light frame. Good stable manure, well worked and fermented, and sound Oak leaves, in equal proportions, will work up well together.

FLOWER GARDEN.

THE exceptionally mild, open weather is proving a boon to all who have much planting or top-dressing labour on hand. Owing to recent winters being so severe, and work consequently being delayed, we have long arrears of the latter kind of work to make up, and others, no doubt, are in the same position. As a matter of course, some must stand over for another season; it therefore follows that the trees most requiring renovation should have attention first. For all Conifers and American plants the top-dressing is vegetable soil, that is, peat or well-rotted leaf soil. If well decayed stable manure can be afforded to be mixed with it, the trees will better appreciate it. Before applying the dressing, remove all the loose top soil, Moss, Couch Grass, or other troublesome weeds, and then give at least double the quantity of the new dressing in lieu of the old soil cleared off, well firming it over the roots, and if the trees are on turf, the sods may be at once rolled back, but should not be beaten down till a good soaking of rain has taken place to wash the soil in about the roots. Ornamental trees of every sort that seem waning may often be resuscitated by treatment of this kind. Thorns, Beeches, Limes, Oaks, and the like are not particular as to character of soil, provided it is good. For these kinds of trees we usually use the refuse from Vine and other fruit tree borders, and apply the manure in the form of a mulching over the entire space of the new dressing. When the weather is such that top-dressing cannot be proceeded with, the trenching of ground, draining, &c., by way of preparation for new plantations, should be done, it being desirable that all planting be completed and the roots established in their new quarters ere there be danger of a check from drying March winds or early summer drought.

Bedding plants.—It is now time that any plants that are required in quantity and of which the stock is limited by reason of restricted space for wintering should be started into active growth for the production of cuttings. Coleus, Iresines, Alternantheras, and variegated Pelargoniums are among those that we have now so to start, and of the kinds to be raised from seed the following are now being sown, viz., Cannas, Solanums, Ferdinandas, Grevilleas, Ferulas, Centaureas, and Chamæpeuces; all are sown in pans and covered with glass till germination has taken place; bottom heat required 65°, top heat 70°. It is too early as yet to sow such quick growing kinds as Castor-oils, Hemp, and Maize, because if sown now the pots get so full of roots that the plants get stunted before planting-out time. Cannas that were lifted and wintered in sheds may now be divided into single crowns, and be potted in small pots and started into growth, but the slower the growth is excited the more robustly will the crowns come up. Dahlias, too, sorts that are required in quantity, should be at once placed in heat; they produce cuttings most freely when planted on a bed of leaves in the propagating pit. Cocoa fibre refuse or leaf soil is just as good to plant them in as the best soil that can be got. The single varieties are now so much to the front that everyone will be expected to have them, and now is the time to set about their production. Violas, Calceolarias, Gnaphaliums, Echeverias, and Sempervivums in cold pits have suffered this season from damp more than they usually do from frost, and to prevent further mischief in this direction they should be frequently picked over, and every particle of decayed foliage removed, the surface-soil stirred to hinder moss formation and prevent a soured state, and air should be freely given whenever the weather is fine and unaccompanied by a frosty air.

Sowbread.—I have now an interesting specimen of Sowbread (*Cyclamen europæum*) before me. It has four full-blown flowers, three of which are perfect, but the fourth has a six-parted calyx instead of being a five-parted one. There is nothing else irregular about the plant. The corolla

is notched on all the flowers with a revolute limb, and the capsule has five valves. In all my researches in botany I have never seen anything more curious, as this plant has not been tampered with in any way.—THOMAS E. WARDE, 9, *Charlotte Street, Bedford Square.*

THE CARNATION AND PICOTEE.

(Continued from p. 32.)

To beginners in the cultivation of this plant I should recommend a selection from the following varieties:—

CARNATIONS.

<i>Scarlet flakes.</i>	<i>Crimson bizzarres.</i>
Clipper (Fletcher)	Rifleman (Wood)
Jas Cheetham (Rhodrick)	J. D. Hextall (Simonite)
Annihilator (Jackson)	John Simonite (Simonite)
John Bayley (Dodwell)	Albion's Pride (Headley)
Sportsman (Hedderley)	Albert Chancellor (Abercrombie)
Bayley, jun. (Dodwell)	Warrior (Slater)
John Ball (Dodwell)	Eccentric Jack (Wood)
Wm. Mellor (Dodwell)	John Harland (Adams)
William IV. (Wilson)	Stanley Hudson (Dodwell)
<i>Rose flakes.</i>	<i>Scarlet bizzarres.</i>
Jas. Carter (Adams)	Admiral Curzon (Eason)
Flora's Garland (Brooks)	Dreadnought (Daniels)
J. Merryweather (Wood)	Sir J. Paxton (Ely)
Rose of Stapleford (Headley)	True Briton (Hepworth)
Mary Ann (Fletcher)	Lord Napier (Taylor)
John Keet (Whitehead)	Mars (Hextall)
Sybil (Holmes)	Mercury (Hextall)
Lovely Ann (Ely)	Othello (Dodwell)
Mrs. Anderson (Dodwell)	Mr. Holiday (Dodwell)
<i>Purple flakes.</i>	<i>Pink and purple bizzarres.</i>
True Blue (Taylor)	George Rudd (Dodwell)
Jas. Douglas (Simonite)	George (Dodwell)
Juno (Baldon)	Campanini (Turner)
Earl Stamford (Addis)	Sarah Payne (Ward)
Premier (Millwood)	Falconbridge (May)
Squire Meynell (Brabbin)	Unexpected (Wood)
Dr. Foster (Foster)	Jas. Taylor (Gibbons)
Mayor of Nottingham (Taylor)	Purity (Wood)
Florence Nightingale (Sealey)	Twyford Perfection (Young)
	Dr. Masters (Dodwell)

PICOTEE.

<i>Heavy red edge.</i>	<i>Light purple edge.</i>
Brunette (Kirtland)	Cynthia (Turner)
John Smith (Bower)	Ann Lord (Lord)
Miss Small (Fellowes)	Minnie (Lord)
Mrs. Wilson (Fellowes)	Mary (Simonite)
Master Norman (Norman)	Her Majesty (Addis)
J. B. Bryant (Ingram)	Cheltenham Beauty (Abercrombie)
Mrs. Dodwell (Turner)	Silvia (Simonite)
Lothair (Fellowes)	Fanny (Lord)
Peeress (Turner)	Emily (Addis)
Dr. Epps (Smith)	<i>Heavy rose edge.</i>
<i>Light red edge.</i>	Fanny Helen (Niven)
Violet Douglas (Simonite)	Miss Lee (Lord)
Clara (Bower)	Edith d'Ombrian (Turner)
Thomas William (Howdy)	Juliana (Turner)
Rev. F. D. Horner (Lord)	Mrs. Payne (Fellowes)
William Summers (Simonite)	Miss Horner (Lord)
Mrs. Keynes (Fellowes)	Royal Visit (Turner)
Rev. F. D. Horner (Turner)	Mrs. Nicholls (Simonite)
<i>Heavy purple edge.</i>	Elise (Kirtland)
Alliance (Fellowes)	Louisa (Addis)
Norfolk Beauty (Fellowes)	<i>Light rose edge.</i>
Mrs. Douglas (Simonite)	Mrs. Allerott (Turner)
Mrs. Niven (Niven)	Daisy (Dodwell)
Mrs. Chancellor (Turner)	Julia (Dodwell)
Zerlina (Lord)	Edith Turner (Abercrombie)
Lizzie Tomes (Dodwell)	Miss Williams (Norman)
Tinnie (Dodwell)	Ethel (Fellowes)
Alice (Lord)	Estelle (Fellowes)
	Miss Wood (Wood)

CLOVES.

<i>Yellow grounds.</i>	
Alice, Aurora, Cyprus, Congress, Eleanor, Gazelle, Flaming, Lady Aitchison, Ne Plus Ultra, Sultana, Bride, Coronet, Fire-eater,	Rosa Bonheur, Ghost, Mrs. Teigner, Susan Askey, Mrs. Wheeler, Purity, Sulphur King (All raised by C. Turner.)

Perpetual or Tree Carnations.—Twenty years ago or more there existed a Tree Carnation, such a Tree Carnation, and such a stalky, lanky, dyspeptic-looking thing it was, that few, if any, cultivated it at all. Mr. Turner, of Slough, however, took these really useful plants in hand, and by dint of judicious crossing with foreign seed and assiduous propagation, raised the nucleus of the beautiful collection we now have. They are called Tree Carnations, because, instead of keeping a compact little herbaceous plant, they rear themselves on a stem like a dwarf standard Rose. They are called Perpetual Carnations because, as one set of blooms dies down, another springs up

to take its place, so that these plants have a very much more protracted season of bloom than ordinary varieties. The name winter-flowering Carnation speaks for itself. It is their winter-flowering habit which makes them so valuable for bouquets, &c., for they have not often the characteristics so much sought for by florists in the blooms of the show section, and there are no exhibitions devoted to these flowers, though the earlier blooms are frequently exhibited in a class by themselves at the exhibitions of the florist section.

Habit.—As a rule you will find Tree Carnations as dwarf shrubby plants, but there are some sorts which exhibit a strong tendency to climb or trail, such as Souvenir de la Malmaison and La Belle. As to varieties, they exist as in the florist section, namely, flakes, bizzarres, Picotees, and selfs, but the selfs are the most cultivated in consequence of their great commercial value as cut flowers.

Soil for seeds: Loam, 1 part; leaf-mould, 1½ parts; silver sand, 1 part; well rotted manure, 1 part, to be used rather dry than otherwise. For pipings or layers: Loam, 1½ parts; leaf-mould, 1 part, silver sand, 1 part; well rotted manure, half part. For potting and repotting: Loam, 2 parts; well rotted manure, 1½ parts; silver sand, 1 part. All these composts should be thoroughly mixed and allowed to lie exposed to wind and sun (but not to more rain than can be helped) for as long a time as possible before any attempt is made to bring them into use.

Propagating by seed.—These Carnations may be very easily raised from seeds, which should be very carefully sown in March or April about an inch from one another in a well-drained shallow pan. Fill the pan to within an inch of the brim with the compost prepared for seeds, the coarsest part at the bottom, and the finest at the top. Sow the seeds regularly distributed, and sprinkle them lightly with very friable leaf-mould and silver sand. Let the seed pans be put into a cool greenhouse where they will be protected from late frosts or noxious winds and rain, but that is all. They quickly grow, and when they have made a few pairs of leaves let them be put in round the edges of pots filled with the same compost as that in which the seeds were sown. When they have attained a height of about 3 inches they may be potted with a little ball of earth, if possible, singly into small pots, and grown on till winter, not allowing any side shoots to grow up the first 3 inches at least of the stem, when, if you are lucky, some of them may flower, after which they may be treated as established plants.

By cuttings.—The principal way of increasing Tree Carnations is by cuttings or pipings, which should be taken in three batches; the first very early in January, as soon as possible after the 1st, the next in March or April, and the last in the end of October or beginning of September. The youngest off-shoots make the best pipings, so the smallest growths at the sides of the main stem should be used as soon as they have made two or three joints. Early in January, as aforesaid, take off the first set of pipings, as young shoots as possible, or, if they are at all older, the lowest pair of leaves must be completely peeled off, leaving only the soft wood underneath. They must then be cut off clean, close up to the joint, and put into pans prepared in the following manner: Take a pan some 4 inches or 5 inches deep, and put a layer of drainage at the bottom. Over this place a thin layer of fine moss sprinkled with a little lime or soot to keep out worms. Then fill up to within 1½ inches of the brim with the compost previously described, and on the top scatter half an inch of silver sand; into this pan or box let the cuttings be put about 2 inches apart; and the soil pressed pretty firmly about them, and let the pan be put into a frame or warm house. In about three weeks or a month they will be rooted, and then they may be potted off singly and grown on till early winter, when they will flower well. In March or April repeat the process, excepting that the pans need not

be placed in such a warm position as those struck earlier. It is as well to keep them always in a cool pit till autumn, but where this is not available, let them be placed in a cold frame after they have been potted singly till they become established, and then put them in the open air in a moderately sheltered place. As soon as they require it shift them into 5-inch pots in the compost before recommended for potting, placing a layer of moss mixed with lime or soot immediately over the crocks. Be careful not to let the plants make any off-shoots or side-stems for the first 3 inches, as it is of great importance that air should circulate freely below the branches, damp being particularly fatal to this class of Carnations. The third batch of cuttings should be put in at the end of August or beginning of September in the following manner: Prepare a bed under a north wall thus: Make a compost of silver sand two parts, loam one part, cow manure half part, and dig it well into the ground. Take off cuttings of rather strong young wood, peeling off the lower leaves entirely, and put them in about 2 inches from one another. If the weather is fine and hot they will root very soon, but in most cases they will root early in October. Pot them up about eight or ten in a 12-inch pot, and keep them in a cool house, pinching off shoots as fast as they appear till spring, when they may be potted singly in 6-inch pots and treated as ordinary plants. Do not cut off the tips of the grass, as is sometimes recommended. These cuttings should be cut off very clean with a very sharp knife; in fact some growers prefer to "pull" the pipings, which is done by taking the tops of the grass and pulling it till it breaks off or draws out at a joint. When first put in they should be watered rather heavily to settle the soil firmly about the roots. In all cases where they are put under glass the latter should never be removed till they are rooted, so as to keep up a temperature of about 60°, under which conditions they will often root in a fortnight or less. Grown in a high temperature like this, they must be very gradually hardened off before they are exposed. Be careful not to overdo the richness of your compost at any time. Cocoa-nut fibre and charcoal are very good additions to the compost if mixed in moderate quantities, as they tend to keep it open, moist, and sweet.

By layers.—Tree Carnations being of so stiff a habit, are not at all well adapted for layering. If the branches were bent down to the ground they would in all probability snap, so if this mode of propagation is adopted they must be layered into small pots placed on the surface of the ground or flowering pot. This operation, if performed at all, should take place about February or March, but, as I have said before, the best mode of propagation is by cuttings or pipings.

Potting.—The cuttings, as already directed, should be potted into 3-inch or 4-inch pots. About the middle or end of May they should be potted into their flowering pots, which should be 6 inches or 7 inches across, unless they are very large, old specimens suitable for repotting. It is best, however, not to keep them in pots more than two years, for the best flowers are produced the first year, and the greatest profusion the second, after which they should be bedded out. Let the pots be thoroughly clean, and place at least 2 inches of drainage at the bottom. On this place a layer of moss sprinkled with lime and soot, and then enough compost to bring the ball from the 3-inch or 4-inch pot to within half an inch of the top of the new pot. Then carefully turn out the small pot and remove the drainage and old moss; gently scratch the lower surface and sides of the ball to loosen the roots, place the ball into the new pot and carefully fill in with fine compost to within three-quarters of an inch of the top of the pot; give a slight watering, and stand the pots in a sheltered place on stages or coal ashes under a north wall. They should now and then be watered with lime water (*i.e.*, water in which a little lime has been slaked) to expel worms.

Repotting.—The first year the plants will flower well in 6-inch pots, but when they have finished their first season of bloom, or about February, they will have to be repotted. Turn the plant out of the pot in which it has flowered and remove the old drainage, moss, &c. Remove as much of the old soil as you can without damaging the roots in any way, unless the old roots are very voluminous and fibry, in which case the very fine and meagre fibres may be cut off. Then repot the plants into the same pots, which should be thoroughly cleaned before repotting, and repot them in as much of the fresh compost as possible. They may be stood in a cool pit or house till May, when they must be shifted (for the second bloom) into pots 9 inches larger, thus 6-inch into 8-inch, 8-inch into 10-inch, placing sticks neatly to them at the same time; in these pots they will flower the second year. Second year plants may be kept on from year to year in 8-inch or 10-inch pots, unless, as I strongly recommend, they [be treated as suggested in the next paragraph.

Subsequent treatment.—When the layers or cuttings have been potted, they should be placed in a sheltered spot beneath a north wall till the end of August, in the case of young plants carefully stopping all shoots up the sides of the stems, and in the case of old plants preventing them flowering by pinching out the buds as they appear. After the end of August stopping may be discontinued and the plants induced to make a strong head at the top of the stem, but guard still against flower until the beginning of October by pinching out the buds as they appear. After that buds may be encouraged. At the end of August they must be top-dressed with a mixture of fresh loam and manure well rotted and be thoroughly saturated with lime water finally to expel worms from the pots. Place stakes to any of the plants which have not been already tied up, let them be carefully cleaned, placed in a cool greenhouse and periodically watered with weak manure water or other stimulant. Keep them tied up neatly, but not too closely, for if tied together so that air cannot circulate among the branches, green-fly and mildew attack the plants; therefore large specimens will want two or three stakes to a plant. They must be kept in the cold house till November, earlier or later, as you want them to flower. For early flowering they must not be stopped after July and must be put into the greenhouse early in November; if for midwinter, they must be stopped until November, and be placed in the house afterwards. For spring flowering, stopping must be continued till they are put into the house early in November. Water frequently overhead until the bloom appears, and periodically stir the soil on the surface of the pots to admit air to the roots. The houses in which they are bloomed should have a night temperature of at least 50°. They do not require to be forced. This is a mistake too often made with this winter flowering section. Be careful not to let the soil in the pots become too dry, but guard especially against keeping them too moist, one of the worst enemies of this plant being damp. Keep them quite clean, and with the above directions a succession of blooms ought to be obtained from November till March. Often these plants make long lanky, weak stems; this must be prevented by placing the plants near the glass when they are put into the greenhouse.

Bedding.—For cutting from freely in the summer there is nothing like these perpetual flowering varieties, and for all the ordinary florist purposes I should strongly recommend making a good bed of these plants. Let the cuttings be struck in early spring; as soon as they have thoroughly rooted and the weather is settled, warm, and fine, let them be planted out in beds about 12 inches apart. Let the bed be situated under a south wall and prepared in the following manner: dig into the ground very thoroughly about equal parts of good, sound loam, thoroughly rotted manure, and good sharp sand, so as to keep the soil rather inclined to dryness. The plants in the bed must be made to grow into short standards about 6 inches from the ground, as of course in the open air,

their enemy, damp, will attack them with great perseverance. As soon as they are bedded out they must be neatly staked or else they present a great field for destruction to boisterous winds and rains. A good way to produce standards and at the same time increase your stock is to let the shoots grow on the standard stem till they get two or three joints, when they may be at once piped as before described. They are when grown thus in beds most extraordinarily prolific bloomers, so I prefer to leave the bedded-out plants to their own devices and pipe in spring from the potted plants. If the plants throw up a quantity of very late flower buds (as they sometimes will) they should be potted up to flower indoors. After the first year of planting they grow to an enormous size, so after two years or so they must be moved 2½ feet or 3 feet apart, and this will not be found at all too wide after a season or two. In winter the ground over the roots may with advantage be strewn with litter and Cocoa-nut fibre as a protection from frost, but as a rule when well established these plants are quite as hardy as common Cloves. It is a very good plan, and the one I invariably pursue myself, to plant out, not cuttings or seedlings their first year, but plants which have twice done duty in the greenhouse, for these winter Carnations flower best as to quality the first season, but the second year plants are always the most profuse bloomers. After the second year they become large and unmanageable, and so are best planted out. When planting these Carnations it is as well to dig a hole and fill it with good sandy loam, well mixed with soot as a protection against wireworm, which will speedily find these plants out unless this precaution is taken. It is very convenient when the plants are in the bed to grow the back rows as tall standards. This takes some patience, but with perseverance it may be accomplished; a good long stick should be placed to the plants, and one shoot trained carefully up it, not allowing it to make any flowers or side shoots; the lower branches will continue to flower, but should be very considerably thinned down to three or four, so as to give the standard shoot a better chance. Each year let the flower bud on the top of this stem be pinched out, and as soon as it appears leave one side shoot on close to the top and train it up as a continuation of the first shoot. Protect this shoot with straw in winter, and in a few years you will have standards on good strong stems a yard high. Each successive year let the plant make a head of Grass and train up a shoot of the new head, cutting off the shoots from the lower part of the stem which formed last year's head. A very excellent form of bedding is practised with old plants very often when one has a border in the greenhouse. The plants when turned out of the pots in spring may be put in here in the ordinary way in good rich sandy earth, and they will flower either long before or long after the ordinary potted Tree Carnations according as you stop or encourage them.

Climbing kinds.—Some sorts of perpetual Carnation are what are called climbing kinds, because they grow up long and straggling, and are best trained against a trelliswork or round a pillar in a moderately warm greenhouse. They should be potted and treated exactly as the ordinary kinds until they begin to show a tendency to climb by spindling up long-jointed, thin and ragged. The pots should then be moved to an airy corner of the greenhouse against a trellis or pillar, to which the shoots as they advance should be carefully tied and twined; or else sticks should be arranged round the pots, and the shoots twisted round and round them after the manner of ordinary creeping plants in pots.

Saving seed.—This operation is not a matter of such importance or difficulty with winter Carnations as with the ordinary show varieties. As regards time to save, I prefer the spring, and therefore save from plants which have been kept to flower rather late (March or April), as there is more chance at that time of year to ripen the seed than if one depended on the short periods of sun which we get in the winter time. There is much

more pollen on these varieties, as they very often produce seed of their own accord, and this fertile property renders the operation of crossing for new varieties one not of difficulty, but of tact to perform the operation exactly at the right time before the bloom is self-fertilised. As these flowers are not often exhibited, their chief value lies in their beauty and usefulness as cut flowers; the chief points to be borne in mind beyond substance and form are purity of colour (in a self), distinct marking (in a flake, bizarre, or Picotee), and size in all. As I have just remarked, their chief value and use is as a cut or bouquet flower; the very pure and characteristic colours are most sought after, but in this class of Carnation there is a great field for the raising of "fancies," i.e., blooms of distinctly characteristic tint and marking, such as are usually carefully avoided among exhibition varieties, such, for instance, as Sir Garnet Wolseley, Tricolor, Princess Christian, and Hermann Stenger, which are all curiously beautiful flowers. The operation of crossing is similar to that described for show varieties, but the seed takes longer to ripen, and is even more liable to rot and damp off. Insects will not be so troublesome as with the ordinary kinds, in consequence of the time of year, but plants set for seed must be allowed every second of sun that can possibly be obtained for them.

SPRING TREATMENT.—In spring the plants will be going to rest after the bloom, and must be stood out in a warm sheltered spot after being potted as above described.

SUMMER TREATMENT will consist mainly in stopping the buds to prevent the plants flowering and keeping them clean from dust, dirt, and insects which attack the plants a good deal during the time they are under glass in frames at the end of the summer.

AUTUMN TREATMENT.—Stopping may be discontinued and the plants housed for flowering as described, and so on into the

WINTER TREATMENT, which, as before set forth, must be carefully adhered to when the plants come into bloom, especially as to not letting them get too wet.

Diseases and insect enemies.—The principal disease of the Tree Carnation is the immediate consequence of its chief enemy, damp. This is a state of things that must be particularly looked to after stopping has been discontinued and the flower buds have begun to form. If the roots are kept too moist, the buds decay and drop off as soon as they ought to begin to swell; it is, therefore, of great importance to see that the drainage is thorough and perfectly efficient, and to keep the surface soil well stirred to admit air to the roots. Never water, unless the soil feels dry on burrowing with the fingers under the surface of the soil in the pots. Whilst the plants are kept close the chief insect pest will be found to be green fly, which must be carefully brushed off as soon as it appears. It not often happens that a grub settles itself round the base of the stem, and, eating away the bark, kills the plant. This must, therefore, be periodically searched for, not waiting until the mischief is irremediably done and the yellowing of the leaves indicates the presence of the intruder. Periodically the plants get infested with red spider or affected by mildew when the temperature has been kept too hot or dry. The cure for this, which should be set about as soon as symptoms show themselves, is effected by means of liberal sulphuring with flowers of sulphur tied up in a muslin bag. The plants must be carefully gone all over, and when the sulphur has remained on for three clear days it should be washed off with a rag or syringe. Mildew and rot are often produced by careless tying up. If all the shoots are tied together in a bunch they soon become affected, so when necessary three or even four stakes must be put to a single plant.

The best varieties now cultivated are as follows: Avalanche, white; Congress, vivid scarlet; Hermann Stenger, rose, flamed with light rose; Garibaldi, rosy scarlet; Miss Jolliffe, pale pink (Masters); Indian Chief, deep crimson; King of

the Belgians, deep rose (Turner); Empress of Germany, white, flecked with rose (Turner); Eclair, dark crimson; A. Alegatière, bright crimson; Vulcan, bright scarlet; Lillian's Glory, light rose; Fairy Queen, rose flake (Turner); Tricolor, pink and purple bizarre; Guelder Rose, white, fringed (Turner); Rose Perfection, rose (Turner); Bride, pure white; Oscar, yellow self; Prince of Orange, yellow Picotee, red edge; Princess Christian, pink fading off to white (Turner); Mons. Baldwin; Proserpine, bright scarlet; Gloire de Lyon, bright scarlet; Duke of Wellington, bright scarlet; La Belle, white (Blackley); Celestial, Picotee; Rosy Morn, deep rose; Scarlet Defiance, rich scarlet; Queen of the Belgians, white striped with rose (Turner); Sir Garnet Wolseley, buff Picotee, red edge (Turner); Jessica, white (Turner); Mrs. Fowler, bright rose (Turner); Coronation, bright scarlet (Turner). A.

KITCHEN GARDEN.

EXPERIMENTS ON POTATO CULTURE.

DURING the past year a very important series of experiments has been conducted on the Albert Model Farm, at Glasnevin, near Dublin, with the view of testing the comparative productive and disease-resisting powers of different varieties of Potatoes. The results obtained are very important, and, at a time when the ravages of Potato disease are being keenly felt, these results possess peculiar interest. The land selected was dressed with 20 tons of farmyard manure per statute acre. Thirty-three varieties of Potatoes were obtained, and planted on February 17 and the crop was raised on September 20. Perhaps the most striking feature in the results is the remarkably low average yield realised. The gross yield of the thirty-three varieties tried does not average more than 5 tons 14 cwt. per acre, while in 1881 and 1880 the gross average produce of the different varieties of Potatoes grown at the Albert Model Farm was respectively 9 tons 10 cwt. and 10 tons 10 cwt. per acre. These results, we believe, are fairly illustrative of the character of

large portion of the enormous quantity of Potatoes now grown in Ireland as the staple food of the cottagers and small tenants. Not to speak of its liability to disease, which is alarmingly strong, the Potato is very susceptible of damage by close, wet weather—characteristic features of the Irish climate. The first lessons, therefore, which these experiments would seem to teach are that Potatoes form an exceedingly risky crop in a wet, hazy climate, and that in an abnormally wet season a small yield may be looked for.

The produce derived from the different varieties will be indicated more clearly by the following table than by any summary of the results, as from the table the relative positions of the various sorts, and the gross yields, as well as the quantities of marketable, small, and diseased tubers, will be seen at a glance. It will be seen that the lead in marketable tubers is taken by the Reading Hero, a new variety that did well in England last year. It gave very close on 8 tons of marketable Potatoes, and only 6 cwt. 2 qrs. of diseased tubers. The White Rock variety gave the highest gross yield, but its much greater proportion of diseased Potatoes brought it below the Reading Hero in marketable tubers. Then the Imported Scotch Kemp also exceeded the Reading Hero in gross yield, but having shown disease in more than one-fifth of the whole crop, it fell to the fourth place in the list arranged by the marketable test. The Scotch Kemp gave more diseased tubers than any of the others, but the Flounder variety showed a larger proportion of disease to its gross yield, nearly one-fourth of its total produce having been diseased. The loss by disease could not, on the whole, be said to be very heavy, although in a few instances it was considerable. Ten of the varieties, it will be seen, entirely escaped disease; but of these the Magnum Bonum and Early Vermont were the only sorts that gave more than 5 tons of marketable Potatoes.

The following table shows the gross yield per acre, and the quantity of marketable, small, and diseased Potatoes obtained from the different varieties arranged in accordance with the yield of marketable tubers.

the Potato crop throughout Ireland in the last three years, and they bring out very clearly the main cause of the distressed condition of the poorer districts of the country at the present time. The small crop of Potatoes in Ireland this year was brought about chiefly by the excessive rainfall in the month of July and in autumn, and here we have fresh evidence of the great desirability of strenuous efforts being made to discover and introduce some hardy and suitable substitute for a

The future of the Potato.—I observe a note (p. 17) as to the origin of the Potato. Both historically and botanically it may be of interest to have all possible information as to that matter, but far greater interest attaches to the future of the Potato, for without doubt it has a great future before it. We might, under ordinary conditions, congratulate the present generation that it has kinds as regards table quality far in advance of what were the best varieties of fifty years ago.

Reasoning from analogy (for in gardening everything must be either progressive or otherwise), Potatoes will in the future be much better than they have been in the past, proving more profitable to the grower and more nutritious to the consumer. Our only difficulty with the Potato lies in the disease, but that may in time be largely subdued. Mr. Jensen has, in his eminently practical way, pointed out methods which, if universally adopted, might help very materially to keep the Peronospora in check. With fine new kinds in abundance and with more enlightened treatment the Potato should yet have a great future.—A. D.

ROTATION OF CROPS.

THAT moving to fresh soil, if of a suitable character, does tend to benefit a plant is, I think, certain; or, if it is inconvenient to move the plant, if the fresh soil can be brought to it and placed within reach of its roots, a corresponding advantage will be obtained. Sometimes, where the sub-soil is capable of improvement, the new soil suitable for some crops may be found on the spot by going deeper down than hitherto. In this way vegetables, such as Potatoes, Onions, &c., have been grown for many years on the same land without any apparent falling off in bulk or quality, especially if the seed is changed frequently. Though Potatoes and Onions are largely composed of water, yet by reason of their bulk they certainly do take a good deal out of the land; still they do not exhaust it like Cabbages, which in most gardens occupy the ground for a much longer period. Most of the so-called permanent crops would be much improved by more frequent removal. Strawberries, all are agreed, are improved by being shifted every three years or so on moist soils; and I have long been convinced that if Raspberries were moved more frequently the fruit would be finer and the crop generally of more value. I like to move the plants bodily, that is, dig them up as one would dig up any other fruiting bush or tree, and after discarding the oldest stools, plant a selection of the best canes on the new site. In this way there is no trouble in establishing a Raspberry plantation, for the plants have good accumulated roots to begin work with; and a mulching of manure when the days lengthen will swell the fruit to a good size. Rhubarb, Seakale, Globe Artichokes, and Horseradish, all usually classed as permanent crops, would be better moved at frequent intervals. I like to sow a portion of each annually so as to have plants of different ages. This is important in the case of Rhubarb and Globe Artichokes, giving a successional character to the produce as well as adding to its size and succulency.

Herbs, such as Sage, Thyme, Mint, &c., often occupy the same beds too long, and become patchy and unsatisfactory in consequence. Indeed, nearly all the herbs, especially those increased by cuttings, such as Sage and Mint, will be better shifted annually by cuttings planted in April and May. The beds when so managed always have a close, full appearance, are more productive, and suffer less during severe winters than they otherwise would do. And it is not uncommon for Sage, Fennel, and Tarragon to be much injured by frost when the plants remain long enough in one place to get straggling in habit.

Fruit trees on moist soils are much benefited by having their roots lifted, even if the trees cannot be lifted out altogether and moved to a fresh site. Though this is a matter of the very first importance, scarcely anybody gives it as much attention as it deserves. In this respect I do not think much progress has been made since Bacon wrote recommending the manuring of fruit trees with fresh soil. Then again

Hardy herbaceous plants of nearly all kinds are better for renewal occasionally. Some plants, such as Fuchsias, when isolated, seem to thrive when left alone. But in the case of plants that have to struggle with rivals a renewal of soil is one of the best roads to success. How very

poor the flowers of herbaceous Phloxes become when left on one spot more than two or three years. And the same thing occurs with Pyrethrum, Potentillas, and all the class of hardy florist flowers. A few things chiefly having bulbous or tuberous roots do best without any disturbance; for instance, the winter Aconite now springing up should occupy a position where the spade or fork is never used; and the *Alstroemeria* and many others dislike interference.

THE CHRYSANTHEMUM AND ITS CULTURE.

(Continued from p. 35.)

It is interesting to find that the Siamese have adopted the Chrysanthemum as their national emblem. Breynius in 1689 described it as *Matricaria japonica maxima*, from which name we may infer that the earliest known large flowering kinds came originally from Japan, especially so as he speaks of yellow, white, blush, purple, rose, and crimson varieties. Linnaeus in 1753 referred to two species, *C. sinense*, with large white flowers, and *C. indicum*, with very small yellow blossoms, both double and single.* The Dutch florists seem to have been the first to cultivate *C. indicum* (Pompones) which had found its way to Amboyna and Malabar. Rheede figures it as early as 1699. Kämpfer noticed it in 1712, and Thunberg describes it (also as *Matricaria*) in 1784.

Large-flowered Chrysanthemums.—

The credit of introducing the first living plants of the large-flowered or *C. sinense* race (1789) belongs to M. Blanchard, an enterprising merchant of Marseilles. The consignment consisted of three varieties, white, violet, and purple, the latter only reaching him alive. This identical variety is so well figured in the *Botanical Magazine*, t. 310, that we have no doubt as to its identity. It was not the wild type, but one of the many semi-double forms at that time cultivated in Chinese gardens. This kind caused such a sensation, that Sir A. Hume and Mr. John Reeves turned their attention to introducing other of the Chinese varieties. These, according to Mr. Salter, were as follows: In 1798 the Rose and Buff-coloured varieties were introduced; in 1802 the Golden Yellow, Sulphur Yellow, and Quilled Pink; in 1806 the Spanish Brown; in 1808 Large Lilac and Quilled White; in 1816 the Tasselled White; 1817 the Superb White; 1819 the Red Purple and Flamed Yellow. In 1820 only twelve distinct varieties were known in England. In 1821, however, came the Paper White, Large Pale Purple, and Small Single Yellow; this last possibly may have been the one grown at Chelsea in 1764. In 1822 came the Early Crimson, a semi-double flower with open flat florets in size and form like Marigold, and one or two others. In 1824 Mr. Parks, a collector for the Royal Horticultural Society, sent home about twenty kinds—the Brown Purple, Blush Ranunculus, Curled Blush, Changeable Buff, Clustered Pink, Early Blush, Golden Lotus, Late-flowering Yellow, Pale Pink, Pale Buff, Parks' Yellow, Quilled Pale Orange, Starry Purple, Tasselled Yellow, Two Coloured Incurved, Two Coloured Red, Windsor Yellow, and Yellow Waratah, the first of the Anemone section, both ray and disc, being yellow. In 1826 forty-eight varieties were growing in the Horticultural Gardens at Chiswick, only fifteen varieties being known in France in 1822.

In 1850 Mr. Salter tells us that the varieties usually seen on exhibition stands were: Annie Salter, Beauty, Bixio, Christine, Campitroni, Defiance, Duke, Golden Chester, Goliath, King, Lysias, Mad. Comerson, Mad. Poggi, Nonpareil, Orlando, Pearl, Pilot, Phidias, Princess Marie, Queen of England, Temple of Solomon, Vesta, and Two-coloured Incurved. Most of these were grown in 1865, but as numbers of growers increased great improvement took place not only

in England, but in France and the Channel Islands. In Guernsey, Messrs. Clarke, Smith, Pethers, Wolsey, and Davis raised many good kinds, including Sir S. Carey, Abbé Passaglia, Beverley, General Bainbridge, Lady Harding, Lady Slade, Prince Alfred, Novelty, Cherub, Little Harry, Rifleman, and many others. Mr. Ingram, of Frogmore, raised several good kinds, Pompones Little Gem, a late-flowering kind, being good in colour and form. Mr. Salter, writing in 1865, says that only six or seven of the varieties originally introduced were then in cultivation, and only one Chinese name was retained, viz., Golden Lotus—some of these native names being, as he informs us, curious and interesting, such as White Waves of Autumn, Purple Pheasant's Tail, Gold Thread, a name more recently aptly applied to one of the Japanese varieties; Purple Butterfly, Crystal White, and Yellow Tiger's Claw. In 1830 seedlings were first raised, in France, the produce being remarkable for variability, much to the delight of the amateurs of Toulouse and Avignon, who now began to christen their seedlings after their national celebrities. Chevalier Bernet, of Toulouse, raised the first European seedlings, some of these being, as Mr. Salter tells us, still (1865) highly prized. Among these were Christine (Ne Plus Ultra), Chevalier Damage, Maréchal Duroc, and insigne. Other growers followed, such as MM. Boisgiraud, Regnier, Rantonet, and at a later date MM. Bonamy, Pelé, and Lebois.

The first English seedlings were raised in or about 1830 by Mr. Isaac Wheeler, gardener and porter at Magdalen Hall (now Hertford College), Oxford. These he reared from home-saved seeds at Beaumont Buildings, in that city, and on December 2, 1832, he exhibited some of his seedlings in London, and received a silver Banksian medal for them as the earliest seedling Chrysanthemums raised in England. This medal, and also a drawing of one of the plants, may yet be seen, being in the possession of a member of the Wheeler family still resident in Oxford. Other seedling varieties were raised in Norfolk by Mr. Short and Mr. Freestone about the year 1835, Nonpareil, Norfolk Hero, and Prince of Wales, with others, being the pioneers. About 1836 seedling Chrysanthemums were produced in the Channel Islands for the first time, and a great improvement began to be effected among large flowered varieties. Many of these early Channel Island varieties were obtained by Mr. Chandler, then of the Vauxhall Nursery. Beauty, formosum, and lucidum were really good show kinds. In 1838 Mr. Salter settled at Versailles, and, finding the climate suitable, imported many of the best known varieties from England, and set about their further improvement. In 1840 his collection of English, French, and Jersey seedlings amounted to between 300 and 400 distinct kinds. In 1843 seedlings began to be raised in the nursery at Versailles, and some of the results are given by Mr. Salter himself as follow: In 1844 Annie Salter, Mad. Poggi, and Queen of Yellows; in 1846 Fleur de Marie, Cyclops, and Nancy de Sermet; in 1847 came Queen of England, one of the best of white kind for cut blooms. The first public Chrysanthemum show for cut blooms was held at Stoke Newington in 1846. To Mr. Fortune, as has been stated, we are indebted for the original Pompones from China, namely, Chusan Daisy and Chinese or Omnium minimum. These were introduced in 1846, and thence dates a new era in Chrysanthemum culture so far as this section goes. In the "Gardener's Magazine of Botany" for 1850 we find many varieties of these French Daisy kinds described, and four sorts are represented in a coloured plate.

Modern Japanese varieties.—Both the large-flowered and Pompones varieties were largely grown and much improved up to 1862, when again Mr. Fortune introduced a new strain in the shape of seven varieties from Japan. So singular were these in shape and colour from all reputed standards of perfection of the time,* that they barely escaped total neglect and consequent extinction. At the present day, however, these once-neglected kinds stand in the first rank as decora-

tive plants, and finer and still finer varieties make their appearance every year raised by Major Carey and others in the Channel Islands and on the Continent. Mr. Salter in 1865 lamented that some of the best original Chinese tasselled kinds were wholly lost. Of those then grown, however, he mentions Golden Lotus, Quilled Pink, Tasselled White, Tasselled Yellow, Two-coloured Incurved and Yellow Waratah. Where are these kinds now? Lost, no doubt, in the race after novelty. One Japanese kind which Mr. Fortune tried to bring home was unfortunately lost on the way. This had its florets edged very beautifully with a hair-like fringe. Writing from a florist's point of view in 1865, Mr. Salter says: "The form of the flower has become so beautiful that it seems scarcely possible any amount of cultivation can improve it, but both size and colour may be augmented."

It is true that we have many fine selfs white, yellow, orange, rose, and crimson, but violet and scarlet are at present unknown. There are but few edged, mottled, striped, or tipped varieties. Now, to-day we have, however, form more perfect in Mrs. G. Rundle; colour more vivid in Progne, Crimson Velvet, and others, and size has been considerably augmented by improved methods of culture, if not also by actual seminal variation. In the modern Japanese varieties we have form and colour of the most beautiful, and also another valuable, quality, many of them blooming a month later than the other kinds, and so we can extend the Chrysanthemum season by their aid. Early blooming races of large flowered, and also of Japanese varieties, are now a desiderata, and we yet live in hopes of seeing the Chrysanthemum in all its forms thus rendered amenable to open-air culture in our climate. A blue Rose may be an impossibility, but we are told that a variety of the Chrysanthemum exists in Japan with blue flowers. It is represented very frequently on Japanese porcelain, both ancient and modern, especially that of Satsuma and Kioto; it also appears on *cloisonné* enamels and embroidery. In the "History of Nin-toku-ten-wau" the following passage occurs: "In 386, in the seventy-third year of his reign, seeds of the Chrysanthemum were first introduced into Japan from a foreign country, both blue, yellow, red, white, and violet." The Japanese commentator remarks: "By a foreign country is meant the kingdom of Paik-tse, one of the States of Corea." F. W. B.

AMERICAN NOTES.

Celery culture made easy.—I believe I have learned the easiest way to grow a family supply of Celery. We this year filled our old hot-bed frame, 3 feet by 12 feet, with Celery plants, setting them about 8 inches apart each way, making 60 plants in the frame. They have grown splendidly, and as fast as they grow we fill in with earth, and they blanch nicely. I believe that they would have done as well if planted closer, say 100 plants in the frame. The advantage is that they occupy but little space, are not much trouble to cultivate, and require much less water than if planted in the usual way, with the rows 6 feet or 8 feet apart, besides a much smaller quantity of earth answers for banking up for bleaching, and of course less labour. If one has not a hot-bed frame, he can set boards round the edges of a bed in the garden, and manage in the same way. Boards 1 foot wide should be used, and very cheap refuse timber will answer for the purpose.—*New York Tribune*.

Dry sand as packing.—The Citrus men of Los Angeles, Cal., have made a discovery of great value to Florida. Dry sand is the best packing for Oranges and Lemons. It must be quite dry and no paper must be used. The fruit must touch the sand. Experience warrants keeping for five months at least. The dry sand has absorbing power that apparently takes up all exudations subject to decomposition, the rind being very porous. Naturally the thoughtful mind suggests that, on the same principle, dry sand must have a similar preservative effect on other fruits, such as Pears, Plums,

* It is curious to note that single flowered Pompones after having been lost sight of for over a century are again coming into favour. Of such is *New Departure*, as now grown by Messrs. Cannell, with white ray florets and a golden disc. (See GARDEN, Jan. 6, 1883, p. 8.)

Nectarines, Apples, and other smooth-skinned varieties.

Classification of soils.—Professor Johnston classifies soils, says the *Massachusetts Ploughman*, according to their clayey or sandy proportions, thus: First, pure clay, from which no sand can be washed. Second, strong clay or brick clay, which contains from 5 to 20 per cent. of sand. Third, clay loam, which contains from 20 to 40 per cent. of sand. Fourth, loam, which has from 40 to 70 per cent. of sand. Fifth, sandy loam, which has from 70 to 90 per cent. of sand. Sixth, light sand, which has less than 10 per cent. of clay.

Labels.—We think that the label problem is solved. Lead pencil upon zinc will endure for many years—nobody knows how long. Over three years ago we marked a zinc label 2 inches long as follows: "Ulmus gras. Written with lead pencil Aug. 20, 1879." On the other side was written: "President Gale's suggestion." President M. P. Wilder has since told the readers of the *Rural New Yorker* that he has used these zinc labels written upon with common lead pencil for many years. When first letters are written, they show very indistinctly—just as if written upon glass; but in a few days they grow more distinct and finally show as plainly as if upon painted wood. Copper wire alone should be used, for the reason that iron wire soon rusts, and the rust is washed over the zinc. This label is so far free from objections that we are now using it for all of our plants as the old wood labels wear out or the marking becomes indistinct.

The Switzer, a new Russian Apple, grows wonderfully fast in the nursery, rivaling, if it does not excel, in vigour the widely-spread Haas. The Switzer fruit as to quality is by excellent judges very highly commended.

Tomatoes.—Dr. Hexamer says he obtained a supply of Tomatoes for a month after the frost had destroyed the crop in the open ground in the following way: Dig up the plants carefully, with as much of the entire and uninjured roots as possible, and plant them in the ground in a cold greenhouse, watering as may be necessary. They soon recover from the wilting, and continue to ripen the fruit on the branches.

Rye and sheep in orchards.—We find a statement, in some of our exchanges, of the management of an orchard, which has so many good points that we give the substance below. The trees are cultivated for twelve years while young with hoed crops, and with enough manure to keep them in a good growing condition, which is determined by the length of the annual shoots. A thorough summer fallow succeeds, and in the autumn the mellow ground is sown with Rye and Timothy, followed by sowing Clover in spring. Sheep are turned in when the Rye is a foot high, and it will continue to sprout up and grow as it is eaten off. As soon as the young, wormy Apples drop the sheep eat them. The sheep are taken out in time to gather the Apples. They are pastured in the orchard for four or five years, or until the growth of the trees becomes diminished. The ground is then ploughed and fallowed as before. Unless the trees are in a thrifty condition, a broadcast top-dressing of manure is applied in autumn every alternate year.

Evaporating fruits on a small scale.—Fruit raisers who have a limited supply of fruit often wish to know of the facilities for doing the work of drying with their own hands, without much outlay. We lately examined the work of a neighbour who performed all himself. He uses the American dryer, costing 75 dols. (formerly 40 dols.), which will dry twelve bushels of Apples in a day, although much of his fruit is so wormy that he can cut only nine bushels. A hundred pounds of coal does the evaporating for twelve hours. Four hours are required to complete the process, or four bushels at a time. A bushel will make five pounds of evaporated fruit. Wormy and defective Apples will give only four pounds. They are pared, cored, and sliced by machinery. The entire cost of drying is three cents per pound of dried fruit.

Manuring Apple orchards.—Intelligent orchardists discovered the advantages many years ago of fertilising the ground in Apple orchards by top-dressing with yard or stable manure. We have seen old trees, partly dying and pronounced entirely superannuated, so far recovered by copious and broad top-dressing as to give again good and heavy crops. At a late meeting of the Dayton Horticultural Society, Mr. Waymire stated that he had five Bellflower trees remarkable only for their unfruitfulness. He heavily manured four of them, and from these he had good crops. The fifth, which was not manured, bore next to nothing.

Planting black Walnuts.—Mr. J. H. Joly gave to the Montreal Horticultural Society directions for planting black Walnuts, of which the following is the substance: Avoid transplanting the trees if practicable by planting the nuts where the trees are to remain. The rows should be 4 feet apart each way. At this near distance the trees will grow up without lateral branches (which are apt to be torn off by snow or wind), and they may be thinned as their growth requires. The nuts should be sunk about 2 inches in the ground. The rows should be perfectly straight, set with a line, and marked from place to place with stakes, so as to show accurately the young plants the first year in cultivating. The ground must be thoroughly prepared beforehand, and the richer, the more rapid the growth. Always sow in the fall if practicable. If the nuts are left till spring out of the ground, they become dry and will not grow. We have found no difficulty in transplanting the young trees at 5 feet or 6 feet high, and have measured a number set in streets more than twenty years ago which are now about 14 inches or 15 inches in diameter.

Large trees in Massachusetts.—Some of the members of the Massachusetts Horticultural Society mentioned at one of its meetings the dimensions of trees of great size growing in the vicinity of Boston. Mr. G. Hill said that one of the white Oaks in the Waverley district in Belmont is 8 feet in diameter, and that 8 feet of its trunk would make two cords of wood. Another, nearly 100 feet high, was hollow, so that a man of ordinary height could lie down at full length in it. Agassiz said they were the largest white Oaks in the United States. Mr. W. M. Hunt spoke of a magnificent Elm near his house in Concord, which is 88 feet high, and has a spread of 125 feet. The trunk a foot up is 8 feet in diameter; three of the branches are each over 3 feet in diameter. Mrs. Horner knew a Chestnut at Georgetown, 147 years old, which was over 4½ feet in diameter.

Large Strawberry plantation.—Some of the western journals give an account of the extensive and well managed Strawberry plantations of Mr. Parker Earle, of Cobden, Ill., who is widely known as one of our most skillful fruit cultivators. He has twenty acres of the Crescent, and several acres each of Downing, Capt. Jack, Sharpless, and other sorts. The Crescent succeeds admirably in wet seasons. His entire eighty acres are liberally treated with manures. Before being sent to market, the fruit is thoroughly cooled in cooling houses, and it is then shipped in refrigerator cars, by which soft berries are carried with safety. Besides the wide Strawberry plantations there are thirty acres of the Turner Raspberry, and sixteen acres of Blackberries. Mr. Earle has also eighty acres of Pears on another, of which fifty acres are in bearing, and one-half are Bartletts, but many have died of blight.—*Country Gentleman*.

The late frost in Ireland—December commenced with 9° of frost, which kept increasing until it reached 30° on the 9th, 29° on the 11th, again 30° on 10th, 26° on the 13th, zero on the 14th, and 1° below that point on the 15th; then a thaw set in. From the 1st of the month till the 15th we had altogether 176° of frost, which almost equals in rigour the cold of 1879–80. The readings just quoted, I may remark, were taken from a thoroughly reliable, self-registering, maximum and minimum Negretti & Zambra thermometer; also I may add that we lie low and are subject to late

spring and early autumn frosts. Four or five years ago we had all half-hardy flower-garden plants and tender vegetables in the kitchen garden cut over, by frost so early as September 3. As regards the late frost, fortunately we had an even depth of 6 inches of snow, which thoroughly protected all low-growing vegetation, such as herbaceous roots (now for the most part dormant), Cabbage plants, and the like. Broccoli are all killed where not "laid;" those laid, however, have wintered so far wonderfully well, being doubly protected by their own leaves and snow. Brussels Sprouts stood firm, likewise Cottager's Kale, a most useful vegetable. Those which have succumbed more or less are Curled Borecole, Cabbages, and Savoys. Several rows of Backhouse's Broccoli planted later than the main crop afford an instructive hint. They were pricked out on a north border in nursery rows until we could find room for them, when they were planted out finally a month after the others, and they are now as fresh as if they had not been subjected to frost at all, a fact worth remembrance.—S. K. T., *County Antrim*.

PROPAGATING.

DROSERA DICHOTOMA.

THIS Sundew is one of those curious plants rarely seen in cultivation. It is a native of Sidney, New South Wales; and although it was introduced into this country nearly thirty years ago, under the name *Drosera binata* (Bot. Mag., t. 3082), it still remains very scarce in British gardens. Hitherto, the mode of increasing the plant has been by sub-division of the crown of the root, which is done during early spring before the leaves unfold. This is a slow method of propagation, as the plants require to be of considerable size before subdivision can be resorted to. Of late years attention has been directed to the root propagation of the *Ipecacuanha* and other plants. Mr. Lindsay, Royal Botanic Gardens, Edinburgh, endeavoured to increase this Sundew by root propagation, and his efforts have been crowned with success. The roots for the purpose of propagation are generally taken from strong growing plants during the process of crown division. They are black, and of a wiry consistency, and are cut into numerous pieces from half an inch to an inch or more in length. These are laid on the surface of shallow earthen-ware pans or flower-pots, filled with a mixture of sandy peat soil, and are covered about half an inch deep with the same mixture. They are then enclosed with a bell-glass, and are placed in a damp, warm, propagating house. In the course of a fortnight, swellings begin to appear on the surface of the detached roots, which increase in length till they reach the surface of the soil. This generally occupies five weeks. When the leaves become developed, they are mostly of a binate form, and soon cover the surface of the pan as if they had been a crop of seedlings. When about 2 inches in height, they are separated and put into small pots, containing soil similar to that in which the roots were originally placed, with the addition of some chopped Sphagnum moss freely mixed through it. If carefully attended to, they soon make excellent plants. This Sundew may be grown to a large size, and will flower abundantly either under basket culture in Sphagnum moss, or in pots covered with Sphagnum, and placed in a damp, but sunny situation, or in shallow pans of water. It thrives well in a greenhouse, or in cool glazed pits, placed near the glass. It also succeeds in the rock garden, where a flat saucer is sunk below the pot to prevent the moisture from escaping. In such a situation it was kept alive during the winter of 1871, merely having some loose leaves thrown over it. Under open-air culture, however, the plants generally become black with dust and insects, collected by the viscid secretion given out by the leaf glands. Other species may also doubtless be propagated by cuttings from the root like the *D. dichotoma*. The first species introduced from Sydney to Kew was named *Drosera binata*, having each leaf once forked. Judging from the figure of this plant in the "Botanical Magazine,"

it must have been drawn from a weakly specimen, as the flowers are small compared with those which the *D. dichotoma* produces. In cultivation this plant seems to vary much; the original binate form has, no doubt, becomes dichotomous, and can also be reversed. In proof of this, several of the plants now in the Edinburgh Garden have their leaves binate, although produced from the dichotomous form by sub-division and root formation, while some plants have their leaves divided into two, three, four, and five parts on the same individual. These circumstances satisfy me that there is no permanent distinction of these supposed species, and as the dichotomous form is the most prevalent, it ought to retain the name. Planchon, in his excellent paper on the *Droseraceae*, published in the "*Annales des sciences naturelles*," vol. v., makes the *D. binata*, *D. dichotoma*, *D. pedata*, *D. intermedia*, and *D. Cunninghamii* all synonymous. He also states that the leaves often vary on the same specimen, a fact confirmed by the specimens in the Edinburgh Garden.—*Edinburgh Botanical Society's Proceedings.*

GARDEN DESTROYERS.

MEALY BUG.

THE discussion that has taken place on the destruction of this, the worst pest with which gardeners have to contend, is a fitting subject for this time of the year, for it is during winter that its annihilation can be attempted with the best results. I had some plants once in exchange affected with it. In winter they showed no sign of it, but when spring came it quickly made its appearance and spread apace. We kept on battling with it more or less for two years, during which time it got possession of six or seven plant houses and the Vines in a house adjoining the stove. The plants were yearly getting larger, and I could see that if the bugs were not got rid of the work entailed would be enormous. The first thing done was to move the plants out of the principal stove, disposing them in two other houses. The tan was then cleared out of the bed, the coping taken off the wall which enclosed it, and laid afresh in new mortar. Every joint of the brickwork and every crack or crevice in it was filled up with fresh mortar, and the whole had three coats of hot limewash. The woodwork was alike treated. Paraffin was not then known as an agent for the destruction of insect life, but we used the much more expensive ingredient turpentine, brushing it in where there was a crack or a joining in the wood, or between the wood and iron-work, using putty where needful, with two coats of paint laid on in a way that would seal up any eggs that were left; the plants were then thoroughly washed with

Gishurst, five or six ounces to the gallon of water, some being dipped. Such things as *Stephanotis* were taken down, the pots laid on their sides and the tops steeped overhead in the mixture; those that were syringed were laid down on their sides over a large trough and turned over and over, much more time being expended in this way than usual; the soil was taken from the surface of the balls and the mixture brushed right down well to the collar of the plants before putting a little fresh material on the top. In this way the whole of the stove stock was gone through; two other houses that were the most affected were similarly treated, and all the heat-requiring plants on which the insect thrives and breeds were brought into them. All the stock infested were thus gone over four or five times; two men did nothing but dip and syringe for eight or ten weeks; as soon as they got through one end they began again at the other. Although in the first instance the care and labour bestowed were such that one might have thought nothing living could have escaped, yet still we found some, but in all cases they appeared to be full-grown insects and had lost a good deal of their mealy jackets. No eggs or small fry were found after the first dressing. The other houses that had contained affected plants were all cleaned

and painted, including the vinery, which as soon as the leaves were ready to drop was pruned, and such of the bark as was loose rubbed off, but not scraped. The Vines were then dressed with the ordinary clay mixture, which was thinned with water in which 8 ounces or 10 ounces to the gallon of Gishurst had been dissolved. They were painted over with this three times before the end of the year. The same precautions as regards the painting and lime-washing the house were taken that had been exercised in the others, and the means collectively were successful, as I was completely rid of the pest for several years, until it was got again, as I supposed, on some specimens that had been at an exhibition, and there staged in dangerous proximity to others that were affected. The bugs got possession of some *Dipladenias* and *Ixoras*, from 4 feet to 5 feet through, before they were discovered, but in this case they had not got into the wood or brickwork, and were got rid of by three or four successional washings. This time I used Stevenson's "Abyssinian Mixture," a much more effectual remedy for bugs than Gishurst, but neither this nor anything else I have tried at all approaches

Paraffin as a destructive agent for bugs. Gishurst, though useful in some cases, is one of the last remedies I should now employ for bugs, as, like a good many other insecticides, unless applied too strong for many plants to bear, it is not certain to kill. If the plants are large, excepting the few things that admit of being steeped overhead for a time in the cleansing liquid, it is scarcely possible to get at every insect and every deposit of eggs at a single or even a second dressing. Some of our large specimens that were affected the second time of having the insect had each two men at work on them with syringes for over an hour, keeping them continually turned, and giving them a shake now and then so as to separate the leaves in such a way that the liquid would reach every particle of surface, sopping it with a sponge into the cracks in the bark about the collars of the plants and up the stems, loosening all the ties where the nests of young fry laid between the bast and the sticks, and painting every stick afresh before again using it. It is only by close attention to such small matters as these that anyone who ever has a considerable number of plants affected by mealy bug can expect to get completely clear of it. Of the different

Dressings for Vines, I have not the slightest hesitation in giving the preference to the coal tar and clay mixture for the simple reason that it is the most effectual and the least dangerous. It is not nearly, indeed, so dangerous as paraffin diluted with water, inasmuch as the paraffin is of such a thin, searching nature that it penetrates at once to the inner living bark, whereas the tar mixture lies like paint on the outside, yet, even without necessarily touching every egg that may be deposited underneath, its strength and odour are such as to kill them. It is all the more certain to do so, as it is a long time in drying up and evaporating, and when the Vines are coated with it, as they should be as soon as the leaves are off in the case of late started houses, it has plenty of time to effect the work which it is required to do. Those who know and have seen what the effects of the pernicious scraping are when carried so far, as is sometimes done, until the green living bark is all but perceptible, will not require to be told that to do anything more than remove the loose outside shreds of dead bark before using the tar dressing is to court injury. When Vines have been close scraped into the quick I have more than once seen the crop half destroyed through dressing with the ordinary mixture of clay, soft soap, and sulphur when the sulphur has been used too freely, and mischief can scarcely fail to follow the application of a still more powerful agent like coal tar if it is brought in contact with the living under bark.

T. BAINES.

Paraffin as an insecticide is one of the very best that can be used, and also one of the cheapest, but such directions as the following are

misleading: "In syringing with this mixture, the syringe should be drawn full and again discharged into the vessel, then quickly refilled and discharged on the plant." This is a very unsafe way to use paraffin, as I and many others have proved. Some years ago I carefully followed the same instructions, using one wineglassful of paraffin to three gallons of water applied to some *Crotons*. The result was some of my plants died, and the others lost every leaf. I therefore discontinued paraffin for some time, but meeting with a friend who said he used nothing else, and that he mixed it with soft soap, I ventured again to try it, and this time was more successful. I find it now to be the best of all insecticides for general use. I mix it thus: to half-a-pound of soft-soap, I add one pint of hot water, stir until the soap is thoroughly dissolved, then add half-a-pint of paraffin and stir well; to this I add two quarts more of hot water and put the whole into a stone bottle and shake it well before using. This I always have in readiness, and for syringing or sponging we dilute it as may be necessary. It mixes readily with cold water, and thus mixed may be safely applied to any plant.—J. LAINE, *Randon, Leeds.*

NOTES OF THE WEEK.

MAGNOLIA CAMPBELL.—We learn that this Sikkim tree, said to excel all other *Magnolias* in the splendour of its blossoms, is about to flower at Lakelands, Cork.

DIARIES.—We have received Charles Letts's admirable diaries, which are as well produced as it is possible to make them. Among others is one on housekeeping and poultry keeping which have advantages for some.

NEW REMEDY FOR PHYLLOXERA.—A French chemist claims to have discovered a method of overcoming the danger threatening vineyards from the ravages of the *Phylloxera*. His process is to inoculate the vines with the phenol poison. The *Phylloxera* does not attack plants thus treated, and is extirpated for want of food. The Vines are in no way injured by the inoculation process.

TREE PLANTING IN THE ISLE OF MAN.—By direction of Sir Henry Loch, Her Majesty's Commissioner of Woods and Forests, a large extent of Crown lands in the Isle of Man is about to be planted with forest and ornamental trees. About 500 acres are now being so planted on the mountain called Archallagan, where cabins have been erected by the contractors for the accommodation of the men. Messrs. Little & Ballantyne, Knowlfield Nurseries, Carlisle, have been entrusted with the contract, and already the first instalment of a quarter of a million of young trees has been shipped from the Carlisle Nurseries for the work.

FASCATED ECHEVERIA.—The other day the Rev. H. H. Dombain drew our attention to a plant of a curiously fasciated *Echeveria secunda glauca*, from Mr. Brown, gardener at Great Doods, Reigate, with whom it originated. The stem is flattened much in the same way as in the *Cockscomb*; the plant which we saw was some 6 inches broad, and the crest furnished with crowds of tiny leaves of the same glaucous grey hue as in the normal type. It is very similar to the variety of *Sedum reflexum* called *monstrosium*. It is an interesting and curious monstrosity, and perhaps will be fuller developed later in the season.

JAMAICA BANANA TRADE.—A large and increasing export trade in Bananas is being carried on between Jamaica and the United States, chiefly from the ports of Kingston and Port Antonio, from which regular lines of steamers ply monthly or bi-monthly to New York, Philadelphia, Baltimore, and New Orleans, each of them carrying from 5000 bunches to 10,000 bunches. Jamaica contains a good many Banana plantations, varying in size from 25,000 plants to 200,000 plants, for the most part cultivated by the small settlers in the different parishes. These holdings generally consist of three or four acres of land. The cultivation is very primitive. The land being

cleared by a big iron hoe, a hole is dug and the sucker is planted in it, in most cases Nature doing all that is necessary; but in larger plantations the Bananas, the trunks of which reach a height of 8 feet or 10 feet, are planted with some degree of system in the form of squares, and trenches are dug for irrigation, the Banana thriving best in damp, stiff soil. A bunch consisting of eight pips is the usual size of fruit for shipping.

AURICULA CULTURE AT ROCHDALE.—At a meeting held on Monday last at Rochdale, attended by well-known cultivators of this flower, it was resolved to revive the Auricula show in that town. The forthcoming show is fixed to take place on the day following the exhibition of the Natural Auricula Society at Manchester. Mr. C. M. Royds, J.P., Rochdale, was elected president; and Mr. Samuel Barlow, J.P., Stakehill; Mr. R. Gorton, Eccles; and Mr. William Bolton, Warrington; vice-presidents. Mr. James Cheetham was requested to accept the office of hon. secretary and treasurer, and Mr. James Brodie, Mitchel Street, Rochdale, is to be the assistant secretary.

ROYAL EXOTIC NURSERY, CHELSEA.—We understand that Messrs. Veitch & Sons have just acquired the freehold of this nursery, the area of which is about 5½ acres. This has been a nursery for nearly 70 years. In 1814 Mr. Knight commenced business here, and was subsequently joined by Mr. Perry, who, after Mr. Knight's death, sold the business in 1853 to the late Mr. James Veitch, then a nurseryman at Exeter, and to whom a lease was granted which would shortly have expired. This nursery as a centre, and the numerous auxiliary nurseries which belong to it, make Messrs. Veitch's establishment rank amongst the most valuable and extensive nursery businesses in this country.

NEW LONDON NURSERIES.—Though many of the old London nurseries have ceased to exist, new ones are constantly springing into existence to take their places. Among those recently established is the Morland Nursery, Portland Road, South Norwood, belonging to Mr. Bausé, several years manager of the General Horticultural Company's Melbourne Nursery, at Anerley, and well known in the gardening world as a skilful hybridist, and for the many beautiful plants, such as Caladiums, Coleuses, Dieffenbachias, Ferns, &c., with which he has enriched our collections. Mr. Bausé intends now to cultivate a general collection of ornamental plants, particularly those of the fine foliaged type, such as Palms, Crotons, Ferns, and already his houses are crowded with an excellently grown stock of these and numerous other classes of plants. We hear, too, that Mr. Tudgey, so well known both at metropolitan and provincial flower shows as a successful exhibitor of stove and greenhouse plants, has started in business as a nurseryman at Waltham Cross. Having acquired the fine specimen plants from his previous employer, he intends to exhibit them in nurserymen's classes.

A LILY SCREEN.—We have come to a time when naturalistic designs begin to replace to some extent the conventional twistings of a very popular school—lines without meaning or suggestion. There is now in New Bond Street (No. 67) a specimen of a screen boldly painted with hardy Lilies as they grow in the garden. It is very effective and artistic, and worth a visit from those who have the opportunity. Among the various arts at which women may successfully work is that of flower painting. Many get a feeble degree of power in it, seldom enough to make their work worth looking at a second time. They often present their drawings for republishing long before they can either draw, compose, or colour. The life is worn away by so many petty "accomplishments," that no strength or soul is left with which to take up anything with the devotion and ceaseless loving work necessary. Yet here no "model," costing so much per hour, is required, but beautiful things are around us everywhere. Yet so idle and weak are those who dabble in drawing, that all the lovely aspects of flower and tree life in Nature are allowed to pass unseized.

FORESTS AND HAILSTORMS.—Herr Riniker, chief forester of the canton of Aargau, Switzerland, brings forward some interesting facts tending to prove that a direct connection exists between forests and hailstorms. In support of the theory that where there are forests there are, as a rule, no hailstorms, it is asserted that in the region of the Lindenberg, a low chain of mountains stretching for a distance of about 20 miles in the southern portion of the canton, and with an average height of about 800 feet, hailstorms were very frequent at a time (some twenty years back) when the mountain slopes were in considerable part denuded of their forest growth, but that since the period of partial re-plantation (in 1868, with a growth of Fir) hailstorms gradually decreased in frequency, and altogether ceased with the year 1871. The explanation offered by Herr Riniker for the facts as observed is, that the meeting of the negative electric current drawn from the earth by the trees with the positive electric current saturating the hail-clouds, produces heat sufficient to prevent the complete congelation of the clouds, even to melt the hailstones that may have already been formed from them, thereby converting the frozen particles into rain.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—At the annual meeting held the other day at the Bedford Hotel, Covent Garden, Mr. G. Lambert in the chair, the annual report and audited financial statement were read and adopted. From the balance-sheet it appeared that the annual subscriptions amounted to £1141 8s., the largest sum, it is said, which has ever appeared under that heading, while the donations received amounted to £679 10s., and other items brought the income up to £2326 17s. 6d., which, with the sum of £441 14s. 10d. brought forward from 1881, made a total of £2768 12s. 4d. The expenses during the year amounted to £1679 2s. 1d., and included the payment of £1220 13s. 4d. in pensions and gratuities, and £700 have been invested in 3 per cent. Consols, leaving a balance in hand of £377 17s. 9d. The number of pensioners on the books last year was 82—40 males and 42 females; and the amount invested in 3 per cent. Consols in the names of the trustees is £14,750. With reference to the Pension Augmentation Fund, the amount collected last year by 313 collectors was £602 7s. 5d., the expenses incurred in connection therewith being £61 4s. 3d. The total amount received on account of this fund is £1926 14s., and £1800 have been invested in 4 per cent. Victoria bonds. Sir Trevor Lawrence, Bart., M.P., was elected a vice-president in the room of the late Mr. G. W. Norman, and the election of officers resulted in Mr. Wrench being again appointed treasurer; Mr. Sherwood, a trustee in place of the late Mr. William Hurst; Mr. John Lee, Mr. J. F. Mes-ton, and Mr. James Gray (re-elected) as auditors; Mr. Sherwood, Mr. Jacob Rose, Byfield; Mr. Bruce Findlay, Manchester; Mr. R. P. Ker, Liverpool; Mr. B. Maller, Lewisham; and Mr. John Roberts, Gunnersbury, as members of the committee in place of the retiring members; and Mr. E. R. Cutler, as secretary, for the forty-first time. Nineteen persons were placed on the pension list.

Shoddy.—"R." speaks (p. 6) in high terms about this waste, and all he claims for the Lancashire shoddy may be true. Practically, I know nothing of the kind from that quarter. What I wish to do is to put your readers on their guard respecting some sorts of shoddy. I have had some experience with certain kinds, and have also seen them used by others; there is shoddy and shoddy, and the bulk of that made in the woollen districts of Yorkshire requires to be used with much care, even for strong-growing crops, whilst for the flower garden it is quite unsuited. The "extracting" process consists in soaking the rags in oil of vitriol, diluted, of course. That destroys the vegetable fibre, which falls to dust when passing through the machinery, and so the shoddy is made; the vitriol may be traced for a long time; there are other kinds not so made. Some years ago Hop growers used to give a good price for shoddy from these parts; that was before the vitriol process became so general. Now they will not have it at any price, and I have repeatedly had tons of it offered to me for the fetching. I tried a few cwts. and I have yet cause to remember the parts where it was laid on; many plants were damaged, and even now where the waste came to the surface may be seen masses of fungoid growth. A nurseryman used it for plunging Roses and Clematises in; it heated and did a deal of damage in that way. Besides, where young shoots came in contact with it they were eaten off as by slugs. It had the same effect where used as a top-dressing. I think, therefore, before anyone uses shoddy something should be learned as to the kind, as I am sure the vitriolised cotton dust is a poor manure and a dangerous stimulant, to say the least about it.—J. WOOD, Woodville, Kirkstall.

— I have for some time used shoddy as a manure, and find it very useful for plants, vegetables, and fruit trees.—C. FISON, Merlwood, Parkstone, Dorset.

Lima Bean.—Referring to the paragraph (p. 45) describing the success met with in the cultivation of this Bean in America, allow me to ask if anyone grows it in this country? and, if so, with what results?—J. H.

Nymphæas and Nelumbiums.—What is the best material in which to pot choice Nymphæas and Nelumbiums? also the best time to start them, and the temperature at which the tank should be kept?—AQUATIC.

Hay ashes (J. B.).—The ashes from the burned stacks will make good manure, especially if soaked with liquid from the stable yard or cow house. Apply it to all crops for which ordinary manure would be useful. The sand mixed with the ashes will do no harm.

Boundary fences.—Would someone acquainted with such matters kindly answer the following questions: I have bought a small business; part of the land has been let for building purposes, but I cannot tell when the owner intends to build. What I wish to know is whether he is not bound to fence his part off, and, if with a wall, what height ought it to be? I am intending to put a fence 6 feet high up to my boundary. How near can I go to the divisional line? also, is it quite legal to plant the fence very near his ground, so long as it is on my own, and I do not allow it to encroach on my neighbour's? I am really in a fix what to do; all I want is what is fair and just.—W. J.

"This is an Art

Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

PROFITABLE FRUIT CULTURE.

ALTHOUGH not what may be strictly termed a market grower, I have had good experience in fruit growing districts, and number among my personal friends several practical men who not only are successful fruit growers, but who are particularly good judges of what kinds and varieties are most profitable. I venture, therefore, for the benefit of intending planters, to supplement the valuable and concise information conveyed in *THE GARDEN* (p. 18) with a few observations of my own.

Competition, it appears, owing mainly to the extensive imports, is now very keen, and it is not entirely a question, when selecting, as to which varieties are most prolific, but which sell the most readily. With this end in view, the intending grower at the outset should frequently visit the markets and ascertain, as far as practicable, what is most in demand at the different seasons, the best methods of sending, and other serviceable details. The friendship of a salesman is especially valuable, not only then, but later on when the orchards are in full bearing, as these men know better than anyone what should be grown, how to send the produce, and when best to push the sales. It will be found that there are three very important agencies in connection with the success of a fruit grower, and which should not be lost sight of by beginners, viz., suitable soil, favourable position, and convenient locality of the orchard.

Soil.—Not a little depends upon the natural soil of the intended site. A shallow surface soil, with perhaps a gravelly subsoil, is altogether unsuitable, as the majority of fruits that ought to be grown succeed only on a comparatively strong and deep soil. To double dig this, however, on a large scale is almost out of the question; but a well-horsed sub-soiler will do much to break up and eventually improve the hitherto unbroken subsoil. If naturally retentive of moisture and imperfectly drained, then by all means resort to artificial draining; but rapid shallow draining must be guarded against, or this may prove nearly as injurious as stagnation. As a rule, the subsoil only requires draining, and this both deeply—say about 4 feet—and at wide intervals—say about 20 feet, or midway between each row of trees. This, with good outlets, will insure the requisite slow, but certain percolation of the surface water through the whole depth. With regard to a

Favourable position, as a rule I should prefer to plant an orchard on a gentle declivity, with a S.S.W. inclination, and would provide a belt of Spruce or other Firs to afford further shelter from easterly winds, which so frequently greatly injure our orchards. If a comparatively light soil prevails, then I should prefer a level, but not low-lying position for an orchard, avoiding land in proximity to a stream, which inevitably contributes to, if not the sole cause of, late spring frosts. We not only are anxious to secure a good "blowth," as an abundance of bloom is suggestively termed by the natives of some of the western counties, but like to avoid the great anxiety prevailing in low-lying districts till a good set is secured. More than is at first apparent depends upon commencing fruit growing for profit in a

Favourable locality, and this, to deserve the designation, should be in the neighbourhood of a large provincial town, or within comparatively easy distance of London. After a fair experience in more northern districts, I can safely assert that better crops on an average can be secured in the more favoured southern counties, and there is a greater certainty of effecting better sales in London than elsewhere, not excepting even such important towns as Manchester, Liverpool, Leeds, Notting-

ham, &c. Kent, Surrey, Sussex, Essex, Herts are all available for the production of, and each does contribute largely to, the requisite supplies of fruit. The south-western counties are all highly favourable for fruit culture, but the bulk of the produce must be sent to a great distance to secure profitable prices, the demand in such towns as Bristol, Bath, Southampton, Portsmouth, &c., apparently not being extensive. At times fruiterers in these important towns can give good prices for a moderate quantity of fruit, and it may be best to let them have it. As a matter of fact, however, many provincial fruiterers are in close business relations with London market salesmen, and from them procure the bulk of their choicest fruits. At times the fruiterers find it necessary to send much surplus fruit to the salesmen, and this does not improve the "returns" of the growers. Another advantage attending the proximity of an orchard to a large town is the certainty of being better served by the railway companies, and in this case the produce will be delivered quickly and well.

What should be grown.—There are certain kinds of fruits that invariably prove profitable, and which may safely be planted in large quantities. Of these, the most in demand are Damsons, kitchen and preserving Plums, kitchen Apples, black and red Currants, Gooseberries, Strawberries, and Morello Cherries. As will be seen, nearly the whole of the foregoing are applied to two or more purposes, being either fit for dessert, making into jam, or for cooking. Damsons are also largely employed in the production of a dye, while Plums are frequently bought up wholesale for various purposes. Kitchen Apples, notably the early sorts, sometimes sell very readily; besides they are available before the heavy foreign supplies reach our shores. Black and red Currants are extremely popular fruits, and I am informed on good authority that the former are largely exported; added to this they seldom fail to bear well. Gooseberries give two chances, being oftentimes very profitable when sold in a green state; besides this, insures the thinning of heavy crops, and thereby greatly affects the quality of those left to ripen. Strawberries are an expensive, but at the same time remunerative crop, as when sent in good condition they find a ready sale (at least such is my experience in the metropolitan markets, to which I ought perhaps to state my remarks have especial reference). Standard trees of Morellos when planted in the middle of an orchard seldom fail to bear heavily, and a remarkably pretty sight they present. Dessert Cherries occasionally prove extremely profitable, but are a glorious uncertainty, nevertheless.

Apples generally, Pears, Filberts, and Raspberries each in their turn may prove profitable, and may well be grown in limited quantities, the aim being to have as many chances as possible. At times, though seldom of late years, there is a glut of Apples in the market, many sending in large quantities to avoid storing, and in this case probably the "returns" are *nil*. If properly stored, and this is no easy matter, the American and Canadian supplies spoil the markets, and, strange to say, our Transatlantic brethren better understand what sorts are the best adapted to the work and prove most saleable. Neither do they risk failure by sending inferior or mixed samples. All their fruit, are even in size, bright in colour, and, in addition, whether rightly so or not, are considered adapted to either culinary or dessert purposes. Here lies the secret of their undoubted success in finding good markets, and their tactics should be imitated by would-be successful fruit growers in this country. That is to say, a few only really good sorts should be grown, but the bulk of the trees should be of varieties adapted for either purpose, and if highly coloured so much the better. When sending, keep the very small fruits back, or, at any rate, in separate sieves, as they tend to spoil the samples, and hinder the sale accordingly. Pears are not to be depended upon, but a few rows may occasionally prove profitable, none more so than "Williams," as the costers and others sensibly abbreviate

Williams' Bon Chrétien. Raspberries seldom fail to crop heavily, but they travel badly, and, as a rule, have to be sold locally.

Filberts and Cobs only succeed in rich, loamy soils, such, for instance, as will grow good Hops. In Kent they are particularly well managed, and in a good season more than compensate for the labour bestowed upon the orchard. They are either disposed between the widely-planted rows of Apple trees or are alternated with the Apples. They are not allowed to grow at random after the manner of the Hazel in hedgerows, but are trained similarly to Red Currant bushes, only much taller, or, as some prefer, similar to a dwarf Apple tree with a clear centre, and are as closely pruned, with the exception of retaining a quantity of spray-bearing catkins to provide pollen for the proper fertilisation of the apparently insignificant, but most important, fertile flowers.

A good arrangement, of which I for years have had an insight into, might well be adopted by others. The orchard comprises all the kinds of fruit I have mentioned, with the exception of Strawberries, these after the first seven years being grown quite clear of all other crops. All the Apples, Pears, Plums, and Cherries are grown as standards, the lines as a rule being formed with one sort, running through a length of about 20 feet apart, the trees in the lines being the same distance asunder. All the available space between the trees each way is rather thickly planted with Gooseberries, Currants, Raspberries, and Filberts—large breadths, each containing several thousand plants, being thus worked in. When the standard trees had grown considerably and the bushes become crowded, half of the latter were removed and planted in a new orchard. On the same farm numbers of Damson trees were planted almost in the hedgerows and are doing well; and if a new hedge should be required (and they are sometimes serviceable in preserving a path or restricting a right of road), these are formed of either Gooseberries or Currants. Every foot of ground is thus utilised, and should be in every case. Many of the trees I have seen planted or have assisted to plant were "miserable scraggs," and these are preferred to vigorous and more attractive looking trees. Being probably grown on a poor soil, the change, instead of being injurious proves highly beneficial, and the trees soon get established and grow freely. It is advisable to stop the lower branches, but as they materially assist to swell the stems, they should on no account be removed till this is accomplished. Trees infested with

American blight should by no means be planted, as this pest is not easily eradicated, and if allowed to spread, quickly ruins an orchard. Experienced men are always anxious to procure trees true to name, but are doubly solicitous with regard to the possibility of having American blight sent to them. They would destroy these infested trees rather than plant them. In planting, unless the young cultivator has secured the services of a trustworthy and experienced foreman, no dependence whatever should be placed upon untried workmen. If left to the latter, the chances are the trees and bushes will be both mixed and badly planted. A spit taken out with a spade, the roots of a bush thrust in, and the soil returned without breaking and trodden in, will not answer in an orchard, if it does sometimes for nurserymen. A good-sized hole should be dug, the bottom made firm, and on this the roots, previously trimmed where bruised or unequal, may be evenly disposed and surrounded with well broken-up soil. Deep planting, although it saves stakes (I know of no other reason why people should plant deeply), is simply ruinous. If the soil be poor, it should be enriched at the commencement, and all well-established trees and bushes on any soil well repay for annual and biennial top-dressings with fresh manure. Very seldom do market growers resort to root-pruning. This is rendered unnecessary by simply withholding the knife after the trees are once framed out. Let alone, they soon fruit abundantly, and all that is necessary is to occasionally shorten

back straggling shoots and to thin out where crowded. The bushes are annually pruned.

A selection of varieties that have been found profitable in a southern county is as follows: Of Apples—Kewick Codlin, Manks Codlin, Lord Suffield, Red Quarrenden, King of the Pippins, Duchess of Oldenburgh, Hawthornden, Cellini, Cox's Orange Pippin, Blenheim Orange, Warner's King, Reineette du Canada, Fearn's Pippin, Jolly Beggar, Stirling Castle, and Sturmer Pippin. Pears—Williams' Bon Chrétien, Louise Bonne of Jersey, Duchesse d'Angoulême, Crasane, Beurré Diel, Hacon's Incomparable, Hazel, Beurré d'Arenberg, and Beurré Rance. Plums—Early Rivers, Victoria, Orleans, Green Gage, Coe's Golden Drop, Pond's Seedling, Washington, and Mitchelson's. Cherries—May Duke, Bigarreau, Black Tartarian, Elton, Red Jacket, Kentish, and Morello. Gooseberries—Whitesmith, Early Sulphur, Crown Bob, Red Warrington, Golden Drop, and Lancashire Lad. Of Red Currants—Raby Castle and Red Dutch; White Currants—White Dutch; and of Black Currants—Lee's Prolific and Black Naples are preferred. Strawberries—Alice Maud, Vicomtesse Héricart de Thury, President, Sir J. Paxton, Dr. Hogg, British Queen, and Eleanor are all largely grown for the markets, though, as a rule, the growers depend upon three varieties and which form a good succession. I ought not to omit mentioning that the Damsion largely planted by those in the secret is the Cluster or Crittenden Prolific.

FRUIT GROWER.

STRAWBERRY CULTURE.

AMONGST all hardy fruits there are none that so soon repay—and that with liberal interest, too—for high cultivation as the Strawberry; moreover, it will thrive in almost every variety of soil, provided the culture is suited to the particular kind of soil that has to be dealt with; yet there is a best soil, and all who are fortunate enough to have this will find little difficulty in carrying out cultural details:—

Soil.—A deep loam, inclining to clay, or what may perhaps be best understood by the term, "neither heavy nor light," is suitable for Strawberries, but of the two I would prefer that clay had the predominance; and this fact should be kept in view in the preparation of other kinds of soils. If, for instance, a light peaty soil has to be dealt with, it should first of all be trenched as deeply as the nature of the subsoil will admit, then be given a heavy dressing of well-rotted manure, this to be forked in, and then to be well consolidated either by rolling or treading, this consolidation serving to some extent the same purpose as the stiffer loam. All light soils, of whatever nature, should be similarly treated. The one prerequisite in regard to heavy soils is effective drainage, and deep cultivation is just as desirable as on lighter soils, but a manure of lighter character may be employed, such as long stable litter, spent hops, or vegetable soil.

Preparation of the plants.—These should be had from runners, layered into 3-inch pots early in July. A piece of turf in lieu of crock should be used for drainage, and the pots be filled with good loam, which should be well firmed in the pots and then be plunged between the rows of the old plants. Select the strongest runners, and secure them on the pots with pegs, and keep them well supplied with water. In from three to four weeks they will be well rooted and ready for planting out, and as soon as this is the case the operation should on no account be delayed, otherwise the plants get root-bound in the pots, and are liable to be checked in growth by the ball getting so dry that when planted out new roots have to be made before the plants start into growth.

Planting.—First, as to season. Well, any day in the 365. But as with soils, there is also a best time to plant, and that is the month of August. This, too, is the only season if the mode of preparing the plants advised above be followed; and though, of course, it does not follow that this is

the only successful way, a comparison of results between this and taking off rooted runners that have been simply layered on the ground, or the planting out of old forced plants, would soon decide waverers in the matter in favour of the first-named plan. Next, manner of planting. Use trowel and fingers only, making the hole sufficiently large to admit of fine soil being placed round the roots with the fingers; this done, use the trowel, and with the handle of the same well ram the soil about the roots, and the lighter the soil the harder should be the compression of it about the balls of the plants. Next, distance apart of plants. This must necessarily be regulated somewhat by the nature of soil and sorts grown, but, as a general rule, 2 feet apart in the row and 2 feet 6 inches from row to row will be ample space, but none too much where the ground has been prepared as just recommended.

Varieties.—Of these there are far too many; indeed they are to be had by the score, the difference in many being perceptible in name only, or at all events such a trifling difference as not to warrant their being grown as distinct kinds. After trial of very many kinds, I name two only as the best sorts to grow, viz., Vicomtesse Héricart de Thury and President; these never fail, are of first quality, prodigious croppers, good growers, and travel well—properties that are alike desirable for the market and for the private grower. To any that require a greater variety I would recommend Keen's Seedling, British Queen, and Sir Charles Napier as being the next best kinds.

General culture.—Mulching is of first importance, and should be done as soon as the plants are put out with the best manure that is to be had. This will render artificial watering unnecessary, except in exceptionally dry, hot weather; and as winter approaches it should be added, too, as a protector to the crowns and surface rootlets. The spring and summer culture will be simply to keep the plantation free from weeds, and perhaps a mulching with clean straw or litter as soon as the fruit is set. I say perhaps, because very frequently the autumnal mulching gets so washed by the winter and spring rains as to make it unnecessary to replace it for the purpose of keeping the fruit clean. As soon as the fruit is gathered and the necessary runners have been obtained the plants should be cleared of all runners and dead foliage, the old mulching removed, and be replaced by well decayed manure, and this will end all the attention requisite till spring-time, except it be an occasional weeding. Digging between the rows should never be thought of till the plants have to be dug up, which, at the latest, should be after the third time of fruiting.

W. W. H.

SHELTER FOR FRUIT TREES.

THE violent gale that swept over this country on April 29, 1882, whereby all trees exposed to its fury were defoliated, and the crop nearly destroyed in a few hours, gave us one more lesson of a most practical kind as to the value of shelter not only from cold north-east winds, but also in a smaller degree from all points of the compass, for in this case it was not the cold, but the violence of the gale lacerating the leaves that caused the mischief. The gale began in the south-east and gradually worked round to the west, where it died away, leaving its track as visible as if fire had passed through the branches. Disheartening, however, as the prospect was early in May, it was surprising how soon the trees recovered, and the beautifully clean growth that was made later in the season, and the smallness of the crop, giving them a decided rest, has allowed them to perfect a splendid show of buds for another season. Apple growers for market are therefore by no means discouraged by the failure of one season's crop, or dismayed by American importations. The demand for fruit appears to grow quite as rapidly as the power to supply it; we may, therefore, look for an increase in the way of Apple orchards for some years yet to come. We may also look for distinct methods of Apple culture becoming more

marked as time passes onwards. Wide-spreading orchard trees, though they do bear great crops of second rate fruit, must in many cases give way to dwarf trees of the very best kinds, and that will bear fruit of the best quality. Anyone interested in Apple culture could hardly fail to notice that dwarf trees in gardens or in other sheltered spots mostly carried good crops even last year, and although the cost of planting an acre of Apples at about 10 feet or 12 feet apart is a large increase on first outlay compared with the ordinary cost, yet the fact of trees on the Paradise stock fruiting well the same season in which they are planted makes the prospect of return on capital invested a far more immediate affair than when the notion prevailed of planting trees only for the benefit of future generations. One November I planted many of the sorts enumerated in previous numbers as dwarfs on the Paradise stock, and they carried a better crop in proportion to size than any of the large orchard trees, fruit of some of the early kinds like the Red Astrachan and Irish Peach being gathered within eight months of planting. I would strongly advise all intending planters of dwarf trees to only plant those on the Paradise stock; it does the dwarfing far better than the knife; a little pinching of the strongest shoots in the growing season is all the pruning they require; the less pruning indeed the better, as all cutting off surplus shoots is so much wasted energy. Extension-grown standards expend their force on growth and are afterwards fruitful, while the dwarfing stock limits the supply of sap, thereby curtailing growth, so that while the fruit is of maximum size and abundance, the growth from the first is minimised to its proper amount.

Gosport.

J. GROOM.

Josephine de Malines and other late

Pears.—The ripening of Josephine de Malines in December is not an unusual occurrence with us. This season we commenced using them on the 22nd of that month; these were from a south wall. We are now using the same variety from a west wall; they are all of good size and flavour this season. Last year they were ripe by the latter end of November, and were all over in a short time, most of them turning soft instead of ripening, and those that did ripen were poor in flavour. Glou Morceau is very good with us this season; this variety commenced to ripen in the beginning of November, and lasted about seven weeks, a few being used on most days during that time. Last season, although we had a good crop of this variety, and also of good size, we were not able to use many of them, as, like Josephine de Malines, nearly all of them rotted instead of ripening, and those which ripened were not worth eating, whilst this season they are delicious. Bergamot d'Esperen we rely upon to supply us through February and March; last season its fruits all shrivelled long before this date, but this season, at the present time, they are quite sound, and do not as yet show any signs of ripening; this and Olivier de Serres I consider to be the two best late Pears. Easter Beurré we can generally keep until the end of March, but with us it is seldom worth eating, being mealy and flavourless.—A. BARKER, Hindlip.

Beurre d'Amanlis Panachee Pear.

Amongst Pears there are few that have secured a better reputation than has been accorded to the Beurré d'Amanlis. It is large, handsome in appearance, and of fair quality; it comes into use amongst the earlier varieties in September, and at that season has no equal, and it is an almost certain cropper. Very rarely indeed does a season pass without a crop of Beurré d'Amanlis; consequently it has found much favour with the market growers. Mr. Dancer, of Chiswick, grows it extensively—a pretty good criterion of its worth—and finds it to be one of the most profitable sorts. The tree is a very free and somewhat strong grower, and succeeds well on the Quince—so well indeed, that it is used as the intermediate stock for those varieties that do not themselves take freely on the Quince. There is a striped (*panachée*) form of this Pear in every respect the

same as the type excepting that it is far more beautiful, the broad bands or streaks of yellow and rosy orange with which it is furnished being exceedingly pretty. This variegation is not uncommon, every fruit being more or less marked, and remaining so until quite ripe. It is exceedingly handsome for the exhibition or dinner-table, and should be grown in preference to the ordinary form. Portions of the young shoots are frequently striped in the same manner; very rarely the leaves.—*Florist*.

MISTLETOE CULTURE.

To grow Mistletoe upon suitable trees is by no means a difficult matter if only the seed be set in a natural way. I have a Hawthornden Apple tree with many luxuriant and fruitful growths of this interesting plant upon it, and my own raising, and the simple means by which I have here and elsewhere succeeded might be described in almost a single line of print. I stick the naked seed upon the clean, smooth bark of a young bough, and protect it for a year from birds and insects. It is, however, a curious fact that nearly everyone who asks how it is done will volunteer the supposition that a slit is made in the bark to cover the berry; but slits in the bark are altogether unnatural and unneeded. Nothing in Nature suggests such a plan. There is no wild bird that goes oddly out of its way to insert Mistletoe seeds under the bark of proper trees; no beetle, under the impression that it is providently laying by something for itself, bores holes for the storage of Mistletoe berries, and conveniently forgets its buried treasure in order that its industry may be turned to another account.

The seeds depend for their successful germination upon some agency that affords them a chance of adhering to the bark. They seem to need that soft texture for a seed bed until the time comes for them to penetrate the harder tissues of the inner wood. They cannot thrive upon the rugged old bark that is congenial to Mosses and Lichens, though they will start into growth almost anywhere—inside their own berry, or on a gatepost. To produce a plant a Mistletoe seed must come in contact with the bright, clean, vital bark of a young stem or bough, and into this one, and often two, green fangs from the seed will soon be seen to fasten themselves by a sucker-like mouth. These bite the bark, and nothing more is visible of the first year's growth. In the second year the body of the seed is absorbed and the green fangs strengthened; but still no upward growth is observable. The roots progress among the fibres of the wood, and the bark is made to swell as if there were a knot beneath. This is a sure sign that the young plant is safe, and in the second year's stage of growth. In the third year's course there will be developed a tiny pair of Mistletoe leaves, perhaps from the green stem that broke from the seed, but this is very frequently dead, and the pair of leaves rise as from a sucker. There will soon be several of these young stems, and when once their leaves are developed the growth becomes bold and rapid. Although only one joint of stem and its pair of leaves are produced in a year, other stems keep breaking from the neighbourhood of the seed, and there is soon a "bunch." At the fifth year the sex of each plant will be discernible, for the Mistletoe is dioecious, and for this reason I have always planted a group of four or five seeds together, so as to have both flowering and fruit-bearing plants near each other; but it is surprising to see how the pollen from a single male will set the berries on plants quite separate on the same tree or growing about the garden on different ones.

Sowing.—The seeds may be sown whenever a ripe berry can be had, and if this is an old one on the plant it will be found already sprouted within. It is best to sow them in the late spring if they can be had fresh, for the advancing foliage helps to hide them from the birds, that have keen eyes and sharpened appetites in winter. They are best placed on the under side of young boughs, and

may be protected for the first year by a wrapping of gauze; that, however, should not press upon the seed. This will preserve them from birds and also from snails and wood-lice and such like, but must not be so arranged as to form harbourage for vermin.

The flowers are insignificant as such, the female being only four greenpoints surrounding a viscid stigma; and the male a four-cleft cup of pollen, that adheres in a very firm way to the inner side, like the sand on sandpaper. These flowers expand in the early spring, and last several weeks, the crops of berries depending upon some spell of dry, not fine, weather, to enable the pollen to be blown about from the male flowers. The fall of the leaf, or rather the change, on this evergreen plant is curiously sudden. All at once, in the mellow summer, without one sign of weariness or serenity, the large, old foliage drops off, leaving only one (and that the last) pair of leaves to furnish the plant at every extremity, and for a short time it has a leggy, stripped appearance. Mistletoe is very fond of the Apple tree and various Poplars, and also grows well on the mountain Ash; on the Thorn I have only had it rather crabby. Of course its life is dependent on that of its foster parent, and its vigour varies with the health of the supporting tree. Often as I have tried to get it on the Oak, I have only once succeeded, and most unfortunately the branch on which I had established a nice young plant got lopped off by an all too unobservant woodman. For those who are anxious to save time, I may say young Apple trees with Mistletoe on them may be had. It does not perceptibly affect the fruitfulness of the tree when not sown too much upon it, and one would willingly sacrifice for its sake a few Apples. F. D. HORNER.

Kirkby Malzeard, Ripon.

PROPAGATION OF MISTLETOE.

I AM glad to see that some one is taking an interest in the propagation of this curious and not unhandsome parasite. Being naturally slow of growth and multiplication, it is not unlikely that the large and increasing drafts made on it annually at Christmastide will, sooner or later, result in a dearth that will take years to rectify. The following method, which I have adopted with great success on several occasions, is recommended by Loudon ("Arboretum et Fruticetum," p. 1023) and Burbidge ("Cultivated Plants," p. 383). The berry should be rubbed gently but firmly backwards and forwards on that part of the tree to which it is desired to affix the plant; the smoother the bark the more certainty of success. There is a knack in holding the berry in the hollow formed by bringing the first joints of the first and second fingers together, which is easily acquired with a little practice, otherwise the performer may have a difficulty in keeping it fast from its slippery nature. The rubbing process should be continued till almost all the viscid matter is removed from the seed, leaving only enough to keep it firmly attached to the bark. If properly performed as regards the selection of suitable stocks, and fully ripe berries are employed and at the proper season, success is almost a certainty. I have never failed in getting at least 70 per cent. of the seeds to germinate, the others no doubt being imperfect seeds. No incision of the bark is necessary. If sown in the latter part of February or March, germination commences in a few weeks. The first indication of it is the appearance of a dark coloured proboscis-like radicle, which at first holds itself erect, but, after having attained sufficient length, gradually and gracefully bends over in the form of an arch and fixes its point on the bark. The point of this radicle then swells out, and seems to act as a sucker in procuring nourishment for the embryo. If more than one radicle proceeds from one seed, they each represent distinct embryos, and eventually become separate plants.

Some prefer to perform the operation earlier than the date just named, but I think it best to delay it till the approach of the natural season of

growth, and this also allows the berries full time to come to maturity. The only stock I have used is the Mountain Ash, always preferring the under-side of a branch, as in that position the seeds are less liable to offer temptation to birds, which, I believe, are a chief means of failure as regards the propagation of Mistletoe; they are fond of the succulent matter which surrounds the seeds, and therefore this should be rubbed off as already described, or some sort of protection should be put over it when the seeds are inserted on a tree. Burbidge gives a long list of trees on which this parasite has been found, chiefly deciduous, such as Apple, Oak, Sycamore, Brier, Ash, Lime, Elm, Willow, Birch, Poplar, and Hazel, and also the Silver Fir. And Loudon makes mention of its being found in immense quantities on *Pinus sylvestris* in the neighbourhood of Magdeburg.

Wedge grafting in spring on Apples or Limes is also recommended by the former author as being successful. This I have never tried, but intend doing so this spring, and hope to prove the practicability of it. Can some one give me any information regarding a red-berried variety, mentioned by Loudon as occurring in the vicinity of Jerusalem, or of a variegated form mentioned by Burbidge, and whether it is persistent? The mythological, legendary, and poetical allusions in reference to the Mistletoe, as given in the "Arboretum et Fruticetum," are well worthy a perusal by any one interested in this curious parasite.

Altrincham, Cheshire.

JAMES GREEN.

COLOUR IN THE FLOWER GARDEN.

ALAS for the poor amateur! What has become of him during the time this discussion has been proceeding? If he has had the patience to wade through it, what a state of muddle he must be in. Well may "Peregrine" exclaim that if we have to go through a probation in such elaborate detail, we shall, like the rustic, have to go back to "first principles" and beans and bacon. Notwithstanding all that has been said on this subject, I say let the amateur arrange his colours in accordance with rules which, I repeat, are practised every day by every artist, and if he should be at any time criticised on that point, he will have something definite to fall back upon as justification. In each of my articles I have been compelled to quote freely from "J. D." for the purpose of showing that his best efforts of tasteful management, instead of being adverse to the theory I have advocated, tend most, unmistakably to support it. Why he should repeatedly bring forward practical witnesses to upset the complementary code, but whose evidence only spoil his own case, I cannot say, except it be that unless they were supported in theory by the said code, they would be too odious to be allowed even to take the oath in the witness-box. Here is an almost solitary case of genuine evidence. "The best contrasts to place on a grass-green ground are the bluer shades of green, blue, yellow, white, and tinted white." May not this "greenery-gallery" lady stand down? Here are other witnesses who play him false in his last article. "Where the bordering line is yellow, the centres will be best mauve and white." (Mauve is a shade of purple; therefore we have our purple and yellow.) So it is throughout the sentence. Again, "with blue, white, and primrose, orange-brown and crimson, or green and creamy white with pink would be suitable." Further on, "I should always surround a bed of scarlet Pelargoniums with a very broad band of neutral greens and greys, &c." So on to this *moreau choisi*: "A good harmony of red, blue, and yellow, with red as principal, could be arranged in seven beds"—the very arrangements he later on stamps as discords. They may be softened down in various ways by the interposition of related tints and neutrals, but our old friend the complementary theory is the principal factor in the composition.

In his valedictory sentence a suggestion is made that each must test the amount of colour perception he possesses for himself. Excellent! And to

that end I will give a table of single and compound contrasts and harmonies, so that he who runs may read, and compare for himself with the coloured plates of THE GARDEN, Vols. XXI., XXII.—that is, if he be not already satisfied:—

HARMONIOUS COLOUR TABLE.

The numbers refer to page in Vol. XXI. for coloured plates, with an asterisk for Vol. XXII.

All Reds in gradations		Where one colour only is used.	Where two colours are used, any other one may be used <i>ad lib.</i> — tint, keeping clear of too great preponderance.	Where three or more colours are used.
Red	42, 93, 162,	Red		
Green	200, 292,	Green	6*, 46*, 230*	
Red	208*,	Brown		
	296*	Yellow		
Green	150, 466*	Purple	2:6	
Brown		Olive		
Yellow		Blue		
Purple		Orange		
Purple	142	Gray		
Olive		Red		
Purple	60, 526*,	Yellow	252*, 574*	
Green	24*	Blue		
Blue		Green		
Orange	422*	Purple	6, 328, 424, 441	
		Orange		
		Brown		
		Olive		
		Gray	130

		Purple	146, 366, 386,	
		Green	406	
		Gray		
		Purple, Olive,	254	
		Brown		

Harmony is augmented by interposing between two colours softer shades of the same—neutral greys, white, or related tints.

I have had to be rather roughshod in classifying the colours, but it is quite sufficient to say that no single coloured plate has appeared in the last two volumes of THE GARDEN, printed in pigments, in which each of the three primary colours, red, blue, and yellow, does not appear, either in a pure form or mixed into secondary or tertiary combinations, but ever present; and surely we shall not have these colour arrangements also marked "executable." Let the amateur, then (and others), arrange his garden beds or borders in any of the above combinations, and if he be so unfortunate as to be unable to see beauty in them himself, submit them to his visitors, who may. Were we all to be debarred from attempting harmonious arrangements until we had passed through such examinations as are suggested, we could no more hope for beauty in our gardens than the youth could speak German whose only acquaintance with German was that his brother played the German flute, and that his fruit-knife was of German silver. We should have to say "we cannot arrange colours artistically ourselves, but we once read a correspondence in THE GARDEN in which the disputants said they could." To the amateur I originally named I would say, "Read no further;" but to such as have waded after us through all sorts of mixtures, I would say that most of this correspondence might have been spared us had "J. D." at the outset mentioned the fact of his having been afflicted with attacks of colour-blindness to red. His hatred of red and green can thus be accounted for; and *en passant* I may remark that the colour artists of THE GARDEN have given us three to one of this combination. I regret to say, however, of "J. D." that he must see colours where they do not exist, if we may judge from his statement that "London warehousemen cannot match delicate shades of colour, and even in the height of summer when the air is purest, a dozen shades of grey merge into one." On November days when "particular" fogs of pea-soup colour and consistency prevail, it is so, I agree, but let anyone go and inspect the

Turner collection of water-colours under the National Gallery (and see what he does with primary and secondary combinations by the way); let him go to our picture exhibitions on an ordinarily clear day, and I will warrant that unless his perceptive faculty be aborted or suppressed, there will not be many tints merged into one unless the artist intended them to be so in a natural way. At that rate our metropolis, instead of being the home of pictorial art, would shrivel out of itself every bit of coloured art.

Throughout I have gone on the assumption that the chemical cell contents of leaves and flowers, the presence of pigments, so deal with a white ray of light, containing, as it does, all colours, as to absorb all but one hue which is reflected to the eye. I have tried to show how those reflections may be arranged so as to please the eye instead of offend, just as a milliner would arrange ribbons on a lady's bonnet; and although there has been much said on the scientific theory of light which would be new to some readers, I did not yield to the temptation of following into this field, else why my original article asking for a "hark back" to something which could be resolved into practice for the benefit of a large class of gardeners particularly. On the other hand, I think "J. D." got on the wrong line at the commencement of the journey by interposing coloured glass between the eye and the light ray. He has dealt all along with direct light and its effect through a prism instead of dealing with the reflected colours of pigments. For instance, light through red and yellow glass does not make orange, whereas reflected from red and yellow pigment it does. In like manner red and blue for purple, and so on through the whole chapter; hence his list of correct combinations (except where he borrows from the theory I support) is reduced almost to unity, and may be properly styled unique. Thus, having got the wrong direction to start with, small in its beginning, like many other things, his list of discords comprises nearly the whole list of colour harmony, several combinations of which he allows, and thus contradicts himself. For example, he says: "These three last, citrine, green, russet, are beautiful as Nature uses them; scarlet and blue are passable (scarlet partakes of the nature of orange); green and purple are passable." He appears to lose sight of the Shakespearian quotation which meets our eye every week on the opening page of THE GARDEN, that "the art itself is nature" if he condemns the scarlet Pelargonium with its green leaves; the purple and yellow blossoms of Solanum Dulcamara; the blue and orange flowers of *Exacum macranthum*; the golden and purple sunset mixing in the eye with the green verdure; the varied tones of greys, olives, and russets of vegetation's sunset—glorious autumn. Are we to try and imitate Nature in her colour combinations? Must we agree to differ, as "J. D." says on page 3? or may we not differ to agree with Pope—

All discord's harmony not understood,
All partial evil universal good?"

Horsforth, near Leeds.

RECENT PLANT PORTRAITS.

Anthurium Scherzerianum var. Madame Emile Bertrand (*Illustration Horticole*, plate 470).—A double plate of a fine hybrid form of this well known plant, raised by M. E. Bertrand, and somewhat resembling M. Bergman's *A. Rothschildianum*, with bright red spathes mottled all over with pure white.

Pescatorea Lehmanni (*Illustration Horticole*, plate 471).—A very beautiful and conspicuous flowered Orchid, with large rosy violet flowers, each petal clearly and distinctly margined with pure white; also known under the name of *Zygopetalum Lehmanni*, and is a native of the Equatorial Andes, whence it was introduced by the collector whose name it bears.

Pellonia Daveauana (*Illustration Horticole*, plate 472).—A beautifully variegated-leaved greenhouse trailer, with small and inconspicuous green flowers borne in bunches on stiff upright

stems well raised above the foliage. This plant was introduced by M. Godefroy-Lebeuf, and was originally described and figured in the *Revue Horticole* of Paris by M. Carrière under the name of *Begonia Daveauana*. It seems well adapted for the decoration of hanging baskets in a warm greenhouse.

Phlox decussata (group of six varieties—*Revue de l'Horticulture Belge* for January, 1883).—These fine new hybrids are from the collection of M. Burvenich, of Gendbrugge.

Caraguata cardinalis (*Revue Horticole* for January 1, 1883).—A very handsome vermilion flowered Bromeliad, a native of the Western Andes of New Grenada and Ecuador, whence it was introduced in 1876 by M. André. W. E. G.

INDOOR GARDEN.

MARIE LOUISE AND NEAPOLITAN VIOLETS.

THE Marie Louise well deserves the many eulogies bestowed on it for its good and free-flowering qualities, especially as a late summer and early autumn variety. The blooms are also very fine and richly coloured. The quantity of flowers that may be gathered from it from August to November is something enormous; but for midwinter, when the supply begins to diminish in the case of this variety, the Neapolitan is just in its glory. Our plants of the last named sort are now masses of flowers and buds. This characteristic of the Neapolitan in succeeding the other at this season makes it especially valuable; therefore an equal quantity of both kinds should be grown where a continuous supply is required. The Neapolitan is doubtless the more difficult to manage, but under good cultivation the flowers are equally fine as those of Marie Louise. We find a half-shaded cool and moist border the best position to produce good plants. Violets are very subject to red spider, and must have plenty of water in hot weather. If there is the least suspicion of red spider when the plants are lifted in the autumn for placing in frames, it is a good plan to dip all the foliage in a solution of nicotine soap, as unless thoroughly free from that pest the leaves will damp and rot off in damp, cold weather when the frames are kept more or less closed. On the other hand, if the foliage is healthy, this great evil will be avoided. We use ordinary two-light frames placed on beds made of leaves and stable litter in preference to brick pits, as we find the plants remain close to the glass throughout the winter; whereas, when planted in brick pits, from the gradual subsidence of the material in which they are planted, they settle too far from the glass. With double mats in sharp weather, and manure linings if necessary, it is an easy matter to keep the temperature at 45° in the sharpest weather, a temperature which suits the Violet well. A rise of 5° or 10° should be allowed if the sun should shine at this dull season.

WILLIAM ALLAN.

Guntton.

GREENHOUSE PLANTS FROM SEED.

FEW have any idea what numbers of different kinds of plants there are suitable for the decoration of greenhouses and conservatories that may be raised from seed, and got up large and strong enough to flower the same season. First and foremost come the

Tuberous Begonias, which, as regards showiness, are quite unsurpassed. To have these really good the seed must be sown early; and as it is very fine it is necessary to have the soil in the same condition and quite smooth on the surface, where the seed should be scattered and not covered, except with just a sprinkling of sand to hold it in its place and prevent damping when the plants come up. This they will do speedily if the pots or pans in which the seed is sown be placed in moist heat and have a sheet of glass or some damp moss laid over them till the seeds germinate, when a frequent gentle bedewing with water from a syringe will keep them right. As soon as the young plants are large enough to handle they

should be pricked off in pans filled with rich mould, and returned to the stove or other house in which they can have the benefit of a genial growing temperature till they become strong, when they may either be potted singly or planted out thickly in pits or frames where they can stand till they show bloom. The best can then be selected and the remainder used for bedding, a purpose for which these Begonias are well suited. Next in point of importance to the Begonias are

Gloxinias, which have been so much improved of late, as to render the flowers very large and fine in texture and colour; and although requiring stove heat in which to raise and start them, they will stand well in any ordinary greenhouse during the summer. The way in which the seed should be managed is to fill a pan with sifted peat or a mixture of peat and loam pressed firm and level and then watered through a fine rose, when, after standing a few hours, all will be ready for sowing the seed. This requires the same protection and care as that of the Begonias, and can only be got up successfully by treating it in a similar manner. Gloxinias being shade-loving plants should be placed where they can be protected from sunshine, but at the same time they need plenty of light, and generally do best on a shelf near the glass, where, if they can have a temperature ranging anywhere between 60° and 70°, their growth will be rapid and strong.

Cinerarias have also become greatly improved; instead of the small, thin, narrow petaled flowers which we used to see, they are now round and regular, and often as large as a five-shilling piece. To possess plants bearing flowers such as these it is necessary to obtain seed from good strains. The first sowing should not be made later than March, as plants raised then will flower quite early in winter and last long in bloom. By sowing again early in May others can be had to succeed them and keep up a supply till the spring. The soil best suited for Cineraria seed is a mixture of leaf-mould and loam, which, with the addition of a little well-rotted manure, is also the best in which to grow the plants, as, being light, they can root freely in it and find the kind of food they require. The best place in which to grow Cinerarias during summer is a damp pit or frame with its back to the sun or in a place naturally shaded, as then they can be kept cool and enjoy the full light without shading, conditions under which the leaves acquire great size and substance. To prevent premature flowering they must have no check from want of potting or water, but be shifted on as they require it, and always be kept properly moist at the roots. The only insects that affect Cinerarias are red spider and green fly, the former of which may be kept in check by syringing late in the afternoon during dry weather, and the latter may be destroyed by fumigating with tobacco, which must be done cautiously, or the plants will be injured.

Primulas.—Amongst these there is now great variety, and as few can grow all, the best way is to get a mixed packet of the choicest sorts and sow in April, which is quite soon enough to get them strong and good for the winter. Seeds of Primulas being dear, it is necessary to take great care in sowing them, as any failure in getting them up is very disappointing. The way in which I have been always most successful is having a well-drained pot or pan, and filling it with sifted peat and leaf soil, and after watering, sowing the seed, and just covering it; then I use a bell-glass or lay a piece of ordinary glass over the top. Managed in this way, and placed in gentle heat, every good seed will germinate; whereas when kept wet and slopped with water, nearly all rot. Like Cinerarias, Primulas require shade and moisture, and the two may very well be kept in the same frame during the summer and treated alike, as the conditions that suit the one agree with the other, although it is perhaps best to have them in separate frames.

Calceolarias have not been forgotten by the florists, as they, too, show that great improvement has been made, as the blooms are quite double the size they used to be, and display the

most varied and wonderful markings. The middle or end of June is quite soon enough to sow herbaceous Calceolarias, and the best place to get the seed to germinate is a north or shady border under a hand-light, where it can be kept moist and cool. Being very fine, it should be sown on the surface and treated in the way recommended for Begonias and Gloxinias till the plants are up, and when these are large enough they must be pricked off in light soil and kept close and moist till they get a fresh hold. This they will do in a few days, and in a short time after they will be ready for potting. Light, rich soil is the most suitable for Calceolarias, which, during the whole of summer, require shade and an atmosphere well laden with moisture. This is best secured by having the plants in a frame standing on the ground on a floor of coal-ashes, by sprinkling or watering which every evening a damp, genial air may be produced. In the autumn and through the winter a pit or house is necessary to keep the plants in, and if they have a temperature ranging from 40° to 45°, and a light position near the glass, they will grow very sturdy and strong, and push up fine heads of bloom. As soon as they begin to show signs of this, liquid manure is a great help, but at no time should it be given strong, weak and often not only being the safest, but best.

Cyclamens are also far ahead of what they used to be, and are quite indispensable for the embellishment of greenhouses, flowering as they do in the depth of winter. To have them next year at that season seed should be sown at once in light sandy soil or peat, and placed where it can get a good brisk heat in a stove, where it will quickly germinate; soon after that it will be necessary to pot off singly, when the best place for the plants will be on a shelf near the glass. There they should be kept in a nice growing temperature till about the end of May, after which time they will do well in any cold frame if shut up early after being syringed or damped down. Some plant them out in peat beds in shady places in the open, which is a very good plan as far as old roots are concerned, but to get young, fresh raised ones strong it is necessary to keep pushing them on all the season, and this can only be done under glass.

Celosias are plants that make a fine display, especially the best forms of pyramidalis plumosa, the inflorescence of which is exceedingly graceful and beautiful, and produces a very fine effect in a house where it lasts a long time in perfection. Besides being many shades of scarlet and rose, there is a yellow variety of the above-named Celosia which should be got to grow with the others, as they then show up well by contrast and help to set each other off to the greatest advantage. Unless plants are wanted very early, a month hence is quite soon enough to sow seed, as raised before that time they are apt to draw up weakly and not furnish well at the base. To have them do this later on the plants must be kept well up to the glass in a light sunny position where they can have a temperature ranging between 60° and 70°. The soil that suits Celosias best is a light rich one, such as loam and leaf-mould in about equal parts, and to keep the plants clear from red spider, they must not be allowed to get dry at the roots, and they should be freely syringed overhead.

Balsams still hold their own as decorative plants during the summer, and when well grown are unsurpassed for their general usefulness and the fine show they make, as they flower in the greatest profusion. To have stocky, good plants, seeds should not be sown till April or later, and the plants must be kept well up to the glass and have plenty of room between for the lower branches to spread. In potting it is necessary to keep the collar well down, and also to peg or tie the side shoots so as to bring them low down; if this is done early while they are young and tender, they soon assume a natural position and lose any stiff look they would otherwise have. Balsams, being gross feeders and quick growers, will take a good deal of manure, and if this is quite rotten

and mild the soil and manure may be equal in bulk. The best place to grow Balsams is a light house or pit where they can be plunged in bottom heat and kept with a fair amount of air at the top, which keeps the plants short-jointed and strong.

Petunias make fine pot plants, especially the double and semi-double kinds, both of which can be raised from seed, and if this is sown in March the plants will flower by the middle of summer, if nursed on and got strong. Petunias do best plunged out of doors after the end of May, as the growth they make there is more hard and woody, and produces many more flowers than that made indoors. If kept under glass the plants should have plenty of light, with full sun and a good amount of air, or they are sure to draw and present a weedy appearance. S. D.

PROPAGATION OF THE DAHLIA.

IN large nurseries where Dahlias are propagated to a great extent, the work of propagation has to be commenced early in the year, and a low pitched lean-to house, with a south or east aspect is generally used for the purpose. This is heated by means of hot-water pipes passing along the house immediately underneath the propagating bed, which is raised near the glass. The roots are placed on the bed, and partially, but not entirely, covered with soil; this is kept fairly moist, and when a temperature of from 70° to 80° is maintained, a number of young growths spring up round the crown, and of these cuttings are made. The propagating house is generally at the end of a snug potting shed, so that the tender cuttings should not be brought into contact with cold currents of air, for the Dahlia is a plant of peculiarly tender growth, and is soon affected by cold.

In addition, it is usual to have a series of brick pits sunk below the ground level, so that manure lining can be placed about them to heat the beds. These pits are indispensable, for it is found that the cutting house is required almost entirely for obtaining cuttings, and striking these cuttings has to be done in the brick pits. In these pits a moist heat of about 60° is required, and should be maintained as equably as possible. But let us return to the cutting house. When the shoots are about 3 inches in length, they are taken off close to the roots and inserted in pots containing light soil and then placed in the brick pits plunged in soil. When rooted, and this is a pretty quick result, the cuttings are potted singly into 2½-inch pots, returned to the hot bed, where they are kept close for a few days, and then follows a careful and gradual process of hardening off, so that by the middle or end of April they can occupy a cold frame. The great thing is to keep the plants sturdy, dwarf, and stocky, and this can be secured only by constant care and attention. Amateur cultivators, who require but a few plants, can begin the work of propagation early in March, using for the purpose an ordinary hotbed in which the roots can be placed, and, resting on a bed of soil, be also covered with it, but not to hide the crown. When the shoots are about 4 inches long, the roots may be divided with a sharp knife, leaving a piece adhering to each cutting, and in this way good plants are formed after they have been potted and plunged in the hotbed.

Too much heat or damp must be guarded against, and also, if there is a decline of heat, fresh manure must be added. In all stages of the work of propagation the peculiarly tender character of the Dahlia must be borne in mind, and the effects of cold guarded against. It is surprising what a large demand for Dahlias still exists, though new varieties do not fetch the high prices they did twenty years ago. Dahlias are largely grown by gardeners, and as they can be purchased so cheaply, many find it better to buy than to propagate. The liking for single varieties of the Dahlia will give a great impetus to the work of Dahlia propagation this spring, and, without doubt, increase the demand for the large show varieties also. They are still very popular as border plants, and they are likely to remain so for

years to come, notwithstanding they are subject at times to many disparaging remarks. R. D.

FERNS.

BEST CULTIVATED KINDS.

Adiantopsis radiata (*Cheilanthes radiata*).—This interesting evergreen Peruvian Fern is of a very striking habit, and although closely related to the genus *Cheilanthes*, it resembles much more an *Adiantum* with its beautifully polished slender stems as black and as shining as those of any Maiden-hair Fern. The fronds, which are produced freely from a succulent crown forming a short caudex with age, are of a bright dark green, from 10 inches to 15 inches high and 8 inches or 10 inches across. The pinnae, which in their turn are pinnate, start all from one point, and thus form an uncommonly pretty radiating frond with six to eight branches. This plant dislikes loam. Stove.

Aglaomorpha Meyeniana.—A fine species from the Philippine Islands, also known under the synonyms of *Polypodium* and *Drynaria* *Meyeniana*, from which genera, however, it is perfectly distinguishable by the beautiful fertile portion of its fronds, which hang out so prominently that it gives the plant quite the appearance of what is called one of the flowering Ferns. These fronds, barren in their young stage, with age become all fertile; they average, when in the latter stage, 24 inches to 30 inches long, two-thirds of which are barren, that is to say, the lower portion of the frond, which is also cordate at the base; they are pinnate and of a leathery texture, and produced from a fleshy rhizome covered with light brown shining scales, which add very much to the beauty of the plant. It is, as a rule, a difficult plant to manage in pots, but it thrives apace if treated like a *Platycerium*; either planted on a stump, in a shallow pan, or in a hanging basket, care should be taken that its rhizomes be not buried in the soil, which should be pure fibrous peat, on which they should be pegged down, free scope being allowed for extension. This plant, as curious as ornamental, will soon repay for the extra trouble bestowed on its culture. Stove.

Alsophila.—Although over two dozen arborescent *Alsophilas* are known in herbariums, and many of them are even to be seen in botanical gardens, there are only eight or ten species which are really worth cultivating from a decorative point of view. They mostly come from Australia, Brazil, and the West Indian Islands, and all have a tendency to attain great dimensions; some of them, such as *A. excelsa*, *contaminans*, and *pycnocarpa*, being exceedingly rapid growers, are often seen in their native habitats, where they grow in dark, moist places, with stems 30 feet or more in height; there they produce large heads of magnificent long fronds. To induce them to make equally good growth under artificial conditions it is necessary that the *Alsophila*, as well as indeed any other Tree Fern, should have an abundant supply of water allowed them, which will produce more efficacious results by its being distributed over the stems with a syringe liberally during the summer, taking care to moderate the sprinklings during the winter months, without, however, suspending them altogether. They also require a good quantity of moisture at the roots. Like all other arborescent Ferns, a very little pot room will be found sufficient for *Alsophilas*, which should be potted, tubbed, or, better still, planted out in the houses in a compost of three parts of peat, one of good fibrous loam, and one of sand as coarse as procurable, in which they will delight and grow luxuriantly for years without requiring further attention than constant moisture at the stems, and partially shading especially over the young growths. Those marked "greenhouse" will, during the winter, stand a temperature of 40° or 45°, and prove a valuable addition to the winter garden vegetation.

A. armata, from Brazil, is a very elegant species with a stem comparatively slender and covered

with whitish spines. The fronds, of a pleasing light green colour, are tri-pinnate, often 6 feet or more in length, and of a graceful appearance; their stalks and rachis are also densely clothed with the same white spines as the stems, although of smaller dimensions. In their undeveloped state the fronds are covered with large white and light brown chaffy scales. Stove.

A. australis.—This noble and magnificent Australian Tree Fern is one of the handsomest of the genus. It is also probably one of the best known arborescent kinds, forming a generally very straight stem of great height and well proportioned—neither too slender nor too bulky in appearance. A stem of 15 feet high generally measures about 24 inches to 28 inches in circumference, and produces a somewhat flat head of numerous fronds from 5 feet to 9 feet long, bipinnate and of a light green colour. Their stalks and rachis, although not spiny, are very rough when touched, and covered at the base with dark brown chaffy scales; they are also of a more coriaceous texture than most other Tree Ferns. Greenhouse.

A. capensis.—This very interesting species, from South Africa, is seldom met with in collections, although it is of easy culture and is very attractive on account of a sort of Hymenophyllum or Trichomanes-looking growth covering the crown, and which is produced by the lower pinnae becoming abortive and forming a mass of membranous segments, so that each frond in coming increases the quantity of this peculiar growth, which does not fall with the leaves, but remains behind, giving the stem all the appearance of being covered with Filmy Ferns. The stem is slender, seldom perfectly straight, and rarely attains more than 10 feet in height. It often produces young plants on its sides, being in that respect totally different from the *Dicksonias*, *Cyatheas*, and most of the other *Alsophilas*. The fronds, which are not very abundantly produced, are of a bright pale green and from 3 feet to 5 feet in length; they are tripinnate and serrated at their margins. Greenhouse.

A. contaminans (*A. glauca*).—A very robust species from the Philippine Islands, producing beautifully bipinnate fronds from 8 feet to 12 feet long. The pinnae, set rather loose, are of a very fine glaucous colour underneath, and of a bright glossy green above. Every part of the frond is very brittle. It forms a slender stem, which is said to attain great dimensions in its native habitat, but which to my knowledge has never reached more than 5 feet or 6 feet under cultivation. The base of the gigantic fronds, that is, their junction with the stem, is of a peculiar purple colour, and the stalks as well as the crown are densely clothed with long white chaffy scales. Stove.

A. excelsa.—This species, no doubt the most rapid grower of the whole genus, comes from Norfolk Island. Young plants of it are yearly sacrificed in enormous quantities for indoor decoration, as very little time is required from the seedling state to get them strong enough to be useful for that purpose, but those which are kept and grown on soon make a fine tall stem, producing a fine head of massive upright fronds, often reaching 4 feet in length; they are of a light green, and their stalks as well as the crown of the plant, which is very succulent, are densely clothed with broad, light-coloured chaffy scales. Stove.

A. pruinata.—Although very scarce in cultivation, this beautiful Brazilian species deserves every attention, if only on account of its distinctive characters, which should not be allowed to pass unnoticed. The handsome fronds, which are as glaucous underneath as those of *Cyathea dealbata*, are produced from a thick caudex rather than from a real stem. They are tripinnatifid and very finely cut, of a shining green, and the pinnules deeply toothed at the margins. They grow from 3 feet to 6 feet long; the thick clump generally produces several crowns or heads which can be divided. Greenhouse.

A. pycnocarpa.—A Brazilian species of perfect habit very seldom met with in collections. The stem, which is thick and thorny, rises from 12 feet

to 15 feet in height and produces long bipinnate arching fronds with pinnae and pinnules set far apart, the latter almost lunuliforme and serrated at their edges; they are of a very pleasing green colour and possess the advantage of remaining for a very long time on the plant. Greenhouse.

A. Rebeccae.—This handsome Tree Fern, of recent introduction, is well furnished with broad fronds from 2 feet to 3 feet in length, and arching very gracefully over. They are bipinnate, and their almost black stalks make a striking contrast with the glossy deep green to be seen on the upper surface of the fronds.

A. Van Geerti.—A very distinct and highly ornamental Tree Fern, whose stem never reaches a great height; it is slender, tortuous, of a bright brown colour, and, like the stem of *A. capensis*, produces young plants on its surface, which, after a while, can be detached. Although of comparatively short stature which the stem is, it produces very fine fronds 5 feet to 6 feet long of lanceolate form; they are bipinnate, and have their pinnae deeply toothed; a quantity of short black spines cover the stalks all over, which are of a light brown colour. It is of very good habit, the fronds being conspicuously arched in a very graceful manner. Greenhouse. PELLEA.

ROSE GARDEN.

BANKS FOR TEA ROSES.

THE useful article by Mr. George Paul in last week's GARDEN on raised beds for Tea Roses reminds me that some of the finest Teas I have ever seen have been on banks, and the latter in counties so widely separated as Lancashire, Warwickshire, and Essex. In the two former the Roses were on raised banks of considerable height and area, but quite detached from walls or other buildings. In the latter the bank was in front of a south wall, and fell with a sharp pitch from it. In all the Roses were remarkable for their vigorous growth and abundance of flowers. The additional warmth to root and top was no doubt the chief cause of the more perfect condition of the Tea Roses on banks. Bold banks of earth also afford the best of all protection against wind. This mode of making use of the earth itself in sheltering vegetation has not been developed to anything like the extent to which it is capable. For the purposes of shelter banks are far superior to raised beds, though no doubt these are better for Teas in many cases than level or sunk beds. But in climates such as East Anglia, raised beds or banks must be used with caution and judgment. Inspired by some striking examples, our first rosery here was formed of raised beds, and happening to have a few hot, dry seasons in succession, not a few of the Roses succumbed to the drought, and since then we have mostly got back to a level surface. Still, where abundant supplies of water are available, or the normal rainfall is more ample, raised beds or banks for Teas and other Roses have many advantages. For example, they are more effective in the landscape. One of the strongest arguments in favour of standard Roses is they lift the Rose several feet above the ground, and thus break up the level monotony of the Rose bed, border, or rosery. But by diversifying the surface of the ground to start with, the beauty of the Roses may be made to sweep over hills or undulate in graceful curves through lovely dales, thus immensely improving the line of beauty as well as heightening the effect of every Rose or group by constantly changing the standpoint from which it is seen. For example, how different Roses look in sunlight and shadow looked up to or looked down on, seen near at hand or from a distance, examined singly or seen in masses. Undulating banks would afford rare facilities.

For the tasteful grouping of Roses as well as for their closer approach and more facile enjoyment. The two latter are of great importance. Too often, as at present cultivated, the Rose is al-

most inaccessible to the delicate, infirm, or aged. The dwarfs are too low, the standards too tall, the rosery too far off or too damp to be safely visited at all times, especially at the witching time for Roses—the early morn or dewy eve. Placed on undulating banks, we can get as near to them as we choose; and intersected with dry paths, each Rose or group may be reached at any time of the day or night and in all kinds of weather. Nor must the improved climate on raised beds or banks be overlooked. Mr. George Paul takes note of this in his remarks on raised beds for Teas. Some reckon an elevation of a few feet of little moment in a climatal point of view. It is, however, far more important than appears at first sight. Slight elevations above dead surrounding levels act on the atmosphere somewhat as an upstanding rock, even of small dimensions, on the smooth waters of the sea; the latter breaks the still water into spray. The raised bank or bed does the same to the air, and whatever disturbs its stillness tends to conserve its warmth. Nor is this all; the coldest line of the atmosphere is probably within a distance of from 2 feet to 6 feet of the earth. It may be impracticable to raise single beds bodily above that line. Bold banks may readily be raised above the line of greatest cold, and, besides the unevenness of the ground line, keeping the air in constant motion, prevents it from reaching the low minimum it would reach on level ground. Another advantage of raised beds and banks is the deeper and drier root runs provided for the Rose. The Rose where it thrives, and the Tea Rose in particular, is a deep-rooting plant. It has also a tendency to root more deeply as well as more rapidly on raised beds or banks than on the flat. Various causes may be assigned for this, such as the better quality, greater depth, higher temperature, and drier character of the soil. Where the latter is not allowed to run into aridity, it no doubt favours the rooting of Tea Roses and most others as well, the greater dryness at the root remaining, especially in winter, also furnishing a powerful antidote against severe frosts. No one but practical cultivators familiar with what so often seems the mere erratic doings of the frost and its differing degrees of melting power within a few yards, could have any correct idea as to the wonderful power that dry soil has to arrest and not to augment its destructive effects. From this cause alone, two plants alike in age, character, size, one is frequently taken and the other left; and no doubt, could our rosaries be more generally formed on bold, undulating ground, we should have far fewer fatalities among them, and could grow the Teas and other more tender varieties to greater perfection.

Earthing up Roses.—Permit me to express my pleasure at seeing the advice I have often given in *THE GARDEN*—that of earthing up Roses for protection as one would Potatoes—reiterated by such an experienced rosarian as Mr. George Paul. Practised as he recommends, it not only renders the collars of the Roses frost-proof, but keeps the roots comparatively dry, and hence warm enough to be safe. With safe collars and safe roots, everything is safe with Teas the following season.

D. T. FISH.

VARIABILITY, ESPECIALLY IN ROSES.

It is admitted by nearly all who have studied the laws which govern the vegetable and animal kingdoms that variability is the universal rule. If I say nearly, it is because a very distinguished writer whom I esteem has written recently that reproduction is the rule and variation the exception. But in support of his opinion he has not adduced one example, nor explained why there are not two grains of sand of the same size or the same weight; why there are never two leaves of the same tree identically alike, nor two seeds of the same pod producing two plants in every respect the same; or why we never meet with two twins resembling each other exactly. Time and reflection, and particularly observation, will, it is to be hoped, settle this question. I have been myself for a long while in error respecting it. I attributed the variation obtained from seed to the

interference of insects, and thought that when rambling amongst flowers they carried the pollen from one variety to another and thus produced crossings. But my friend M. Carrière pointed out my mistake, and directed my attention to the natural law of variation. I searched for proofs, particularly amongst Roses, and I soon perceived that nearly always natural fecundation takes place before the expansion of the flower buds, and that consequently the intervention of insects was of no avail.

What makes me desirous to call the attention of Rose growers to this subject is that its evidence, the law of variability, is not generally perceived, principally as regard horticulture, and that because it is in the vegetable kingdom that there is the largest field for study. Is it not the expectation of getting something new by variation that induces us to raise plants from seed? It is in the Rose tribe that variation has without our intervention given us so much delight, by the numerous and beautiful varieties raised since the beginning of this century. This natural result, obtained since rosarians have begun to save seed and sow it, has induced some, and amongst them Mr. Henry Bennett, to have recourse to artificial fecundation, an art yet in its infancy, and often ill practised, but which will certainly lead to the production of marvels, provided attention is paid to judicious selection.

A fact associated with variability which has been often passed unnoticed is dimorphism, commonly called sport or accident. Why a sport? Why an accident? Because the law which has produced it is unknown. Some say that these variations are produced by an unhealthy state of vegetation; others by over-culture. I suspect people who thus reason to be in error, and I tell them, "Seek and they shall find." In the Rose tribe some very remarkable sports have sprung up recently, viz., Mabel Morrison, White Baroness, and Merveille de Lyon, all three with white flowers sprung from Baronne de Rothschild, which has pink ones. Tea American Banner with striped flowers was detected on Tea Bon Silene, and it is very different in habit from the type. Lately, too, Mr. Peter Henderson, of New York, wrote to me that he has found dimorphism in the case of Tea Rose Perle des Jardins, the sport having the colour of Tea Madame Falcot. It is very likely that until lately very often such sports have occurred without being noticed, and will occur again. I therefore invite rosarians, particularly amateurs, who have leisure to pay attention to the slightest deviation they perceive, and to endeavour to fix it by means of budding or grafting.

JEAN SISLEY.

Monplaisir, Lyons.

PLANTS IN FLOWER.

KENNEDYA MARRYATTIANA, the pretty greenhouse climber to which we drew attention some time since, is now in flower in the Camellia house at the Victoria Nursery, Upper Holloway, trailing beneath one of the rafters of the roof. The bright carmine-red of the large Pea-like flowers at once arrests attention at this dull flower time.

RIBES SPECIOSUM.—A plant of this on the herbaceous ground wall at Kew is now producing a number of blossoms, thus anticipating its usual flowering season by some months. Doubtless the mild winter we have had up to the present has induced this early display, but the blooms do not now stand out so conspicuously as when the plant flowers in its proper season.

BOMAREA CONFERTA.—This plant, the subject of our coloured plate this week, is now beautifully in flower in Sir Trevor Lawrence's garden, at Burford Lodge, Dorking. A fine specimen of it in a huge pot in one of the greenhouses covers a considerable portion of the roof space, and one of the shoots is terminated by a dense drooping umbel numbering between twenty and thirty blossoms, while two other shoots bear umbels of buds almost as numerous. The colour is not so

high as that shown in our plate, but this is no doubt attributable to the season. The summer flowers are quite as rich in colour as that shown in the plate. The value of Bomarea for greenhouse decoration is well seen at Burford Lodge, where we noted a fine, vigorous plant of B. Carderi, likewise an extremely handsome plant.

LEUCOPOGON CUNNINGHAMI, an old-fashioned Australian shrub, is not by any means a common plant, and certainly is not so much appreciated as it might be. In winter its twigs, furnished with numbers of tiny white blossoms, are admirable for mixing with other cut flowers. It is a neat-growing shrub of simple culture under ordinary greenhouse treatment. We saw it in bloom the other day in Messrs. Laing's nurseries at Forest Hill.

A SEEDLING **BOUVARDIA** sent to us by Mr. Balchin, Hassock's Gate Nursery, Keymer, is a beautiful variety, with flowers of a delicate rose, very similar to those of the new sort called Priory Beauty. Mr. Balchin states that it is "a cross between Rosalinda and Umbellata carnea. It has a very dwarf, compact habit, very free flowering, and a good, hardy constitution." The brilliant Bouvardia Dazzler originated at this nursery a year or so ago.

HIBISCUS LAMBERTI is the name of an extremely fine double-flowered variety which we saw in full beauty at Burford Lodge the other day. The flowers are very double, and as large as Perpetual Roses usually are. The colour ranges from deeper crimson to a lighter and brighter tint, varying apparently with the age of the flower. The plant is bushy in growth, vigorous and floriferous, and particularly welcome in a stove in midwinter. It is no doubt a double variety of *H. rosa sinensis*.

CAPE PONDWEED (*Apocyneton distachyon*).—This aquatic plant possesses the merit of flowering almost continuously, several blossoms being expanded in a tank in the herbaceous ground at Kew, and although, owing to the heavy atmosphere, not quite so pure in colour as when under glass, nor the Hawthorn-like perfume so strong, yet its winter-blooming qualities give it a great advantage over its associates. Being, as it is, a native of the Cape of Good Hope, its hardiness is all the more remarkable.

APHELANDRA PUNCTATA.—This new South American species, pretty both in foliage and flowers, is now in bloom in Mr. Bull's nursery, Chelsea. It has erect stems furnished densely with leaves, beautifully variegated with silvery veins and markings on an emerald green ground. The flower-spike terminating the stems consists of closely arranged, long tubular flowers of a clear chrome yellow, while the bracts which accompany them are of the same colour tipped with green. It is quite out of the ordinary run of ornamental plants, and one particularly valuable in winter. It thrives under the ordinary conditions of stove plants.

A **DOUBLE EUPHARIS AMAZONICA** has been sent to us by Mr. Vicary, Mr. Peacock's gardener at Sudbury House, Hammersmith. It is not double in the ordinary sense of the term, but a fusion of two flowers, one within the other. It is twice the ordinary size, has twelve petals, a corona $1\frac{1}{2}$ inches across, twelve stamens, and two pistils and ovaries fused into one. It is an unusual production, and if a variety bearing such flowers as these could be fixed it would be an acquisition. The Eupharis is seemingly grown well at Sudbury House, for Mr. Vicary informs us that he has cut during the last month some 150 blooms.

BEGONIA ROEZZI.—Last year when we saw this plant in Sir Trevor Lawrence's garden at Burford Lodge we spoke of it in high terms, and a sight of it the other day even more deeply impressed us with its extreme elegance of growth and beauty of colour. To those who know it not it may be best described as almost the counterpart of the well-known *B. nitida*, only instead of the flowers being white they are bright cherry rose, a colour which in contrast, or rather harmony, with the ample green foliage produces a most

charming effect. Mr. Bain, Sir Trevor's gardener, evidently knows well the requirements both of *B. Roezli* and *B. nitida*, for he grows them far finer than we have seen them elsewhere; indeed, we have rarely seen such a lovely floral sight—no, not even in the Orchid houses adjoining—as a group of a score or so of large plants of these two *Begonias*. They range from 3 feet to 5 feet in height, and their tall slender stems carry wide-spreading clusters of flowers. The two colours, (white and cherry red) are charming mixed as they are here. The plants are growing in a moderately warm stove, and it would be interesting to know further how Mr. Bain deals with them as regards culture.

THE BOTTLE BRUSH PLANTS are very different in character from most others, their flowers being arranged round the shoots towards their ends in the shape of a dense bottle brush. Under this head are included the *Beaufortias* and *Calothamnus*, besides the *Callistemons*, a fine large bush of *C. rigidum* has been flowering throughout the winter in the temperate house at Kew, and has at the present time six or eight expanded clusters on it, besides a great many more to open. These bright, glowing, crimson masses of flower are produced much earlier than usual, but they are doubly welcome at this dull season.

HARDY FLOWERS IN JANUARY.—Of hardy flowers in season, we have now (January 22) as many as are wanted for the decoration of a sitting-room—a large bowl of Christmas Roses, with dark red foliage of *Berberis Aquifolium*; long and short sprays of *Jasminum nudiflorum*, with *Alexandrian Laurel* and large-leaved, dark green *Ivy*; a bunch of *Iris stylosa* by itself, with its own narrow, sword-like leaves; *Chimonanthus fragrans*, filling the room with sweetness, and a bright golden bunch of winter *Aconites*; *Czar Violets* in profusion; *Snowdrops*, *Crocuses*, and *Cyclamens* of winter-blooming species; *Anemone coronaria* and *fulgens*, and good bunches of *Primroses* and *Polyanthus* anticipating their true season, but as strong as in spring.—G. J.

SOLANUM JASMINOIDES FLORIBUNDUM.—Such is the name we saw attached to a variety of this old-fashioned greenhouse *Solanum* the other day in the garden at Burford Lodge—a name which the plant well justifies, for while yet in a small state only about a yard high it is bearing a copious crop, consisting of clusters of white flowers. Usually this *Solanum* does not flower until it has grown into a tall plant, but this variety being dwarf can be grown in pots on a stage, and is a useful subject for affording white cut flowers in winter and spring. If not absolutely new, it does not seem to be much known, for we have seldom met with it elsewhere.

SOLOMON'S SEAL.—When forced into bloom under glass the flowers of this are whiter than when they expand naturally in the open ground, and the plants form very pretty objects for conservatory decoration at this season, besides being useful in a cut state, as from the size and graceful appearance of the sprays they can be employed for large stands or vases, which are as a rule difficult to furnish satisfactory at this time of the year. For forcing clumps of them they may be potted just as they are grown, or the strongest eyes may be selected and potted about half-a-dozen in a 6-inch pot, or if larger specimens are needed both the number of the crowns and the size of the pots may be increased. This latter method is in one respect greatly to be preferred, as when potted in clumps just as they are grown, the mass is often of an irregular shape, which necessitates a large pot being used in proportion to the size of the plant, while when the strongest eyes only are taken they do not require so much pot room. Treated about the same as its relative, the *Lily of the Valley*, it will succeed perfectly. The conservatory (No. 4) at Kew now contains some good forced examples of this plant.

NERINE ERUBESCENS.—Mr. T. Cam, Hereford, sends us a plant of a new hybrid *Nerine* bearing this name. He says: "It has been produced by fertilising *N. undulata* with the pollen of *N.*

flexuosa, the result of which has been a winter flowering variety of a uniform blush colour and an increase in size. The petals are crisped, and the deeper coloured midrib, which is present in the other light coloured varieties of this *Amaryllid*, is absent; the foliage is evergreen, and consists of long pointed bright green leaves; the bulb is nearly globular. [It is a delicately pretty plant, and being a winter flowerer is a welcome acquisition.]

CHRYSANTHEMUM WHITE VENUS.—I send you flowers of this variety, which I find to be one of the very best to grow for late bloom. Being fully aware of its excellent qualities, I recommend it to the notice of others who may be in want of a really good late white *Chrysanthemum* that will without fail give satisfaction. I have to-day (Jan. 23) gathered a fine basketful of flowers from plants of it, and have taken promiscuously from the basket the blooms I send you. They are not "giants," but, as you will observe, they are large enough for purposes of general decoration.—JOSIAH JEFFREY, *Derry, Rosseberry, Co. Cork*. [Lovely flowers of one of the purest white sorts of incurved *Chrysanthemums*.]

SIX-SEPALED HELLEBORE.—I send you a few *Hellebore* flowers gathered from the open, and grown under the name of *H. niger*. I wish to direct attention to the six sepals in several instances, the extra one being a converted bract, though it is so close to the flower as to be barely distinguished from the normal sepals. Then on the single flowered stem may be observed a bract with a development in the opposite direction, viz., a rudimental floral leaf such as accompanies the flowers of the coloured species. Again, the leaf sent is far from the usual form, being very irregular; some of the segments are obovate, all are jagged, and nearly as sharply toothed and pointed as in *H. argutifolius*. The flowers are mostly in pairs, and I have seen three sometimes. I should like to know if such sports have been observed by others of your readers, and if you think they are caused by some cross or cultural conditions, or what?—J. WOOD, *Woodville, Kirkstall*. [We have not observed the peculiarities here referred to before.]

Preservative for fungi.—Three years ago I invented what I think a very good and cheap liquid for the preservation of fungi, composed of the following ingredients: $\frac{1}{2}$ ounces of common salt; 5 ounces of pulverised alum; and 1 quart of white wine vinegar. Mix thoroughly, and keep in a wide-mouthed glass jar. Brush off any dirt that clings to the fungus, and drop the freshly gathered plant into the liquid. I have beside me a large jar of plants collected in the summer of 1879. They are now in a perfect state of preservation. They have diminished somewhat in size, but their structure is preserved, and the larvæ are effectually destroyed. The liquid often gets filled with sediment and floating particles, to free it from which I pour it off, strain it through a piece of thin muslin and return it to the plants.—M. E. BANNING, in *Proceedings of the Torrey Club*.

Testing seeds by fire.—In the purchase of seeds one is apt to be deceived. A correspondent of the *Journal d'Agriculture Pratique* recommends a test which he has used for many years with complete success. It is that of fire. Take a number of seeds from the sample, put some live coals on a shovel and deposit each of the seeds successively on it. Blow the coals and watch how the seeds behave. If the combustion is slow, merely giving off some smoke, you may conclude that the seed has a damaged germ; if, on the other hand, the seed leaps and turns about on the coal, producing a dry sound proportional to size, it may be inferred to have good germinative qualities. In this way the proportion of good and bad seeds may be ascertained. As for the larger seeds, such as Acorns and Chestnuts, it is sufficient to throw them into a fire and keep them in view. If the quality is good, this will be very plainly indicated ere long by the detonation of the seeds.—T. C. W.

TREES AND SHRUBS.

RAISING FALLEN TREES.

THE reinstating of large trees is more simple and easily accomplished than is generally supposed, at least judging from a little experience we had in this way lately. During the memorable gale of October, 1881, when so many fine trees were uprooted all over the country, amongst others in the park here were several large specimens of the Cornish Elm, one of which could ill be spared from the surrounding landscape. Resolved, if possible, to reinstate this tree, the attempt at which has been quite a success, I venture to give the mode of operation, which may perhaps prove interesting, if not useful, to others having a similar undertaking, especially as replanting large trees when blown over is rather a novel feature in forestry. Before attempting to raise this tree, which was about 50 feet in height, 15 feet were cut from the top, which not only lessened the weight, but also left less surface exposed to the storm.

Special facilities were afforded for raising this tree, as growing alongside were others to which the blocks and tackle used in lifting were attached. These being affixed, and also ropes from the top of the fallen tree to one on either side as guides; a number of men were put to the rope to which the blocks were attached, and, by steady pulling, succeeded bit by bit in raising the tree to its former perpendicular position, the soil beneath the roots having previously been excavated and a bed prepared for its reception. The large roots were then firmly pegged down and all re-covered with soil, a coating of decayed leaves being placed on this to prevent the too speedy evaporation of moisture. Three double wires were stretched from the top of the tree to the base of others in close environ, one on either side and one directly opposite that on which the tree had fallen, and, being twisted to the tightness required, served not only to keep the tree in proper position, but also to prevent unnecessary strain on the roots when swaying with the wind. The tree thus operated upon, as well as others of less size, have all done well, and during the present season had not the least appearance of having been reinstated from the fallen position they occupied less than twelve months before.—A. WEBSTER.

Variegated Oak tree.—I have under my care a magnificent variegated Oak tree, which is much admired, being when in leaf nearly white, but I am at a loss to know how to propagate it. Cuttings do not succeed; Acorns from it have been planted, but when they have grown up the foliage has been green like that of any other Oaks. It is a large tree, the trunk measuring 6 feet 6 inches in circumference. It has been budded or grafted 1 foot above the ground. I am very anxious to get some young trees from it. Suppose I graft it, when is the proper time to select the grafts? and is the grafting performed as in the case of other trees?—E. B.

Fungus on evergreens.—The remarks of "W. G. S." on *Capnodium Footi* are very interesting and quite in accordance with my own observations. Although this fungus is frequently accompanied by scale insects, and undoubtedly grows with greater luxuriance where the excretions of these are present, yet the presence of the one is by no means necessary for the growth of the other; indeed, I have repeatedly found the fungus without the scale and *vice versa*. This fungus appears to spread rapidly, for since my communication about it nearly twelve months ago, when it so badly disfigured the *Ivy* on the castle here, I have found this fungus abundantly on the following trees and shrubs, with the scale insect as often absent as present, viz., *Sycamore*, *Beech*, *Holly*, *Aucuba japonica*, *Bay*, *Laurel*, and *Ivy*, the two latter being perhaps the worst infested. The rapidity with which it spreads, and the disagreeable sooty appearance of the plants infested by it, lead one to ask if no remedy but destroying the foliage has been found effectual.—A. D. WEBSTER, *Penrhyn Castle, North Wales*.

SPIRÆA FLAGELLIFORMIS.

A GLANCE at the annexed illustration will make our readers better acquainted with the elegant beauty of this *Spiræa* than any written description could possibly do. It is, we consider, one of the most beautiful of all *Spiræas*, and unquestionably the finest of the white flowering kinds. We met with it last summer in Mr. Joseph Stevens' richly stocked garden at Grasmere, Byleet, and thought at the time that we had rarely seen a shrub possessing such a combination of gracefulness and beauty. From a spray of this bush our drawing was made. It is a slender growing, viry twigged shrub, ranging from 3 feet to 6 feet in height in favourable soils and localities. During the latter part of May and the beginning of June each of the preceding year's shoots is densely wreathed with small, erect clusters of white flowers as in the spray shown in the illustration. When a good sized bush is thus furnished with blossom its beautiful appearance may be better imagined than described. This *Spiræa* belongs to that section of the shrubby class characterised by their flowers being produced in hemispherical corymbs or loose umbels. The species and varieties belonging to this section are more numerous than in any other, and unfortunately there exists a good deal of confusion with regard to their names, and more especially as respects the particular species around which the plant we illustrate and several other varieties rally. This species is undoubtedly *S. hypericifolia*, so named on account of its foliage resembling that of some of the smaller kinds of St. John's Wort. The general appearance of *S. hypericifolia* is very similar to our plant, but it is much less floriferous, and it differs from it in several other particulars. *S. flagelliformis* is no doubt a garden name for a distinct and handsome variety of this species, but even with regard to this name some confusion exists, as Mr. Stevens has the plant under the name of *S. platyformis*, probably a corruption of *S. flagelliformis*, the latter a recognised name on the Continent, where we imagine the variety must have originated. It is in the collection in the Kew arboretum in company with the allies, or possibly synonyms of *S. hypericifolia*, but the variety we figure may be singled out easily from all the rest. The most noteworthy of these allied kinds are *S. crenata*, *pikoviensis*, *acutifolia*, *confusa*, and *nuttans*, all of which are tolerably common. The names under which *S. flagelliformis* might possibly be found in gardens and nurseries are *S. adiantifolia*, *vaccinifolia*, *rhombifolia*, and *foliosa*. There seems to be some misapprehension, too, respecting the native country of *S. hypericifolia*; some hold that it is a Canadian, or, at least, a North American plant; others, again, assert that it is European.

Be this as it may, the plant here illustrated is one that everybody should endeavour to secure, and the best way in order to this end would be to see it when in flower, or a spurious imitation may be sent instead. Mr. Stevens, we believe, got his plant from either a French or Belgian nursery.

As to its culture, nothing need be said scarcely: it is not at all fastidious as to soil, and is hardy enough to brave even the worst of our winters. However, it is grateful for liberal treatment as to soil, and at planting it is advisable to put it in a good mixture of turfy loam, made still richer by the addition of a little good decayed leaf mould, or, better still, a little rotten manure. In material of this description the young plant will grow apace and make long, vigorous shoots, and in a year or two it will have exhausted the goodness of the soil considerably, and then it will begin to yield a yearly crop of wreaths of snowy blossoms. It should not be placed in a shrubbery, but should occupy a prominent position where it can get plenty of light and air and be seen to advantage.

EVERGREEN WALL SHRUBS.

Cratægus Pyracantha.—Few hardy evergreen plants excel the *Pyracantha*. It is so thoroughly hardy that it will thrive in any position, and it is not very particular as to soil, but the better and deeper the latter is the more satisfactory does the plant grow, and its dark glossy foliage is always an agreeable sight, while its bright red berries when ripe make it one of the most effective of wall plants during the winter season. It may be raised either from seed or layers, but it is so inexpensive to purchase, that it is hardly necessary to wait for home-raised plants. It is grown in pots in most nurseries, and may, therefore, be planted at any time, but perhaps April and September are the best months in the whole year to select for planting it. If received in pots it is necessary to thoroughly disentangle the roots before planting, and to spread them out over a bed of fine soil, covering them with the same material after planting. Be patient for a year or two; the plants do not make much headway the first year and not over much until the third, but after that they ought to make vigorous

shoots, and in a few years cover a moderately large space. I have known a strong plant to reach a height of 12 feet on a north wall, and I think that is about the height it can be reckoned to grow. Many do not succeed with the *Pyracantha* so well as they might do, because it is pruned with a total disregard of its requirements. The best time to prune it is in February, when the berries begin to fade; those branches which have produced fruit should be cut quite out or shortened back as the shape of the tree will best admit. Much of the old wood that has borne fruit should be removed to make room for young growth. If it be borne in mind that the plant flowers, and as a result bears fruit on the preceding year's growth, we have the key to the proper system of pruning required. It is a common oc-

currence to see all the branches at the top of the tree well laden with bright red berries and none at the bottom, but this need not be so to such an extent as it commonly is, if some of the lower branches were cut away or rather shortened back well to induce young growth, which will in due time both flower and fruit, and as a consequence the tree will have a better appearance. To preserve the fruit from birds which frequently attack it in a most determined manner, as early as November we have to spread over the trees a piece of 1-inch fish net, which we do not find detracts much from the appearance of the fruit.

Cotoneaster microphylla.—For covering low walls from 4 feet to 6 feet high in any aspect with a dense mass of dark green growth there is no hardy plant equal to this, and it is sometimes very bright in appearance, as, for instance, when it is in flower in the spring and early in winter, when gaily clothed with cheerful red berries. With the aid of a little training it adheres close to the wall and really gives but very little trouble, and if a little extra attention is paid to it, it may be so trained as to form any desired figure on the wall. I remember once seeing the name of a village very clearly shown on the wall of a cottage garden by means of this plant, the branches forming the letters, and those who know anything of its accommodating character will not consider that any difficult feat was accomplished, as it bears clipping and pruning with impunity.

C. Simonsi.—Although this makes a good climber for a wall of moderate height, I do not consider it equal to the preceding. It grows more rapidly, but does not show such an even, close growth. I find that it fruits freely when grown as a bush in the open, but it does better on a wall, and its berries are acceptable, and have a cheerful appearance in the autumn months.

Ceanothus azureus.—In the west of England and also in many parts of the south this fine plant passes through a severe winter unharmed, and when it does so we have few things to compare with it, for it flowers freely and the leafage is ample. A warm south or west wall should be chosen for it. In a good deep soil it will reach a height of from 12 feet to 14 feet. It requires rather careful pruning to induce it to flower regularly all over the plant. It is best not to prune it until March, and then to nail in a fair proportion of the last year's wood, and to cut out some of the old, as it is the young wood of the previous year that principally produces the flowering shoots. It is a plant of quick growth, and requires rather a large space in which to develop its branches in a proper manner.

Escallonia macrantha.—This well-known evergreen admits of being grown either in bush form or as a wall plant. It is fairly hardy in most parts of England, and is not very particular as to soil; if not wholly composed of a stiff cold clay it does not want any special preparation made for it. On walls from 6 feet to 7 feet high its flowers look cheerful in summer and its leaves have always a bright green appearance. What pruning it needs should be done early in April. Thin out some of the old exhausted shoots to make room for young growth, and shorten back some of the growth that is always freely produced near the main stem and largest branches.

Berberis stenophylla.—In a position well drained and where the soil is rich and deep this Barberry makes a capital climber. It is perfectly hardy and flowers with great freedom for several weeks together during summer, when it is an admirable subject to cut from, as its lovely flowers studded thickly on arching lateral branches are capable of being turned to good account in the decoration of vases, &c. In the proper sense of the term it is not at all a creeper, nor do I recommend it for walls that are more than 8 feet high, but with moderate care it can be trained so as to make a beautiful object, as its growth is not so formal as the general run of creepers. As soon as it goes out of flower is the proper time to prune it, and then some of the old growth must be removed to make room for the young.

Magnolia grandiflora.—This makes an imposing wall plant. In a rich deep soil and in warm localities it frequently reaches a height of from 16 feet to 20 feet. It requires time to produce a good sized plant, as at first it is of slow growth. In all doubtful cases the soil should be specially prepared for it; a hole 3 feet deep and 6 feet wide should be dug for it, and if there is any choice of soil select the top spit of an old pasture field, regulating the depth according to its composition; then let it be stacked in a heap for six months before using it, and as regards the future progress of the plant, it does not object to a bit of well-rotted manure. About every second year we fork in over the roots one or two barrowloads, and the way in which our plants grow shows that they like it, but our plants are large, covering many square yards of wall, and reaching a height of 14 feet. In dealing with this *Magnolia* we find the greatest difficulty in keeping it against the wall. For several years past we have used large nails 5 inches long and strong tar cord; this secures the branches firmly. Young plants should not be pruned at all, and old plants do not require much done to them in that way. It is advisable sometimes to cut out a branch where too thick, but not otherwise. Plants of this description do not like much disturbance at the roots; therefore they should be only planted where they are likely to remain for some years, and in a general way it is better to plant young and vigorous plants than to renovate old ones. They are best planted in April, and they should receive some protection during severe weather the first year after being planted.

Broad-leaved Myrtle.—All along the south coast, as well as in the western counties, this Myrtle will withstand a severe winter on warm south walls if protected by frigi-dome during severe frost, and few wall plants are more appreciated, as old plants flower freely and their foliage is always in good condition. It requires a good deep soil and should be kept trained close to the wall. Here in the west we rarely protect it at all, and it thrives without it. Further south I have known it to reach a height of 10 feet in warm aspects with no other protection than that which has been mentioned, but it was put on about the end of November, and allowed to remain over the plants until the beginning of March. Very little care in pruning will keep this Myrtle clothed with foliage from top to bottom.

Benthamia fragifera.—This plant is much hardier than it is supposed to be. We have it here on a wall with an east aspect, reaching a height of 12 feet. It passed through the severe winters of 1880 and 1881 unharmed without any covering, and I think a plant that will endure 26° of frost with only the points of the leaves injured is not likely to suffer much if the thermometer should go down to zero. Even this winter we have experienced 16° of frost, and still our plant looks as fresh as a common Laurel which stands only a few yards distant. This *Benthamia* is altogether distinct from any other evergreen. Its growth is rather stiff, and there is a greyish appearance about the leaves quite different from that of any other plant. With us it grows in a very luxuriant manner, and although it flowers in very warm summers, it has not yet matured any fruit. It is not at all particular as to soil, but no doubt it would do better on a south wall than in any other aspect. I should say it is just the plant for those who have glass-covered verandahs or balconies, and who may want to cover the walls with evergreens. On the Devonshire coast the *Benthamia* may be seen occupying positions in shrubby borders, and in warm situations it fruits freely, and is then very effective.

Euonymus latifolius.—On warm walls and in districts somewhat favoured as to climate I believe this *Euonymus* will prove a very acceptable plant for walls ranging from 4 feet to 7 feet in height. It is, in my opinion, the brightest of all the Spindle trees. With us as a bush in the open border it has grown to a height of 5 feet, and I have no hesitation in saying that in a climate equal to that in the neighbourhood of

Taunton it will, in a good soil, reach a height of 12 feet. To make room for other plants, I quite recently had to remove from a south wall a plant of it that had grown to the height of 8 feet. During the winter months this plant was the brightest of all our occupants of walls, and I miss it immensely for cutting from, as during the winter it was bright and cheerful, its well defined and silvery variegation affording a capital contrast to that of the golden *Eleagnus* when placed side by side. *E. radicans variegatus* makes a much better wall plant than its first appearance indicated. With us, against a warm south wall, it has grown to a height of 10 feet, but in order to induce it to grow upwards it required to be planted thickly, and the soil must be rather light and of a good depth. On our soft sandstone walls it supports itself almost as well as the Ivy. J. C. C.

FLOWER GARDEN.

GLADIOLUS FAILURE.

"DELTA" has striven long and manfully against the inevitable, but it seems that his own collection as well as that of Mr. Banks, of Deal, is in much the same condition as mine at Loxford. For my own part I have long arrived at the conclusion that money spent on *Gladiolus* bulbs is little better than wasted. I came to this conclusion some years before "Delta" did, and for saying so in the pages of THE GARDEN and elsewhere incurred a considerable amount of criticism. It is pleasant to look back to the time when "Delta" and myself were the principal private exhibitors of *Gladioli* at metropolitan exhibitions, and I do not think it probable that I could have competed successfully with "Delta" but for the large number of seedlings which I raised annually. We are not likely to have such exhibitions in future, but what has been done once may be done again. Before finally giving up the culture of the hybrid varieties of *Gladiolus gandavensis*—for it is of those only that I and "Delta" write—I tried many different ways to attain success. I believe Mons. Souchet does not grow his bulbs two years in succession on the same ground, and, in fact, finds that it answers best to allow his *Gladiolus* ground to remain fallow for a year. We were always most successful with them when we trenched the ground in September, even if a crop of something had been grown on the land the previous summer. I always put in two layers of manure, one at the depth of 18 inches, and the other 9 inches below the surface; the best manure is that from the cowhouse and stable mixed together in equal proportions.

Seedlings are easily raised, and good varieties can be obtained if some judgment is used in crossing them. It is almost certain that if we are to have beautiful varieties of the *Gladiolus* in our gardens in future, seedling raising must be carried out on new lines. Hitherto there has been but little done in the way of crossing distinct species, or introducing new blood into the varieties of *G. gandavensis*. The late Mr. John Standish made an attempt to do this by introducing the blood of *G. cruentus* and some other distinct species into the best forms of *G. gandavensis*. As was naturally to be expected, the first produce of this cross was not up to the standard of the best named varieties, the flowers were much smaller and not so well nor so thickly placed on the spikes, and from the standpoint of the florist they were considered a failure. Later Mons. Lemoine has given us the result of crossing *G. purpureo-auratus* with the *gandavensis* section, and several beautiful varieties have resulted therefrom. What we want if we can get it is

A more hardy section that will not only endure our winters in the open borders, but will also thrive, if left undisturbed, for years in the same place. Plants are doubly interesting if they can be established in the garden; one gets at last to welcome them as old friends as they push through the ground in due season. I have known

some of the species to remain in the same place in rather a sheltered corner for nearly twenty years. At Loxford a plant or rather clump of *G. Colvillei*, or a form of that species, has flowered annually for that time in a sheltered corner. I have also known certain species grown as border flowers in Scotland. Probably it would not answer as a commercial speculation to undertake the crossing of different species of the *Gladiolus*; the only result possibly would be the pleasure to be derived from such work, and to most amateurs this would be quite sufficient. The only one who treated the

Gladiolus as a hardy plant, and practised hybridisation from that point of view, was Dean Herbert, and his success ought to encourage others to labour in the same direction. He found them succeed well in the ordinary yellow loam of his garden, and also in artificial borders of peat and sand, but in the latter they required more water in dry summers than in the loam. His crosses of *G. cardinalis*, *blandus*, *carneus*, *inflatus*, *angustus*, *tristis*, &c., gave him flowers of every shade of colour, such as white, scarlet, rose, purple, copper colour, and the crosses of *tristis* afforded beautifully speckled flowers. The above were planted out and allowed to remain for years in the same place, giving, as he says in his work on "The Amaryllidaceæ," a "profusion of blossom and contributing quite as much to the embellishment of his garden as the Rose." His treatment of seedlings was the same as that which I have previously recommended in THE GARDEN. With the hardy sorts, he says: "Sow the seeds in pots and give them shelter until the seedlings are pretty strong; then turn out the ball unbroken into the border, where they will produce a crowded nosegay of flowers of various shades of colour." The Dean's seedlings also flowered the first autumn. Evidently both climate and soil were in their favour. It is nearly half a century since "The Amaryllidaceæ" was published, and probably the result of Dean Herbert's work is now lost; but it is evident that we have better material to work with now than was available then. There are greater numbers of distinct species, and the varieties of *G. gandavensis* are of almost every shade of colour combined with beauty of form. J. DOUGLAS.

MULCHING HERBACEOUS BORDERS.

In the majority of cases these are dug up in winter—a mistaken practice, unless done for the purpose of dividing and rearranging the plants, as the digging, especially when done with a spade, breaks or cuts the greater portion of the roots, and thus does serious damage. Hardy as most outdoor herbaceous subjects are, they are all the better for being protected, and the easiest and most natural way of doing this is to top-dress the ground among them, and the most suitable material for doing this is leaf mould, of which all plants are exceedingly fond. Besides being highly congenial to them on account of the rich vegetable matter which it contains, it is one of the best non-conductors that can be had; from 1 inch to 3 inches in depth of it will keep out the severest frost, which gives it a double value. The only thing that equals it as a protector is

Cocoa-nut fibre, a good substitute for leaf soil, but when used to shelter plants care should always be taken that it does not become mixed up in the ground, as when thus buried there is always danger of its generating fungi. With leaf mould there is little or no risk, as its decomposition being so much more rapid, fungi have no time to form; whereas Cocoa-nut fibre lies for years in the soil. For all this, it is exceedingly useful for placing round the collars and up the stems of such plants as *Pentstemons* or *Antirrhinums*, or for surfacing beds of *Alstroemerias*, *Belladonna Lilies*, *Tritonias*, *Ixias*, or other bulbs of doubtful hardiness, as in the spring it can easily be raked or cleared off and laid by or discarded. Where leaf soil is scarce the most economical way of applying it is to heap it over the crowns of the plants, and in order to prevent birds

from disturbing it it is a good plan to stick a twig or two of Gorse or other evergreen close around it, which will not only keep the leaf soil in its place, but hides its rather unsightly appearance.

Re-arranging the plants.—If the plants are crowded or irregular as regards height and size, and require re-arranging, the best plan is to take the whole up and then trench the border, laying them in and covering them while the work is going on, so as to prevent any drying of the roots or damage to them by exposure to frost. In trenching a good dressing of rotten manure should be worked in, but in doing this it is always advisable to keep it well down, as then the roots go down to it, and the plants are thus enabled to endure dry weather better than they otherwise would do during the summer. Phloxes and similar subjects will be much improved by division of the clumps, which may be effected by cutting them through with the edge of a sharp spade or large knife, selecting the strongest and best parts for planting, when any to spare may advantageously be made use of to adorn shrubby borders or woodland walk borders, where strong-growing kinds hold their own and look well. S. D.

LIST OF PRIMULAS.

It may be interesting to know how many of this beautiful genus of plants are known in a wild state up to the present time, both genuine species and hybrid kinds; also the synonyms and other kinds in culture. Those marked with an asterisk (*) are only known to me by description; the others are cultivated here.

A.—GENUINE SPECIES OF EUROPEAN ALPS.

<i>acaulis</i> (Jacq.)	<i>intricata</i> (G. G.)

I am unable to give here all the names of varieties cultivated in gardens and of species insufficiently known. H. GUSMUS.

Villach Botanic Garden.

SELECT HARDY PERENNIALS.

ONE of the chief reasons why gardening has so large a number of devoted followers is doubtless its great variety of work, or, if one may so express it, many-sidedness, not to mention the changes anent the varying phases and fashions that in a greater or lesser degree take place every year. At present Orchids and Chrysanthemums are all the rage; last year it was Sunflowers, single Dahlias, and Marguerites; previous to that it was carpet bedding; and prior to that succulents, sub-tropicals, and Pelargonium, Calceolaria, and Verbena bedding, all the various branches having numbers of devoted admirers; and this is as it should be so long as space for the expansion of gardening ability remains (as it always will) an unlimited quantity. Certainly as regards the branch of gardening that forms the subject of this paper we seem to be going at express speed, for on every hand one hears enquiries for hardy flowers, and more particularly for single flowers, such as the Japanese Anemones, Rudbeckias, Geums, Poppies, Hellebores, Irises, and Lilies. This single flower mania is but a passing nod to fashion, for every species that helps to make a garden cheerful for the longest period will be equally highly prized a year or two hence, and all who do not wish to be left in the rear in this matter would do well to set about making a selection (not collection) forthwith. Taking into account length of flowering season and showiness or effectiveness, the following are

The best of the kinds grown by us, viz., *Acanthus latifolius*, *Anemone alpina*, *A. japonica* and its white variety, *Aquilegia chrysantha*, *A. cœrulea*, *Aubrietia purpurea*, *A. purpurea variegata*, *Bocconia cordata*, *Caltha palustris fl.-pl.*, *Campnula glomerata alba*, *C. rotundifolia pallida*, *C. turbinata floribunda*, *Cypripedium spectabile*, *Delphinium nudicaule*, *Dodecatheon Media*, *Funkia marginata*, *F. Sieboldiana*, *F. grandiflora*, *F. argentea vittata*, *Gentiana acaulis*, *G. verna*, *Geum coccineum fl.-pl.*, *Geum pyrenaicum*, *Helianthemum*, several kinds; *Iberis corifolia*, and other kinds; *Linum leuteum*, and other sorts; *Lithospermum prostratum*, *Lychnis chalcedonica fl.-pl.*, *Melanthus major*, *Oenothera macrocarpa*, *O. Youngi*, *Pæonia anemoneflora*, several kinds; *Papaver* (Poppy), scarlet, yellow, and white kinds; *Pentstemons*, several sorts; *Phlox Nelsoni*, *P. ovata*, *Polygonatum multiflorum*, *P. verticillatum*, *Potentillas*, several kinds; *Primula cortusoides amœna* and its white variety, *P. denticulata*, *P. farinosa*, *P. japonica*, *P. sikkimensis*, *Pyrethrum uliginosum*, *Salvia azurea*, *Saponaria ocymoides*, *Schizostylis coccinea*, *Silene acaulis*, *Silene alpestris*, *Spiraea Aruncus*, *S. japonica*

variegata, *S. Filipendula fl.-pl.*, *S. palmata*, *Thalictrum anemonoides*, *Tritoma Uvaria*, *Veronica prostrata*, *V. pulchella*, and *V. rupestris*. This list is longer than I intended it should be, but there being so many good species and varieties, it is difficult to know where to stop or to draw the line.

As to cultivation, all the kinds which I have enumerated are by no means fastidious, but they will fully appreciate moderately deep loam and a liberal allowance of well-decayed manure, which may be the more readily afforded when it is said that if well done at first planting, but little further in the way of cultivation will be needed for at least a couple and perhaps three years. With regard to arrangement in beds and borders, this, to some extent, must be determined by space at command and the taste of the planter, for whilst some prefer the plants in groups or masses, others incline to the single plant and straight line form of arrangement, and for a long border having formal surroundings, such as statuary, vases, clipped shrubs, and the like, this latter plan would be strictly in character, and perhaps the best, but even under such circumstances I should think twice before adopting the plan once. For my own part I certainly prefer

The grouping arrangement, and in numbers proportionate to the growth and spread of the plants; and though I would not adhere too severely to the rule of grouping them in lines as regards height—that is, to begin at front with the lowest, and gradually rise to the back of the border—I would take care that there was no undue prominence in the front lines by excluding all that attain a greater height than $2\frac{1}{2}$ feet or 3 feet, whilst, on the other hand, in the back lines with the tall growers, I would have groups of all except the very lowest. Another thing to be studied should be an even or regular display of flowers at the same season throughout the entire border; groups in duplicate are, therefore, a necessity, but the repetition should be at as rare intervals as possible. With a view to a cheerful winter aspect, the same rule that applies to the regular distribution of flowers over the entire border should be put in practice as regards the distribution of evergreen kinds; indeed, there is no reason why a few choice evergreen shrubs should not be used with special reference to winter effect, and this would be very much enhanced by the further addition of plots of the mossy Sedums and Saxifrages planted over Lily and other bulbous clumps.

W. W. H.

WHITE HOOP PETTICOAT DAFFODIL. (NARCISSUS MONOPHYLLUS.)

IN THE GARDEN of November 23 (p. 457) there was a note on this bulb by Mr. Redhead. He suggests that it is a desideratum in most English gardens, though common in Algeria, and recommends gardeners to plant it in turf that the flowers may show to advantage amongst the short Grass. The bulb, however, is no novelty in England, having been known to Parkinson, who described it as a garden plant 250 years ago, and it is still offered at a reasonable price in many bulb catalogues. Within a fortnight I observed several lots of a hundred each offered in one of Stevens's auctions. The great desideratum with respect to this plant is directions for its successful cultivation in the open ground in England. There is no doubt much successful gardening of which we have not the good fortune to hear through the gardening journals, but I have not heard of *N. monophyllus* being established as a garden plant anywhere in England, though two or three of my acquaintances have flowered it in a frame, or in very favourable soil and situation under a hand-light. One cause of the difficulty is that it flowers in the middle of winter, but besides this atmospheric conditions difficult to determine or to imitate are required for its welfare; and there is no doubt that the cause of failure with this and many other natives of South Europe and North Africa is in the air rather than in the soil

or situation, and depends upon other things than temperature. The common Hoop Petticoat Daffodil (*N. Bulbocodium*) is difficult enough to establish permanently in the open air in England, though a friend told me it flourished well with him in Northumberland. I have often obtained it both from dealers and from a relation at Bayonne, where it is common wild, and where *N. monophyllus* is also found, but nothing I can give it in the way of warm soil or drainage will make it (*N. Bulbocodium*) flower more than once. The same remarks apply to many other plants which do not die of cold, especially the pretty Algerian terrestrial Orchises of the insectiferous class, which are equally easy to obtain, but still more difficult to cultivate. C. WOLLEY DOD.

Edge Hall, Malpas.

SOWING ANNUALS.

TENDER annuals if sown too soon get checked and stunted in their growth. The end of April or beginning of May is quite soon enough for such things as Zinnias, Asters, and Salpiglossis. They should then be sown in pans or boxes of finely sifted leaf soil, as in this they make a quantity of fibrous roots, and may be lifted and pricked off without feeling the change. To get the seed to germinate freely, it is necessary for it to have heat, which may be afforded by placing the pans or boxes in a Cucumber frame or pit for a few days, when the warmth will soon bring the plants up. As soon as they show themselves, the boxes or pans should be raised so as to bring them up near the glass where the plants can have plenty of air and light to keep them from drawing. In order to nurse them on and get them strong, it is advisable to make up a slight hotbed for them on which they can be pricked out at about 2 inches or 3 inches apart—a much better plan than potting and coddling them up. The soil most suitable for pricking them out is leaf mould, and as soon as they get well hold of this, they should have plenty of air to keep them sturdy and harden them off, so as to fit them for turning out by the first week in June. The way in which

Zinnias and Asters look best is in large beds, the earth in which should be trenched or broken up deeply and made rich by a good dressing of rotten manure. If this be done now the manure will become incorporated with the soil in such a manner as to suit the plants better than if they get it fresher later on. In planting, 1 foot to 15 inches is quite far enough apart for Asters, but Zinnias, being robust and branching, require a little more room. If planted in borders I like to see them in patches of three; and when placed triangularly within 6 inches or 9 inches of each other, they make compact groups that look well from any point from which they may be viewed. Although tender annuals should not be sown till late,

The hardy section cannot well be sown too soon, and many of these make the strongest and best plants if got up in the autumn. Sweet Peas and Godetias, for instance, are always very fine after standing the winter; but these and any others now in the borders should be thinned betimes, as nothing injures them so much as crowding, for when they stand thickly they quickly draw up and starve each other, and no wonder that they then present a poor and weedy appearance. Any who have not Sweet Peas in or up will find this a good time for sowing, and if many blossoms are wanted for cutting it is a good plan to sow in rows in any odd piece of ground where they can be staked with twigg sticks, which they soon climb up and cover. In borders, patches here and there towards the back look best, where they can be supported in the same way. As the soil is yet wet and cold, it will be quite as well to wait another month before doing much with the others, but those having frames, and who do not mind the trouble, may at once get a quantity up in pots. This is always advisable where slugs are troublesome, as then the plants can be kept out of their way till the season becomes advanced and growth is more rapid, when they can be turned out and

protected by being dusted over with soot. As the plants do not stand long, 4-inch pots are quite large enough to sow in, and if these are filled with light, rich soil, the seed can be scattered thinly and evenly over the surface, when it should be slightly covered and the pots kept close under glass. Plants raised and managed in this way soon get good hold of the border. Before planting these or sowing in patches out of doors, the ground in the positions they are to occupy should be dug up and have some well rotted manure worked in, on which the plants will feed and flower with the greatest of freedom. S. D.

GARDEN FLORA.

PLATE CCCLXXIII. BOMAREAS.

(With a coloured figure of *B. conferta*.)

DURING the past year our gardens have been enriched by the introduction of several handsome species of Bomarea, the flowering of which has already been noted in the pages of THE GARDEN. The coloured plate given along with the present issue represents one of the most beautiful of these plants, for the introduction of which we are indebted to Messrs. Shuttleworth and Carder, who have succeeded in importing and flowering this and other handsome species of the genus. *B. conferta* is distinguished by the brightness and distinctness of its colour, which is soft carmine crimson, and also by its large compact umbellate inflorescence. Both in the Royal Gardens at Kew and in the nursery of the above-mentioned firm fine flowers have already been produced, and it is expected that this year much finer blooms than hitherto will be borne by established and now vigorous plants. In THE GARDEN (Vol. XXII., p. 192) I drew attention to some of the best of the not yet introduced kinds in the hope that collectors might look out for them. The cultural requirements of the genus have also been touched on at various times in these pages. It will therefore be unnecessary to occupy space with a reiteration of what has been said on these points. A short description of the kinds now in cultivation may, however, be acceptable to readers of THE GARDEN.

B. Carderi is the largest flowered of the introduced kinds. It is one of the most useful greenhouse or conservatory climbers we have, growing freely under ordinary treatment, and yielding every year immense bunches of rose and brown Lapageria-shaped flowers. There are at least two varieties of it in cultivation, the poorer of which is most likely *B. Jacquesiana*, a name once borne by the true *Carderi*. Umbels of flowers have been produced by this plant which measured almost 3 feet in diameter. The flowers are very useful for cut-flower purposes, as indeed are those of all the Bomareas, lasting for at least a week when kept in water.

B. conferta has already been described. It grows very rapidly, some of the shoots on the Kew plant measuring from 15 feet to 20 feet. The foliage is dark green, closely set along the stems, and retaining its fresh colour for the whole year, which renders it of excellent

* Our plate was drawn from a plant in Messrs. Shuttleworth and Carder's nursery, Park Road, Clapham, in June last.

Growers or introducers of new plants will oblige us much by early intimation of the flowering of new or rare species, with a view to their representation in our "Garden Flora," the aim of which is the illustration in colour, and in all cases where possible life size, of distinct plants of high value for our gardens.

service for covering pillars or columns. The flowers are borne at the ends of the stronger shoots, and when well grown there are from fifty to sixty flowers in each umbel. These characters, together with the exquisite colour of the flowers, render further comment needless.

B. frondea is another new introduction which flowered for the first time last year both at Kew and Messrs. Shuttleworth's. It is a slender growing species, well adapted for places where room cannot be afforded for the larger kinds. At Kew the plant which flowered was weak, and not more than 3 feet high, yet the inflorescence was quite 5 inches through and very brightly coloured. When well grown the flowers measure about 2 inches in length, are funnel-shaped, the inner segments being longer and broader than the outer, and a clear canary-yellow colour with numerous brown spots, whilst the outer segments are bright yellow with a darker shade towards the margins. These flowers are borne in close umbels measuring about 8 inches across. This species promises to be a good subject for pot culture.

B. oligantha is an older species, having been first introduced by the late Mr. Wilson Saunders, in whose collection it flowered, and was named by Mr. Baker. It is a very free flowering kind, and forms one of the most attractive among the species grown in the succulent house at Kew. The flowers are yellow with dark brown spots. The bright coral-red berries of this species are rather ornamental, the capsule opening and curling back so as to display about twenty berries or seeds in each, which hang on the plant for some weeks.

B. caldasiana, **B. multiflora**, and **B. edulis** are other better-known kinds which, although botanically distinct from each other, may be described as not unlike the last-mentioned species.

B. Shuttleworthi is a new species not yet flowered in this country, but described as bearing large loose umbels of flowers 2 inches long, with inner segments of a bright canary-yellow colour, the outer segments being orange-red, spotted with purple. It is very distinct in the foliage, resembling in shape and texture that of *Lapageria alba*.

B. vitellina is yet another recently introduced kind, said to have flowers 2 inches long, orange-yellow in colour, and borne in large, pendulous umbels. It has not yet flowered in cultivation.

B. Williamsi is the last described of Mr. Shuttleworth's introductions, and is said to be a very handsome species. It has large compound umbels of rose-coloured flowers, and is said to come near the finest of all the *Bomareas*, **B. formosissima**, which is not known to be in cultivation. The flowering of this plant, which is looked forward to with high expectations, is likely to be soon accomplished by Mr. Shuttleworth, who holds the stock of it, and hopes to be able to distribute it shortly.

A small hardy species (*B. Salsilla*) was recently noted in these pages as having flowered and proved itself a handsome plant for the outdoor border. *Bomareas* are closely allied to *Alstroemerias*, with which they have been included by some botanists. They are, however, easily distinguished from each other, *Bomareas* being true twiners and bearing their flowers in pendulous umbels, whilst *Alstroemerias* are erect growing, and bear their flowers in erect umbels.

Culture.—*Bomareas* are not new to cultivation, for although until recently almost unknown, yet they were once strongly represented

in British gardens, Dean Herbert, in his book on "*Amarylloideæ*," enumerating a considerable number of cultivated species. I have also been told that Messrs. Veitch introduced a number of species of *Bomarea* into their Exeter Nursery some years ago, but owing to their failing to sell or attract notice, they were stuck into some out-of-the-way place out-of-doors, were neglected, and so lost. There are instances on record of some of the *Bomareas* having withstood our winters. Dean Herbert, I believe, grew several of them in the open air, and recently we heard that in Devon *B. multiflora* had stood the winter for three years and flowered freely every year. Careful experiment and a gradual reduction of temperature may yet reveal the hardiness of at least some of these newer kinds. All the *Bomareas* are found at a very high elevation on the Peruvian Andes in exposed and cold situations. The most likely cause of failure will be the wetness of our winters, yet this may to some extent be prevented by sheltering with a handlight or planting on a high well-drained position. B.

PLANT NAMES.*

What's in a name? That which we call a Rose,
By any other name would smell as sweet.

THE truth of this well-known dictum seems undeniable. And yet the fair Capulet whose thought it embodies was nevertheless anxious to get the name of her ideal altered, or even (in which I believe she would not in the present day be singular) to change her own. This may be merely a characteristic bit of feminine inconsistency, but I think it at once casts a doubt on the literal acceptance of the apparent truism put by the bard into the lips of Juliet. If we look into the matter we shall find that the principle is true in itself, but that its truthful application is rarely if ever met with. For when is a name merely a name? Perhaps it is to such a country bumpkin as Wordsworth has described, whose

Primrose by the river's brim
A yellow Primrose was to him,
And it was nothing more.

But almost invariably a name has meaning and associations; it calls up in the mind a picture, awakens memories, and affords food for thought and reflection. Now I want in this paper to try and paint a few pictures with plant names as subjects, touching up old ones and presenting perhaps for criticism a few that may be new to you. Botany used to be contemptuously spoken of as a science of hard names; but that was before organic chemistry existed—organic chemistry with its many-syllabled names, which are the astonishment of the vulgar, and at which even pharmaceutical students will sometimes open their mouths, yet which are generally what names should be—pictures of the things named, albeit often sadly wanting in arrangement (which is form) and clearness (which is colour).

Of plant names, as given by botanists, the chief fault is that there are too many of them, portentous lists of synonyms being prefixed to the descriptions of very many even of our well-defined British species. This arises mainly from the imperfect knowledge of the structure and affinities of the plants which have been by fabricators of floras distributed into genera and species. Thus the original discoverer of a plant may, after a cursory examination of it, assign it to a particular genus, or create a new one specially for it; while another observer by more patient and detailed investigation obtains a more accurate knowledge of it, and may change the generic and specific names accordingly. Then comes perchance another ardent student who discovers our plant in some other locality, and if, as will probably be the case, it is unknown to him, whether he

be Smith or Jones, promptly is *Smithia viridissima* or *Jonesia unica* installed in the new flora, where its affinities may from time more or less prolonged give rise to interesting discussions, until on comparison of authentic specimens in old and new floras the duplex designation becomes apparent. Or of two observers describing the same specimen, one may assign greater diagnostic importance to some one characteristic, and the second to some other characteristic, and the plant may go to this or that group accordingly. This difference of opinion is due to the laxity of the definitions of many genera and species, a laxity which must always exist to a greater or lesser extent, but which may be removed in great part in many cases by careful investigation and reasoning, and also by the study of new species in relation with older ones. As an example of the benefit of this last suggestion may be given the following extract concerning the genus *Parnassia*: "It has been most generally placed among Thalamifloræ with *Droseraceæ*, next to *Violaceæ* and *Polgalaceæ*, but its close affinity with *Saxifraga* and *Chrysosplenium* has now been fully proved, especially by the recent publication of several curious Himalayan species" (Bentham). At the same time it must be noted that the continual normal variation of species will often render a particular individual difficultly referable to its proper species, and that many species are so nearly allied that they provide links between one genus and another, rendering sharpness of definition impossible. In connection with this subject it may be mentioned that many of the plants alluded to in classical writings are now difficult of identification; first on account of vague description, and secondly on account of change of name rendered needful by modern knowledge. Thus the Greek *Jasione* is our *Convolvulus sepium*, while we give the name *Jasione* (the healer) to the Sheep-bit. Again, *Hibiskos* is the Marsh Mallow (*Althæa officinalis*), and not the shrub now termed *Hibiscus*. And in Virgil's beautiful lines, Ruskin translates the "*pallentes violas*" which the white nymph Nais was to gather for Alexis, as "pale flags," not Violets, which we now associate with *Viola*. The multiplication of synonyms appears then in the present state of our science to be to a great degree unavoidable; and having pointed out the reasons for this, I will pass to the consideration of the names of the plants as most commonly accepted. In the first place,

Have names been given to plants according to any known plan?—I may answer, Distinctly not. Linnæus was, as students of Bentley will remember, the first who definitely laid down the system of binomial nomenclature, that is, the giving of both a generic and a specific name to each kind of plant, and numbers of his names are still the accepted ones. Jussieu and De Candolle defined most of the natural orders. In analysing the British orders, genera, and species we shall find examples, so far as I am aware, of all the origins of plant names. I shall, therefore, refer almost entirely to them. First, then, of the natural orders: 1. The names are taken from some typical genus of the order. To this heading place all the British orders, as *Rosaceæ* from *Rosa*, *Ranunculaceæ* from *Ranunculus*, &c., with the exception of those to be next mentioned. 2. The names are taken from some peculiarity of flower, leaf, &c., running through the order. Such are: *Crucifereæ*, *Aquifoliaceæ*, *Umbellifereæ*, *Caprifoliaceæ*, *Compositæ*, *Labiataæ*, *Amentaceæ* (*Cupulifereæ*), *Gramineæ*, *Conifereæ*. Next: Genera. These are—1. Either named after themselves by discoverers, or after discoverers by subsequent describers; or again by discoverers or by subsequent describers are dedicated in the name and to the memory and glory of more or less distinguished botanists whatsoever. The practice has some merits, but it leads in many instances, as I shall show later, to the most barbarous cacophony and word-coining. 2. Names are given at the sweet or malicious will of the name-maker, and with or without reason (generally the latter, so far as my imagination will let me discover), commemorative of some

* Read at a meeting of the Chemists' Assistants' Association, December 20, 1882, by C. E. Stuart, B.Sc.

celebrated personage or place; and these are of two classes, historical and mythical. Of this practice, the obvious criticism is, where there is rhyme and reason for the doing, where the name fits the plant and violates no probability nor stretches the imagination too sharply, and specially if the name is good Latin or Greek, then let us applaud it; if not, then be it condemned. And 3. Some peculiarity of a plant or plants of a genus, peculiarity either real or imaginary connected with size, shape, properties, and so on, has earned it its name. This is by far the most general origin of the generic name, and, to my mind, is about the most legitimate method of name formation. For as

The natural system of plant classification has in its broad basis the advantage over the Linnean system, in that it brings together plants of similar structure and habits which by the latter were arbitrarily separated and grouped by mere numbers of certain parts, a method erroneous in principle, for throughout Nature number is consequent on structure, and not structure on number; so in the details of the natural system an arbitrary plan of distributing generic names is to be deprecated and abandoned in favour in this case also of a natural system of name giving, a system carried out on such excellent lines as shadowed forth in the names *Aconitum*, *Convolvulus*, *Stellaria*, and shall I say *Myosotis*? the last a name at which I have heard some sentimentalists rail, but which in its meaning of mouse-ear as applied to the shape and texture of the leaves of the genus has always seemed to me far more appropriate than the English *Forget-me-not*, while its Greek softness is equally pleasing to the ear. For examination of the various reasons governing the adoption of specific names I can do no better than refer you to Gray, as quoted by Bentley, in his "Manual," who takes as an illustration the genus *Viola*. You will remark that nearly all the specific names indicate qualities or peculiarities of the several plants, but that frequently a botanist's or other name is dragged in as a substantive or as an adjective, and also that as many old species have been transferred to other genera, their former generic name has been retained as a specific name, as is the case with *Lythrum Salicaria*, *Dianthus Armeria*, &c. Turning back now to develop the peculiarities of

The generic names.—Of the first, the discoverer's or celebrated botanist's class, I will remark that the cases are very rare in which it is not a positive insult to a plant to connect it with the name of a man. So delicate is the charm, so quite and unobtrusive is the growth of our wayside flowers, so elevating are the thoughts which they naturally suggest, that any connection of them with human affairs seems utterly out of place. True, types may be found in plant life of many, I think not of all, of the varied habits and instincts, faults and virtues, littlenesses and greatnesses of human nature; but that is no reason for connecting any plant with that specific unit of humanity known as a botanist. To the great, however, to the illustrious pioneers of the science, it may be permitted that their names should be enshrined in and so adorn the catalogue of plant names. Thus I exemplify the name *Linnaea*, and a modest little alpine herb has an undying interest thrown around it by its sweet-sounding and honouring name of *Linnaea borealis*. But apart from the above somewhat sentimental objection to proper names as generic terms, there is the real one of untranslatability. How many common English, German, or French names will translate themselves into Latin with euphony and without outraging the ear of the scholar? Glance down the list of genera and say what you think of such terms as *Clarkia*, *Bougainvillea*, *Eschscholtzia*, *Rodriguezia*, *Cattleya*, *Ludwigia*, *Saussurea*, *Scheuchzeria*, *Sibthorpia*, *Teesdalia*, *Wolffia*, *Zannichellia*. These are names proper enough and significant enough in their native garb; but when, like Bottom the Weaver, they are "translated," behold they, as applied to plants, are as much out of place, as ugly and as earthy as was that otherwise worthy Athenian citizen among the fairy denizens of the

woodland shades. Ruskin says, in his odd, but suggestive botanical work, "Proserpina," that "a day will come when men of science will think their names disgraced, instead of honoured, by being used to barbarise nomenclature," and I hope such may come speedily. I will, however, note that there are some names which seem made to Latinise; as that of the great Swede Linné already mentioned; Asa Gray, which as *Asagrea* looks a thoroughly Greco-Latin designation; and Lobel, for which, until I read a sentence in Professor Atfield's address to the School of Pharmacy Students' Association, I should have been fully prepared to turn in my Latin dictionary and find as *Lobelia* its hidden kernel of meaning. Lobel is perhaps unknown to many of you; as adding, therefore, henceforth a new interest to the medicinal plant, I may state that Lobel was a native of Flanders, born in 1538, died 1616, and was botanist and physician to our James I. Next, of

Proper names arbitrary and imaginative.—These are in many instances not sharply defined from the next or peculiarity class, some peculiarity of habit or structure often dictating the imaginative proper name. In this class much of the poetry of plant names is found. We are told by one of Virgil's shepherds that the anger of *Amaryllis* is to be feared as the wolf to the fold, showers to the ripened corn, or storms to the stout trees; and truly the beauty of many of the *Amaryllids* is so superb that one can imagine any slight to it being rebuked with a proud and glowing scorn. *Andromeda* is to be found by the adventurous vasculum-bearing *Persens* in trembling watery peat bogs, growing blushing erect in the domains of the amphibian monsters, the frogs and newts. *Atropa* suggests the Fate, *Atropis* the Infexible, whose shears cut short the thread of human life; hence most appropriately given to the Deadly Nightshade. The specific name *Belladonna* comes oddly in opposition with *Atropa*, for the Fates were not usually represented as beautiful, but rather as grey old women. *Adonis vernalis* with its crimson petals tells of the fatal wound inflicted on the Thracian hunter by the fierce wild boar; but are there not many other things which might with no further exercise of ingenuity be thought to shadow forth? *Iris*, the messenger of the gods; *Hercules*, as *Heracleum*, *Acteon* as *Actaea*, are other mythological names, the suitability of which my imagination is not sufficiently active to discover. On the historical side *Valerian* is called after *Valerius*, who first used it in medicine and who has therefore a rightful claim to memory; but what claim has *Gentius*, King of Macedon, to immortality in connection with the beautiful tribe of *Gentians*? Ruskin hints him rather undeserving, and suggests *Lucia* as a generic name; *Lucy* of *Teesdale* then being the Spring *Gentian*, whose blue eyes thrilled a friend and myself with delight as we saw her in April for the first time on her native heaths around the high Force of the Tees. Now comes an instance of naming which is at first sight puzzling. How comes it that the genus *Euphorbia*, so acrid and poisonous, bears the Greek name for "good nourishment," which it most distinctly is not? The mystery becomes clear only when we find that this is a historical name. *Euphorbus*, the first to use the plants of the genus for medicine, was physician to King Juba of Mauritania, and possibly this name of his, with its meaning given above, was but a nickname given to him by his patients signifying that as court physician he lived on the fat of the land. Thirdly, as to

Intrinsic generic names.—It is in this class of name that we find most of the quaint conceits, old delusions and superstitions, and imagined resemblances of and concerning plants, as well as happily caught characteristics and vestiges of simple craft still more or less credited. They may be best divided into names more and names less imaginative. I will give you one or two examples of each, taking the latter first. Such is *Acanthus*, from the Greek *akantha*, a Thorn, *akanthis* being a Thistle, probably like our Scotch Thistle, and *akanthos*, that *Acanthus* whose spine-tipped leaves adorn the capitals of Corinthian pillars. *Crataegus* is a name a step removed from the evident correct-

ness of epithet of the above example; *kirasos*, its root, meaning strength, and this, as applied to the wood of the wild Service-tree, the original *krataigos*, is not so fitting a bestowal as that of the thorn bound up with the thistly *Acanthus* *Fumaria*, the smoky, applied to the *Fumitories*, is apt, as all will concede who know the grey misty foliage of the genus; but it is more imaginative than the two former instances. The *Geraniums* of our summer woods recall with their long beak-like fruits the crane whose Greek name, *geranos*, they bear. The Robert of *G. Robertianum* is, as some suppose, a Benedictine abbot to whom is dedicated the 29th of April, about which time the herb comes into flower. But it appears to me that it cannot count for nothing that names Robert and Robin are given to red creatures, as to this same Herb-Robert, to

That little weed of ragged red,
Which bids the robin pipe;

and to robin redbreast; the inference being that savage and almost inarticulate primeval man, struck with the stimulating brightness of the rays of slow vibration in the solar spectrum, signified the effects of them by the purring pleasure of the rolling R, which is more fully developed in *Rhodon*, *Rosa*, *Rose*, *Rhocas*, *Rhoia* (*Pomegranate*), applied to red plants, and in *Robin*, *Robert*, *Rupert*, applied to red men. *Rubus*, again, has the same root of redness; and the genus, whether in its pink-hued flowers, its purple fruits or fruit juice, or its crimson autumnal leaf-tints, is fully worthy of its name. *Lysimachia* and *Lythrum* are both Englished as *Loosestrife*; this should etymologically be only of the former; and as I am unable to find that it does loose strife, I think we must fall back for explanation on the theory that the name commemorates *Lysimachus*, a friend and general of Alexander the Great, and hence this belongs properly to the second class of names. A splendid example of the purely imaginative name is *Chelidonium*, meaning Swallow-wort, so called because it flowers at the time when the swallows return in the spring. *Lamium* offers us an open choice of derivation. It may either be from *Lama*, a ditch from its place of growth; or from *Lamia*, a snaky monster given to preying on unwary youth (Keats has a fascinating study of one); or else from *laimos*, the throat, the root whence *Lamia* is derived. This latter, seeing the gaping throat of the flower, seems the most fitting starting point. *Scrophularia* and *Pedicularis* are instances of plants named from diseases for which they were once supposed efficacious. Now I have run through a few illustrative instances of the various methods of plant naming which I have enumerated. It remains for me to say a few words on hard names. It is a habit with the unreflecting to stigmatise names which they find lengthy and unfamiliar as pedantic, harsh, and unnecessary. But they do not perceive, what a little thought would tell them, that in the language to which they belong they may be as fitting and as fraught with pertinent meaning as any familiar English name. Thus, *Pardalanchis* is a hard, uncouth-looking word, but it is simply our English *Leopard's-bane*, and as a Greek word it is by no means unmusical. And so with *Anisopetalum*, *Cryptarrhena*, *Eulophia*, *Ornithidium*, *Pleurothallus*, *Stenorhynchus*, *Xylobium*, at which Ruskin grimly sneers. And this reminds me of

A new system of plant naming and classification proposed and partially carried out by this distinguished art-critic. Its leading principles are somewhat as follows: Starting with no scientific botanic knowledge, many of the prejudices of the past may be thrown aside. Begin, therefore, by relying on your own poetic judgment for the division, so that (for instance) *Oxalis* and *Anemone* both come into the same order, since both are delicate flowers delighting in the woods. That they do delight in the woods is a historic fact, and a historic fact (it is well known), equally with "relative conditions of character and climate," are so unchangeable, if plant classification and naming is founded on them rather than on distinctive differences of form which are so many, so subtle, so liable to continual re-

interpretation, then we shall have unalterable groups which may be added to, but not disturbed or reconstructed. That is, in this world of change and imperfections we shall have at least a perfect and immutable system of both terminology and nomenclature. Note, that the reasons given for this change are, first, that many names are barbarous distortions of Greek and Latin words; second, that many names carry with them coarse and degrading suggestions. Both these propositions may be acquiesced in, but do they furnish sufficient reason for the upsetting and total remodelling of all plant arrangements as well as all plant naming? The third reason is, that the botany of Ruskin, being intended to be useful to the vulgar rather than to the scientific, should give to plants names characterising them individually, and not founded on their connection with other plants at the Antipodes. Thus, Herb-Robert might be called shortly "Rob Roy, and have done with it," rather than, dwelling on its connections, christen it "Macgregoraceous." This reason, which is no reason but a dogma, strikes at the root of natural classification, and at once places the system outside serious consideration. It sets out the dream of a poet, imaginative, beautiful, but unpractical. However, there is much to be learnt from the eloquent imaginings of its gifted author, one great lesson being not to look upon plants simply as material for dissection or for preservation in dusty folios. Text-books must and text-books do take chiefly this

view, but it is a healthy change from the consideration of plants as "subjects" (as the medical student would put it) to regard them as "objects" full of life, beauty, and character, with ways, wills, and instincts of their own. Dryad-baunted tree, starry flower, fertile grass of the field, to these are we indebted for the filling up of a great portion of the wants and pleasures of our existence, and the fuller knowledge of them in all their varied forms, habits, and necessities cannot but have a favourable effect in human joys both actual and ideal. —*Pharmaceutical Journal*.

THE CHRYSANTHEMUM AND ITS CULTURE.

Races or Sections.

In order to give a clear idea of the cultivated races of the Chrysanthemum now popular in our gardens, we have tabulated them according to their distinguishing characteristics. Of course it must be understood that these distinctions of race are of an arbitrary character. Some of the races, especially the Incurved, Reflexed, Pomponé, and Japanese, have become more or less blended by the efforts of the cultivator and raiser of new seedlings; thus we have sub-races in the hybrid Japanese kinds, of which Elaine, Peter the Great, and Ethel are examples. The varieties of Cedo

Anemone flowered Chrysanthemum Madame Montels (disc florets yellow, ray florets peach-rose).

Japanese Chrysanthemum James Salter (florets strap-shaped and wavy, colour lilac).

Nulli unite the Pomponé with the small-flowered Anemone race, and there are hybrid Pompones with reflexed florets and large flowers, such as Trevenna, Aurore Boreale, and Sœur Melanie. Such also are some sorts among the early blooming Pompones. A variety called Garnet seems to be a forerunner of a sub-race of Japanese Anemone-flowered Chrysanthemums. Progne (Reflexed) and Japanese Violet (Japanese) also are welcome as varieties having a distinct and really appreciable fragrance or Violet-like perfume; thus another charm is now added to this already popular flower. For all practical purposes, however, the following arrangement of races may stand as it is written:—

Race I.—*Incurved or Ranunculus flowered*, generally known as show or exhibition kinds.—The florets are strap-shaped, curving inwards, so that in the most full and perfect blooms the backs of the florets only are seen. Examples: Mrs. Rundle, Alfred Salter, General Bainbrigge, King of Denmark, Lady Slade, Queen of England, &c. (see illustration p. 88).

Race II.—*Recurved or Reflexed flowered*.—Plants mostly of excellent habit of growth, and so good for specimens. Florets strap-shaped, but curving outwards from the centre, so that the inner surface of the florets only is exposed. Examples: Annie Salter, Progne, Golden Christine, Dr. Sharpe, &c. The inner face of the florets being fully exposed in all reflexed flowers, it naturally follows that the varieties of this group are most remarkable for deep and vivid colouring.

Race III.—*Anemone or Quilled Aster-flowered*.—The varieties of this race have an outer circle of strap-shaped florets, only the disc or centre of the flower being raised cushion-like and made up of closely arranged tubular florets. Examples: *Large-flowered Anemones*—Fleur de Marie, Glück, King of Anemones, &c. *Small-flowered or Anemone Pompones*—Marie Stuart, Madame Montels, Calliope.

Race IV.—*Pomponé small reflexed or Chrysanthemum daisy-flowered*.—The plants of this race have an

excellent twiggy or bushy habit of growth, and produce numerous small button-like flowers for the most part having reflexed florets. Examples: Bob, Snowdrop, Mlle. Marthé, General Canrobert, &c. Some varieties of this class have florets fringed or toothed at their tips. Examples: Marabout, Innocence, fimbriatum, Princess Metelia, &c. These are often known as fringed or fimbriated Pompones, and the larger flowered kinds are sometimes called hybrid Pompones, being intermediate in size and character between the typical Chusan Daisy or Pomponé proper and Race II. or large-flowered Reflexed kinds. Example: Trevenna and its varieties.

Race V.—Quilled or Pin-feathered Japanese.—This race is characterised by plants naturally rather tall and straggling in habit. Flowers very large, 6 inches to 9 inches in diameter, when the main shoots only are strongly grown. All the florets are involute and tubular or quill-like for four-fifths of their entire length, their tips being dentate or toothed. Example: Meg Merrilies, Sultan.

Race VI.—Japanese or Tassel-flowered.—Plants of tall and robust habit, requiring exceptional good culture in order to obtain large blooms. Flowers rather loose, composed of long, flat, or narrow strap-shaped florets. Modern examples: Elaine, Ethel, Fair Maid of Guernsey, Oracle, Peter the Great, James Salter, all with strap-shaped petals, tolerably flat or unconvoluted. Tokio, Gold Thread, Bronze Dragon, Dr. Masters, and others have florets revolute, twisted, and thread-like, but not really quilled or tubular, although apparently so at first sight. Some Japanese varieties have tubular florets—Rob Roy, for example—and serve as the connecting link between the Races V. and VI.

When in Japan, the late Mr. Fortune sent to this country seven remarkable Chrysanthemums, which proved exceedingly distinct in size, form, and colour from the ordinary kinds grown here. From the types then introduced have been raised the following, which are still more remarkable for their diversity, possessing as they do either enormous size, peculiarity of form, or novelty of colour. Although of a distinct type from the Chrysanthemums in general cultivation, no difference in treatment or soil is necessary to secure a succession of flowers from November until January or February. Many of them remain longer in bloom, and bloom later than the Chinese kinds, so that we may have our greenhouses gay with them all through the dull winter months when flowers are scarce. The effect produced in the conservatory by their fantastic forms and brilliant colours is most novel and pleasing, many of their immense blooms having more the appearance of tassels formed of the gay plumage of tropical birds than of flowers. These original varieties were Japonicum, Bronze Dragon, Roseum Punctatum, Striatum, Laciniatum Grandiflorum, and Yellow Dragon. Concerning these Mr. Fortune gave us some interesting information. He collected several kinds from Japanese gardeners, which he brought over to Shanghai, where he left them in the charge of a Chinese gardener while he went northward to Peking. On his return he found that many of the roots he had collected were dead, and that only a few remained, some of which were imported safely into England. Of these two or three kinds only fell into the hands of Mr. Salter, of Hammersmith; but, from seeds of these two or three, seedlings were produced which yielded flowers not only differing from those of the parent plant, but identical with those which Mr. Fortune had collected in Japan, and which were lost in China. This could be no case of hybridisation, for no flowers of the kind had been previously seen in Europe. It was a case of pure seminal variation.

It has been proposed to class Japanese Chrysanthemums into three divisions as follows: Ribbon varieties, Twisted varieties, and Thread varieties. The first or Ribbon varieties would comprise those of which the florets are reflexed and droop below the calyx—namely, Meg Merrilies, Baronne de Prailly, Fulgore, Gloire de Toulouse, Triomphe du Nord, Fulton, Elaine, Madame C. Audiguier, Arlequin, Rosa Bonheur, Triomphe du Châtelet,

and others. The second or Twisted varieties would include Yellow Dragon, Grandiflorum, Hero of Magdala, James Salter, Chang, &c. Thirdly, the Thread varieties would be such as Cossack, Gold Thread, and Madame Godelet. Then we have many of our best varieties with their florets erect or partly so—namely, Sarnia, Ethel, Fair Maid of Guernsey, Peter the Great, Daimio,

A new classification is certainly desirable for the now numerous and handsome Japanese varieties, but it is necessary that such classification should rest, if it be possible, on sound structural ground and not upon mere external appearances. The three sections just proposed scarcely allow of scope for future improvement, nor does it comprehend all the structural differences as displayed by

Incurved Chrysanthemum Queen of England (blush white).

Madame Lemoine, Jane Salter, Soleil Levant, erectum superbum, Oracle, Diamond, M. Maney, La Nuit, Bouquet Nationale, and others. The beauty of the Japanese consists in their great diversity of colour and form. There are two varieties of Japanese, or rather now classed as such, which might with advantage be added to the large Anemone-flowered sorts—namely, Duchess of Edinburgh and a variety named Minnie Chate. The former has pure white guard florets with a pretty mauve centre; the latter has lilac guard florets with lilac centre.

the kinds as already distributed. A noted raiser sent me some very fine seedling blooms this season, and much as I had known and expected of the Japanese Chrysanthemums, I never even dreamed that such changes could so quickly and surely be wrought in this beautiful class. Anemone-flowered Japanese as large as tea-saucers, and of all colours from white to crimson-scarlet and purple through all the shades of sulphur, primrose, buff, yellow, and red, are surely enough to make a grower's "mouth water." Several of my friends are taking Mr. Forsyth's advice, given as long ago as 1872,

and are saving seed from good varieties of large-flowered and Japanese varieties. Both Mr. W. Thompson, of Ipswich, and Mr. Benary, of Erfurt, offer *Chrysanthemum* seed of the various sections for sale. Florists are a little too apt to have set ideas, and quite right they are in adhering to them (from their own standpoint), but what I and many other lovers of the *Chrysanthemum* desire are some of the lovely single-flowered seedlings which the florist persistently throws away should they appear among his seedling plants. Now that single Dahlias and Pyrethrums of the *P. roseum* section are so popular for their brilliant colours, is it not desirable that some of us should have single-flowered *Chrysanthemums* of Daisy-like form and good distinct colours as brilliant as it may be possible for us to obtain? I submit the following as an example of the classification required in the Japanese section:—

SECTION 1.—Florets strap-shaped for more than half their entire length; (a) florets erect, displaying almost as much of the colouring of the back part as of the front. Ethel, Erectum superbum, Oracle, Peter the Great, &c.; (b) florets reflexed, showing front colouring most. Elaine, Beauté du Nord, &c.; (c) florets twisted, curled or variously contrasted, showing both back and front colouring of the florets in a more or less irregular manner. Cossack, Gold Thread, Tokio.

SECTION 2.—Florets quilled or tubular for more than half their entire length; (a) florets curving upwards or erect. Soleil Levant, Red Dragon, Meg Merrilies; (b) florets reflexed.

SECTION 3.—Florets of the disc tubular, densely packed in a raised cushion-like mass. Florets of the ray flat, slightly recurved. Popularly known as Japanese Anemone-flowered. Garnet and one or two others afford good examples of flowers in this section.

Speaking of the Japanese varieties in 1881, Mr. Henry Cannell, of Swanley, writes as follows concerning their distinctness and beauty:—

“These are very novel and striking in appearance, and perfectly distinct from the ordinary kinds of *Chrysanthemums*; most of the varieties do not fully develop their flowers until Christmas, and are therefore valuable on that account. They are useless for small specimen plants, as their habit is long, and they require to be treated similar to the incurved varieties, that is to say, to let the plant grow upright. They must have good cultivation, and as soon as the flower buds appear they must be reduced to one on each shoot and grown very strongly, otherwise they will possess no beauty. If damp is kept from them they will continue in bloom a long time.”

Race VII.—Early-flowering Pompones and hybrid Pompones.—A valuable modern race of Continental origin consisting of plants of bushy habit, bearing a profusion of reflexed and Pompon-like flowers. When well established on open-air borders and on warm soils they commence flowering in August, and continue in bloom until the severe frosts of November or December. They form valuable early autumnal decorative plants when grown in pots. Examples: St. Mary,* Fred. Pelé, Illustration, Précocité, Gold Button, &c. It is by many erroneously supposed that the early-flowering or summer *Chrysanthemums* are of recent origin. The following extract is from the “Gardeners’ Magazine of Botany” for 1850, and shows that even thirty years ago a start was actually made, and hopes entertained which are realised only as it were to-day: “M. Pelé, a distinguished horticulturist of Paris, has also obtained many varieties, the most interesting of which is called Madame Pépin, and which flowers constantly about a month before the others. It is probable that this new type will furnish other varieties as early, which will impart a novel and important quality to *Chrysanthemums*.”

Race VIII.—Single-flowered Pompones or Indian. Example: New Departure (Cannell).

Race IX.—Single-flowered Chinese or large flowered. The large-flowered Anemone varieties

are semi-single forms of *C. sinensis*, just as the small-flowered forms of Anemone kinds are semi-single Pompones.

Race X.—Single-flowered Japanese. Example: John Rae (Burbidge). A single Daisy-like flower, with slender bronzy ray florets, raised in 1882 in the College Gardens, Dublin. F. W. B.

SEASONABLE WORK.

FLORAL DECORATIONS.

THE pendulous blossoms of *Thrysacanthus* rutilans look bright and attractive just now suspended around the edges of trumpet vases. They could be advantageously used in conjunction with *Calanthe vestita* around the edges of any tall vase or epergne as a central arrangement to a dinner table, filling up the centre of the same with spikes of *Calanthe Veitchi*, a few blooms of *Lælia anceps*, and the same of *Eucharis amazonica* around

Chrysanthemum sinense (spray of flowers, reduced).

the last named *Calanthe*. This would give an effective centre-piece that no lover of choice exotics would despise. Another change as a centre-piece for a moderate sized table or for the drawing-room may be made by choosing a well variegated example of *Pandanus Veitchi* as good as it can be had in a 4-inch pot; from this it may be removed and placed in the centre of a soup plate for want of a better receptacle. Fill with a little sand to keep the plant steady, and finish off either with good Moss or some fresh *Selaginella* into which may be inserted a few bulbs of Tulips in flower, say, for instance, Duc Van Thol, scarlet and white, allowing the former colour to slightly predominate. With these the *Pandanus* will show itself to good advantage. As a finish a few plants of a durable kind of Fern (*Davallia*, for instance) would greatly improve it. This would prove a lasting arrangement and be well adapted for a room kept at a maximum temperature. Of hardy subjects the pendulous blossoms of *Garrya elliptica* are now most attractive. A few sprays of these would associate well with the bronzy-coloured points of *Berberis Aquifolium* and *Jasminum nudiflorum*. *Rhodocendron Nobleanum* in the open air has developed several trusses of flowers; these look well arranged by themselves

with their own foliage. The smaller flowered kinds of Azaleas, as *amœna*, *obtusæ*, and the various hybrids raised therefrom, are useful in a cut state, lasting longer than many of the large flowered varieties. They all answer well for specimen glasses, and can oftentimes be better arranged therein than in larger receptacles, owing to the necessity of allowing only a short stem, especially in the case of small plants. For button-holes the various kinds of *Epacris* are very useful. *Erica melanthera* also looks well used with the former, and both possess greater durability than many forced plants.

FLOWER GARDEN.

Spring flowers.—The weather still continuing mild, these are springing up in every direction, and being so forward, a severe frost would be likely to do much injury. It would be impracticable to protect all, but the most valued should have that attention. Ilyacinths and Tulips are most liable to injury, and the neatest of all protections for them is Cocoa-nut fibre refuse. Where, however, the bulbs are planted in a ground-work of Sedum or Saxifrage, this protection cannot be employed; therefore, under such circumstances, a covering of Yew or Laurel boughs must be used. The ground being so wet, the slightest frost will be sufficient to raise or rather to loosen autumnal planted spring flowers; therefore their well-doing will be best assured by well firming the soil about them after each recurrence of frost. Over our reserve stock of such plants and dwarf hardy summer bedders planted on warm borders in the kitchen garden we run a light roller as soon as the state of the ground after the frost will permit, an operation that seems to be doubly beneficial, as it firms the plants and apparently conduces to their more rapid lateral extension. Certainly this is the case with such plants as *Herniaria glabra*, *Mentha Pulegium*, *Cerastium avense*, *Sedum lydium*, Thyme, dwarf Veronicas, and various Stonecrops.

Herbaceous plants.—Many kinds of these are also too far advanced in growth for the time of year, but that should serve as an incentive to get all removals and rearrangements completed as soon as possible, for, though they may with safety be transplanted at almost any season, it is but reasonable to suppose that they will do better if moved before growth has become too active, not to mention the importance of their roots getting well established in the fresh soil before dry weather checks root action. The reaction in favour of this class of plants still continues, and, being combined with the present prevalence of æsthetic ideas with which many of these plants are associated, there is some danger that the cultivation of many kinds little better than weeds may be resuscitated. Intending planters should therefore only select kinds of real merit. As to the best mode of arrangement, tastes vary, some preferring to plant single plants in straight lines, the tallest at the back of the bed or border, and the dwarfier in front, and for a formal border this plan has some merit; we, however, prefer planting them in groups or clumps of moderate size, say three plants in a group of *Pyrethrum uliginosum*, double Sunflower, and similar growers, five or seven plants of *Spiræa Aruncus* and *Anemone japonica*, and in still larger numbers of the dwarfier growing kinds. I would then advise the filling in of every vacant space possible with surface-rooting plants, and particularly round those varieties that are least furnished with foliage. The carpet thus formed adds greatly to the general effect of the arrangement.

INDOOR PLANTS.

Ferns.—These are best potted a short time before they commence growing, for if their roots are subjected to the disturbance unavoidable in repotting after growth has commenced, the first fronds produced afterwards are sure to be deformed. In the case of Ferns, the habit of the species has much to do with the pot room required. Tree kinds of a strong vigorous character have

* St. Mary (Cannell) is the same as *Souvenir d'un Ami* (Wate).

often much more root room given them than they need or should have, the result being that the fronds grow to such a size as to become too large for the houses in which they are located, and when overgrown they never look well, and often injure smaller sorts that usually have to be accommodated under them. There are no plants that can be kept so long in a healthy state with limited root space as Tree Ferns. They will continue to thrive and look well, even when their roots have so filled the pots or tubs that there literally seems scarcely any soil remaining. Under such conditions they should, however, be regularly supplied with manure water during their season of growth. Those that are of a spreading habit, like the *Gleichenias* and *Davallias*, must have sufficient space for their creeping rhizomes to extend, or they are sure to get injured, their surface stems being forced to break back, which they usually do weakly. Ferns possessing this habit of growth should not be divided into too small pieces, or they suffer considerably. This is especially the case with *Gleichenias*, the creeping stems of which appear to be incapable of forming fresh roots when they have assumed a hard woody state. Species of a close tufted habit, such as the *Adiantums*, will bear dividing into much smaller pieces if required. Where

Ferns are in beds and on imitation rock-work it is equally important that they should not have more root room than is sufficient to support them in a healthy state. If care is taken in preparing the places where each is to be planted it is an easy matter to confine the root space for them proportionate to the requirements of the individual plants. Ferns are not so particular as to soil as many plants; most of them succeed in either peat or loam. As a rule, however, they make the best growth in peat, but those intended to be grown for cutting, such as *Adiantums* of the cuneatum section, and the different kinds of *Pteris* that are adapted for this work, are best in loam, as in that the fronds usually stand better in a cut state. Whichever is used the soil must be kept open by a sufficient addition of broken crocks or coal cinders, the latter being quite as good as the former. In all cases Ferns ought to have a thorough cleaning from insects, such as scale or mealy bug, before being potted, as the mature growth will bear a stronger dressing with insecticide than could be used later on when the young fronds have made their appearance. Where thrips have been numerous it is a good plan to dip the fronds in strong tobacco water or to syringe them with it, as even if none of the living insects are present, there are almost sure to be eggs that will come to life when there is an increase of heat.

Palms.—Such of these as require a warm house to grow in are rarely quite at rest even in the winter season, unless the temperature is kept so low as to check all growth, and the most dormant time should be chosen to pot those that want it; but Palms, like Ferns, do not need so much root room as is often given them. When too much root space is allowed the strongest growers in particular over-shade everything near them, and unless the house in which they are grown is of unusual height, when the roots are not kept within limits the leaves grow to such a size that they seem to be always struggling to get through the glass. Palms will succeed in almost any kind of soil, but heavy loam, almost approaching the consistency of clay, is the material which they like best. For all purposes where plants with green foliage are required there are none superior to Palms, inasmuch as, with the elegance of Ferns, their leaves possess a stout texture which enables them to bear without injury the wear and tear of frequent removal when used for grouping with flowering and other plants in halls, corridors, or rooms. A still further recommendation which Palms possess is that a good many species which come from warm countries may be kept for a considerable time in a much lower temperature than that in which they are indigenous. Even such elegant kinds as *Leopoldina pulcher* (*Cocos Weddelliana*) will bear keeping through the winter in a temperature from 45° to 50° without showing any ill effects therefrom, the only difference being that so treated

their growth is comparatively slow, but that will generally be looked upon more as an advantage than otherwise. *Chamaedorea gracilis*, *C. graminifolia*, *C. glaucophylla*, and *Areca lutescens* are beautiful habited species that will bear a lower temperature than the countries from which they come would lead one to suppose. If at all affected with insects an effort should be made to get them clean whilst in a small state, as the work involved is much lighter than when the plants get large.

ORCHIDS.

East India house.—Whatever may be said against the unseasonable state of the weather as regards outdoor vegetation, it is certainly very suitable for Orchids under glass. Get the potting of all the occupants of this house done that require it. The largest proportion of Orchids require as potting material either Sphagnum alone or mixed with turfy peat. In either case a liberal proportion of broken bits of charcoal and clean potsherds should be added. Many, too, do not pot firm enough—especially if Sphagnum only is used. The best grown *Vandas* and *Aerides* ever seen perhaps were in pots quite three parts filled with drainage, with the Sphagnum pressed very firmly on the top. The Moss should be well washed before it is used, and all extraneous matter should be picked out of it. After washing we lay it out to dry for a few days, but it must not be dried so much as to kill it. In potting with peat added to the Sphagnum, this is also pressed together rather firmly. It ought also to be noticed that some plants have the roots clinging so firmly to the pots that they cannot be turned out without either causing great injury to the plants, by breaking or lacerating them, or breaking the pot. The latter course we take rather than injure the roots. Now that repotting and surfacing are finished, and most of the plants are pushing fresh roots, a rather moist atmosphere and also a higher temperature are desirable. With the fresh Moss, small snails may have been introduced, and it will be necessary to watch for them every night with a good lamp, as though small, they soon eat the ends off the young rootlets, and they also get at those immediately under the surface where they are not readily observed. This is a good time to repot *Cypripediums* requiring a warm house. *C. Dominionum* seems to require a good shift every year; considering what the parentage of this is, one would not expect that it would succeed best in the warmest house, but that is the case. We have also repotted *C. niveum*, using a liberal proportion of turfy loam in the compost. *C. Lowi*, *C. laevigatum*, and *C. Stonei* we also grow in the warmest house, and as a rule it is best to turn them out of their pots and repot them annually.

Cattleya house.—Cattleyas that require repotting should now receive attention; where plants of these are doing well, a large proportion of the roots will be growing over the sides of the pots, the insides of which will also be well furnished with roots. In a case of that kind it is quite necessary to break the pots in order to preserve the roots. In potting such plants as may have made a quantity of roots outside we would not cover them with compost; on the contrary, we would have at least the greater portion of them outside the compost. We have noticed sometimes that when such plants have had all their roots potted in peat and Sphagnum they have not done so well as previously. *Miltonias* in some cases are now started into growth, and they are also making young roots; therefore, such as require repotting should be seen to at once. *M. candida* requires much the same treatment as Cattleyas. It should be repotted in peat and Sphagnum, removing the old rotten compost; we keep the roots moist all the year round. The section of which *M. Moreliana* and *M. spectabilis* is the type does not require so much depth of compost, and should be potted in pans, or if pots are used, they ought to be filled to within 3 inches of the surface with drainage, and it may be necessary to secure them to the compost with pegs. The

peculiar yellow tint of the foliage of these *Miltonias* lead many to believe that they are not in good health, but this sickly hue is common to most of the species, and is most apparent when the plants are in a light position near the glass. Newly imported Cattleyas should be potted in clean crocks without any Sphagnum or peat. The crocks should just be kept moist with tepid water, taking care not to wet any part of the plant above the drainage. When fresh roots issue from the base of the last formed pseudo-bulbs a portion of the crocks should be removed, and some of the usual potting material substituted. If Cattleyas arrive in pretty good condition, and have not been caught by the frost, they soon become established. *Laelia purpurata* and Cattleyas of the *elegans* and *guttata* type are included amongst those requiring the treatment just recorded. There ought now to be a good many *Dendrobiums* in flower, and a succession of them should be kept up from now until midsummer. Those still out in cool houses must be kept dry at the roots, and it is best to gradually inure them to a higher temperature, as if transferred from a low to a high temperature suddenly some of the species will lose their flowers prematurely.

Cool houses.—Repotting ought also to be proceeded with in this department while the weather continues favourable. We have potted all our *Masdevallias* that were not potted last summer. These very speedily make large specimens, but when grown on for seven or eight years without being divided the amount of flowers produced is not in proportion to the foliage. We have plants of that age that have now been divided into eight or ten parts, and each of them has been potted in 4-inch or 5-inch pots. *M. Harryana* is the most vigorous grower, and, taking it altogether, certainly the best of them. They also vary very much in colour and form of flowers. *M. Veitchiana* when well grown is also a very fine species. It does best divided and potted like the other. The leaves ought to be carefully sponged over with soapy water to clear them from dust and to prevent the attacks of thrips. We find in repotting the *Odontoglossums* that nearly all of them are just starting to make fresh roots, therefore all requiring repotting have received attention in that way. We would rather repot when the young growths have started a little, but where there is a large collection it is not possible always to repot or to in any way attend to plants on the very day when they require it. In instances in which any of the plants had flower-spikes in course of development it was thought best not to repot them until they had passed the flowering period. *O. cirrhosum* is either in the state in which the growths are completed, or nearly so; the flower-spikes are in course of development, and therefore only a few could be repotted. The flower-spikes of *Oncidium macranthum*, which luxuriates in the coolest house, are also in course of development; a few of this species were potted, but the others will not be done until the flowering period is over, probably in August. Slugs are very fond both of the flower-stems and the succulent roots of this *Oncidium*, and therefore must be carefully watched, and when found destroyed. This species succeeds well in pots with rather more drainage than is required for *Odontoglossums*. It will also thrive on a block of wood, but in that case more care is necessary as regards watering.

PROPAGATING.

This is a good time to make the principal sowing of Fern spores; when sown now they have the whole of the growing season before them, whereas if sown in summer they frequently fall a prey to damp during the ensuing winter. The most critical time with seedling Ferns is when they require pricking off for the first time, which will be as a rule in about a couple of months from the time of sowing. Old plants of *Chrysanthemums* intended for spring propagation must be protected from frost, but should have all the air possible, or a weak growth and consequently puny cuttings

will be the result. Chrysanthemum cuttings put in a month ago will need attention in the way of removing decayed leaves; if the foliage is much inclined to damp, give air for a little time each day till the damping is arrested. Where it is desired to increase the stock of Bamboos, such as Fortunei, Metake, Simoni, and Maximowiczii, the Eulalias, and similar plants, they may now be divided and placed in a frame, where out of the way of frost and heavy rains they will start into growth in spring without a check. If not already done no time must be lost in securing pieces of the roots of any plants that are propagated in that way, such as nearly the whole of the hardy Primulas, especially the varieties of Sieboldi. Senecio pulcher increases readily in this way, all that is necessary being to cut the roots up into pieces about 1 inch in length and dibble them in well drained pots in a perpendicular position with the upper part just below the surface of the soil. Placed in a gentle heat, they will break freely and grow satisfactorily. Stock plants of any subjects that it is desired to propagate largely in view of the coming summer should be introduced into heat to push them into growth, and thus get an early supply of cuttings. Cuttings of most things required for summer decorations strike without much difficulty, and where there is not a propagating house for the purpose a close case can easily be fixed in any house which is kept at a sufficient temperature in which such as Fuchsias, Bouvardias, Heliotropes, Lobelias, Alternantheras, Verbenas, Coleus, and the like root readily. For such bottom heat is not necessary, provided the temperature of the house is kept up to a sufficient height. For spring propagation I employ the following method with great success: In a stove there is a stage about 4 feet wide in a good light position near the glass; on it is placed a good layer of ashes or Cocoa-nut fibre, over which the propagating cases are set. They are made the width of the stage, and resemble miniature three-light pits, so common everywhere; the sloping lights obviate drip, and a width of 4 feet is very convenient for closely examining the cuttings. The cases may be made very light for the convenience of shifting them about when required. Pelargonium cuttings are much better on a shelf than where moisture condenses on them.

FRUIT.

Pruning and manuring orchards.—

The pruning of all fruit trees should be completed before the sap is in motion if we except Nuts, which are usually left until the tiny little female blossoms can be discerned; then all useless spray is cut, and a Kentish Filbert or Cob Nut bush looks almost as bare as a Vine when pruned, yet the crops gathered testify to the soundness of the practice. In counties in which Filberts are allowed to grow on the extension system the fruit is neither so numerous nor so fine. All young Apple, Pear, Plum, or Damson trees are now having their strong leaders cut back; although we hear of cases where shoots left at full length have set fruit like ropes of Onions, extension is not found to answer in practice; the trees require strength of branch to carry a crop as well as willingness to do so, and the only way this can be secured in the case of young trees is to stop the erect shoots at least one-third of their length. We have ample proof of what the result is when this is neglected. The trees rush upwards instead of filling out laterally; the first crop bears them down so much that the limbs have to be supported, or they inevitably get broken off, and nothing is gained as regards quantity or quality of fruit. If the rampant erect shoots are checked in their upward career, the weakly undergrowth comes into bearing far more quickly, and the fruits are finer. Market gardeners look to quality as much as quantity, and if pruning did not pay they would not do it. One sieve of good high-priced fruit is worth two or three of seconds, and the expenses of transit and commission are the same in each case. Ma-

nuring is also on a liberal scale; where are the orchards attached to private gardens that are supplied with manure at the rate at which they are by market growers? We have, however, lately had some sensible remarks on the folly of keeping a garden half starved. That is bad enough, but a starved orchard is worse; it can yield nothing. There are more reasons than ungenial seasons for barren fruit trees; and if we would but take that old advice, viz., "I will dig about it and manure it, and look for fruit another year," we might yet find that the seasons were improving, at least as regards fruitfulness. Some growers have had plenty of fruit, even in bad seasons, some none; moderate pruning and more than moderate manuring is the secret in the case of those who are successful.

Cherries.—When the trees in the early house show signs of opening their flowers fumigate with Tobacco paper on a calm day; repeat the following morning if necessary, and syringe well to free the buds from insects. Examine the borders, and give sufficient tepid water to keep them in a satisfactory condition until the fruit is set. Discontinue syringing during the time the trees are in flower, and let external conditions regulate the damping of walls and other surfaces, as Cherries, like Peaches, set best in a well ventilated house free from stagnant moisture, but at the same time not so dry as to shorten the flowering period by causing the petals to drop prematurely. With the thermometer now standing at 50° in the open garden the most gentle circulation through the pipes with liberal ventilation will suffice, but in the event of a change to colder weather 40° at night to 50° by day will be quite high enough. The succession house started early in this month may be brought on by warming the pipes for an hour or two every morning, by syringing with tepid water when the temperature begins to rise, and by closing from three to five o'clock every afternoon. If late kinds in pots and tubs are still out-of-doors get them housed, and place nets over the open ventilators. Young trees may still be taken up and potted in strong virgin loam. Let the pots be clean and well drained, ram the soil firmly, and plunge in a warm, airy situation out-of-doors where they are to remain during the season, unless house room is plentiful and not better occupied.

Plums.—In many places these are grown with the Cherries, and they do very well through the early stages, but the time comes when the latter require more air and less moisture than would be good for the Plums, and on this account it is best to keep them separated by means of a glass division placed across the house, and to have the ventilating gear made to work separately in each compartment. If kept clean and brought forward in a low temperature with plenty of air, the Plum is one of the most prolific and interesting fruit trees that can be selected for growing under glass, but anything like hard forcing at any time will prove fatal to the crop. When grown in pots the trees soon become very fruitful, and unless timely thinning of the flowers is attended to the uninitiated may find the favourite at the outset the least profitable at the end of the race. Where glass is plentiful, the cost of fuel being trifling, a whole section should be devoted to that king of dessert Plums—the old Golden Drop. In cold districts or bad seasons it does not always lay on its fine amber colour, without which it never attains its proper flavour, but with a glass roof over it every fruit becomes a sweetmeat, and may be kept hanging for weeks and months after it is ripe.

Figs.—With the weather all in favour of rapid progress, the fruit on early pot Figs is now swelling fast, and the young tender leaves are beginning to expand under the genial warmth which mild sunny days enable us to secure without having recourse to sharp firing. Old trees which have filled the space allotted to them will soon require stopping and thinning in order to insure an even spread of foliage without crowding, as it is more than useless having more leaves than can be exposed to the action of sun-heat and light. Younger

trees having space to fill may be allowed to extend in every direction, when the firm, short-jointed growths so made will produce a succession of fine fruit after the earliest crop is gathered. The temperature of this house may now range from 58° on mild nights to 70° by day, when air must be admitted and taken off in time to run up a few degrees higher on fine afternoons. Pay particular attention to watering, and while guarding against clogging the fresh compost before it gets filled with new roots, see that the trees do not receive a check through becoming too dry. Syringe backwards and forwards twice a day when fine, and damp the floors only on dark, dull afternoons when there is danger of the foliage remaining wet after nightfall.

Succession houses started at the commencement of this month may be kept at a temperature of 50° to 55° at night, with a corresponding rise by day. Syringe well and see that the inside borders are brought into proper growing condition before the terminal buds burst into growth. Economise fire heat by the use of fermenting material placed on the borders, and set ammonia at liberty by turning it at short intervals. Give an abundance of air to the latest houses and wall cases. Prune, or rather thin out, the shoots and wash well with soapy water, but defer tying and nailing in for the present. Put in eyes or cuttings and treat as Vine eyes. If cuttings are preferred, the buds should be removed from the base, otherwise they will give much trouble by throwing up suckers after the trees get established. Also pot on young stock, using rich calcareous turf with a liberal admixture of old lime rubble and bone dust, and place the plants in an intermediate house for fruiting through the late summer months.

Strawberries.—The early forcing of Strawberries, like Cherries and Plums, requires great patience and unremitting attention to details. Where forcing is commenced in November, many good plants are sacrificed for the sake of a few Strawberries, which neither give credit to the grower nor pleasure to the consumer; while by deferring this work until the end of the year, a better supply of finer fruit would be secured until Strawberries are ripe in the open air. For the use of town-going families, April and May are the months in which a good supply of the finest kinds, including the old British Queen, should be in force, and in order to secure this supply, plants of two or three sorts should be selected from the cold plunging pits, every ten days properly prepared by washing the pots and top-dressing with rich loam and manure preparatory to placing them in the pits or houses in which they are to be brought forward. In this dark, variable climate it is difficult to give the exact temperature at which the forcing pit should be kept. At the present moment plants in the open air are in a state of excitement; last year at this time we had 30° of frost, two facts which show that the successful forcing of all kinds of fruit must be conducted upon the give-and-take principle, by running up to 55° or 60° on mild afternoons, and allowing the temperature to descend to 40° on cold nights. When the first batches of Héricart de Thury begin to throw up their flower-stems, a little extra warmth may be given to them through the day by shutting up early with solar heat and moisture from the syringe, but air must be again admitted at night, otherwise the foliage will become drawn and incapable of performing its proper functions when the fruit begins to swell. When in flower, remove the plants to the lightest and most airy part of the structure, and discontinue syringing, but keep them regularly supplied with tepid water, choosing the early part of the day for the operation. Remove weak side blossoms and fertilise with a small brush when the day temperature has reached the maximum.

Hardy fruit.—A continuance of unusually mild weather is beginning to tell unfavourably upon all kinds of fruit trees, particularly the easily excited Peach and Cherry against walls, Currants and Gooseberries upon open quarters,

and although the latter are regarded as of less value than the former, it is questionable if the loss of the crop of bush fruit would not be quite as severely felt as that of the Peach and Cherry. Under these circumstances steps should be taken to keep everything as backward as possible, as well as to have protecting material of various kinds ready for use when the proper time arrives. Peaches and Nectarines are, of course, unnailed, pruned, and securely supported by means of stakes and ties some distance away from the walls, and in this position they must remain until we have a change in the weather, or the rapid swelling of the buds press on the annual tying or nailing in. In the absence of frost a little extra care in washing the walls and trees of all kinds to free them from the larvæ of insects will be well repaid, the more so as birds of many kinds, friends as well as foes, have not recovered from the decimation of the past winter. For stone fruit trees after they are nailed in, a barrel of soap-suds from the laundry, with two or three pounds of sulphur and a like quantity of soft soap added, will make an inexpensive wash, which may be applied freely without fear of injury to the most tender buds.

If Gooseberries have not been pruned, the sooner they are done the better, as the crowded state of the trees induces early growth, and pruning checks it. An idea prevails that birds are not so likely to spoil an unpruned tree, but it matters little whether the tree is pruned or unpruned if a pair of bullfinches find their way into it. The safest and best way is to prune and dress with a mixture of soot and lime reduced to the consistency of cream, and passed through a fine sieve to admit of its being taken up and discharged by an old syringe. If time admits, trees in orchards should be thinned out and divested of Moss which may have gathered on the stems and branches by scraping with a piece of hoop iron. When this has been done, wash with the composition recommended for Gooseberries, and top-dress the roots with fresh soil, road scrapings, or rotten manure. Select clean ripe shoots from healthy trees for grafts, and lay them in under a north wall to be ready for use in March or April. For large standards which have been headed back, two-year-old shoots are generally used by experts in this country, and it rarely happens that a graft fails.

KITCHEN GARDEN.

It is neither desirable nor practicable for gardeners to save their own seeds, as they can buy them both cheaper and better than they can grow them, taking all kinds of seeds into the question. Nevertheless, a few special things should always be grown for seed. Among them, and what is most useful, is white or Seakale Beet. Select a couple of the best and pot them, placing them in a cold house where they ripen their seed properly between October and Christmas. This Beet is used as Seakale. The midrib is as white as snow, and makes a beautiful-looking vegetable. Of Onions, a small quantity should always be seeded merely to have a few specially large bulbs. There is no more beautiful sight in the kitchen garden than a border of Onions when kept trim and free from weeds. Celery, again, particularly the white variety, can always be got true from home-grown seeds. In the forcing department keep up good successional crops of French Beans, bearing in mind that good French Beans at this season cannot be too plentiful. Cucumbers are already feeling the good effects of the warm genial weather. Shut up early and give air early if at the expense of a little fire heat. It keeps the house sweet and the atmosphere moving and healthy; 65° is quite enough for the evening temperature. Plant Potatoes in frames if not already done, and keep up good supplies of Tarragon and small salads.

Composition of the Ice plant.—This plant, remarkable for the transparent vesicles filled with water, and resembling frozen dewdrops that cover its fleshy stem and large, thick leaves, is also a striking instance of the elective power

of roots, whereby plants can take up from a complex soil the materials proper to them. M. Mangon has cultivated it for seven or eight years, in La Manche, on the same ground with Cabbage, Celery, &c., and while these latter had their normal composition, the Ice plant, dried and burnt, furnished an ash with so much of chlorine and alkalies that at first he was inclined to think that some mistake had been made in weighing. Upon analysis the plant was found to be formed of a weak solution of alkaline salts, held by a vegetable tissue whose weight reaches less than 2 per cent. of the total mass. The ashes formed of salts of soda and potash form nearly half (43 per cent.) of the dried plant. This composition recalls that of Seaweed. M. Mangon asks whether the cultivation of the Ice plant as a potash plant might not be lucrative under certain conditions; in any case, it would probably be useful, he thinks, in removing from the salt ground on the Mediterranean coasts (its place of origin) the excess of alkaline salts which render it unproductive.

NOTES AND READINGS.

QUICK RETURNS.—A remarkable example of Grape growing is that recorded in THE GARDEN last week by "T. B.," and very encouraging to growers for market. It would seem almost as if we were yet only learning some things in relation to fruit culture. Vines planted "two years ago last spring" produced, in 1882, from canes two years old, between 30 lbs. and 40 lbs. of Grapes each. There are two rods to each Vine, and each rod bore an average of 8 bunches ranging from 2 lb. to 3 lb. apiece. Something like extension this, and the Vines, it appears, were not cropped their whole length, but are to be this year. The narrator forgets to state the length of the young canes, but we hear they are both long and strong. It will be remembered that about the very time these Vines were being planted, "T. B." predicted that the plan of having long canes and cropping them proportionately would fail and had failed. Peaches by scores of dozens, from a few trees the first and second year after planting, as has been recorded, and Grapes by the hundredweight from permanent Vines eclipse everything that was imagined but a few years ago.

ORANGE CULTURE.—It is said that in order to taste an Orange at its best it must be eaten just off the tree, and judging by the difference between the flavour of fruit produced at home in our hothouses and that of the shop Oranges, there must be a good deal of truth in the saying. Oranges are a most acceptable dessert fruit, and they are very wholesome as well; but before February or March they do set one's teeth on edge, and they are sparingly eaten except by children, and even the youngsters fight shy of them at first. The Brazilian Oranges imported lately in small quantities are sweeter and better flavoured, but are too seedy and too fleshy to be esteemed, and St. Michael's are becoming a precarious crop, it is stated. As a rule, imported Oranges are not in season till months after their arrival in this country. In private gardens, then, where they are esteemed, why not substitute Oranges for Pineapples? Some of the home-grown crops we have seen and heard of in orchard houses have been of the most encouraging description possible. Crops in perfection before and after Christmas, and fruit delightful in flavour—"a thing to be run for." The culture is easy and crops certain, a few good bushes yielding a large quantity of fruit. Whether Orange culture would pay is another question; but we imagine a good many west-end people would buy them faster than either Grapes or Pines if they once tasted the home-grown fruit.

FRAMES v. HOUSES.—Which are the best, most convenient, and most economical? Houses, both gardeners and nurserymen probably will say; at least for hardy and half-hardy subjects, or such as need hardening off. Frames with sliding sashes

are convenient for salads, bedding plants, and the like, but for mostly all other purposes—Cucumbers, Melons, Tomatoes, plants, and propagating purposes, houses or low pits with fixed roofs are best. The tear and wear of frames with moveable sashes, breakage, &c., is a hundred per cent. greater than in houses with fixed roofs, and work can also be done far better and more economically in the latter. It is only a question of shape of house and ventilation. For lofty plants lofty houses, and small houses for small plants, with few paths and the most plant space providable. The work of airing and shifting of lights in frames is very great, and the painting and cleaning needed to keep them in order is costly in the extreme.

FRUIT STORING.—A writer in the *Field* refers to the subject of keeping Apples in barrels as a plan worthy of general adoption. It appears Apples and Pears keep better and longer stored in barrels from the time they are gathered than in the most scientifically constructed fruit room, managed in the most approved fashion. All the gardener needs to do is to pack his fruit in barrels as he gathers it, head it up, and set it away in a cool, dry place, out of the reach of frost, till he wants it. As fruit rooms are chiefly needed for the storage of Apples and Pears, it would appear from this that they need not be such very special and costly structures as has been commonly supposed. All the American Apples are barrelled when gathered in autumn, and keep in perfectly sound condition for five or six months afterwards.

APPLE AND PEAR SHOWS.—Another writer asks in the interests of fruit culture in this country why we should not have Apple and Pear exhibitions as well as Potato exhibitions, &c., where the fruit could be shown in quantity at the right season or at various seasons, and so extend our knowledge of those varieties most suitable for home culture and other matters pertaining thereto. There certainly would not be the same objections to special shows of this kind as has been urged with some force against special Picotee, Pansy, and Auricula, and other frivolous societies in which so much energy and money have been wasted in times past. It cannot but occur to the most superficial observer that horticultural societies have in numerous instances pursued a rather aimless direction in the way of paltry objects, and neglected broad interests. One cannot read of the transactions of Continental and American horticultural societies, especially the last, without thinking that our neighbours have lifted such subjects on to a distinctly higher level than we have done in England, and regard them with far greater earnestness and purpose than we do. The subject in these countries seems to be taken up too more generally, and by men of greater standing and influence than with us. Their transactions are invested with far greater importance generally than ours, and the results are apparent in that rapid successful extension of fruit and vegetable culture which has aroused our wonder in this country and injured home trade so much. If, as many writers maintain, it is the fault of our land laws and aimless system of culture pursued, that the Americans have monopolised the fruit trade to such an extent, why have we had to learn the fact from abroad? and whose fault is it that while pomologists in this country have been aimlessly multiplying varieties of fruit to an innumerable extent, the Americans have been selecting severely from the old as well as the newer varieties, planting few sorts, and cutting the ground from under our feet in the matter of trade? How have the Frenchmen and Americans discovered that it pays best to plant their orchards exclusively with so few varieties, while we are still debating furiously about the best sorts of Apples and Pears to grow and not one authority amongst us could certainly tell us what half-dozen of either fruit was the most suitable under any given set of circumstances or situation? The idea of special hardy fruit shows is a good one if properly carried out.

As a rule the system of exhibiting half-a-dozen Apples or Pears on a plate in the early autumn to be judged, as likely as not, by men who do not know the name of one of the kinds before them, or anything about their qualities is a farce, but a sensible prize for the best barrel of English fruit between Christmas and May and at other seasons would bring us some tangible knowledge of the business, interest everybody, and confer a real benefit on fruit growers, who need nothing so much at the present moment as special knowledge concerning the varieties most suitable for culture, and their adaptation to circumstances of climate and soil, and no subject could more worthily engage the attention of horticultural societies.

*
FRIGHTENED SCRIBES.—A small coterie of "mutual admirationists" connected with the gardening press, on whom the breath of criticism seems to act like a shot in a covey of partridges, complain, in pathetic language, that the world is deprived of their wisdom because they cannot "record their experiences and opinions without being pounced upon" by vultures in the shape of critics, who, it appears, are ever on the alert to gobble up such innocents, and who haunt their imaginations, like Poe's "raven above the chamber door." These complaints have been rather frequent for some time back, and readers begin to enquire what magnificent genius has been smothered in this way, more especially as not one familiar face, or rather pen, is missed from the pages of the press, while new ones continue to be added. The pages of the horticultural papers continue to be filled as usual with interesting matter, and the editor's basket overflows. It is shrewdly suspected that the complaint of these craven-hearted ones is a want of confidence in themselves, and more particularly the want of courage of their opinions.

PEREGRINE.

ORCHIDS.

ORCHIDS IN THE MIDLANDS.

JUST as we find exotics dwindle in luxuriance the further we travel from the equator, so the cultivation of Orchids becomes less general as we leave the metropolis and pass northwards. There are oases, however, which keep appearing in both cases, and although not exactly "green spots in memory's waste," they are nooks and crannies in very unlikely places where these delightful forms of vegetation find "a foothold and a resting place" under specially advantageous circumstances. Such an one is the oasis at the Bridge of Allan, where that chief amongst Orchid growers, Dr. Paterson, holds sway. Indeed, it is as we travel to the north that the doctrine of the survival of the fittest can be best seen, so far at least as regards Orchids—that one particular branch of horticulture which is without doubt the most costly, and in which failures are so numerous as to make successful culture the more highly prized. Successful management of this kind in the midlands is exhibited in the collections of Mr. Salt, of Ferniehurst, and Mr. C. Stead, The Knoll, Baildon. Such also is Mr. J. Grimshaw's range of houses at Armley, near Leeds, of which I propose to give a few notes. Mr. Grimshaw is an amateur in the strict sense of the word, preferring to grow his Orchids by attending to them with his own hands whenever this is practicable. Is it not a treat, for example, to pay a visit to Burford Lodge and notice Sir Trevor Lawrence lovingly giving so much personal attention to his plants, although having so much cultural skill at his command? Or, shifting to another point of the orchid triangle, find at the Bridge of Allan just alluded to some of the best examples of successful culture this country has yet seen, entirely the result of the individual care of Dr. Paterson and his sons. There are five houses set apart by Mr. Grimshaw for the especial culture of Orchids, each of which was constructed to suit the class of plants intended for its future occupation, and whatever improvement suggested itself in current horticultural literature, so long as it appeared

rational and a move in the right direction, was adopted—cautiously and tentatively at first, of course. I was sorry to notice a deep railway-cutting within 200 yards of the houses, and to counteract the drawback of the consequent smoke requires no small amount of ingenuity. Ventilation through tiffany I will suggest as one way by which smoke may be arrested before it reaches and suffocates the plants by giving them carbon in a form they cannot assimilate. This tiffany may be nailed on the inside of the woodwork where the ventilators open outwardly, and *vice versa*. There are several customs here which commend themselves, and as they may be of service to others, I will recapitulate them. It is an axiom that to keep the roots of potted Orchids healthy there must be perfect drainage. Now, as Sphagnum which is not alive when used for potting soon decomposes and becomes sour, matted, and almost impervious to the requisite supply of water, it follows that the best means of keeping it alive and in a flourishing condition is the best for the Orchids. To this end sheep droppings are baked or dried so as to destroy all living organisms, and subsequently pulverised, the dust being carefully sprinkled amongst the Sphagnum during potting and repotting. Not only does this material feed the Sphagnum, but it acts in a powerful manner by assisting the growth of the plants. In those houses where

Making growth is proceeding I observe a freer use of moisture than is general, and if we take it for granted that the leaf is the most highly organised part of the plant, I can understand stimulants and strength being supplied in quantity in the best medium for absorption, viz., water, and a plentiful supply of this at a proper temperature, be it in a vaporised or liquid form. To disperse this moisture in a steady perpetual manner is the next question, and this is done by having long, low tins filled with water and placed under the hot pipes; a sheet of wet scrim is then spread over the pipes, one edge in the water, the other hanging a short distance over the pipes. The heat of the pipes causes the water to evaporate from the cloth, and by capillary attraction perhaps, or a sort of syphon action produced from the overhanging edge, the water must rise from the tanks, thus giving a constant supply of what Orchids must have when making growth—humidity. For houses containing much bloom, I need scarcely say that to adopt this plan would be to certainly spoil the flowers, and the incipient buds of *Dendrobiums* would in all probability be diverted into growth at their nodes instead of flowering. There is also another method of producing moisture in a fine dew-like shower at damping-down time by using a syringe furnished with Cooper's patent. This gives an almost impalpable mist very similar to what I imagine falls on vegetation in the Tropics just after sundown. In the house devoted to

Vandas, Angræcums, &c., a tank has been excavated below the ground level, about 15 feet long, 5 feet wide, and 3 feet deep, where aquatic plants may be grown with advantage. This is in the centre of the house, and over it a stage has been erected, through the bars of which the plants send their aerial roots, and show by their robust vigour that they are at home. Below the water-line is laid a series of hot-water pipes, which by their heat bring the water to a very suitable temperature for watering with, besides giving off a slight but constant supply of atmospheric moisture. This tank is also at a handy distance for allowing water to be taken up by syringe, and also for dipping blocks and baskets in, for if the presence of woodlice, &c., be suspected, they are soon brought to the surface of the pot or basket if the same be very slowly immersed in the water. Down the side of one house, on the usual staging, a long shallow dish of galvanised iron is placed the length and width of the stage, turned up at the edges about 4 inches. This dish is half filled with broken crocks and filled up with growing Sphagnum. On this the pots are placed, so we see that a continuous supply of moisture is always at hand when needed, and this may be dispersed in a natural

manner without having resort to so much drenching of the floors, &c., as is frequently done. Should it, however, be found that there is a superabundance, the tank in the floor may be emptied in a short time by tap and pipe connected with an outside drain, and allowed to remain empty for as long a dry season as required. So, too, in the house set apart for cool *Odontoglossums* provision is made for a steady, silent supply of imperceptible vapour by means of stone slabs edged by a strip of Portland cement, say an inch deep; on these slabs water is allowed to stand. In the water are tripods of strong copper or galvanised wire, bent to a circle at the top, and in this circle the pots are dropped, being slightly pressed in to give firmness. This excellent plan has the double advantage of giving perfect drainage to the pots and also preventing the passage from pot to pot of all manner of creeping nuisances—woodlice, ants, &c. If these vermin do happen to increase, it is on an island so small that their whereabouts soon becomes known, and they get crushed out of existence in a very literal sense. Along the side of another house, about the level of the waist, a sort of drain is built of brick the length of the house, about 2 feet wide by 1 foot deep, open at the top, and filled with clean, bright red burnt shale. Pots rest on the top of this, and it is surprising how the roots seem to revel in it if allowed, burrowing in it rapidly, and when brought to light, they seem stained with the colour of the shale. I say *seem* stained advisedly, for upon examination they will be found to have appropriated unto themselves small particles of the substance which they are in the act of dissolving by the peculiar exudation of roots, and afterwards assimilating through the ordinary channel in solution.

Flat tables are likewise used, edged with strips of wood projecting upwards about 2 inches, and on these are placed fine washed black cinders such as are used at smithy fires (they are known as "breeze"); on these again are placed the pots. These cinders are easily procured of any blacksmith, and when well washed do not look at all unsightly; they are about the size and uniformity of beans, and as moisture stores cannot be surpassed, this being the principal reason for using them. They give perfect drainage, besides providing such an agonising highway for creeping things as to be quite a barrier. Mr. Grimshaw's success as an Orchid grower is shown by the gradual increase noticeable in the size of the pseudo-bulbs year by year. Orchids are different from most plants in that they give us a yearly record plainly written of successful treatment or otherwise. Where one sees the imported pseudo-bulbs gradually dwindle in size, we can form a pretty sure guess that the end is not far off unless there be a radical alteration. On the contrary, if, instead of signs of dissolution, an annual development is evident, we may be sure they are thriving, so far as growth is concerned. The blooming of Orchids is quite another matter, being produced by a change of treatment at the correct season for different species in almost inverse ratio to the production of growth. They give us, by the way, another record of flowering as of growing, by the remains of the old stalks which supported the bloom, and here there is no lack of such persistent stems. By careful experiments in each house, the dew point has been found, the point at which vapour condenses, and at these points such Orchids are placed as would be found in a natural state luxuriating at the daily dew point. I observe also that

Choice Ferns, most of the spores of which have come attached to the imported plants, are allowed a liberal latitude amongst the Sphagnum and on the blocks. It is argued that as they only require a reasonable amount of moisture for their sustenance, and of this there is ample store, the harm they do, if indeed any, is more than compensated for by keeping the Sphagnum porous and sweet. They also contribute to the luxuriant beauty of tropical vegetation by their elegant fronds hanging in all manner of graceful lines and hiding the truly hideous pseudo-bulbs of many Orchids. It

may be worthy of remark here that wherever Nature has bestowed upon plants beauteous flowers, so as to allure certain insects to them for purposes of cross fertilisation, she almost always withholds attractions from the foliage; the opposite is also the case when the leaves bear enticing colours. This may hold good too with regard to form, for of all foliage which lacks grace and beauty of outline or colour Orchids are paramount. I speak generally, and do not of course include the *Anacochilus*. Consequently, if we can render this ugliness less obvious without much sacrifice we should do so. Anyway, to see a vista of blocks and baskets bearing rare Ferns above and below strikes one as being worth a little sacrifice of moisture. By watching current literature and applying in the houses such conditions as are found amongst Orchids at home, and by carefully experimenting on rational suggestions, such results are obtained at Arlsey as quite go to establish a reputation for the satisfactory culture of these delicate plants, even though the collection may not be so extensive as its owner might desire. But whoever had a large enough collection of Orchids? Who has had as many choice varieties of alpinas as he wished, or Roses, or, for the matter of that, anything beautiful? The love of flowers "makes the food it feeds on" until it becomes almost a passion, for do we not hear of an intense liking for any speciality being designated a mania? So be it; but it is such a delicious frenzy that we cannot wonder at the wealthy sacrificing their time and even small fortunes in its pursuit, and botanists sometimes life itself.

R. A.

Horsforth, near Leeds.

CATTLEYA LABIATA PERCIVALIANA.

THERE is an old proverb, "Let those laugh who win." In this case the losers need not cry if they possess a fair stock of this *Cattleya*, and hardly are losers, for they have a beautiful flowering plant. By yesterday's post came a bloom of this plant from Mr. R. P. Percival, who may now well be proud of his *protégé*. There now can remain no doubt that it is a very grand *Cattleya*. I will describe it as accurately as possible and without any "varnish." I have in front of me two flowers of the dark variety of the old *C. labiata* to see the truth of a quotation that I hereafter refer to and find correct, but that *C. Percivaliana* has even a larger blotch. It is as follows: Sepals (all three), $2\frac{1}{2}$ by $1\frac{1}{2}$ inches; petals, $2\frac{1}{2}$ by $1\frac{1}{2}$ (slightly quilled towards points), all uniformly dark rosy purple; lip, $2\frac{1}{4}$ (much arched) by $1\frac{1}{2}$ in the expanded portion. Dark rosy purple runs all along the upper edges for $\frac{3}{4}$ deep. Inside it is a dark brown orange (which is so dense as to show through to the outside, thereby eliminating the rosy purple) with deep crimson-brown lines traversing the whole way from the base to the somewhat indistinct brown-orange mark that backs up the solid deep crimson-lake blotch which is margined by a little paler shade than the petals. Mr. Percival tells me he has a plant developing eight such blooms, and when these plants attain their full strength we shall be able to say we have as handsome a flower as that of the old *labiata*, though, of course, its value must be less, for there are in cultivation as many scores of *Percivaliana* as there are units of old *labiata*. It seemed as if a well-known writer on Orchids in the late periodical *The Gardener*, who signed "F. W. B.," fancied I was of opinion that these two plants were one and the same. I was not, nor am I now, but I always considered *C. Percivaliana* to be a beautiful variety of the *labiata* section; now I am more than that ever. Of course, inferior varieties may bloom with the good ones, but there is no doubt now that many fine ones have bloomed. Then I may refer to "F. W. B.'s" remarks in *The Gardener* of September, 1882, when he says: "It is just a little disappointing to be told in THE GARDEN that it resembles *C. Mossie* more than it does *C. labiata*." Perhaps this was said of the plants (few, I think) that bloomed last summer; there may have been *Mossie*, true, and bloomed in proper season;

there might have been a few amongst the rest. Further on in the same journal he quotes from Reichenbach's "Walper's annales," where the professor says: "In *C. labiata* the lip is stained with a deep uniform tint of crimson." His disappointment, then only a little, will now, I hope, vanish entirely if the above description, especially that of the blotch, chances to come under his notice, which undoubtedly corresponds very much with the one he quotes, and I think "F. W. B." will now agree with me that Professor Reichenbach was warranted in calling it *Cattleya labiata Percivaliana*.

D. B. CRAWSHAY.

ORCHIDS IN BLOOM.

THE Orchid houses at the Victoria Nurseries, Upper Holloway, are particularly gay with bloom for January, and had not the fogs so decimated the incipient flower-spikes the display would have been finer. The evil effects of the fog are especially noticeable in the *Vanda* house; no fewer than two dozen spikes were cut off, but for all that there are a score or so of fine spikes of such species as *V. suavis* and *tricolor* which alone fill the house with delightful perfume. The *Cattleyas*, in which Mr. Williams' collection is so rich, already make a fine show, chiefly effected by *C. Trianae* and its numerous varieties. For many years Mr. Williams' aim has been to collect from every available source the finest and most distinct varieties of this species—which is one of his favourite *Cattleyas*—that could be got, the result being a particularly fine series, many of which are at present in bloom. Those of which we took special note were *C. Trianae rosea*, remarkable for the uniform delicate rose tint pervading the sepals and petals as well as the labellum with no other tint whatever; *nivea*, so named on account of the pure whiteness of the flowers, which have only a dash of yellow on the lip to mar their purity; *Corningi*, with fine, large, and broad-petalled flowers, which are white with the lip suffused with a soft rose hue; *Rougieri*, also with white petals and sepals, but the labellum has the greater part of the terminal lobe of the richest carmine-magenta imaginable; *Hilli* is similar, but the lip, though somewhat larger, is not so deep in colour; another called *Thomsoni*, a charming variety, likewise resembles *Hilli*, but is nevertheless distinct as regards the peculiar shades of colour. Two splendid forms unnamed, but distinguished as Cox's variety and Brooke's variety, are of special merit; both have gorgeously coloured lips, particularly the latter, the labellum of which bears a great resemblance to that of *C. labiata* in its broadness, exquisite fringing, and resplendent hues. Among other flowers in the *Cattleya* house are *C. Percivaliana* (a good form of it), *C. Warszewiczii* delicata, *C. chocoensis* and its variety *formosa*, which, by the way, is much superior to the type, inasmuch as the blossoms expand more fully, and the colour is very delicate and beautiful, while it retains the delicious aromatic perfume. Among flowering *Laelias* is the rarely seen *L. Lindleyana*, which reminds one of *L. Perrini*, but the flowers are smaller and inferior; the petals and sepals are narrow, and together with the lip are washy in colour, and the plant is altogether unworthy to perpetuate the name of the great orchidist after whom it was named. A greater beauty is *L. harpophylla*, one of the choicest Orchids grown, as the colour is so uncommon. It is in the way of *L. cinnabarina*, but the flowers are larger and the colour is a bright orange inclined to vermilion, a colour rarely seen in any other flower.

The *Odontoglossum* house is bright with a host of flowering plants, chiefly of *O. crispum* (*Alexandrae*), which include some superb varieties, such as *Horsmanni* and *Chestertoni*. Both are remarkable for the large and handsomely shaped white blossoms, heavily blotched with cinnamon-brown, the latter being the darkest tinted. *O. Horsmanni* has a gracefully arching spike of about a dozen flowers. One of the finest forms we have yet seen of the variable *O. triumphans* is in perfection. Compared with the ordi-

nary form, the flowers of this are a third larger, and the colours are brighter and the markings more pronounced. Another exceptional variety is *O. Halli leucoglossum*, so named on account of the labellum being white instead of brownish. It is one of the handsomest of this section of the genus. Among other kinds in bloom were *O. cristatum*, *sceptrum*, *hebraicum*, and the dainty little *O. Krameri*, from Costa Rica, a small growing species allied to the summer-flowering *O. citrosimum*. Like it, the bulbs are flattish, and from the base of them spring the pendulous spikes, the flowers on which are over an inch across and have mauve petals and sepals and a beautifully violet-tinted labellum. It is a little gem for growing in a suspended pot or pan, and thrives admirably in an intermediate house. *O. cariniferum*, with enormous bulbs, has produced a spike nearly a yard high, widely branched, and bearing a profusion of buds which in a few weeks will be expanded. The modest little *O. Elstedii*, still comparatively rare, was beautifully in bloom in the *Masdevallia* house. It is very dwarf and bears numerous waxy white blossoms about an inch across from the base of the bulbs.

Among the *Masdevallias* were *M. ignea* and its lovely violet-tinted variety *Massangeana*, *M. amabilis*, a small, but pretty flowered species; *M. tovarensis*, triangular, *Shuttleworthi*, a beautiful form with large highly coloured blooms; *Haryana lilacina*, with large flowers of a bright bluish purple with white tube; and *M. Veitchii grandiflora*, the finest coloured and largest flowered variety of this the undisputed queen of the genus.

W. G.

Odontoglossum gloriosum.—A spike of this species, over 2 feet long and bearing 14 blossoms, comes from Sir William Marriott. Such a fine wreath of bloom as this it not a common occurrence, and shows well how admirably cool Orchids are cultivated at The Down House Blandford.

Cattleya Trianae.—A lovely variety of this superb Orchid reaches us from Mr. Fowler, Ashgrove, Pontypool. It is remarkable for the great breadth of the petals, which are of a delicate lilac-rose, and the richness of the labellum, which has a bright golden yellow throat, while the rim and lower half is of the richness amethyst tint. The plant Mr. Fowler possesses of this variety bore this year three spikes with two blossoms each.

Phalaenopsis buds not opening.—Can any of your readers inform me why the buds of my *Phalaenopsis* fail to open? They seem to grow up to a certain point and then instead of opening turn yellow and go off. This has happened with four plants of *P. amabilis* and one of *P. leucorhoda*. They are in the house in which they have always grown, which is kept at a minimum of 60° by night. Some few buds of *Dendrobium Wardianum* have gone off precisely in the same way without my being able to account for the fact.—IGNORAMUS.

A variety of Odontoglossum crispum, with flaked and spotted flowers, has been sent to us by Sir William Marriott, Down House, Blandford, who rightly thinks that he possesses a treasure. The flowers are over 3 inches across, the sepals and petals being very broad, so as to overlap each other, the latter beautifully crisped at the margins. Both petals and sepals are pure white, flaked and spotted on both sides with bright violet-purple, giving the flower a beautiful appearance, which the white and golden crested labellum considerably enhances. This is another instance of the variability of this *Odontoglossum*, but we have never seen a variety so singularly beautiful as this one.

Orchids and frost.—Under this heading (p. 50) I see the experience of a writer who found Orchids to stand frost better than other plants. I, who can vouch for the accuracy of the following, can corroborate it, and also show that they will stand even more than "frost having obtained a footing in the houses." My plants, purchased at Hooley House, Coulsdon, Surrey, were packed in

hay and newspapers in a van with a tilt over it, and travelled the night of January 15, 1881, to Sevenoaks in 20° frost, and roads a foot deep in snow. These were as follows: *Vanda tricolor*, *Angraecum eburneum*, carrying eighteen flowers, *Saccolabium retusum*, *Maxillaria punctata*, *Aerides Lindleyanum*, *Cattleya Trianae alba*, *Dendrobium Findleyanum*, *Parishi*, and noble, and *Aerides Warneri*. With the exception of Nos. 3 and 5, they are, nor were, the least the worse, and are all now in perfect health and vigour, with one exception, as to quantity of bloom, as *A. eburneum* then carried eighteen flowers, in 1882 nineteen, and now but ten, otherwise all the plants have progressed; the *Cattleya* has made an extra lead since its freezing. I publish this to ease the minds of many who perhaps may fear their plants have been chilled. Of course the great secret was they were dry at the time; otherwise death was certain.—D. B. C.

KITCHEN GARDEN.

PITS AND FRAMES FOR VEGETABLES.

ACCORDING to my experience the majority of proprietors of moderate sized gardens scarcely realise the value of pits and frames, more especially for forwarding the supply of a few kinds of popular vegetables. In large gardens, as a rule, we find an imposing array of them devoted, in the first instance, to early vegetable culture, and later on, according as cleared, to hardening off bedding plants, the summer culture of Cucumbers, Melons, Capsicums, and Tomatoes, and the preparation of various kinds of flowering plants for the beautification of the houses during the winter. Now, if these pits and frames are found indispensable in large gardens, it is evident a proportionate number would be equally serviceable in smaller establishments. Some years ago I was in this predicament. Pits and frames we had in abundance after a fashion, but they were literally all to pieces, the lights being shaky and nearly clear of glass; much of the brickwork was falling, and the stout woodwork was rotten. We commenced our rough repairs by glazing some of the soundest of the lights at the expense of the remainder, as we preferred to have a few good ones, more especially for the earliest crops, rather than a greater number of bad ones. The skeleton lights were covered with strips of felting, and more of this was employed on frames destined to cover some large rough pits, which we constructed with boards of various descriptions obtained as best we could. In addition to these coverings we found it advisable in case of extra cold weather to have a heap of rough dry litter from the stable yard in readiness to throw over the top and sides of the frames. Yet in these cobbled-up makeshifts we, during two seasons, grew a capital lot of early vegetables, some of which frequently figured prominently at horticultural exhibitions, and certainly have not been excelled by any we have since grown in the orthodox fashion. Moreover, the rough pits were of great service in rearing early plants for the kitchen garden, and we still prefer them for this purpose. Now my present object is to induce others to attempt early vegetable culture even with apparently unsuitable appliances, or, better still, with good pits and frames. It is true they must be prepared for a considerable amount of work, but they will be amply compensated. It may also, as in my case, eventually result in old pits being repaired and new pits and frames added. Employers are not blind to their own interests, and my advice to newly-engaged gardeners is to first merit and then ask for encouragement in the shape of improvements. At the commencement

Heating material, and this in considerable quantities, will be found indispensable, nothing, in my opinion, being better than a mixture in equal portions of fresh stable manure and leaves. The former alone is apt to become violently hot even after careful preparation, and this, besides injuring the occupants of the frame, leaves the manure in a mouldy state. Leaves alone cannot

always be depended upon for retaining heat for any length of time. This will be especially the case this season, as by no means could they be collected sufficiently dry to prevent rapid decomposition. Stable manure requires to be well shaken up into a heap, to stand for a week or ten days according to the weather, when it should be turned and again allowed to heat for the same period. In this manner much of the poisonous rank heat will be thrown off, and the manure and leaves may then be well shaken up together, and in most instances may be used at once—vegetables, as a rule, not needing deep hotbeds. We usually require three large heaps of heating material during the season, the first being now prepared, and the remainder according as the manure is forthcoming.

Suitable soils are not always easily obtained, especially during the first season, in sufficient quantities for a large number of frames. The following season much of the old material is available if freshened up with loam, leaf-soil, &c., as the case may be. Our compost is made up with old potting soil, old Cucumber and Melon soil, leaf-soil, and road trimmings, not mixed promiscuously, but regularly and carefully stored away in heaps, and employed according to the requirements of the various crops. It is almost impossible to preserve a tidy appearance where this kind of forcing is carried out, and for this reason no garden should be without a frame-ground, or Melon-yard, as it used to be termed. This, if possible, should be outside the garden proper, being then more accessible to carts. It ought to be well drained, and if sheltered from cold winds, much heat will be preserved in the beds that otherwise would be quickly blown out.

Carrots and Radishes, we find, are always most acceptable in a young tender state. For this reason a sowing is made as early in January as circumstances permit, followed by another sowing about six weeks later. A shallow hotbed is formed about 3 feet high at the back and sloping well to the front. A shallow two or three-light frame is placed on it, and filled to within 9 inches of the lights with the shortest of the manure, and on this is disposed about 6 inches of sifted soil, nothing being better for this purpose than old potting soil. If the manure has been well prepared, there is little danger of its overheating, but should this be anticipated, the soil, in this and all other cases, should not be put on till it declines to 75°. When the soil is warmed through, drills are formed with an angular strip of wood, and about 4 inches apart, every alternate row being sown with Carrots and the remainder with Radishes, the soil being levelled over them. It is a great mistake to sow the seed at all thickly, as every good seed is certain to germinate, and crowding spoils the seedlings, besides necessitating much thinning out. The frame may be kept close and dark till the Radishes, which germinate much the quickest, are pushing through, after which air must be given on all favourable occasions. Both the Carrots and Radishes will be benefited by having the lights thrown off during the warmest part of sunny days, and should be protected during the nights. When closing the frame early in the afternoon it is advisable to lightly damp the surface of the bed. By the time the earliest Carrots are fit for drawing, the lights may be dispensed with, any light, protecting material being substituted in case of frost. The best Carrot for all purposes is the Nantes Horn, and if some of the sturdiest of the seedlings are reserved and kept watered as required, these will give handsome roots, invaluable for exhibition purposes during May, June, and July. Of Radishes, Wood's Early Frame is still the most profitable early variety, while the French Breakfast and the new Extra Early Forcing Red and White Turnip varieties are quick-growing and good in quality. Very little bottom heat is necessary for Carrots and Radishes sown later than February.

Potatoes are now being fast planted in pits and frames, and where Radishes are in great demand these are sown thinly either between the rows or over the whole bed. I do not recommend sowing Ra-

dishes with Potatoes, however, if sufficient can be grown elsewhere. All our earliest seed kidney Potatoes are stored on their ends in shallow boxes, and all side shoots either rubbed off or picked out with the point of a knife, as we prefer to depend entirely upon the strong central sprout. Those intended for the earliest plantings are plunged thinly in boxes of leaf-soil and placed in a gentle heat to sprout. They root strongly into the leaf-soil and can easily be moved and planted into the warm soil of the pits and frames without experiencing the slightest check. Glazed unheated pits are prepared for them by first securing a depth of about 3 feet of well-turned heating material; on this is placed a layer of short manure, finishing off with a depth of 10 inches of compost. Any light soil is suitable, but our favourite compost consists of old Melon and Cucumber soil and finely sifted old potting soil in equal proportions. Out of such a mixture we have turned some of the cleanest and best Potatoes we have yet seen, and fit for any purpose. The frames we use for early Potatoes are about 27 inches deep at the back and 18 inches deep in front, and for these the beds are made about 4 feet high at the back and a foot less in front. As it is necessary to have the growth as near the glass as possible, we sink the frames into the bed to about half their depth, and otherwise prepare them similar to pits. The frames can be raised whenever the haulm gets dangerously near the glass. Potatoes should not be planted till the trial stick, which ought always to be plunged into the centre of the beds, can be borne comfortably in the hand. The drills are drawn with the hand—three to each light, or about 18 inches apart—from the front to the back and 8 inches deep. The tubers are disposed 8 inches apart and only slightly moulded over, preferring to level the bulk of the soil drawn out about them as they advance into growth. But little air is given in the first instance unless the heat is very moist. In this case a little air should be constantly given. Later on air must freely be given whenever the state of the weather permits, always guarding against cold winds, the aim being to secure a sturdy growth. The soil should be kept in a moist state till ripening commences. The frames may be closed early in the afternoons, but it is not advisable to damp the foliage, as this may be the means of inviting the Potato disease. The earliest crops should be covered up every evening, and the later ones whenever frost is imminent. We fill as many pits and frames as we can possibly spare with Potatoes, and according as the manure is prepared. Two large rough unglazed pits are not filled till March. We have tried several varieties of Potatoes, but for frames we now rely entirely upon Veitch's Improved Ashleaf. Those who prefer a round variety should grow either Sutton's First and Best or Early Border. We tried a few of the latter last season, and have formed a high opinion of its merits.

Peas are not extensively grown in frames, not so much in fact as they deserve to be. At one time we grew Laxton's Unique in unglazed pits, and by these means secured remunerative crops fourteen days in advance of the earliest outside pickings. We next grew Laxton's Minimum in addition in a glazed pit and gained another fortnight. Now the same results are obtained by growing American Wonder under glass, to be followed by the same variety grown at the base of the warmest garden walls. The latter variety is particularly well adapted for this purpose, but it has one fault, if I may so term it: it spoils the palate for the earliest round-seeded varieties. The shallow pits in which they are grown being now filled with Strawberries in pots, we sow the seed at the present time in boxes of leaf-soil and transplant. These boxes are placed on the border near the glass of an early Peach house, and before the plants become drawn are transferred to a cooler house. In the meantime a depth of about 18 inches of the shortest of the prepared heating material is well trodden into the pits, and over this is disposed about 9 inches of good loamy soil. When warmed through deep drills about 18 inches apart are drawn out with a spade, much as we would for a Box hedge; the Peas are shaken out of the soil, dis-

persed in a single row about 2 inches asunder, and the roots carefully covered. This simple plan we find to answer better than several others we have tried, as the strong roots with their clusters of rootlets are easily preserved, and, when carefully planted, take quickly to the fresh soil, no appreciable check being given to the growth of the plants. Between the rows we are able to get a line of early Paris Market Lettuces, these being previously sown in a box at the same time as the Peas, and are fit to dibble out when the latter are. Planted 6 inches asunder, they soon fill up their allotted space, and, owing to their extreme earliness and excellent quality, more than compensate for the labour bestowed upon the two crops. A few Radishes may also be obtained from these pits. Peas require little or no bottom heat, and no protection other than the lights of glazed pits or frames or mats where grown in unglazed structures. When well established, and not till then, they should receive air freely on all favourable occasions, and never be allowed to get very dry at the roots. They may be grown with or without stakes, but we prefer to keep them upright with the aid of Birch twigs. Years ago we saw what should have been a good pit of early Peas spoilt owing to being planted in shallow soil over dry mouldy manure which no watering would change. It was a good lesson, and I have never failed to provide early Peas with a bed of short, moist manure for them to root into.

Cauliflowers we grow in a rough pit, prepared in a manner similar to that described for Peas. We now have glazed lights for the earliest, and prefer them to hand-lights. The plants are wintered in boxes, and early in February are planted out, about 15 inches apart each way, and treated similarly to the Peas. If large heads are required, say for exhibition purposes, when these are commencing to form it is advisable to water frequently with strong liquid manure. The Extra Early Forcing varieties are very early, and to succeed these we grow the Dwarf Erfurt Mammoth. W. I. M.

Turnip-tops.—We find these extremely useful at this time of the year. When sufficiently blanched they become remarkably crisp and serviceable for kitchen purposes. Planted under any suitable stove central stage amongst sand, leaf-mould, or soil, or in boxes placed above the boiler in stoke-holes, shading the sets or plants from the influences of light, they will be ready for cutting in the course of eight or nine days afterwards. By planting fortnightly sets and keeping them damp at the root they may be had at any time throughout the winter months, when other vegetables are scarce.—G. D.

Potato culture.—The plan of culture which I have adopted has been very successful. I select good Potatoes for sets, and keep them through the winter from sprouting. If left uncared for they get so much exhausted by growing out before they are put into the ground, that it is impossible to have a good crop. Very often I see Potatoes planted with long sprouts, and in that case they are up before they have made roots. I also see them planted so much too close that neither sun nor air can get through them. I plant all my Potatoes about the second week in March without any sprouts, i.e., if the land is in a fit state to receive them; then both roots and sprouts start together, and when just coming up if you examine one you will find a large mass of roots attached to it. In that case if touched by spring frost they have something under the ground wherewith to withstand the check. I plant early and late kinds all at one time. Some plant late ones first and early ones a month later, and expect the early ones to be fit for table a month before the late kinds. But I say put them all in at one time if you want a good crop, then the early sorts will be fit for use some time before the late kinds. I plant the early ones 2 feet apart, and the late 3 feet apart from row to row. Any person who follows my practice will never fail to have a good crop. I have adopted this plan for

six years without a failure. The crops are, however, heavier some years than others.—E. B.

NOTES OF THE WEEK.

DUKE OF BUCCLEUCH GRAPE PRIZE.—We are requested to direct the attention of Grape growers to the prize offered for this Grape, advertised in this week's GARDEN, and which will, we understand, not appear again.

GOD'S ACRE BEAUTIFUL.—In the second edition of this, just published, there are a series of fine plates of the choicest urns in the collections at Rome, and also an account of the recent cremations in Dorset and of the circumstances which gave rise to them.

THE IMPERIAL HORTICULTURAL SOCIETY OF RUSSIA will hold an international exhibition and congress at St. Petersburg on the 5th of May, and it will continue open for twelve days. Invitations to attend have been issued to the leading European horticulturists and botanists, and a highly satisfactory show is expected.

NATIONAL HORTICULTURAL SOCIETY OF FRANCE.—The first exhibition of this society for the present year will be held in the Champs Elysées, Paris, from March 28—April 1. Foreign exhibitors are invited to compete. The schedule, which comprises sixty-one classes, includes Crocuses in twenty-five varieties, Anemones, Ranunculuses, and other spring-flowering plants, besides new plants and Orchids.

THE PELARGONIUM SOCIETY'S schedule for the forthcoming season is an expansion of that of last year, the classes for new varieties being arranged to admit three, two, or one, at the discretion of exhibitors. The prizes offered last year for hybrids of Geranium pratense and Pelargonium oblongatum are repeated, and the Council of the Royal Horticultural Society have added a silver Banksian medal for the best specimen plant in the show to be held in June next.

IS THE NEWTOWN PIPPIN DISAPPEARING?—I bought some Apples under this name the other day at a very high price. They had some resemblance to the Newtown and were about the same texture, but not the same spotting, shape, and very far from the Newtown flavour! Such is the popularity of the Newtown in England, that even such second class fruit as I describe find buyers at 4d. and 6d. each. If the true Newtown is no longer to be grown with success in America, it may be worth while noting that some people are clever enough to send us a fruit something like it, and bearing falsely the name Newtown Pippin.—V.

SPECIAL PRIZES.—Messrs. Sutton, Reading, ask us to state that they intend to offer the following prizes for flowers, vegetables, fruit, and Potatoes at the Royal Horticultural Society's shows, South Kensington, and at the International Potato Exhibition, Crystal Palace, during the ensuing season.—**March 29.** For 9 seedling Cinerarias (single): 1st prize, £3 3s.; 2nd, £2 2s.; 3rd, £1 1s. **May 22, 23. Great Summer Show.**—For 9 herbaceous Calceolarias: 1st prize, £3 3s.; 2nd, £2 2s.; 3rd, £1 1s. For the best brace of Cucumbers, any variety: 1st prize, £2 2s.; 2nd, £1 1s.; 3rd, 10s. 6d. No variety for which a special prize is offered in the Society's schedule may compete for these prizes. **June 26. Pelargonium Society's Show.**—For 9 Tuberous-rooted Begonias: 1st prize, £3 3s.; 2nd, £2 2s.; 3rd, £1 1s. For 12 Gloxinias: 1st prize, £2 2s.; 2nd, £1 1s. For 4 dishes of Peas, distinct varieties, 50 pods to a dish: 1st prize, £3 3s.; 2nd, £2 2s.; 3rd, £1 1s. No variety for which a special prize is offered in the Society's schedule may compete for these prizes. For six varieties of Lettuce, three specimens of each: 1st prize, £2 2s.; 2nd, £1 1s.; 3rd, 10s. 6d. For three distinct varieties of Endive, three specimens of each: 1st prize, £1 1s.; 2nd, 10s. 6d. **July 3. Great Rose Show.**—For collection of vegetables, 10 distinct kinds, as follows, no restriction as to sorts—12 Onions, 50 pods Peas, 12 Carrots, 12

Turnips, 50 pods French Beans, runners or dwarfs, 4 Cos Lettuce, 4 Cabbage Lettuce, 3 Cauliflowers, 1 brace Cucumbers, 9 Potatoes: 1st prize, £4 4s.; 2nd, £3 3s.; 3rd, £2 2s.; 4th, £1 1s. For a single Melon: 1st prize, £3 3s.; 2nd, £2 2s.; 3d, £1 1s. No variety for which a special prize is offered in the Society's schedule may compete for these prizes.

July 24. Carnation and Picotee Show.—For three heads of spring-sown Cabbage: 1st prize, £2 2s.; 2nd, £1 1s.; 3rd, 10s. 6d. No variety for which a special prize is offered in the Society's schedule may compete for these prizes. For six distinct sorts of early Potatoes, twelve tubers each: 1st prize, £4 4s.; 2nd, £3 3s.; 3rd, £2 2s.; 4th, £1 1s. No variety for which a special prize is offered in the Society's schedule may compete for this prize. For the best dish of any kidney Potato: Prize, £1 1s. No variety for which a special prize is offered in the Society's schedule may compete for this prize. **International Potato Exhibition, 1883.—Class B.** For eighteen distinct varieties of Potatoes, 9 tubers each: 1st prize, £7 7s.; 2nd, £5 5s.; 3rd, £3 3s.; 4th, £2 2s.; 5th, £1 1s. **Class K.** For eighteen tubers of each of the following Potatoes: Sutton's Magnum Bonum, Sutton's Early Regent, Sutton's Early Border, Sutton's Reading Russet, Sutton's Reading Hero, Sutton's First and Best, Sutton's Fillbasket, Sutton's Prizetaker: 1st prize, £5 5s.; 2nd, £4 4s.; 3rd, £2 2s.; 4th, £1 1s. **Class L.** For a dish of a coloured round Potato of English origin, eighteen tubers: 1st prize, £1 1s.; 2nd, 15s.; 3rd, 7s. 6d. **Class M.** For a dish of a white round Potato of English origin, eighteen tubers: 1st prize, £1 1s.; 2nd, 15s.; 3rd, 7s. 6d. **Class N.** For a dish of a coloured kidney Potato of English origin, eighteen tubers: 1st prize, £1 1s.; 2nd, 15s.; 3rd, 7s. 6d. **Class O.** For a dish of a white kidney Potato of English origin, eighteen tubers: 1st prize, £1 1s.; 2nd, 15s.; 3rd, 7s. 6d. **Classes B and K** are open to noblemen's and gentlemen's gardeners only, and the awards to be made by three gardeners, who will not be competitors. **Classes L, M, N, O** are "open," and are for varieties of English origin, whether already in commerce or not in commerce prior to season 1883.

TREES IN STREETS.—An interesting controversy on the utility or otherwise of trees in streets and open spaces has been lately going on in the columns of the Geneva press. The controversy arose out of a discussion in the International Hygienic Congress, which was held in Geneva in August, and Dr. Piachaud, a member of the Congress, has since contended, in a letter addressed to the *Journal de Genève*, that trees in streets do more harm than good, that they impede the circulation of air, and that, as for the shade they afford, people who do not like sunshine, have only to keep on the shady side of the street. Instead of planting more trees in towns, as some propose, he would rather, in the interests of hygiene, remove all existing trees. To him replies Professor Goret, of the University, who treats the matter from an exclusively common-sense point of view. As for people who want shade keeping always to the shady side of a street, he points out that, as streets have generally shops and houses on either side, Dr. Piachaud's advice in this regard, however ingenious, can hardly be regarded as practical. But the functions of trees in streets are not limited to acting as screens for sunshunning wayfarers; they temper the heat and serve as a protection against dust. The evaporation from their leaves tends to keep the surrounding air cool and moist. One of the best means of refreshing the air of a sick chamber is to place in it plants and branches and sprinkle them with water. A like effect is produced by trees. Sunlight is necessary to health; but trees, if not too thickly planted, do not intercept sunlight; the perpetual vibration of their leaves and swaying of their branches admit the light every instant, and in sufficient measure, and serve, moreover, to protect the eyes from the noonday glare. So far from trees impeding the circulation of air, they help to purify

the air; the evaporation from their leaves determines a current from above, and the fresh air thus brought down helps to drive away the heated and dust-impregnated gases of the streets. Another useful property of foliage is that, while in hot, dry weather it moistens the surrounding atmosphere, thereby rendering it fitter to breathe, this effect, which is due to evaporation, ceases in wet weather. Trees, moreover, act as purifying agents by absorbing carbonic acid and giving out oxygen. But the action of trees on the air is far less important than their action on the soil. Their roots draw up stagnant waters and absorb the organic matters contained in the filth from which the streets of a town are never free, and which, after infiltrating the ground, are a frequent cause of fevers and infection. Trees, in fact, have the same effect on the subsoil of towns as fields have on the contents of their sewers—they act as disinfectants. Taking these facts into consideration, Professor Goret ventures to differ from the conclusions of the Hygienic Congress, and strongly recommends the planting of trees in streets and squares. But they must be planted with judgment. They should be placed at proper distances apart, and the branches should not be allowed to come in contact with the buildings near which they grow. The sorts best adapted for street planting are those which grow to a considerable height and spread out their branches. The fashion that prevails in some Continental cities of cutting trees down to a uniform size is highly objectionable. The branches of trees so treated become so compacted together as to be impervious to light, and the shade they give, although deep, is too circumscribed to be of much use.

VARIETIES OF POLYPODIUM VULGARE.—As it will interest hardy Fern cultivators to know the difference that exists between the Irish *Polypodium vulgare* var. *trichomanoides* and that of the Cornwall one named *cornubiense*, I forward for comparison fronds of the latter taken from two plants which vary sufficiently to cause the impression that they represent seedlings from cultivated plants; the single frond is a constant variety; the others, though usually finely cut, vary considerably.—A. CLAPHAM. [The fronds sent represent a very beautiful variety; they are much divided and are of thick texture; therefore do not possess such a delicacy of tint as the fronds of the variety *trichomanoides*, which are almost transparent, at least they are so in the plant from Messrs. Backhouse, of York. Both are indispensable hardy Ferns.]

A NEW AGAVE (*Alibertia intermedia*).—This is a most curious plant from a botanical point of view, and may be briefly described as occupying a place somewhere intermediate between the *Amaryllis* or *Hippeastrum* family and the true *Agaves* generally so called, being, in fact, a deciduous, bulbous-rooted *Agave*, as its general appearance when in full growth much more resembles the *Aloes*, and when at rest the bulbs of *Amaryllis* or *Hippeastrum*. This strange plant is described by the well-known hybridist, Mons. J. B. A. Deleuil, of Marseilles, in the *Revue Horticole des Bouches-du-Rhône* for last September, and its origin is stated to be as follows: In 1877 the writer received from Messrs. Haage and Schmidt, of Erfurt, among the seeds of a number of other varieties of *Aloe* one bearing the name of *A. virginica*, of which only three came to maturity, and turned out to be the singular plant above described. For the name attached to the packet of seeds the senders could in nowise account, save by the very unsatisfactory reason that their collector who sent them the seeds invariably gave them some name or other, as nameless seeds were found to be unsaleable. The three plants resulting from the five seeds sown by M. Deleuil in 1877 flowered in 1881 and again last summer, and have been botanically compared and described by Professor Marion, who, when he found them to be new and distinct from any known species, named them after one of the founders of the Marseilles Society, Mons. Alibert de Berthier. Allographic reproduction of a drawing by M. Penot of the entire plant in flower, reduced considerably in

size, a single flower-pip of the natural size, a seed capsule natural size, and the bulb when at rest reduced to one-third of natural size, is published with the description of this new and singular plant.—W. E. G.

AMERICAN NOTES.

Small Lilies.—*Lilium pulchellum* and *L. tenuifolium* are more easily raised from seeds than any other species of the genus. From seed *tenuifolium* will yield some flowers when two years old, and both species when three years old will give a fair crop of blossoms. Sow the seeds in pots or shallow boxes in the house, or in a shaded cold frame; they should germinate in nine or ten days. After they come up leave them alone for some days; then, if they are in pots, you may transplant them thickly into boxes; if in boxes or a frame, and they do not seem overcrowded, do not disturb them till they are of goodly size. Indeed, I usually transfer the potful of seedlings, without disturbing them in the least beyond removing the pot, into the earth in a cold frame, and let them stay there till the seedlings are a year old, when I lift and transplant them into rows. Both are early-blooming, bright lovely Lilies, and very hardy.—*Rural New Yorker*.

White Tigridia.—Everybody knows the pretty summer flowering *Tigridia* or Tiger flower. We have the red *T. Pavonia* and the yellow *conchiflora*. The white, according to *Revue Horticole*, was raised and recently sent out by M. Hennequin, of Angers, France. In habit and general aspect it is said to be similar to the older variety *T. conchiflora*, from which it seems to have sprung. Its flowers are large, of a dead or pearly-white colour, marked at the base of each division with large spots of a reddish brown or chestnut colour on a yellowish ground, forming a fine contrast with the white of the petals. The style column is bright yellow, of the form of a long hollow sheath, terminated by three mottled plates enclosing the style within them. This should be quite an acquisition to our summer borders and a good companion for the already known and admired varieties of this showy family.

Cost of steam heating.—Steam heating will, I think, give more satisfaction uniformly than hot water or any other form of heating. At least, I am well satisfied with mine. I have two boilers in use now. The price for steam heating is about one-third less than hot water, and gives just as good or better satisfaction. Those who intend to put in steam should see or write to a steam-fitter, tell him how many and how large are the houses you wish to heat. Better to show him the houses before making a contract; then he can give an exact estimate of cost to fit them with steam. The boiler should be ordered by the steam-fitter, who knows just what is needed. Two boilers heat six large houses. All complete in heating order, pipes, boilers, &c., cost me for the six houses about 1500 dolrs. The houses are 64 feet by 24 feet each.—A. D. MYLIUS.

Juglans præparturiens, or early fruiting Walnut.—The California papers have been intelligently discussing this variety of Walnut. It has been thought to be a dwarf—probably because small or young trees are full of fruit. Mr. F. Gillett sums up in the *Rural Press* all that has been said of its dwarf character in these words: "In my opinion, the *Juglans præparturiens* of France and the English Dwarf Prolific of America are the same thing, though it is not clear in my mind why the *J. præparturiens* or fertile Walnut has gone in America under the name of Dwarf Prolific. As to who gave it that name it seems that nobody knows. The name is far from being appropriate, and serves only to bring confusion in names, and gives a false impression as to the tree's habits of growth. As regards the value of the variety in California, Mr. Rusk remarks: "We will soon see the day when no other sorts will be planted than grafted Chestnuts and *præparturiens* Walnuts. To wait from twelve to twenty years

for Walnuts from common sorts will not do when you can have them in bearing in three or four years."

Feast's Scuffle Cultivator.—This vigorous contrivance first cuts up the weeds, and then, by a roller fork behind, shakes out all the earth from the uprooted weeds, by which they are laid out so as to soon dry up.

Mahogany in San Domingo.—In consequence of the demand for mahogany of late, it has been feared lest the supplies should fall short; we are assured, however, in a report of the Vice-Consul at Puerto Plata, San Domingo, that the diminution in the exports of mahogany is by no means to be attributed to a scarcity of the wood, for the forests are apparently inexhaustible; but it is to be accounted for through the absence of suitable tonnage for charter in the neighbouring colony of St. Thomas throughout the year.

Foretelling the weather by the white Pine.—The *Illustrirte Garten-Zeitung*, of Vienna, Austria, says it is the easiest thing in the world to foretell the weather by observing the common American white Pine (*Pinus Strobus*). If we are to expect rain or snow within a reasonably short space of time, the branches of the last two season's growth will be pendulous. If such weather be a long way off, the branches will be raised rather than drooping.

Progress of plant knowledge.—Hippocrates described 234 species; Theophrastus followed with 500. Pliny knew, as well as can be made out now, 800. Tournefort, at the beginning of the last century, described 10,146. Many of these had to be united as not distinct enough for modern science, till at the death of Linnæus 7294 had been described. De Candolle, in the "Theory of Elementary Botany," made 30,000 named species. Lindley, in 1853, gave the number as 92,920. Now nearly 150,000 species are known, with possibly an equal number not yet known. Thus records the *Revue de l'Horticulture Belge*.

Caladium esculentum as a vegetable.—On my arrival in Charleston more than forty years ago Tanyas (*Caladium esculentum*) were commonly sold in the Charleston market as vegetables; and among other things sent by a friend as gifts to us as strangers on our first beginning housekeeping was a bag of Tanyas. What was I to do with them? My Irish cook declared them to be nothing better than rotten Potatoes; she "knew the nasty things well." So they laid on the floor of the piazza till my husband came in; he said they were very nice—"Boil them a long while as you would Potatoes, and eat them with plenty of butter; make them into soup with a good piece of beef." All was done as he ordered. A great dish of greyish white mealy balls appeared on the dinner-table—enormous things tinted with blue and red, very discouraging to look at, worse to eat. The next day Tanya soup was carefully boiled with all sorts of condiments to make it palatable; that was better, but two or three spoonfuls were sufficient, and we have never tried Tanyas as vegetables since, though I planted in my garden what remained of the brown rough balls and reaped a harvest of delight in their lovely growth, which I had then never seen in Europe. On what is called the King Street Road the same summer on the edge of a very muddy ditch, intersected by another equally black and oozy, grew, apparently wild, a magnificent growth of Tanyas. Year after year they increased and multiplied, till they covered both ditches and much of the surrounding field. In those far-off times of which I write the negroes had a legend that Tanyas were originally brought by them from Africa, and certainly to this day they are eaten by them, and a patch may always be found in their gardens.—MRS. D. M. W.

Japan Persimmon in the South.—It is now some six or seven years since the Japan Persimmon was first introduced into Mobile by distributions made by the United States Commissioner of Agriculture. It has fruited three or four years in succession in the vicinity of Mobile and Pensacola, and found to do well there. M. Delchamps has a flourishing orchard in the lower

part of the county, and Mr. Langdon has another in the upper part. M. Delchamps, who is perhaps the pioneer in experimenting with this new fruit, says that he has three hundred trees, all doing well, and Mr. Langdon has about one-third as many—his orchard including no fewer than thirteen varieties, namely, Tanenashi, Hiakume, Nihon, Hatsiga, Yamato, Kurokuma, Royal, Daidaimara, Mikado, Goshō, Goshomara, Imperial, and Mino.—*Gardener's Monthly*.

Adhesions.—Mr. Wilder recently exhibited to the Torrey Club a section of a Hemlock Spruce in which one of the branches had curved inwards and become at its extremity fused with the trunk. Mr. Britton described and illustrated a case of adhesion between the branches of two Maples that had been observed by him recently at Mt. Clair Heights, New Jersey. Many similar adhesions have been observed in this country, but not, as far as we know, amongst Conifers.

Pruning shrubs.—Messrs. Ellwanger & Barry, in their new descriptive catalogue of ornamental trees and shrubs, give the following excellent directions as to pruning: Pruning, as sometimes practised, has the effect to render trees and shrubs unnatural and inelegant, by shearing them into cones, pyramids, and other unnatural shapes. Every tree and shrub has a habit of growth peculiar to itself, and this peculiarity is one of its beauties. If we prune all alike into regular shapes, we destroy their identity. The pruning-knife, therefore, should be used and handled with judgment to lop off straggling branches. Shearing may be practised on hedges, but never on trees and shrubs. Weigelas, Deutzias, Forsythias, and Mock Oranges flower on the wood of the preceding year's growth, and hence these shrubs should not be pruned in winter and spring, but in June after they have finished flowering, when the old wood should be shortened or cut out, thus promoting the growth of young wood which is to bear flowers the following season. But Spiræas, Lilacs, Althæas, and Honeysuckles may be trimmed during the winter or early spring, and the branches should be reduced only enough to keep them in good shape. The old growth should be occasionally thinned out, and suckers and root-sprouts removed. The best time, however, for pruning all shrubs is when they have done flowering. The plumed Hydrangea should be severely cut back and thinned early in spring. In pruning Evergreens, use the knife occasionally to thicken the growth and preserve the shape. This may be done in April or May, just before the trees start to grow.—*Country Gentleman*.

SHODDY AS MANURE.

"A. D." asks several questions about this. It can be had in Bradford or Leeds, though I regret that I cannot give a definite address. Some years since an agency was established in Bury St. Edmunds, and considerable efforts were made to push a trade in shoddy manure. I among others used it for various crops, applying it as a top-dressing to Vines and fruit trees in pots, such as Apples, Peaches, Plums, Pears, and also to vegetables, such as Celery, Cauliflowers, Peas. We also top-dressed Fuchsias, Pelargoniums, and Roses in pots with it, but did not mix it with the soil for pot plants. We liked it, and it seemed to prove a strong, useful stimulant to all the crops to which it was applied. It was rather objectionable as a surface mulching, owing to its heavy, oily, fulsome smell, otherwise its open, porous character rendered it a most efficient mulch, keeping out the heat and cold, and in the moisture. It decomposes slowly, and, being almost wholly composed of rough or refuse wool, is a strong manure. It was tried on root and other crops, either as delivered or soaked with sewage, either from being thrown into tanks or trodden down with farm-yard manure. The object was to establish a trade among farmers rather than gardeners, and those who tried it were satisfied with it. But somehow the agency failed and the supply was cut off, and since then I have seen or heard no more of shoddy as manure, though most of us meet with rather

too much of it in other departments. So far as I remember, the price was about a shilling a hundredweight, delivered in shoddy bags, which went into the ground, the best place for all shoddy, with the manure. D. T. FISH.

Russian fruit.—Prof. Budd, of Iowa, now travelling in Europe in the interests of horticulture, writes to an Iowa paper concerning the orchards of the famous fruit city of Simbirsk, on the Volga, in Russia. "Simbirsk" (he says), "may be more properly named 'The Orchard City' than any town we know of in Europe or America. Literally every available spot in and around the city is planted with Apple, Pear, Cherry, and Plum trees, all of which this year have produced great crops of really choice fruit. But not a single variety can be found that belongs to the races of fruit found even in North Germany. The climate is very trying, both summer and winter. The city is located in the dry steppe region, 500 miles east and a few miles south of Moscow. The air is very dry, and during the day excessively hot. On account of the rapid radiation, the nights, however, are decidedly cool, yet not too cool to prevent the ripening of Tomatoes and first-class Melons. The winters are colder than in any part of Minnesota, that is, the extreme winters which come, as with us, at intervals of from six to eight years. In 1877, for instance, the temperature the last of December reached 50° Fahr. with very little snow, while last winter was very moderate with very heavy snows. Thousands of acres of orchard here are planted with a very few commercial varieties of the Apple, which do not differ materially from those grown in the province of Kazan. The trees are small in size and bushy in habit of growth, but loaded with very showy and excellent fruit. Could our friends at home drop in our hotel room at this moment they would see every stand and table loaded with very fine specimens of Apples, Pears, and Plums. I wish to speak specially of the Pears of Simbirsk. Many thousand trees are found growing under exceedingly varied circumstances. Some Pear orchards slope to the east, and many to the south, west, and north. Some are on cultivated ground, the most are in stiff sod, and very many are found in yards and even planted in the public park. Under almost all circumstances they are loaded with fruit. But as a rule the fruit is not good. Ninety per cent. of the trees are seedlings of the Bergamot type, and the type and race known as Grucha. The true Ironclads have the leaf and habit of growth of the wild Apples found native near the bluffs of the Upper Volga. The trees are low and scrubby in habit, but they are loaded with high coloured and really excellent fruit. With the quality of the Apples here called good we have been surprised."

W. Cobbett as a gardener.—"At eleven years of age," says William Cobbett, "my employment was clipping Box edgings and weeding beds of flowers in the garden of the Bishop of Winchester, at the Castle of Farnham, my native town. I had always been fond of beautiful gardens, and a gardener who had just come from the king's gardens at Kew gave such a description as made me instantly resolve to work in those gardens. The next morning, without saying a word to any one, off I set, with no clothes except those on my back, and with thirteen halfpence in my pocket. I found that I must go to Richmond, and I accordingly went on from place to place, inquiring my way thither. A long day (it was in June) brought me to Richmond in the afternoon. Twopennyworth of bread and cheese and a penny worth of small beer, which I had on the road, and one halfpenny which I lost somehow or other, left 3d. in my pocket. With this for my whole fortune I was trudging through Richmond in my blue smock frock, and my red garters tied under my knees, when, staring about me, my eye fell on a little book in a bookseller's window—'Tale of a Tub,' price 3d. The title was so odd that my curiosity was excited. I had the 3d., but then I could have no supper. In I went and got the little book, which I was so impatient to read,

that I got over into a field at the upper corner of Kew Gardens, where there stood a haystack. On the shady side of this I sat down to read. The book was so different from anything I had ever read before, it was something so new to my mind, that, although I could not at all understand some of it, it delighted me beyond description, and it produced what I have always considered a birth of intellect. I read on till it was dark without any thought about supper or bed. When I could see no longer I put my little book in my pocket, and tumbled down by the side of the stack, where I slept till the birds in Kew Gardens awaked me in the morning, when off I started to Kew, reading my little book. The singularity of my dress, the simplicity of my manner, my confident and lively air, and doubtless his own compassion besides, induced the gardener (who was a Scotchman I remember) to give me victuals, find me lodgings, and set me to work. And it was during the period that I was at Kew that the present king (George IV.) and two of his brothers laughed at the oddness of my dress while I was sweeping the Grass plat round the foot of the pagoda. The gardener, seeing me fond of books, lent me some gardening books to read, but these I could not relish after my 'Tale of a Tub,' which I carried about with me wherever I went; and when I, at about twenty years old, lost it in a box that fell overboard in the Bay of Fundy, in North America, the loss gave me greater pain than I have ever felt at losing thousands of pounds."

OBITUARY.

WE have to record the death of Mr. ROBERT WRENCH, treasurer, since 1849, of the Gardeners' Royal Benevolent Institution, and head of the firm of Jacob Wrench & Sons, seed merchants, London Bridge. In days gone by when the Royal Horticultural Society held its meetings at 21, Regent Street, Mr. Wrench was a constant attendant as a visitor, seldom as an exhibitor, except perhaps to show a sample of the true old Pine-apple Strawberry, of which we believe he was the only stockholder. In later years his interest in the society got diverted into other channels; but not that in the Gardeners' Benevolent Institution, of which he was to the last a warm supporter. He was fond of gardening, and at one time grew a good collection of plants in a small glass house on the roof of his warehouse at London Bridge. He died on the 15th inst., aged 70.

Celery.—I shall be obliged to any of your readers if they will give me the names of the best red and white Celery for show purposes.—BEGINNER.

Moving Rose trees (J.)—It is unlawful to move Rose trees to a new residence, unless you are a nurseryman or have some agreement to that effect with your landlord.

Carnation Susan Askey.—This is said (p. 66) to be a yellow ground. It is a pure white colour. It is also said to be raised by Mr. C. Turner; this is an error; it was raised by Mr. Culverwell, of Thorpe Perrow.—S. A.

Bijou Chrysanthemum.—This is one of the latest flowering of all the Chrysanthemums. It was the only one in really good bloom here during the first week of the new year. The blooms are about the size of a crown-piece, quilled like an Aster, and bright lilac. Owing to its lateness it merits general cultivation.—J. MUIR, Margam.

Names of plants.—B. P.—1, *Abutilon vexillarium* variegatum; 2, *Lardizabala britanica*; 3, *Peristrophe speciosa*; 4, *Alonsoa incisa*.—G. M.—*Dendrobium primulinum* (fine variety).—W. B.—*Odontoglossum Lindleyanum*, *Cypripedium pardunum* (rare species), species of *Epidendrum*.—Forbes.—We doubt if it is possible to name trees correctly from twigs. Can you not wait until your tree or shrub is in flower or leaf?—T. Mackay.—1, *Veronica Andersoni* variegata; 3, species of *Sempervivum* (tender); 4, *Helleborus abschascus*.—Alpha.—1, *Maranta zebra*; 2, *Aspidistra lurida* variegata; 3, *Amaryllis reticulata*; 4, *Cyperus alternifolius*.

"This is an Art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

CONCERNING GARDEN DESIGN.

Formal edgings destroy the good effect of many gardens, particularly in ground of natural and informal design. Where permitted at all, the situation should call for them, as in a true terraced garden, and then they should be of the best stone possible under the circumstances. Formal edgings of mean pattern—tiles, ropes, &c.—are never admissible in any garden for any purpose. Far better, and more easily procured in many districts, are thin stones, which are set on edge more easily than cast tiles. Over a large area of the land some kind of stone naturally cloven into a useful size is procurable. In other districts flints are common; half sunk in the ground, and with rock plants running among them, they are prettier than any form of cast edging. Even bricks half sunk are better, and well fitted for the kitchen garden. If it is not possible to do better, use a live edging of Box or some rock plant. Stones get so prettily mossed over, and are so friendly to alpine plants, that they often may be said to be live edgings.

Variety.—There should be no limit to this consistent with beauty and repose. There need be no limit to variety, considering the rich stores of living things we have from every part of the world and the endless difference they show, and not merely among themselves as species. A single kind often has striking differences, according to the varied soils in which it grows. The still greater variety of aspects, elevations, or climates in which it is hardy will influence it more. A tree may pass without notice in one country and be grand in another.

Plantations should not be hard, angular, or square in outline—a rule good always, and for the sake of near views its truth is fully seen in bold and diversified country, where the outlines of the plantations are what strike the eye most. Excellent work in planting may be weakened in effect by want of attention to this point, as may be noticed in the woods on the hills near Bangor, as seen from Beaumaris, and in many other places. In the case of established plantations it is not difficult to break the outlines artistically by letting bold, chosen groups stand without the true boundary or fence of the plantation. Such groups, or even small groves, would be no disadvantage, but a gain in the grazing fields to which so much of our hill and other land is devoted.

Simplicity.—All other arts depend for their success to some extent on cost and labour. In the garden landscape the highest success results from simple methods—from abolishing costs and complications instead of creating these. Given the understanding and the observing eye, we shall have beauty at less pains than ugliness. But this is only possible where gardening is a reflex of Nature in its happiest aspects, and not a transferring to the ground of the "decorator's" dreadful and profitless art. Keep him to the fire-shovel, side-board, or clock if he "must live," though we prefer even these things without *his* mark upon them.

The colours of rocks in gardens.—

These should be quiet and low. It may seem a rule not often called for, but as I have, the day I wrote this, seen over a dozen rockeries of a staring hard white colour, it is not so. In certain parts of the country it is the fashion to choose colours of a glaring character for this purpose. In parts of Lancashire where smart villas abound it is almost the rule to have these white staring rockeries against the red brick houses! Granting that the only material obtainable was of a bad or showy colour, it would be then possible to soften its effects by using only the best stones, and by burying all but the best points of these, and then softening them with the abundant rock-plant life. In any case, one could avoid using stones at all—not a bad rule where the making and planting of a rock garden are not understood.

Ferns.—Graceful and new effects may be developed in foregrounds by drives through glades, and in many other positions by the bold use of hardy Ferns of the larger kind. The Bracken we see everywhere; but some of the others are more graceful in form, and delight in the partial shade of open woods and drives, and even do in the sun. But few will for a long time practise this, or perhaps understand it, unless they see the fine effect of a colony of some bold Fern (other than the Bracken) in possession of a glade. Then would come in the opportunity for associations with wood flowering plants, according to the nature and size of the Fern. Up to the present time Ferns have, as a rule, been stowed away in obscure holes, and never come into the garden landscape at all. But not only can they give us new and beautiful aspects of vegetation in the garden landscape, but even in parks and ornamental woods of the largest class. The bolder kinds should be selected and multiplied, and the fitness of the position to the Fern must be considered.

Water.—There is no situation where clear running water may not be made a beautiful as well as healthful thing, and the opposite in all ways of the stagnant water—ugly. Artificial water is wrong when it is at all stiff or mean in outline, small, too near the house, unclean, mud-nourishing. The greater number of garden artificial waters are of this class—foul, expensive to clean, occasionally dangerous from steep margins, lawn-destroyers. Artificial water to be good must be large, clean, deep, bold, flashing light in the open, not near dwellings. It should be only attempted where there are means to secure the best results.

Artificial water should not be formed in the immediate neighbourhood of fine natural water, be that river, lake, or sea. I have seen a variety of instances of the violation of this rule, and with invariable bad effects. Artemus Ward's moon was very funny in the Egyptian Hall, but with all his drollery he would not present it to us in the open air. Some public gardens placed on the banks of fine rivers indulge in the weakness here pointed out.

Natural water should be seen. In an island country, seamed, too, with inlets and rivers, the many beautiful aspects of natural water should be jealously brought into every garden picture. The fashion of over-planting the immediate surroundings of the house, however, often leads to fine views being lost in part or whole. The frequent neglect of woods and plantations, too, leads to many bright river, bay, and sea scenes being obscured or hidden.

GARDENING CATALOGUES.

LITERATURE has several departments that are comparatively unimportant, but in which success can only be attained by those who have a special aptitude for the peculiar kind of work required. Such aptitudes, at times amounting almost to genius, seldom make their possessors famous, because of the obscure and confined sphere in which they have to be exhibited. The gardening catalogue supplies a case in point. We do not know the authors of these astonishing works, and few people, it is to be feared, appreciate their literary merits. The ordinary reader selects his seeds and his bulbs while glancing carelessly through the catalogue, and has no idea that he is passing line after line and page after page of brilliant English, remarkable for its unflinching relevancy to the ends the writer has in view. The spring catalogues are now appearing with the gayest of colours upon their covers—the early butterflies of the literary year. Let any unprejudiced critic read a few of them as carefully and lovingly as he reads his Theocritus and say whether this estimate of them is unduly favourable.

It is in diction that the author of the gardening catalogue most signally excels. His vocabulary is full, and he knows all its resources. His mastery over the adjective, his favourite part of speech, is nothing less than astonishing; he wields it with an amazing power and discrimination. Nevertheless, his well-ordered phalanxes of words are marshalled under the most harassing conditions. He must bestow his commendations so judiciously that the customer may find reasons for purchasing every item in the catalogue. The new alba sub-variety must not be so extolled as to make the old rubra (of which there is a large stock in hand) unsaleable. He must indicate, in one sparkling sentence, the satin-like texture and earliness of the alba, and in another the hardness and richness of that "grand old variety," the rubra. He must point out fine shades of distinction (for many of the varieties named by the florist and seedsman are quite undistinguishable to the eyes of the public), and he has consequently to deal with such subtleties as the difference between bronze primrose and primrose bronze. Yet, at the same time, he must avoid much repetition, although he is writing a work in which a good deal of repetition might be forgiven. His office is to charm and allure as well as to enumerate. He must conjure up before his readers the beauty of the garden plots, the scent and colour of the flowers; the burly Savoy, gemmed with diamond drops, the shining Tomato, with its ruddy interior succulence. And so efficiently does he do this that one might imagine him an enthusiast crying out, like Mahomet, "Bread is the food of the body, but Narcissus is the food of the soul." One can see that he regards the prices that follow his descriptions as mere accidents of a cruel world. They are the drossy beds of earth by which his beloved flowers have to be supported. Alas, that it should be so! Take up a gardening catalogue, open it at any page, and you will find traces of the true poetic afflatus. This flower is of a "velvety deep violet," that "plum-purple, with a pencilled throat." Mr. Swinburne might be proud to claim such alliterations as these. Our minor poets, at least, can show nothing so fine as "golden-marbled foliage," "rose, suffused with lake, flamed with carmine-amaranth," or "intense glowing crimson, deliciously fragrant." The author of the gardening catalogue may possibly not originate those parts of the botanical description which mark the gardener's sub-varieties, but they are certainly done by a kindred spirit. What majesty there is in the long roll of superbissima, of atropurpurea, or of giganteum roseum superbum—what suggestions of richness and vividness in rubro-cerulea or orientale splendendum! When the vegetable department of the catalogue is reached, the poetic style will be found to be well sustained, but the tone is very properly changed. The beauty of the vegetable is more robust and masculine, and requires a bolder treatment. The varieties are named in trenchant Saxon. All is large and heroic. We are among

Champions, Long Swords, Goliaths, Giant Supremes, Conquerors, Defiances, and the like, who are "robust," "stout," "hardy," and "prolific." The softer shades are given by tender allusions calculated to make the month water. This has a "rich, melting, and delicious flavour," and that is "crisp, nutty, and pungent." A Broccoli is described as "glorious, magnificent, and white as snow." What is the great office of poetry but to ennoble the common things of life?

The pictures that accompany this letter-press cannot be said to be equally artistic, especially when they are coloured. They are deficient in reserve and refinement. It is to be feared that they represent the ideals of the gardener rather than those of the world of taste. The flowers are in common masses, or if solitary are enormous individually. They grow in shapes as formal and neat as those of a clipped Yew hedge. No flower, or leaf, or petal dares to perk up and mar the clearness of the outline. The Dahlias might be diagrams of bead cushions, done in colours of the most intense crudity. Verily in these pictures no trouble is spared in putting the rawest and most inharmonious colours together. That Petunia would irritate the mildest bull going. The vegetables, again, are massively symmetrical and inconceivably prolific. The Cucumbers are like umbrellas without handles, and the frame is choke full of them. The Potatoes resemble bolsters or cannon balls. The Asparagus is monumental—a cluster of pillars with a cincture. The Cabbages are tightened on with heart until they look uncomfortably plethoric. The rows of Peas are so crowded with pods that only a leaf here and there is visible; an opened pod is depicted, inside which is a row of ten Peas of the size of marbles and as regular and close as a fine set of teeth. The Rhubarb might shade armies. It is possible that such things are to be seen in "our experimental grounds;" the æsthetic amateur will not be altogether sorry if he cannot reproduce them in his garden.

Yet, in spite of its illustrations, a gardening catalogue is not unpleasant reading at this time of year. The garden is damp and dreary; there are a few Primroses, an old Polyanthus, and a few Snowdrops, but these are only oases in the general bareness. Seated by a crackling fire, with the gardening catalogue in his hand, the amateur may enjoy to the full the pleasure of imagination. His old favourites will appear in all their summer bravery—his lowly Pansies, his stately Lilies, his Carnations spicing the warm air. To these he will add such images of new and untried plants as his skilful guide knows well how to suggest. And should his *Adoxa splendissima* not turn out all he had expected, no one can deprive him of his pleasant anticipations.—*Globe*.

ENGLISH NAMES FOR PLANTS.

REFERRING to the controversy on this subject, it has struck me as somewhat singular that while no objection has ever been made to the free use of popular English names for beasts, birds, and fishes, such a violent outcry should have been raised against the endeavour to extend and improve our very defective English nomenclature of plants. No naturalist, so far as I am aware, has ever insisted on the advantages (?) of using scientific names when anyone speaks or writes about the water rat, the prairie dog, the hedge sparrow, the sea swallow, the fresh-water herring, the sand eel, the sea mouse, &c., none of which belong to the genera or species after which they are named. Why an exception should be thought of in the case of plants is, to say the least of it, not very clear, as there is no greater necessity that anyone should employ the term *Cheiranthodendron pentadactylon* in speaking of the Hand plant of Mexico than that he should use the words, "*Ornithorhynchus paradoxus*" when he means the water mole of Australia.

To object to a new and appropriate name for a plant merely because it is new does not seem very reasonable. Like the lady of whom Byron wrote that

Often she was, but had been very young

the oldest of the accepted names must once have been very new, and if everybody in times past had been of the same opinion as some people of the present day, we should now have no popular names at all.

Many of the new names which have appeared in THE GARDEN were absolutely needed for plants which previously had no popular English names, and others are decided improvements on older names. As an instance in which it is a clear gain to "ring in the new, and ring out the old," I may mention Torch Lily, which I should think few would hesitate to adopt instead of Red-hot-poker plant. It would be simply frivolous and vexatious to object that it is not a *Lilium* or Lily proper while we retain such names as Water Lily and Lily of the Nile. I observe that the outcry is almost wholly confined to a few "irreconcilables" in this country. The more sensible Americans, instead of standing still or retrograding, are "going ahead" in this, as in every other matter, and originate and use vernacular names for plants whenever they want them. I trust THE GARDEN will not be discouraged by the opposition met with from "going ahead" also in this direction. It will have the support of everyone who desires that our plant names should be expressive and intelligible to the general public, to whom the entire system of "scientific" names is as unmeaning as the cabala of the rabbins or the chopped Latin names of drugs in a medical prescription. It is altogether in the interest of the public at large that every plant should, if possible, have a well expressed and appropriate popular name; and he who labours to attain this end deserves the gratitude of those for whose benefit he is exerting himself.

MARSH MARIGOLD.

TWO RARE AMERICAN PLANTS.

STREPTOSOLEN OR BROWALLIA JAMESONI AND
SHORTIA GALACIFOLIA OR CALIFORNICA.

IN the second part of the *Révue Horticole* for the current month is given a coloured plate of the first named of these plants, with description by M. E. André, and a woodcut of the second with description, extracted from the *American Agriculturist* by M. Jeau Sisley, of Lyons. The *Browallia* seems to be quite the most showy and ornamental of the small family to which it belongs, and was first introduced some thirty-four years ago by Messrs. Veitch, to whom it was sent by their collector, Mr. W. Lobb, from Ecuador, where it was first discovered by Hartweg. It was then much admired on account of its bright orange tubular flowers with lighter coloured throats, and coloured plates of it appeared in no fewer than five of the leading horticultural works of the day, commencing with the "*Botanical Magazine*," where it is figured vol. lxxvii., tab. 4605. It has since, however, been for many years lost to European gardens till recently re-introduced by M. André, whose stock has passed into the hands of that well-known florist, M. Victor Lemoine, of Nancy, by whom it will be distributed during the present spring, and may be looked upon as quite an acquisition to our stock of hardy ornamental greenhouse plants, even if it do not prove sufficiently hardy (as there is every reason to hope it will) to bed out as an ornament of our summer borders. The name of *Streptosolen*, under which it is figured in the *Révue Horticole*, was given to the plant by Miers in his work on the plants of South America, and has also been adopted by Bentham and Hooker in their "*Genera Plantarum*" as most correct.

Shortia californica or *galacifolia* is a native of Dowell County, North Carolina, where it was discovered as recently as 1877 by Mr. G. W. Hyams, and named by Professor Asa Gray after the late Dr. Short, of Kentucky. It belongs to the small family of *Diapensiaceæ*, and is an evergreen herb, producing with great freedom large, pure white flowers, the petals being sometimes smooth and sometimes irregularly fringed. Seed of this interesting plant can be obtained from the well-known Paris seedsmen, Messrs. Vilmorin, 4,

Quai de la Mégisserie, and plants from Messrs. Woolson & Co., of Passaic, New Jersey.

W. E. G.

FRUIT GARDEN.

PEAR GROWING FOR PROFIT.

ALLOW me to offer a few remarks on Pear growing for profit from my own experience. I have grown a good many sorts of Pears both on the Pear stock and the Quince, and also both as pyramids and trained horizontally on walls, the branches in the latter case being three courses of bricks apart. The two most profitable kinds with me on walls are Glou Morceau on the Pear and Winter Nellis on a south wall on the Quince. I have the latter on both stocks on a south wall, but the quantity and quality on the Pear stock bears no comparison with those grown on the Quince. The trees on the Quince are short-lived compared with those on the Pear stock. I am now replanting those on the Quince I planted twenty-four years ago, while Glou Morceau on the Pear is a model of health and fruitfulness; each sort bears so freely as to necessitate the fruit being generally well thinned, and the summer growth is to a great extent regulated by the amount of the crop. It is also left on to keep off the net which is always used to protect the fruit from being bird-pecked, and remains on as long as possible, thereby retarding the ripening. Bergamotte d'Esperey is also a good late free-bearing sort. For pyramids I find the best are Doyenné du Comice, Louise Bonne of Jersey, Le Curé, Comte de Lamy (on the Quince), Huyshe's Victoria, Williams' Bon Chrétien, Duchesse de Angoulême, Knight's Monarch, and Madame Treve (on the Pear). I have not gone into the cordon system, as it was not the fashion when I planted the trees just named. Your correspondent (p. 545) says: "For exhibition purposes this is the one to follow, as a blind man could pick out cordon grown fruits." I have nothing to say against this way of training, but I am still waiting to see the horizontal and pyramid systems surpassed. I have grown Beurré Clairgeau 20½ ounces, Doyenné du Comice 20 ounces (shown at South Kensington), both on the Quince as pyramids; Easter Beurré, Pear stock, 21 oz.; Glou Morceau, do., 15½ oz.; Van Mons Leon le Clerc, do., 14½ oz. Chaumontel, Quince stock, 14 oz.; Beurré Rance, do., 13½ oz.; and Winter Nellis, do., 8½ oz. The above were a few of the finest fruits I weighed of one season's growth, and they only had ordinary treatment, as given here. I recommend Glou Morceau especially, as it is a good bearer and keeper (last year I had it until April), and I have had 6s. per dozen returned from Covent Garden for my best fruit of this sort. About three years ago last autumn two eminent horticulturists, who were making a tour through the south-western counties, were surprised at the Pear crops produced here, and remarked that they had seen nothing to equal them that season. My own experience is that good crops and fine quality depend more upon the culture and a selection of the best sorts than on any particular system of training. From a pyramid of Doyenné du Comice I was awarded a first prize in the class of any sort at South Kensington two years following, there being respectively twenty-seven and twenty-one dishes against mine.

J. E.

Huyshe's Prince Consort Pear.—Mr. Allan (p. 49) strongly recommends the planting of this Pear, but I do not think it is advisable to plant it in cold clay subsoil. I planted a pyramid of it a few years after it was sent out, and it proved a complete failure. It never ripened, not even in the most favoured summer. I grafted it on a Beurré Rance on an east wall and the result was the same. I had some scions given me in 1878 from a tree the fruit of which was as good as that which Mr. Allan describes. The tree in question was a pyramid, growing on a light soil with a sandy subsoil, and the tree on which I worked the scions was on a south-east wall. The soil was free-working material, but still we had

the cold clay subsoil. The Pear on which I worked was Broompark, but the result was the same as that already named. In 1881 it bore several fruit, but none ripened. I have no doubt of Mr. Allan's success on his warm, friable loam, but I should not advise anyone to plant it on cold, wet soils. The place to which I refer is Barningham, about eight miles west of Gunton.—E. S.

JOSEPHINE DE MALINES PEAR.

I CAN assert from experience that in the matter of ripening this Pear does not differ from other Pears. To me the vagaries of Pears are inexplicable. I find after the middle of November that I can never rely on the reputed ripening time of any Pear. A variety reputed to ripen in December will sometimes be fit for table in the early part of November, and sorts stated to be ripe in March and April will sometimes be ripe in January, and occasionally they ripen in just the opposite direction in point of time and season. I am now sending to table Beurré Rance in good condition, while, according to the most reliable sources of information, the proper season of ripening of this sort is from March to May. I remember nearly twenty years ago being shown a grand dish of this Pear in the month of May by Mr. Page, then gardener at Combe House, Croydon. He grew pyramid Pear trees at that time better than I have seen them either before or since, and some day I may give an account of his practice. He told me that Josephine de Malines could not be relied upon to ripen at the same time every season. Mr. Rust, of Eridge Castle, did at one time (if he does not now) think very highly of Ne Plus Meuris as a sort to ripen in the month of February. Here it is fit for dessert very often in December, and always in January. I can make no attempt to describe why this should be so. Probably soil and climate and varying seasons have much to do with it. The shrivelling of Pears after they are taken to the fruit room is another enigma; treated in exactly the same way, some Pears will be very much shrivelled one year and not at all the next. All that I know is that it is a difficult matter to tell when Pears are in just the right condition to be gathered, and that to secure the whole of a crop from any particular tree in good condition for storing

the fruit must be examined two or three times, and those only that leave the tree without any effort to pull them off should be picked. Where, however, there is much fruit to be stored, this is a troublesome business, and what is more in the case of late varieties it is attended with some risk, for an unexpected frost may come and spoil the crop.

J. C. C.

FRUIT PROSPECTS.

TIME alone can tell how far forecasts in this matter may prove correct, but from a trade point of view there is some reason for discussing the probable condition of the fruit crops now, and an illustration of the value of so doing occurs in my own locality, where some 30 acres of market orchard are just being offered for tenancy by public tender, and where the chances of getting a crop of fruit in the coming season or otherwise may make all the difference in the obtaining of liberal offers as to rent or none at all. This large orchard presents also an admirable illustration of the nature of the vicissitudes which attend market fruit growing. It forms a portion of the once famous Hounslow Heath, a wide expanse of the county of Middlesex that extended from Hounslow to Staines in one direction, and was some half-dozen miles broad. On this heath the inhabitants of the different parishes spread over the ground enjoyed the right of cutting turf and many other privileges. When the heath was enclosed, portions of the land were allotted to each parish, and this particular 30 acres were enclosed, and let at a moderate rental to a market gardener, who broke them up and planted them as a market orchard. In time the orchard, having largely increased in value, and the original lease having run out, and as the land was held in trust by the parish officials on behalf of the poorer inhabitants, the larger portion of the rental being expended in coals for distribution in lieu of the firing once obtained from the heath, it became a matter of importance that a much larger income if possible should be obtained. The land was in the present case submitted to public tender, and the old tenant agreed to give the very large rental of £10 per acre, thus representing to the trust an income of £300 per annum. That such a crushing weight could be borne by any tenant was impossible, and in a few years, by mutual consent, the rent was reduced to £8 per acre, at which point it stood. Even with this reduced amount things went on from bad to worse; payment of rent became irregular; and finally, a few months since, the tenant, a broken-down man, died with some two years' arrears of rent hanging a veritable millstone round his neck. But a crushing rent allied to heavy rates and taxes was not alone the cause of failure. Fruit crops are now, alas, far more frequently failures than successes, and with little return it was difficult to pay for the needful labour and manure, much less a heavy rent. The case presents a good example of the haste exhibited some few years since on the part of many persons to get into the market trade, because it was then thought to be a great money-making business. The past few years have served to explode that notion, for no capital or skill can contend against the unfavourable character of our climate; as long as the seasons are unfavourable to the production of hardy fruit crops, capital and skill may contend in vain.

To any prospective tenant of this poor's land market orchard, as indeed to myriads of tenants of market orchards in possession, the probable character of the coming season's fruit crops becomes of the first importance. In all open land where ordinary vegetable or corn crops are grown a return of some sort always more or less profitable is assured. If the labour needed in cultivation is greater the risks are less, because corn on the one hand, and Potatoes, Peas, Beans, Cabbages, and similar products on the other, are almost always sure to give some return. But whilst these crops are dependent upon the state of the summer and autumn weather (and as a rule those seasons are not often unfavourable) the fruit crop is so contingent upon the most fickle and too often of the year the most inclement of all our growing

seasons, the spring, that it is thus always rendered a far more uncertain element in the grower's calculations than are other crops. No matter how delightful a summer may follow, how warm and how ripening, if sharp frosts and bleak, biting east winds have prevailed in April and May, the fruit crop will probably prove nearly *nil*. Just now we have to regard not merely the present look of the fruit buds on standard trees, which are far from being plump and promising, but the condition of the weather last autumn when the ripening of the wood on the trees and the maturing of the fruit buds should have been in active operation. The autumn was, as we remember, dull, cold, and lacking sun heat, presenting conditions that could hardly have helped to render the trees fertile. We have since had a mild, soft winter, with an excessive rainfall, and this will too probably be followed by a cold, treacherous spring. Should that be so, the prospect of a good crop of hardy fruits becomes dim, and the position of large market growers of fruit anything but enviable. A. D.

Quick returns in the way of Grapes.

—“Peregrine” seems to think that Mr. Rochford's Vines (p. 47) support the practice which he recommends, viz., that of cropping one-year-old canes of young Vines their whole length. He is, however, quite mistaken, as their treatment has been as much opposed to that which he advocates as it well could be. They were planted two years ago last spring, cut back to about 3 feet from the bottom in the winter, and such of them as I mentioned were allowed to bear the few bunches, as stated the following summer. Last winter the rods were all shortened to about 8 feet from the bottom and bore the crop described; the coming season they will be fruited their full length up to the ridge, about 15 feet. The houses, which are span-roofed, are 25 feet wide and the Vines are planted on each side of the house. It will thus be seen that Mr. Rochford's course of treatment does not correspond with “Peregrine's” plan of leaving the rods their full length the first year, a practice by which he will have some difficulty in convincing Grape growers there is anything gained. As I said when he first broached the subject, if the young canes are shortened to half the length of the rafters, there is still length enough of rod to bear as much as the roots of Vines of that age can support, beyond which there is no advantage. Market growers are keenly alive to any treatment that will improve their Vines so as to enable them to bear the full weight of which they are capable in the least possible time, and if there was any gain in retaining the young rods their whole length the first season, they would undoubtedly do so.—T. B.

FLOWER PAINTING.

I NOTICED some remarks on this subject lately in THE GARDEN, under the heading of “A Lily Screen.” The failure of ladies in flower painting is greatly owing to the useless and trifling style of drawing which still lingers in boarding schools, while in schools for the poor a practical system is taught and a useful power imparted. In too many middle and upper class schools only bad copies of bad drawings are produced, and when the power acquired in years of supposed study comes to be tested, it is found to be practically wanting. It is a frequent occurrence for pupils who have taken prizes for drawing and painting in private schools to be totally unable to make an accurate drawing of a few simple letters without the aid of measurement. Accuracy is the alpha and omega of all drawing. When Giotto was asked to furnish the Pope with a drawing as a specimen of his ability in competition with other artists, he took a panel, and with a brush charged with colour drew on it a perfect circle with one turn of the hand. His Holiness knew what the drawing meant, and selected Giotto as his artist. Painting is only drawing with the brush. Ladies who wish to learn flower painting should follow the simple, straightforward course of the Department of Science and Art, which begins with outline from

outline, and proceeds from that to outline from casts, then a single leaf from Nature, then a group of leaves, then a whole plant. The first stage, drawing from ornament, is indispensable, as the forms of Nature are too subtle to be seen by the beginner. Colour and light and shade are taught by the same gradual steps. As every stage is tested by annual examinations, the pupil runs no danger of imagining, as is too often the case, that his or her drawings are works of art, fit to be placed before the public before the foot is well on the bottom round of the ladder that leads to excellence. There is no more pleasant form of work for ladies than flower painting, and none which finds a more ready sale in all its forms, from flat or decorative treatment, giving only the lines of growth and the colour with a little shading to explain the forms, up to drawings which are works of art. Any attempt, however, to learn flower painting by beginning to paint from copies or Nature without previous training is certain to result in failure, being simply trying to jump to the top of a house instead of going up the stairs. J. D.

HEATHS AND THEIR CULTURE.*

THE large Natural Order Ericaceæ (Heath family) is one of especial interest to the horticulturist owing to the number of useful garden plants which it contains. The genera *Rhododendron*, *Azalea*, *Andromeda*, *Kalmia* and many others, along with that to which my remarks will be chiefly confined, are among the most popular of cultivated plants, and from the manner in which they lend themselves to the requirements of the cultivator and hybridiser, it seems not unreasonable to expect that still greater garden treasures may be worked out of the pliable material of which these plants have proved themselves to be made. For the sake of convenience, it may be best for me to divide my paper into two parts, the first of which may be devoted to a short history of the genus *Erica*, and the second to the cultural requirements and other special garden matters in connection therewith.

The genus *Erica* contains about 400 species scattered over the cool regions of Europe, Asia, and Northern Africa, reaching their headquarters in the extreme south of the last mentioned continent. Taking the British species first, we have (exclusive of the common Ling, which is not a true *Erica*) five distinct kinds. These, however, are common European plants, being found in just as great abundance in many parts of Europe as on our own moors and hill-sides. Exclusive of those which are British, there are not a dozen species found in Europe or Northern Asia, the whole of those remaining being natives of the Cape of Good Hope. In the New World *Ericas* are entirely unrepresented, with the exception of the common Ling, which is found, though rarely, in Newfoundland and Massachusetts. Francis Masson, a collector sent out by George III. through the representations of Sir Joseph Banks, was the man on whom the pleasant duty devolved of introducing the Cape Heath to this country, and of the many beautiful and useful varieties introduced by him we have abundant testimony in the "*Flortus Kewensis*" and other books of that period. In a short time the rich colours and beauty of these new introductions caused them to be in great demand. At that time Kew Garden was a private garden belonging to the royal family. Even then, however, the collection of plants which it contained was a very fine one, owing, doubtless, to the many additions that were frequently made by the government botanists sent along with various expeditions to different parts of the world. Masson sent his seed to Kew, and it may be interesting to mention that in 1810 no fewer than 186 species of Heaths were in cultivation there. In those days Messrs. Lee and Kennedy, of Hammersmith, also paid much attention to the introduction and cultivation of

Cape Heaths, and gradually the immense popularity won by these plants at exhibitions and elsewhere resulted in their being taken in hand by various other nurserymen. Messrs. Rolisson, of Tooting, grew great numbers of them, and in addition managed to raise many very handsome hybrids, the majority of which are still in cultivation. Altogether they raised ninety kinds, of which some of the best known are *E. Cavendishiana*, *Clowesiana*, *eximia*, *Archeriana*, *hybrida*, *inflata*, *tricolor*, &c. Other workers in the same field were McNab, who made the Edinburgh Botanic Garden famous through his well-grown collection of Heaths, but which now, alas, are almost all gone. Turnbull more recently raised many hybrids and grew a large collection; while Baines, Ward, Williams, and others have been highly successful in the cultivation of these beautiful plants. According to Andrews, whose finely illustrated works on the Heath doubtless played a not unimportant part in making the genus known, about 300 species have been introduced into this country, and from these it may safely be said quite an equal number of hybrids and varieties have been raised. The superiority of the hybrids over the true species has caused them to gradually push many of the latter out of favour, so that if one takes up a catalogue of cultivated Heaths, by far the larger proportion will be found to be of garden origin. Horticulturally this is no doubt a gain, yet we must bemoan the loss of many of the curiously-formed and botanically interesting species figured in Andrews' works.

The Kew collection of Cape Heaths contains at the present time about 140 kinds, 45 of which are good species, and the rest hybrids or varieties. I do not think there are many species in cultivation in this country which are not in the Kew collection, though there are hundreds of varieties and hybrids to be met with, many of which bear a very close resemblance to each other. Until about fifteen years ago *Ericas* and other hard-wooded plants were generally cultivated, and there were many large nurseries devoted almost wholly to their propagation and growth. Since that time, however, the taste for plants of this character has gradually declined, and although one sees fine collections of Heaths now and then at exhibitions, it, nevertheless, is abundantly evident that hard-wooded subjects are being displaced by plants perhaps a little less difficult to manage and equally beautiful. To the true lover of plants, however, the richness of colour, gracefulness of form, and, when well grown, pleasing habit of hard-wooded plants must always be a source of pleasure, and therefore, it is to be hoped, we shall always be able to see them, if not in gardens generally, surely in such places as Kew. There, if anywhere, these old-fashioned garden plants ought to find a home. But, reverting to the Heaths, a visit to Covent Garden Market in the autumn mornings or to many of our market nurseries during the summer months will show that some members of this family at least are still in favour. The hundreds of thousands grown yearly in nurseries about London afford evidence that they are in request. These consist mostly of the freer growing kinds. The system of cultivation in general practice among market growers, while it produces a marketable plant in a marvellously short time, is, as a rule, a stuffing, cramming, forcing-up sort of treatment which causes the plants to overgrow their strength. The richest collection of *Ericas* of which I have any knowledge is that at the Hanover Botanic Gardens, where they are grown well under the loving treatment of the present director, Mr. Wendland. This garden has long been famed for its Heaths, the present director's father having paid much attention to them, describing and figuring great numbers of kinds.

The home of the Heaths.—Cape Colony has an estimated area of 201,000 square miles. Its greatest length from N. to S. is 600 miles, and its breadth 450 miles. Roughly stated, it is about three times the size of England. The interior of the country consists of table-lands, which range from 1000 feet to 4000 feet high, and are en-

circled by a chain of mountains parallel to the coast and distant from it about 150 miles. The highest peak on these mountains is Mount Compass, which rises to an altitude of 10,250 feet. The central plain is an arid sandy desert, 100 miles across and 3000 feet high, nearly bare for nine months in the year, but after the rains it suddenly becomes covered with brilliantly-coloured flowers—Iris of all kinds, *Gladioli*, *Ixias*, *Sparaxis*, *Babianas*, *Amaryllis*, and many other bulbous plants peculiar to that country all springing from the bare glaring sand. Lower down the *Pelargonium*, *Protea*, and other moisture-loving plants are found in great abundance, while scattered over the whole plain, on marshy lands as well as in dry places, on the hill-sides and reaching to the tops of the highest mountains, are the Heaths—here a small creeping kind nestling by the side of a stone; there a large shrub standing boldly up against the heavy storms and fierce sun, as various in the shapes of their flowers as in their shades of colour, everywhere meeting the eye, and always gay. As might be expected, these plants are so common at the Cape, that the natives have no name for them other than one signifying bushes. Burchell, a botanist, who travelled over a large portion of South Africa, speaking of its flora, says: "All that I had pictured to myself respecting the riches of the Cape in botany was far surpassed by what I saw in one day's walk. At every step a different plant appeared, and it is not the refore an exaggerated description of the country if it should be compared to a botanic garden neglected and left to grow in a state of nature, so great was the variety everywhere to be met with. As I walked along in the midst of the variety and profusion I could not but regret that at every step my foot crushed some beautiful plant. To give some idea of the botanical riches of the country, I need only state that in the short distance of one English mile, though the most favourable season had passed and many of the bulbous and herbaceous plants had disappeared under the influence of the drought, I collected in four and a-half hours 105 distinct species, and I believe that more than double that number might have been found there." I might go on to some length pointing out the various and many beautiful plants which in addition to Heaths are found in this botanically rich country, but sufficient has been said to give some idea of the country itself and the natural conditions under which Heaths are found growing. Of course it will be understood that the Cape summer is our winter, and that the climate in the coldest month at the Cape is as warm as our April weather—warmer indeed than that of recent Aprils. With the exception of the coast lands, where rain falls frequently, long periods of drought are experienced during the warm weather, after which heavy rains are frequent for about three months.

Management of Heaths.—Commencing at the beginning, the propagation of Heaths is an art in itself, requiring for its successful accomplishment much care and attention and treatment of an almost special kind. In large establishments in which these plants are raised by tens of thousands yearly Heath propagation is managed in a very systematic and excellent manner. To walk through some propagating houses at a time when hard-wooded plants are being raised is a treat indeed, and to note the cleanliness and care so apparent and essential in this department if a "large strike" is to be turned out is a lesson well worthy of the attention of all young gardeners. The season for putting in cuttings of Heaths commences in August, and may be practised on through the autumn and winter months until February. Autumn, however, is the best time for putting in the cuttings, as by so doing they have a chance of becoming safe and well rooted before damp and dark weather sets in. The cuttings to select are those wiry little pieces about 1½ inches long found round the base of the plants and clothing the bottoms of the main shoots. When gathered they should be stripped of their foliage from the base upwards about half an inch. Scissors were once used for this purpose, but these are not necessary, the

* A paper read by Mr. W. Watson, Royal Gardens, Kew, before the Kew Gardens Young Men's Improvement Society, January 24, 1833.

leaves stripping from the shoot quite freely if carefully handled. Holding the cutting not too tightly between the thumb and finger, the leaves should be pulled two or three at a pull downwards towards the base. Should the bark come away with the leaves, the cutting may be thrown away, and greater care exercised in the manipulation of the next. After stripping off the leaves, a sharp knife should be used with which to make a clean cut at the base, and the cutting is then ready; 4-inch, 6-inch, or even 8-inch pots may be used, filling them to within 2 inches of the top with clean crocks, over which a thin layer of peat fibre should be placed, and the pot then filled up with a mixture of good fine peat and sand, three-fourths of the latter to one of the former. On this place a layer of clean silver sand and then dibble in the cuttings. These ought not to be placed nearer than half an inch clear from each other, or damp will inevitably prove fatal to them. Water well on the completion of the dibbling, and after the water has drained off the cuttings bell-glasses may be placed over them, and the pot placed in a house where the temperature ranges from 55° to 60°. Wipe the glasses dry about every other morning. Water may be given whenever the sand appears dry, care being taken to allow the water to drain off the cuttings before the glasses are replaced. When rooted, the cuttings will commence to grow, when the glasses should be gradually removed, and the young plants hardened by a little exposure, until finally the pots are transferred to a cool frame to await

Potting off.—This may be done whenever convenient, using for the purpose small pots and a very sandy peat mixture. Pinching the tops out of the young plants may be done as frequently as shall appear necessary for the formation of a bushy little plant. A stake should be given each plant as soon as it begins to make a head. A cool frame, the lights of which may be removed on all fine, bright days and replaced at nights, will be found suitable for these young plants, and afterwards protection from frost, heavy rains, and cold draughts will suffice to keep them healthy and thriving until they are as large as required. For the softer wooded kinds, such as *E. hyemalis*, *E. gracilis*, &c., a less sandy mixture is required than for the harder woollier sorts. Early spring is always the best time for potting Heaths. Pot firmly, and do not give too large a shift, one or two sizes larger than what they are in being quite as much as most Heaths require each year. The watering of these plants is a process on which success or failure largely depends. Many are under the impression that Heaths require comparatively little water from the fact of so many of them appearing to have perished through an overdose of it. Of course, too much water may easily be given, but, supposing the drainage to be perfect and the soil the proper material, water may be given whenever dryness at the root is suspected. Neglect to supply sufficient water is too often the cause of death to these plants, though that is in almost every case attributed to the wetness of the soil consequent on the plant having had a thorough soaking after the mischief has been done. In the warm summer months most Heaths may be placed out-of-doors, where, as a rule, they are much happier than under glass. It may be wise, however, to keep them indoors if one is situated in a rainy or cold neighbourhood, as heavy rains sometimes prove disastrous to many of the kinds.

A cool, airy greenhouse, where plenty of top and side air can be given on all suitable occasions and with a light sunny aspect, is the best house in which Heaths can be grown. A position near the glass, and if possible elevated well above the surrounding plants, so that a free circulation of air may take place all round them, is of great importance. As the specimens increase in size the strongest shoots should be carefully watched and their points pinched out, or they will make a too strong growth at the expense of the lower weaker ones. It is a good practice to overhaul each plant after it has flowered, pinching off the old flowers and cutting back or tying in the most vigorous of the shoots. The staking of Heaths requires a

little practice before one can manage it satisfactorily. It may, however, be well to advise beginners against the practice, too frequently met with as regards Heath training, of placing such a tremendous array of stakes about the plants as to suggest the idea that the stakes are arranged for our admiration rather than being subservient to the requirements of the plant. For my part I object to closely-tied symmetrical plants such as one often sees at exhibitions and elsewhere. The fewer stakes to a plant the better its appearance. Sufficient to support and retain a Heath in the shape in which it grows naturally is quite enough; by supporting the strongest shoots with a stake and looping up any of the straggling smaller ones, we do all that is needed. In the case of some of the softer, freer growing kinds it will be found necessary to cut them back rather freely after flowering, or tall, leggy plants will soon be the result. Some cultivators recommend syringing night and morning during warm weather, but this, I think, a doubtful practice, often producing mildew and misleading one in respect to the state of the soil.

Varieties.—Coming now to the kinds to be recommended for cultivation as being the most useful and ornamental, the first is undoubtedly *E. hyemalis*, a species which grows freely and shapely, and produces large quantities of handsome flowers during the winter months. *E. Wilmoreana* is somewhat similar and also well worth attention, owing to its flowering after *E. hyemalis*. *E. gracilis*, *E. hybrida*, *E. cerinthoides*, *E. persoluta alba*, the *ventricosa* varieties, *E. Parmentieri*, *E. perspicua nana*, *E. colorans*, and *E. melanthera* are also free growing kinds, which will keep up a succession of flower all the year round. I might enumerate a large number of the harder wooded varieties, and then by no means exhaust the list. Specially worthy of mention, however, are *E. jasmiflora*, *E. primuloides*, *E. Macnabiana*, *E. obbata*, *E. inflata*, *E. Jacksoni*, *E. Cavendishiana*, *E. Mar-nockiana*, *E. aristata* and its varieties, *E. Victorice*, *E. tricolor* and its varieties, *E. Massoni*, *E. Paxtoni*, and *E. opulenta*. A word on the

Hardy or European kinds.—These, though less valuable than the Cape kinds, are, considering their fitness for the shrubbery and the gay appearance of many of them when in flower, by no means unworthy of attention. As in the case of the Cape species, many hybrids and varieties have been raised from these hardy Heaths—many of them superior to their progenitors. Growing, as they do, so luxuriantly in peat, or even in good open loam, and looking so fresh all the year round, and especially during their flowering season, which is generally in the winter months, a selection of these plants may be made highly useful for out-door gardens. The smaller growing kinds, such as *E. tetralix*, *E. cinerea*, and *E. vulgaris*, make good edgings to beds or borders, while the larger sorts, such as *E. arborea*, *E. codonoides*, and *E. mediterranea*, grow into good sized plants, and are useful in the shrubbery.

RECENT PLANT PORTRAITS.

THE number of *Illustration Horticole* for January contains well executed coloured portraits of the following plants:—

Cypripedium Spicerianum.—A double plate (473) showing the back, side, and front of four fully expanded blooms of this beautiful and distinct Lady's Slipper.

Cherry Bigarreau des Capucins (Plate 474).—A fine variety of unknown origin, and resembling the well-known White Heart of our English gardens. The fruit is said to be produced in great abundance, to be of excellent flavour, and to be especially adapted for sending to a distance by the firm consistency of its skin.

Yucca gloriosa recurvifolia fol. var. (Plate 475).—A highly ornamental and apparently vigorous growing variety, with a light red marking on a whitish ground down the centre of each leaf. It is said to be marked in a precisely inverse manner to the variety known as *Yucca rufocincta*.

W. E. G.

MARKET PLANTS.—THE CYCLAMEN.

Few plants have burst as it were upon the market with greater suddenness and perhaps in greater abundance than the Cyclamen. But a few years ago, and few indeed were those who could grow Cyclamens at all well, whilst moderate was the quality of the flowers. The change made in the flowers of an earlier Persian to a good giganteum compactum is, indeed, remarkable, whilst not more marked is the present superior cultivation which, instead of consisting of turning out a score of specimens from a hundred corms fairly presentable, rather turns out tens of thousands within little more than twelve months' growth from seed of far better plants than the most carefully, and perhaps too carefully, husbanded corms could give not so many years ago. Old Cyclamens have, indeed, gone the way of named herbaceous Calceolarias, Cinerarias, Gloxinias, and similar greenhouse plants. The ready and simple seeding habits of the plant, the ease with which the flowers can be fertilised, and thus the good qualities of a flower strengthened, the exceeding simplicity of culture to ensure success—these things have all combined to revolutionise the culture of the Cyclamen, and to make it not only one of the most popular, but also one of the most widely grown of greenhouse winter flowers. None the less, however, that the Cyclamen is so universally grown are there some of our market cultivators who stand out prominent amongst their compeers as first-class growers, and of these the names of Mr. Richard Clarke, of Twickenham, and of Mr. H. B. Smith, of Ealing, come uppermost. Both of these have not only high reputations as growers, but also have the finest strains in cultivation, the product of much careful selection and cross-fertilisation. In the case of Mr. Clarke, some 20,000 plants are annually raised; it therefore becomes obvious that the opportunities to select flowers of fine quality and plants of good habit are many. The Cyclamen is so ductile in the hands of the hybridist, that any desired character may soon be impressed upon it, and its quickness to reproduce not only the best features of the parents, but advances in quality makes it specially a favourite with growers.

Calling at Mr. Clarke's nursery the other day, I found Cyclamens in all stages—beginning with recently sown seed not yet germinated, some 6000 seedlings pricked out into $\frac{1}{2}$ -inch pots, the product of last September's sowing, as many in small 3-inch pots, the product of a late sowing the previous year held over to make early bloomers next autumn, several thousands in $\frac{1}{2}$ -inch pots, all more or less in bloom, and being run into market as fast as possible, and not least in importance a long, low house full of late plants for March blooming, many of them in $\frac{1}{2}$ -inch pots, and promising to make very fine specimens. It only needed that we should follow a vanload of Cyclamens to market and from there to some of the places where they bloom and then die, to trace the history of the market Cyclamen from its cradle to its grave. Many of Mr. Clarke's largest houses are lean-to vineries, but these seem less fitted for the culture of the Cyclamen than the low span-roofed houses such as the one now full of the late bloomers. To ensure good bloom through the winter a general temperature of about 60° is desirable, but a warm, sunny day in winter will send a large south lean-to up to 90° if care be not taken, and thus the plants are much distressed and the blooms suffer. Extremes of moisture and drought, too, must be avoided, and the soil should be prevented by judicious watering from becoming so dry that the plants flag and thus suffer. August and September seem to be the favourite months for seed sowing. And from the first until in full bloom and ready for market no rest is permitted; the plants are kept constantly growing. Cool frames form the best positions for them in hot weather. A position that is heated and dry may be productive of green fly, and this aphid is a very destructive enemy. Under the old system of keeping corms over several years, and resting them by drying during the summer, the most elaborate

precautions were needful to prevent aphides during the dry state of the root from settling on the young leafage. Whatever some private growers now may do as to the keeping of old bulbs, market men have long given up the practice except in a very few instances where some good variety was kept to give seed. Still, these are not now dried off or rested, only in a very limited sense. With seedlings there is very little risk, and expert growers can tell to a week when a sowing of seed will, under proper culture, give by thousands plants well fitted for sale in the market. A. D.

FRUIT AND VEGETABLE MARKETS.

ABOUT two years ago a long correspondence was conducted in the daily press on the subject of the general dearthness of fruit and vegetables in the metropolis and in some of the manufacturing towns in the north of England. While consumers in those places were complaining of the high prices they had to pay to the retail shopkeepers, market gardeners were lamenting the low price at which they were compelled to part with their produce to the wholesale dealer. The suggestion was made that in the course of intermediary transactions with middlemen the price became unduly inflated; and there would appear to be some grounds for the allegation. The remedy for this state of things would clearly seem to be proper markets. The tendency in the metropolis, at any rate—whence the complaint of the dearthness of fruit and vegetables first arose—is to accumulate, if we may use the term, these articles of food in a few great emporiums, such as Covent Garden Market, and the markets in the Borough and Spitalfields, which are out of the way of the general consumer, so that to reach him they have to pass through the hands of middlemen, being naturally enhanced in price in the process. This system, though it may benefit a certain number of dealers, is a disadvantage alike to the consumer and the producer. If it were in a measure abandoned, the consumer would pay less, and the producer would receive more than he does now. More markets, easily accessible to the general public, therefore seem in our great towns to be one of the requirements essential to the profitable cultivation of fruit and vegetables. This being so, we notice with regret a decision recently given by Vice-Chancellor Bacon in regard to a proposed new market at the East-end of London.

It seems that the Great Eastern Railway Company some time ago resolved to set up a market for the sale of fruit and vegetables on the site of their old station at Bishopsgate, which is about 300 yards distant from the old-established Spitalfields Market. Thereupon the owners of Spitalfields Market, who claim under letters patent granted so long ago as the reign of Charles II. and James II., applied to the Vice-Chancellor for an injunction to restrain the Great Eastern Company from setting up their market, on the ground that their so doing was an infringement of the rights of the owners of Spitalfields Market. The company endeavoured to show that theirs was not a market in a technical sense, but was rather, what they subsequently called it, a *dépôt*. It was clear, however, that this contention turned upon a mere play upon words, and that what the company sought to establish was nothing more nor less than a market for the sale of fish, fruit, and vegetables. The real point in the case was whether the market set up by the company at their old station at Bishopsgate was so near to Spitalfields Market as to infringe the rights of the owners of the latter, who, under their letters patent, possessed exclusive right to the holding of a market "in or next to" Spital Square. It was shown that Bishopsgate Station was 300 yards distant from Spital Square; and 300 yards in London, especially in the densely-populated neighbourhood in question, means a great deal more than the same distance in the country; and it was also contended that the accommodation at Spitalfields Market was insufficient for the wants of the locality. On both

points, however, the Vice-Chancellor decided against the railway company, and granted the injunction prayed for. The result, therefore, will be that the company can, at the expiration of a month from the date of the order, no longer use their premises, some of which have been newly erected, or any part of them, as a depot, or warehouse, or market for the sale of fruit and vegetables.

We do not know whether the company propose to appeal against this decision; but if they were to do so with success, it would not be the first of the learned Vice-Chancellor's judgments that has suffered a reverse. However, the decision really turning upon the construction to be put upon a document of title, we have nothing further to say on that point. Nevertheless, it does strike us as somewhat anomalous that a monopoly granted 200 years ago should stand in the way of a distinctly advantageous modern improvement. We have no wish to countenance any infringement of the rights of property, however ancient; but if, in such a case as that upon which we have been commenting, those rights could be extinguished or curtailed upon just compensation being given to the owners, we cannot help thinking that little, if any, private injury would be occasioned, while much public good would be effected.

We are glad to see that, yielding to the pressure of public opinion, and in view of a proposed application to Parliament to sanction the Mid-London Market Bill, the Duke of Bedford has at last resolved to take some steps towards improving Covent Garden Market. The promoters of the bill just mentioned have in consequence withdrawn the measure for the present, although they deem the proposals of the duke to be meagre and unsatisfactory. Nevertheless, they think it right, in the first instance, to give due consideration to the scheme of the owner of the property.—*Field*.

ORCHIDS.

ORCHIDS AT BURFORD LODGE.

IT is only those who have had an opportunity of seeing such a collection of Orchids as Sir Trevor Lawrence has in his garden at the foot of Box Hill can form an adequate idea of what these plants really are when grown to the highest perfection. This unrivalled collection at all seasons more than repays a visit, for there are always flowers to be found in one house or another. It is, however, from about the present time up to about the end of May that the collection is at its best, and during this interval flowers are plentiful in every house—a matchless floral display combining brilliant and varied colours with elegance of growth in a manner difficult to express by words. Not only is this collection marvellously rich in species and varieties, but it contains unequalled specimens—the result of the most skilful treatment. One would think that a list of flowering Orchids in January would not be a long one, but such is not the case, there being here far more than space will admit of mentioning; therefore these notes will only include some of the most remarkable.

Dendrobiums contributed largely to the display, and among them were several noteworthy kinds. In great perfection was that lovely new hybrid D. Ainsworthi, a cross between the well-known D. nobile and D. heterocarpum. It has the bright colour of the former and the delicious perfume so characteristic of the latter; therefore it is exactly intermediate between the two parents in these points, besides being so as regards form, size, &c. Here were some fine plants of it with their bulbs 2 feet or more high, wreathed for half their length with beautiful blossoms. We need hardly remark that this is one of the choicest of Orchids at present, though small plants are procurable at a high price. Very similar to Dr. Ainsworth's hybrid is one raised at Chelsea called D. splendidissimum between the same parents as the former. But there is a perceptible difference in the shades of colour and the form of the labellum, though slight. This, too, was in great beauty,

and with D. Ainsworthi and some very fine high coloured forms of the old D. nobile made a charming group. In the way of D. nobile is D. Dominii, a hybrid between D. nobile and D. moniliforme, raised many years ago. It is pretty, but many would prefer D. nobile pure and simple, or a good form of its other parent D. moniliforme or Linawianum, which, by the way, was uncommonly fine here likewise. It is a most distinct species, very delicate and pretty in colour, and quite different from D. nobile, inasmuch as the labellum is spotless. Of especial interest was another new hybrid variety, the lovely little D. endocharis, which is making its way into all the best Orchid collections. Rarely, if ever, has it been seen so fine as the plant which flowered here this season, each of the bulbs, about 1 foot high, being covered with exquisitely beautiful flowers. They are about 1½ inches across, with milk-white sepals and petals, and a fawn-tinted lip with just a dash of purple on it to lighten it up, as it were. One of its parents is D. japonicum, itself a gem, so that the progeny is capable of being grown in a lower temperature than that in which *Dendrobes* usually are. An intermediate house seems to suit it admirably. Still another hybrid remains to be noticed; it is D. Rhodostoma, a Chelsea hybrid between D. sanguinolentum and D. Huttoni. It is an improvement on both of its parents, and possesses a beauty peculiar to itself. The flowers are what would be called small for a *Dendrobe* and rather sparingly produced, but they are of wax-like texture, the petals and sepals white, conspicuously tipped with a rich carmine-magenta tint.

D. *Wardianum*, represented by the richest coloured varieties, was hanging from the roof in gorgeous wreaths, and seemed common enough, but not so the white-flowered variety, which is as lovely as it is rare. One can imagine how chaste the colourless flowers of such a large and fine *Dendrobe* as this are, but only an adequate idea of its beauty can be had by seeing it as it was here with flowers in long drooping racemes. Sir Trevor is the possessor of two or three other albinos amongst *Dendrobes*, such as the white-flowered D. crassinode and D. bigibbum, both charming varieties which will shortly flower. One of the most remarkable of all the Orchids in bloom was what is called the Cobweb Orchid, D. teretifolium, having fleshy cylindrical leaves, from the bases of which are produced myriads of small slender flowers, all matted together with the foliage in a singular way, giving the whole plant the appearance of a big mass of cobwebs. The plant here was a very fine specimen, clothing on all sides a portion of tree stem suspended from the roof. In the East India house in a warm corner was a plant in flower of the D. Goldiei, a near, very near, relative of D. superbiens. It differs mostly in its sepals and petals being less undulated, and by being of a higher colour. Other flowering *Dendrobes* of lesser note were D. fimbriatum, not the black-eyed (*oculatum*) form, now so common, but the typical with large rich orange-yellow flowers without a trace of another colour. This plant has bulbs 5 feet or 6 feet high, a grand specimen rarely matched. The extremely handsome D. Cambridgeanum, in a square basket suspended close under the roof, had its short, fat, pendulous bulbs studded with golden and black-blotched flowers, which, with the green foliage, make a charming contrast. This species possesses the desirable character of flowering on the young growths, the young foliage of which sets the blossoms off to great advantage. Large plants of the old D. Pierardii hung from the roof, and every one of its long slender bulbs—perfect sheaves of them—were wreathed with soft delicate blooms, and the same may be said of the still lovelier D. primulinum, which was represented by some fine varieties. D. luteolum was in fine bloom, and though not thought much of, is not one to be despised; indeed there are few Orchids that possess such delicate primrose-yellow flowers accompanied by foliage. D. speciosum and Hillii, both grown in a Mexican house, were just on the point of bursting their flower-buds, and in the course of a few weeks the roofs and stages of the *Dendrobium*

houses will present a glorious display of bloom, for every plant seems studded with buds.

The *Laelias* in flower just now are alone worth a long journey to see, for it is doubtful if the enormous masses of *L. anceps* could be matched anywhere in gardens. This lovely species may be seen in its richest varieties. Those in full beauty were Hilli, with pure waxy white sepals and petals with just a dash of rosy pink on the labellum; rosea, with the colouring of the lip paler; Barkeri, with larger flowers than those of the ordinary form and with an intensely deep lip; superba, with broader and longer segments of a much deeper colour than the preceding, though the lip is not so rich, but for all that it is a splendid variety, probably unequalled. No one could really form a correct idea of the splendour of *L. anceps* without seeing such grand masses of it as exist here. One huge plant rooting into a bed of peat resting on a flat teak raft a yard or more square was carrying no fewer than eighteen long slender spikes, each terminated by two, three, or four flowers, a rare floral sight in itself. That pretty little species *L. albida* could be seen in numbers in a cool, dry house where their delicate blossoms, would be preserved longest. The varieties bella and rosea, so named on account of the labellum being of a pale or warm rose tint, could be distinctly singled out, and very charming they are in association with the almost pure white blooms of the typical form. This sweet little Orchid should be grown by everyone who likes a flower that remains in beauty for some few weeks, and such delicate beauty, too. Half-a-dozen flowers on a spike was common among the plants here, though usually they do not carry so many. Of a rarer nature was a flowering plant of *L. furfuracea*, which now-a-days is so seldom seen in bloom. It is much in the way of *L. autumnalis*, which has just gone out of bloom, but the flowers are a trifle smaller, but quite as beautiful, the segments being white handsomely tipped with deep purplish rose, as is also the labellum. It may be at once distinguished from *L. autumnalis* when out of bloom by the longer and thinner bulbs. Among Cattleyas the numerous varieties of Trianae were coming into flower, and of *C. Percivaliana* there were three or four flowering plants which helped to enliven the otherwise flowerless Cattleya house.

Ipsea speciosa, a terrestrial species and resembling a *Bletia* in growth, was exceptionally fine. A good-sized plant of it growing in the Phalenopsis house was carrying several flower-spikes, some of which bore four blossoms about 2 inches across and of a rich chrome-yellow. It is seemingly a water-loving Orchid, requiring to be kept while growing as moist as a *Disa*. Another beautiful terrestrial of a similar stamp, *Spathoglottis Lobbi*, will soon be in full bloom; a large specimen of it suspended in the East Indian house has produced quite a sheaf of flower-stalks, each of which will bear four or five bright yellow blossoms, over an inch across and in form like that of *Phalenopsis Schilleriana*. These two species are so distinct from most other Orchids, both in colour and growth, that they deserve special mention, and more particularly as they lend themselves kindly to cultivation. A coloured illustration of both appeared a short time since in THE GARDEN.

Epidendrums, in which this collection is so rich, were represented in flower by such handsome species as *E. Wallisi* and *rhizophorum*, both of which belong to the tall, slender-stemmed group. The first has a large pendulous cluster of blossoms terminating the stem, and these have bright yellow segments copiously spotted, while the ample labellum is white, blotched and streaked with purple—a strange mixture of colour. In *E. rhizophorum* the flowers are borne much in the same way, but are smaller and more numerous, and of a brilliant vermilion colour, as bright as that of *Sophranitis grandiflora*. Those who have no special predilection for this section of *Epidendrum* can scarcely help liking such fine species as these, and, moreover, they are not inelegant in growth, the stems being evergreen. Another species of this section, *E. crassifolium* or

erectum, was in bloom, which, though pretty, has altogether a common look about it compared with the aforesaid two. There are a lot of odd things in the way of *Epidendrums* to be found here flowering at various times of the year, and presently the houses will be enlivened by the glowing blooms of that finest of all *Epidendras*, *E. vitellinum*, which is grown so well here.

Cool house Orchids were bearing an abundant crop of bloom, particularly the *Odontoglossums*, which are always to be seen here so finely, no matter at what season of the year. Just now the variable *O. crispum* is developing crowds of long gracefully arched spikes covered with bloom. As may be supposed, no inferior form is tolerated, but all must either be remarkable for spots and markings or be first rate in form. Among the less common species were *O. crocidipterum*, a pretty variety, but only to be recommended to the notice of the connoisseur, and the same may be said of the rare *O. nevadense*, which was uncommonly fine, as, indeed, it has been for the past two or three seasons. Those two gems of the first water, *O. Ruckerianum* and *Andersonianum*, were in fine form, and represented the finest varieties. There is a similarity between the two, but the first has a sort of vinous purple shade, whereas the ground colour of Anderson's variety is or should be pure white. A long branching spike of either of these two Orchids is a beautiful sight, and one that anyone not specially Orchid lovers can appreciate. *O. prionopetalum*, one of those mysterious mongrels of the luteo-purpureum stamp, was producing a fine spike, as were also a host of others, including numerous forms of *O. gloriosum*, odoratum, and that handsome, but slighted species, *O. Uro-skiner*, which if seen in its best form is as fine as any. Here there was a variety with a labellum an inch or more broad, and of a lovely rose-pink.

Masdevallias in flower were not numerous, but these included some of special note. The showiest was *O. Lindenii superba*, a truly superb plant, with large blooms of a lovely rose-magenta with a white tube. Another fine one was the ever beautiful *M. Veitchii*, represented by its finest form. *M. tovarensis*, with its snow-white blossoms, was in delicate harmony with the brilliant colours of the preceding. Among the *Chimara* section was a fine specimen in a suspended boat-shaped raft of *M. Backhouseana* with seven flowers; while near was an equally fine plant of *M. Chimera* with nearly as many blooms. These and their allies are grown admirably in an intermediate house. In a cooler division were fine examples of the singular little *M. polysticta*, which, when profusely flowered, as here, is an attractive plant. A great variety was *M. leontoglossa*, which seems to have affinity with the coriacea type. It is no great beauty, but curious and extremely rare.

The Phalenopsis house had a brighter appearance than it has had at corresponding dates for some time past, and *Phalenopsis* seem to be thriving uncommonly well now. There is a perfect thicket of spikes of one kind and another, principally of *P. Schilleriana*, *amabilis*, and *grandiflora*. The greatest attraction was a superb plant of the rare *P. leucorrhoda*, a hybrid presumably between *P. Schilleriana* and *amabilis*, with which it is intermediate. The flowers are paler than a good form of *Schilleriana*, but larger, and the specimen in question bore a long, widely branched spike, carrying a large number of blossoms. Another great beauty was a variety of *P. Schilleriana* called *delicatissima*, than which no form could scarcely be finer. The blossoms were large, the segments broad and overlapping, of a deep, rich rose-pink tint, profusely spotted with minute spots, so as to give the markings a clouded appearance. *P. Stuartiana* and its variety *nobilis*, the almost perennial flowering *P. Luddemanniana*, and various others contributed to the floral display in this house.

Other noteworthy Orchids included *Catasetum Scurra*, a great rarity, and moreover a great beauty. Its short, round bulbs bore from their bases short pendulous racemes of white blossoms nearly 1 in. in diameter, pure white except the centre, which was yellow and chocolate, while the lateral wings

of the labellum were prettily lined with green. The labellum is fringed at the extremity in a singular way. It has a delightful perfume, most resembling that of ripe Guavas. *Maxillaria lepidota* in a cool house was a sight in itself; it was a large plant bearing some scores of its yellow flowers with long slender brown tails; the whole form a compact mass, producing a striking effect among the light-coloured *Odontoglossums*. In the same house was a variety of *Oncidium cucullatum* called *Chestertonii*, having an unusually broad labellum of a deep rich violet spotted with purple, and which in contrast to the golden central crest was very fine. *Pothieva maculata* was one of the most curious of all the Orchids in bloom. The flowers, produced in short erect spikes, in form resemble some kinds of moth; the upper sepals are spotted with green on a light ground, while the basal portion of the flower was yellow. Near was a plant of the rare *Vanda Goweræ* just expanding its flowers, which appear to be white. The pretty little *Sophranitis violacea* vied in brightness with its larger congener, *S. grandiflora*, but it has the advantage of being less common. *Aerides Lecanum*, not a very attractive species, was in flower, as were also several rather rare kinds of *Cypripeds*, such as *C. Spicerianum*, *concolor*, *Warneri*, *Harrisonianum superbum* (a very fine variety), and *Dayanum*. *Limatodes rosea* was exceptionally fine, and when grown thus is a bright and attractive Orchid, possessing a beauty peculiar to itself. *Calanthe Veitchii* could not possibly be seen better than it was here, the colour being the deepest of rose-pink, with spikes a yard or more long. Sir Trevor Lawrence most certainly possesses an uncommonly fine form of this Orchid. W. G.

ORCHIDS AT THE YORK NURSERIES.

The most remarkable Orchids now in flower in Messrs. Backhouse's nursery are the following: *Angraecum sesquipedale* and *A. citratum*, *Vanda tricolor*, *Odontoglossum Roezlii*, *Cypripedium Sedeni*, *Roezlii*, *Boxalli*, and a few others, but the chief feature is the large unshaded

Cattleya house, the most noteworthy plant in which is a specimen *C. Trianae*, very aptly named *Aurora*. The pale rosy tints in this flower are exquisite, and its broad petals and bold form place it at once in the first rank. Then comes *Trianae alba*, bearing nine flowers; *Trianae Ruckeri*, grand masses of *Warszewiczii* and its variety *delicata*, and a host of others more or less worthy of notice. The finest of all, however, is *Trianae Backhouseana*, undoubtedly the best form of *Cattleya Trianae* grown. One specimen, covered with gorgeous blossoms, is worth a long journey to see. There are also several smaller plants of this variety in flower, as is also the much-talked-of *C. Percivaliana*.

Other Orchids worth mention are *Oncidium Cavendishi*, *Wentworthianum*, *unguiculatum*, *Krameri*, a lovely variety; *Laelia harpophylla*, a beautiful species, the flowers of which open orange, and after a few days change to vermilion; *Dendrobium Hilli*, with spikes 2 feet long and sweetly scented, and several other *Dendrobies*. There are also examples of *Saccolabium giganteum*, some carrying two spikes, though the plants are not more than 9 inches high. In the

Mexican house *Coeogyne cristata* makes a fine display, many fine specimens being perfectly covered with spikes, many of which bear six and seven flowers apiece. *L. anceps* is almost over, but the numerous dying spikes bear witness to what it has been. One plant, however, is still worthy of notice; it bears eight flowers on two spikes, four on each. Can anyone quote an instance of *anceps* with more flowers than this? *L. albida* and its varieties *bella* and *rosea* are likewise well represented, some fine spikes bearing from eight to twelve flowers. *L. autumnalis* is just over. There is a house almost full of *O. vexillarium* in luxuriant health, just pushing up spikes, and *O. Rossi majus* in variety. The cool house is a beautiful sight, there being a

quantity of *O. Alexandræ*, of all sizes, also of *gloriosum*, *cirrhosum*, and *Halli*. The pretty little *Oncidium cuculatum* also seems at home here, as indeed do the whole of the Orchids in this establishment. E. W.

Cattleya Percivaliana.—By far the finest example of this new variety we have yet seen was one we saw a few days ago in Mr. Stevens' rooms, King Street, Covent Garden. The specimen bore three flowers on one spike. The flowers were only about a third smaller than those of the typical *C. labiata*. The petals were broad, richly suffused with rosy lilac; the labellum was gorgeously coloured with rich velvety maroon, amethyst, and golden yellow, and much fringed at the margin. The anterior lobe of the lip was much prolonged, as in the true *C. labiata*, of which it may justly be considered a variety. There is a bright future for this *Cattleya*.

Phalenopsis amabilis variety.—The enclosed *Phalenopsis amabilis* is the only one of an importation that has spotted sepals. I also enclose a bloom which represents most of the other plants. The late dull weather has much interfered with the blooming of these Orchids and also militated against size and colour. The house in which they were grown has several times been as cold as 55°, with the result of every root in a state of growth being killed, thus proving that *Phalenopsis* will not bear a less temperature than 60° unless in a perfectly dormant state.—M. H. Voss, *De Montfort House, Stratham*. [The spike sent is lovely. We have seldom if ever seen a form of *P. amabilis* in which the lowermost sepals are so beautifully spotted or the middle lobe of the labellum so deeply stained with brownish red.]

PLANTS IN FLOWER.

ANEMONE BLANDA.—The first blooms of this lovely little hardy Windflower have just expanded in the York Nurseries, and shortly there will be a fine display of its beautiful turquoise-blue blossoms.

SENECIO GHIESBREGHTII.—I send you a spray of bloom of this plant, which is very showy in a conservatory here at the present time. My specimen is a standard 8 feet high, and some of the flower clusters measure 18 inches across, and at a distance resemble a gigantic yellow *Hydrangea*. J. M., *Charmouth, Dorset*.

HELLEBORES.—From Mr. Archer-Hind's warm Devonshire garden we have received a wonderfully fine collection of Hellebore blooms, a fact in itself which sufficiently indicates how finely these plants are grown by him. At page 113, Mr. Archer-Hind alludes to this collection at some length, and to which we refer our readers.

SAXIFRAGA LIGULATA.—This, one of the large-leaved or Megasea section of the genus, lends itself kindly to forcing. In the Chiswick garden there are numerous plants of it in flower in pots which have been lifted from the open ground and gradually inured to a warm house, so as to induce them to expand their clusters of rosy pink blossoms. Such plants are valuable for conservatory adornment at this season.

BEGONIA ROEZLI.—This beautiful new Begonia, alluded to last week as being so fine at Burford Lodge, is apparently grown admirably at the Cambridge Botanic Garden, for Mr. Lynch sends us some glorious sprays of it. The deep cherry-red of the newly opened flowers is charming, as are also the densely packed clusters of buds, which just show the tips above the brown membranous covering. We commend this plant to the notice of our readers, as it is one of, if not the most beautiful of all winter-flowering Begonias.

A GIANT ANTHURIUM ANDREANUM.—A remarkable specimen of this comes to us from Sir N. M. Rothschild, measuring 8½ inches long by 6 inches across the scarlet spathe. It is supported on a stem nearly 3 feet long. A plant

bearing such blossoms must be a splendid object. This is a particular variety, though no doubt good culture is increasing the size of the flowers of the species compared with what they were when we figured the plant a few years ago. This fine specimen was grown by Mr. Hill, gardener at Tring Park.

CHINESE PRIMULAS.—The rich collection of these in the Horticultural Gardens at Chiswick is just now in perfection. There are large numbers of plants, and one house which is full of them is a fine sight, the varieties being arranged in rows of various colours. The sorts are numerous, but such very fine kinds as Chiswick Red, white, and purple predominate. These all originated here, and take the lead in their respective colours. The latest addition is Chiswick Red Improved, a kind remarkable for greater brilliancy of colour than that of the original.

LATE CHRYSANTHEMUMS.—I send you blooms of *Chrysanthemum Elaine*, Hero of Stoke Newington, Guernsey Nugget, and Princess of Teck, in order to show how fine they are even so late as this. The three last named are particularly useful as late blooming kinds; they help now (January 30) to make the conservatory gay. By keeping some plants of *Elaine* very cool I have not been without an abundance of its valuable flowers for a period of over three months.—W. JENKINS, *Aldin Grange, Durham*. [Very fine blooms considering the season.]

GALANTHUS ELWESI.—Mr. Kingsmill has this handsome Snowdrop now finely in flower in his garden at Eastcott. A specimen of it which he sends us is as large as we have yet seen it, the flowers measuring nearly 2 inches across, and furnished with three snow-white concave outer petals which spread horizontally. It is the largest and finest of all the Snowdrops. Mr. Kingsmill likewise sends us his first blooms of *Leucojum vernum*, and also examples of the charming little Corsican *Crocus minimus*, which has tiny flowers of a rich purple within and fawn coloured without.

ALOE PEACOCKI.—A new species in the way of *A. abyssinica* is now in flower in the Sudbury House collection, Hammersmith. It has huge fleshy spiny edged leaves, covered with a glaucous hue. The tall branching flower-stem bears from the tip of each branch a crowded tuft of long tubular blossoms of a reddish yellow colour. It is a handsome plant and very rare. In Mr. Peacock's collection there are also several other succulent plants in flower, and among them *Aloe ciliaris*, a slender growing plant inclined to climb. Several fine specimens beneath the rafters of the roof are bearing numerous clusters of bright orange-red flowers in long close heads.

A MINIATURE BROMELIAD.—Among the rarities in flower at Glasnevin just now, what is in sooth a little gem in its way deserves, according to the *Irish Farmer's Gazette*, especial notice. This is a tiny epiphytical *Tillandsia*, of Pine-apple aspect, growing on a morsel of wood no thicker than the middle finger, and the plant itself so small that a pill box would cover it. The leaves have their surfaces glistening as if beautifully frosted with silver, and from their centre rise a slim pair of narrow, tubular, glossy purple, Crocus-like flowers, each not thicker than a crow quill, and crowned with gold in the shape of the yellow anthers, which rise just barely above, and contrast strikingly with, the colour of the flowers. The whole affair, plant and wood, we fancy would scarcely weigh half an ounce.

SPRING FLOWERS IN BERWICKSHIRE.—The spring flowers are now again beginning to bloom with me after their summer and winter's sleep. The Snowdrops are just coming out, also the Hepaticas and *Primula denticulata*. *P. cashmeriana* will soon be in flower. The common Primroses, of which I have some thousands of all colours, including Dean's rich coloured varieties, have begun flowering in my garden. They are great favourites of mine. *Anemone blanda* is peeping above the ground, but it is later this year than last, when it flowered here on the 18th of January. The frost was very severe here in

December, the thermometer indicating 34° of frost on the night of Thursday, the 14th. I do not think, however, that anything in the garden here has been killed. I was afraid of my Tea Roses, but as I had them protected with dry straw and Spruce Fir branches, they are quite safe.—GEORGE MUIRHEAD, *Parton, Berwick-on-Tweed*.

EARLY RHODODENDRONS.—Mr. Launcelot Gubbins, of Salterbridge, Cappelton, Co. Waterford, writes that the Rhododendrons there are just coming into flower already (January 25).

FINE STRAINS OF PRIMULA.—Mr. B. S. Williams, Victoria Nursery, Upper Holloway, sends us flowers of his beautiful varieties of Chinese Primulas, red and white. Of the latter there is one called *alba magnifica*, one of the finest white sorts we have seen. The blooms are nearly 2 inches in diameter, finely crisped and fringed at the edges, pure white, with a conspicuous yellow centre. These fine sorts serve to show what strides have recently been made in the improvement of this useful flower.

PORTEA KERMESINA.—This fine Bromeliad, which is rather new to cultivation, we saw finely in flower the other day in Mr. Peacock's rich collection of Bromeliaceous plants at Sudbury House, Hammersmith. It is nearly related to the *Billbergia*, and, like most of the species of that genus, the foliage is arranged in a vasiform tuft, from the centre of which the erect flower-spike arises about 1 foot in height. This is clothed on its upper part with broad overlapping bracts of a rich rose-pink colour, and these enclose long tubular blossoms of a bluish lilac hue, which protrude here and there from the bracts. This is one of the handsomest Bromeliads we have seen, and if a selection of these plants is needed this should be one of the chosen ones. Being a native of Bahia, it requires a rather warm and moist house. Among other members of this family in bloom in Mr. Peacock's garden is *Vriesia brachystachys*, a Brazilian species with yellow flowers and green and scarlet bracts a singular mixture of colours.

GYNURA AURANTIACA.—We saw this plant for the first time in flower the other day in Baroness Rothschild's garden at Gunnersbury Park, where Mr. Roberts has grown it rather extensively during the last year or so. The plants in bloom are those which were planted out in the open beds during last summer and lifted in autumn. They are now in a frame and are some 2 feet or 3 feet high, and each bears numerous loose clusters of flower-heads from the extremities of the branches. These flower-heads are about half an inch across, and consist wholly of tubular florets of a warm orange-yellow colour. Taken individually, the flowers are not much superior in beauty to those of a Sow Thistle, but in contrast with the purple-plush-like pubescence which covers both surfaces of the leaves the effect is charming; indeed, we have rarely seen in plants such a strange combination of colours. The young leaves which immediately surround the flowers, being more densely hairy than the rest, show off the flowers to advantage. We believe this is the first instance of the plant flowering in this country, but it is for its beautiful foliage that it is most valued. Mr. Roberts speaks highly of it, and he has used it freely as an ornamental foliaged plant in the summer flower garden. It is remarkable that a Javanese plant should be so hardy.

Complete Index to "The Garden."

The general index, embracing the whole of the volumes from the commencement to the end of the twentieth, is now ready. It has been compiled, printed, and bound with much care, and will be very useful in making more accessible to all who possess the volumes the immense mass of practical gardening matter, plates, and woodcuts embodied in its pages. Those who intimated their willingness to subscribe for it will be supplied at the subscriber's price of 10s. 6d. per copy. As its production has been more expensive than was anticipated, the price has to be fixed at 12s. 6d. per copy. There will be no free copies, and no reduction to the trade on the published price.

SELECT SELAGINELLAS.

ALTHOUGH the many handsome plants belonging to this genus bear no relation whatever to Ferns, many of them are so similar in general appearance that it is no wonder if by the side of a good collection of Ferns is often to be found one of Selaginellas equally worthy of note. They are most of them of very easy culture, and as a rule invaluable for decorative purposes, as their elegance can hardly be overrated, and their power of endurance in many instances proves sufficiently satisfactory to enable their owners to utilise them for indoor

at one end of the house; in any case it will be found beneficial to have them kept separate from the Ferns, as they require a greater amount of constant moisture around and about them. To effect that they should be placed on a solid bed which constantly gives off moisture, or, if that is not practicable on account of the house being provided with stages, the latter should be covered with Sphagnum, to be kept wet, and the pans not allowed to rest directly on it, but to be set up above it on three small pots or on an inverted pan, so as to avoid all contact with the saturated material. In

as they cannot endure their massive, feathery fronds to be wetted over at all. They are very variable

In colour and size. Among their numbers may be found all the shades of green from the lightest to the darkest tints; some are of the most dazzling hue, while others have their foliage prettily variegated. One of them even changes to white or grey as the sun sets in the evening; but resumes its green appearance again in the morning. In fact, from their different sizes, modes of growth, and distinctive habits, they may

Selaginella grandis. Drawn from a plant in Messrs. Veitch's nursery, Chelsea, in December last.

decoration, as some of them succeed admirably in a Wardian case. The majority of these beautiful plants come from the East and West Indies, and consequently require a warm, close, moist atmosphere where draughts are carefully avoided, although some are quite at home in a temperate house and even a few of them are quite hardy; but those which are found doing well at a comparatively low degree of heat are few in number. The temperature most suitable for the bulk of them is from 65° to 70°, and they will, by growing more luxuriantly, give even more satisfaction if the heat can be kept up to 70° or 75° all the year round. Growing them in shallow pans is the best method of cultivation, as, with the exception of those belonging to the rosulate section, they all require room to spread, and most of them root upon the surface. They should be kept on the shady side or

that way the plants will derive all the benefit of the surrounding moisture without the soil becoming sour. Although a few species do well in loam, the majority of them delight in an open compost consisting of equal parts of good fibrous peat and chopped Sphagnum, which will prove all the more nutritious to them if old and partly decayed. A good proportion of silver sand and crock-dust might be added with advantage, as it will tend to keep the soil porous, which is very necessary, as they require copious waterings at the roots, although they have a particular dislike to standing permanently in the wet. For the same reason also it is quite necessary that the pots or pans should be thoroughly well drained. Because Selaginellas are moisture-loving plants, it does not follow that they should have frequent syringings over the foliage, treatment really most damaging to them,

be divided into five distinct sections, the first section, comprising all the dwarf-growing kinds, seldom reaching over 2 inches or 3 inches in height; these are principally useful for covering the ground under taller growing plants. Putting aside the popular *S. Kraussiana*, better known as *S. denticulata*, and its white and yellow-tipped varieties, the most remarkable of this section are the pretty Brazilian *S. apoda* (apus), which only grows about 1 inch high, but spreads rapidly, forming a splendid and uniform carpet of a light green colour, which never requires any clipping; the beautifully tinted Chinese *S. cæsia* (uncinata), which, if kept from the strong light, will thrive apace and be very attractive with its fronds creeping on the ground, or if conveniently situated will hang down to a length of several feet, and of a bright metallic colour, sometimes reflect-

ing the most lovely blue. The elegant *S. Poulteri*, also very valuable where dwarf-growing kinds are required, is a very dense, prostrate species of free growth and hardy constitution, with leaves small and dark green; whilst for covering stones, walls, or any rugosities in the warm house, nothing is better adapted than a distinct little species from Jamaica, which clings to anything moist of however hard substance it may be, and which has many names, such as *S. mutabilis*, *variabilis*, *serpens*, and which, as these aliases denote, is of a changing colour; naturally of a bright green, it gradually fades towards the evening to almost a pure white, and is to be found green again the following morning. On that account, and also from the rough feeling experienced when touched by the hand, it is very easily distinguished from any other species.

The second section comprises all those of an erect-growing habit. The representatives of this section are of all *Selaginellas* the best known to the public at large. On account, I presume, of their rapid growth they have been taken in hand by the market grower, and form part of the bulk of decorative plants, where they hold their own with advantage. Of this section the most useful are *S. Mertensi*, a Mexican ornamental species of compact growth; its erect stems are densely clothed with broad, dark, shining green leaves, and they produce a great quantity of aerial roots from the under side and lower parts, in which way they are readily increased. The variegated form of the above species possesses the same habit, but is profusely blotched with pure white, which variegation makes a striking contrast with the other leaves of a shining green. Then the West African species, *S. rubricaulis*, is a pretty and elegant plant interesting in all its parts; the stem is slightly red below and grows to about 8 inches in height, with branches of a beautiful bright green colour. *S. atroviridis*, one of the most beautiful of the East Indian erect kinds, grows from 8 in. to 12 in. high, and produces along the undersides of the branches many adventitious roots; the larger leaves are broad and obtuse, the smaller closely covering the stem and branches. The whole of the plant is of a dark glossy metallic green colour. *S. formosa* is also considered one of the most decorative kinds grown. It is a stronger grower than any of the preceding species, although its foliage is much lighter both in colour and otherwise; it also produces all along the stem a number of aerial roots, grows to about 12 in. high, and is of compact habit. The most attractive plants from an amateur's point of view are those belonging to the third section. They are not such rapid growers as those belonging to the two classes above described, and therefore not so useful for decoration, but they are much more gorgeous in appearance—more aristocratic-looking, if we may use the term, than any of their associates. They are distinguished from all other *Selaginellas* by their stems rising from an underground stolon instead of either creeping on the ground or growing upright; their stems are not, as in the others, provided with aerial roots. Foremost among the gems of this important class is

S. grandis, a specimen of which forms the subject of our illustration. It is a native of Borneo, where it was collected by Mr. Curtis for Messrs. James Veitch & Sons. Its erect stems are produced from a creeping rooting base or stolon as thick as an ordinary pencil; they grow from 10 inches to 15 inches high, and are clothed with ovate acuminate, serrulated leaves, the lateral ones becoming larger and merging into the larger leaves of the fronds, which are bold, and at the same time graceful in habit, of a clear grass-green above, paler beneath, from 10 inches to 12 inches long, dichotomously branched with numerous furcations, some of which measure more than half an inch across in the more matured parts of the fronds. The leaves are also very closely set, indeed, leaving no interval between, and this renders the breadth of the branches much more effective, and gives them a remarkably leafy appearance. Every successive frond in Messrs.

Veitch's grand specimen plant grows taller and larger, and the fertile ones, fringed by the elegant tail-like spikelets which are produced abundantly at the tip of every shoot, add greatly to the already noble appearance of this magnificent plant which last May at Kensington, and last July at Regent's Park, captivated the members of the floral and botanical committees, who, in both instances, justly paid it the honour which it richly deserved.

S. africana (fulcrata), also belonging to the same section, is a fine, strong-growing ornamental species with stems rising from an underground stolon. They grow to the height of 12 inches to 15 inches, and bear handsome fronds about 8 inches in breadth, triangular in form, and of a beautifully dark, glossy green colour. *S. caulescens* is another very elegant and distinct species from the East Indies, which produces from an underground stolon its beautiful erect plumose fronds, nearly 2 feet high, somewhat deltoid in outline, and of a light green; the fruiting points of the branches are prettily contracted, and give the fronds the appearance of so many ostrich feathers. To the same section also belongs *S. eythrops* (umbrosa), producing stems from 12 inches to 15 inches in height and fronds 10 inches in breadth, dark green above, paler below, and broadly triangular in shape, and the beautiful massive-looking *S. hematodes*, both from Tropical America. This latter species is of very strong growth, and produces from its underground stolon thick and plumose fronds often reaching 18 inches in length and 12 inches in breadth, which, instead of standing erect, as in most of the other species, are gracefully arching over, and of a very bright green; it is highly ornamental. The last that will be described belonging to that section is the beautiful *S. Lyalli*, from Madagascar; the stems of this evergreen stove kind rise from an underground stolon, and grow from 10 inches to 15 inches high; the fronds often attain 10 inches in width; they are very finely cut, of a ferruginous dark green, and short, but large fruiting spikes, like *Juniperus* seeds in miniature, are borne at the points of the branches. To the fourth section belong all the

Selaginellas of a scandent or semi-scandent character, some giving branches of indefinite length. Their stems, as those of the plants of the second section, are all provided with aerial roots, but these are produced further apart and not in so great a quantity. The most telling of this class is without a doubt the noble *S. Wallichii*, from Penang. It is difficult to say what size it will attain, but with its beautifully branched stems 30 inches or more in height, and the longest branches quite a foot long, it makes a magnificent specimen. The colour is shining dark green, and the point of each branchlet is adorned with a fertile spike about 1 inch long, giving additional grace to the plant. Indeed, when well grown it resembles a very good specimen of the beautiful *Gleichenia flabellata*. Its nearest rival for stateliness and beauty is the Bornean species *S. Lobbi*, which is also a very robust caulescent plant and grows from 18 inches to 24 inches high; it is thickly branched, the fronds broad, and the leaves, of a dark green, produce masses of fertile spikes on the tips of the branches. *S. chinensis* is also a very distinct species belonging to the same section with fronds rather narrow and of a light green, produced on stems of an indefinite length. If kept cut back now and then it makes a very handsome specimen. The best distinct species of this class is the pretty and compact-growing *S. inequalifolia*, from Java. The stems are produced in abundance, and grow from 10 inches to 15 inches high with fronds of nearly equal width throughout; the fertile portion is contracted, forming spikelets on the ends of the branches. Then the fifth and last section is the one comprising all the species of rosulate or tabulose habit, the best one among them being *S. japonica* with incipient stem rising to about 1½ inches, then producing a profusion of circinate frondose branchlets, rather rigid in texture, which become horizontal as they lengthen,

and are furnished with numerous lateral offshoots, forming a good-sized spreading plant with a regular, but not formal outline. It is of a very deep colour, and succeeds best in the cool house. *S. pilifera*, often called also *S. lepidophylla*, is also a remarkable plant, throwing out its branches in a horizontal manner, and thus forming a flat top like a table; it grows to about 8 inches or 10 inches in diameter. Finally, one of the most interesting members of this rosulate section is the delicate and pretty *S. cuspidata*, whose stems are arranged in a whorl round the crown somewhat like the petals of a Rose; it is of a light green, and grows from 10 inches to 15 inches high. It is one of the most beautiful of the whole genus. C. G.

SOUVENIR DE LA MALMAISON CARNATION.

THIS fine variety is not by any means so well or widely known as it should be, and although occasionally found in good condition, it is oftener met with growing with ordinary tree or perpetual flowering kinds than otherwise, and as the treatment that insures a supply of flowers in winter in the case of true perpetual flowering Carnations, such as *Miss Joliffe*, *Vulcan*, *The Bride*, &c., is enough of itself to spoil all chances of success with this grand variety, perhaps a few notes on the system of culture by which I have yearly produced not only quantity, but quality, may be acceptable to many who attempt its culture, but fail from treating it as a true tree Carnation. In the gardens at the The Grove, Gosport, I lately saw some magnificent plants of it in the most robust health in a cold unheated orchard house, and although they showed their relationship to the perpetual tree kinds by producing here and there a flower-spike, it was not more than ordinary border Cloves will do if placed under the shelter of a glass roof. *Souvenir de la Malmaison* is a summer-flowering kind, and does not answer for forcing. A lengthened season of flowering may, however, be secured by placing a few of the most forward plants of it in a light, airy house, such as on the front stage of a Peach house, where plenty of light and air is admitted and a gently progressive temperature maintained, and by allowing another batch to come on in cooler quarters under glass, and by setting the remainder in a shaded position as soon as the frost is over to constitute the latest supply; thus a succession may be kept up from April to November. At The Grove this plant is made a speciality of; the main stock of plants for flowering this year are in pans made to suit the wants of this Carnation. They are 14 inches in diameter and 8 inches deep. Ordinary flower-pots of that diameter at top would be too deep, as this Carnation is a surface-rooting plant, and does not require a great depth of soil. Good drainage is, however, of the highest importance, and these pans are filled quite one-third with potsherds. On the drainage is laid rough fibry turf, and the rest consists of rather sandy loam, a little rotten manure, pounded charcoal, and silver sand. Only one plant is put in the centre of the pan when potted in spring, but in August when they have made five or six good strong shoots these are layered in the usual way; therefore, now to all appearance each pan contains five or six separate plants, although in reality all are united to the parent plant, and each side plant is furnished with quantities of shoots just starting into growth. The amount of blooms which one of these large plants produces is therefore astonishing. As regards the hardness of this variety, I may mention that the whole stock was out of doors until near Christmas—exposed, in fact, to some of the sharpest frosts we have had this winter; for, owing to alterations in the glass houses, they could not be got under cover so early as usual. I would strongly advise those who have failed with this Carnation through coddling or forcing it to try it on the cool, airy principle. Shelter from heavy rains or severe frosts is all that it needs. When in flower it will well repay any attention bestowed on it, its blooms being nearly as large as those of a *Souvenir de la Malmaison Rose*. Gosport. JAMES GROOM.

HYACINTHUS CANDICANS IN POTS.

THE culture of this plant in the open air has been frequently alluded to in THE GARDEN, but seldom has it been recommended for pot culture, a purpose for which it is admirably adapted. I grow it largely in pots expressly for embellishing the conservatory throughout July, August, and September—a season when plants like this Hyacinth are wanted. My plants range from 2 feet to 6 feet in height, and carry on each of their stout, erect stems waxy white bells from two to three dozen in number. Specimens like these intermixed with flowers of brighter hues, such as those of *Lobelia cardinalis*, *Gladioli*, which flower about the same time, produce a fine effect otherwise unobtainable. The flowers of this Hyacinth, in my opinion, rival those of the Tuberose and white *Lapageria* in purity and substance, and they emit a delicate perfume, and few plants possess such an elegant style of growth. My plan is to pot the bulbs, say about three in a 6-inch pot, at intervals of a week or so throughout February and March, using good turfy loam mixed with a liberal supply of sharp

*Hyacinthus candicans.*

white sand and well decayed leaf-mould. I place the bulbs about 2 inches below the surface and pot firmly. Until growth begins to appear water is withheld, except just enough to keep the soil from becoming dust dry. The pots are placed in a cool pit or frame heated at night only to keep out frost. After the leaves appear water is applied, gradually at first, but afterwards with a liberal hand, and this is the only treatment the plants receive until they come into flower, when they are removed to the conservatory, where they remain in perfection for about three weeks. The three chief conditions needful in order to ensure successful culture are plenty of light, plenty of air, and an abundance of water when once the plant has got fairly into vigorous growth. After the flower-stems and leaves have decayed the bulbs are shaken out of the soil, the offsets removed for propagating stock, and the old bulbs stowed away in a cool, dry place in dry soil in boxes until potting time comes round again in February. The reason why I pot at intervals is to afford a succession of bloom.

G.

Bomareas in fruit.—Besides the handsome flowers of the Bomareas some of them are very attractive when in fruit, owing to the

bright colour of their seeds, which, in the case of two kinds now in the succulent house at Kew, are very freely produced. They are two of the smaller species, *B. oligantha* and *B. edulis* or *oculata*, most of the flowers of which have been succeeded by seed capsules, now open and showing the seeds contained therein, somewhat in the way of the Gladwin. The Bomarea seeds are about the size of small Peas, and each capsule contains from ten to twenty of them. Bomarea Carderi, in the same house, is also fruiting freely.—H. P.

SURFACE DRESSING AURICULAS.

BEFORE the last week in January Auriculas will be seen to be growing even in ordinary winters, but under the mild season through which we are passing they should be surface dressed by the last week in that month. Auricula fanciers in the past put great faith in this surface dressing. They took out a large portion of the ordinary compost and filled up the space sometimes with strong pasty material, into which the roots refused to run. That this system of surface dressing is yet practised I have found on examining plants obtained from some Auricula fanciers. It is, however, injurious; it not only causes the plants to decay at the neck, but paralyses the roots, the result being weaker growth, which in its turn produces inferior flowers. If they are to be surface dressed, which is desirable, it should be done by removing only a small portion of the soil, not enough to injure any of the roots. About a third part only of the surface compost should be rotten manure, and it should be dried, powdery material and well decayed. When surface dressing thoroughly overhaul the entire stock, and take off any offsets that may be sufficiently rooted, although offsets will form roots if they are not furnished with any, but when taken off they get along better if even a very small portion of roots is attached to them. At no time of the year do offsets root more readily than now. We place them in cold frames in an open position, and keep the glass tops over them until they get well established. The offsets now in small pots, and which were rooted last autumn, should be potted. When this is all done and the specimen plants neatly surface dressed, a collection of Auriculas is an exceedingly interesting and pretty sight. And as spring leaves rapidly develop themselves, the different forms and tints of the mealed foliage captivate fanciers almost as much as the flowers do. Seedlings sown last summer will also now demand attention; they will either be through the ground or vegetating. Those large enough should be pricked out into small pots. I plant out about a dozen of these small seedlings into pots 2½ inches in diameter.

The raising of seedlings is now practised by some of the best growers. It is my belief that more really good seedlings have been produced during the last ten years than in the previous half century. Take the late Mr. George Lightbody, of Falkirk, as an example of an Auricula fancier and also a raiser of seedlings of the old school. The results of his work are now in the hands of the public. Another great grower, the late Mr. Richard Headley, of Stapleford, has earned for himself lasting renown by raising the best and most constant grey-edged Auricula in existence. This variety will doubtless long hold a leading place, but it is my belief that there are now in the hands of the raisers seedlings in all the classes that will displace most of the old varieties when they shall have become common. In addition to the raisers just mentioned, the name of a good Lancashire grower, Mr. James Heap, must not be omitted. He was the raiser of the best of the older white-edged varieties, Smiling Beauty, and it is a question if there is yet a better white edge if we except Walker's John Simonite. If superior varieties of edged or show Auriculas are to be raised, it must be done by growers taking care to cross the best varieties belonging to the various sections with others of the same section. Notwithstanding all that has been said about the beauty of the edged sections, it cannot be asserted that the

general public take to them quite so kindly as they do to

The alpine.—There is no doubt a great future in store for these; for one reason, they are much more hardy, and in most situations are well adapted for out-door culture. They are charming plants for the rock garden, and succeed well in dry upland districts in suitable soil. In the rock garden in the York Nurseries not only alpine, but many varieties of the show section succeed. They require suitable compost to grow in, and if the soil is not of a moderately clayey character, they must have some of this material placed round the roots. What Auriculas require, as well as most of the family to which they belong, is a deep, moist loam. More of them suffer from lack of moisture in summer than from any other cause, that is, if we except those that are liable to the attacks of red spider, which the Auricula is not. If the public are to heartily take Auriculas in hand, they must be alpine hardy enough to pass the winter as well as the summer months in the open border and to seed as freely as choice Primroses do. In order to do this they must have suitable surroundings. Primroses will not increase unless the seeds drop into some dwarf herbage not too dense or into a carpet of very dwarf Sedums or Saxifrages, which must not, however, be dense enough to smother the young plants. The various and scattered forms of *Primula Auricula* found in the alpine regions of the south of Europe prove that they seed freely in a wild state, and under suitable conditions there does not seem to be any reason why their descendants should not do so in our gardens. There is an unlimited field open to us in this direction. We know what the florists have done and are doing with alpine in the way of pot culture—"coddling under glass," some will say. Who will grow them in the open air in their gardens and show what can be done to popularise them in that way?

J. DOUGLAS.

BLANDFORDIAS.

THESE New Holland plants form beautiful objects in the greenhouse during summer when in flower, especially those with large, massive blossoms, such as *Cunninghami*, *princeps*, and *flammea elegans*. The two last are the most showy, and they greatly resemble each other, their flowers being pendent, bell-shaped, 2 inches or more in length, of a bright crimson outside, shaded around the mouth with yellow, and borne in an open cluster on a spike about a foot high. More slender in growth than those just named, and with smaller flowers, are *B. nobilis* and *aurea*, two which I find require more water than the others, especially during the growing season. Although the Blandfordias like plenty of moisture when growing, if kept too wet in winter their roots speedily decay; indeed, I find them to flower best when kept in an ordinary condition as to moisture at that time. The soil best suited for them is a good, open, fibrous compost, which the roots can penetrate with ease, and good drainage is absolutely necessary. I had been often troubled by decay in some of the thick roots at the base of the plant till I tried the experiment of just surrounding the base with silver sand—that is, just bedding it in the sand; since then the roots have kept sound. A suitable soil is one-third turfy loam to two-thirds of peat, with a liberal admixture of silver sand. Pot moderately firm, but take care not to bury the roots too deeply in the soil. I like to pot them as soon as flowering is over, as the principal season of growth is in the late summer and early autumn months; in that case they start away in the new soil at once, and are thoroughly established before winter sets in. A cold frame in a shady position suits them perfectly during summer, and in winter they can be removed to the greenhouse.

H. P.

Two good Pelargoniums.—Among the many winter flowering zonal Pelargoniums the two following deserve notice, viz., *Lady S. Stauphoe*, orange-scarlet, good truss; and *Lady Sheffield*, lilac-pink, fine form, and good truss. With me these are the freest blooming of any, and my collection contains most of the kinds that have been mentioned in terms of praise in THE GARDEN.—J. S. T.

HURSTSIDE, MOULSEY.

THIS, the country residence of Sir Henry Thompson, is pleasantly situated amid green fields intersected by tall Thorn hedges, over which Brambles cast their long spiny branches. Scarcely more than a gun-shot distant flows the swift current of the Thames. The house, a pretty creeper-covered villa, stands back from the road, and is approached by a drive through a narrow belt of trees and shrubs, which form a screen or blind. The gardens and grounds (about 5 acres in extent) are surrounded on three sides by belts of shrubs, which as they grow up will give an air of snugness to the place. Though the gardens are small, they contain many objects of interest, for miles of hothouses and lofty garden walls are not essential to good culture or to the gathering together of interesting horticultural products. The house is well situated as regards making the most of the ground, being near the western boundary. On the southern front an ornamental verandah shelters the lower windows, and forms in summer a kind of open-air conservatory, with a background of *Passiflora cœrulea* growing in great luxuriance; borders of Glove Carnations, Wall-flowers, Primulas, &c., load the atmosphere, when they are in bloom, with sweet scents. The lawn in front is open and level, its only garniture being a few small specimen Conifers and several beds of Roses in the distance, with a bed of hardy flowers of considerable size. Daffodils are now pushing up the points of their long lance-shaped foliage, and by-and-by their blossoms will form quite a striking display. As is well known, Sir Henry Thompson entertains a high opinion of the value of fruits and vegetables as articles of diet; therefore special arrangements are made for the production of a constant supply of the choicer kinds, as far as possible, all the year round.

The principal glasshouses, which lie on the northern side of the kitchen garden, are well constructed and fitted up. The young Vines and Peaches which they contain have done well; perhaps in the early Peach house there are signs of rather too much luxuriance, but the first good crop of fruit will rectify this, and in the meantime the same object has been sought by checking the roots. Peach borders do not require manure on their first formation, whatever they may need afterwards, *i.e.*, if the loam is good. The houses have been built with short north lights, which enable trees to be put on the back wall. In front of the principal houses, and a little to the west of them, is a capital forcing house in which quantities of valuable produce are brought forward. French Beans are gathered all the winter; Tomatoes are trained up the back wall, and pot Vines cover the roof, and ripen their fruit early. In this house, too, I saw last spring a crop of Hamburgs and Foster's Seedling Grapes in pots which it would have been difficult to beat, and the Vines were not more than sixteen months old from the eyes. Excellent crops of Strawberries are also produced on shelves overhead, and at the time of my visit, early last year, I saw some good Melons ripening at one end of the house. It is perhaps rather dangerous to the Vines to grow Melons so near them, but in this instance no insect pests were observable, and the two crops were a success. A Mushroom house at the back of the long range, and a row of useful forcing pits on the eastern side of the garden complete the forcing arrangements. On the north side of the poultry houses, which are well stocked with prize birds, especially Bramahs, is carried on

Vegetable culture under glass in a lean-to house, 90 feet long and about 20 feet wide; and the experiment (for in such an aspect it was an experiment) may be said to have answered, though doubtless a span-roofed structure with a better aspect would have answered still better. As it is, however, excellent crops of early Peas, Cauliflowers, French Beans, Horn Carrots, Turnips, Potatoes, &c., were obtained here last spring, and they were succeeded by Tomatoes in summer, and in autumn and winter the house becomes valuable for the preservation of

winter vegetables, such as Cauliflowers, Broccoli, &c. In a place where fruits and vegetables form the leading feature one may be sure the varieties grown are worth enquiring about; I therefore name a few which possess superior merit. Veitch's Forcing Cauliflower is the best of its class, coming in early, occupying but little space, and forming close, white, compact heads; it may be cultivated in pots. The American Wonder, a dwarf wrinkled early Pea, will be found useful for frame culture and for small gardens generally. The best French Bean for winter work is Osborn's Early Forcing, and as a general rule when large quantities are required boxes are better than pots. For open-air culture the Giant White Runner Bean for continuous bearing has no superior. Sutton's Late Queen Broccoli is hardy and late, and is really white, many of the so-called late white Broccoli being cream-coloured. A bed of this Broccoli which I saw here consisted of low-growing plants with leaves resting on the ground, no leg being exposed. A good many Strawberries are forced here, all the houses being fitted with shelves for their accommodation. The following varieties are most appreciated, and they ripen in the order in which they are named, *viz.*, Vicomtesse Héricart de Thury, Alice Maud, President, Sir J. Paxton, and Loxford Hall. This last is one of the best, if not the best, late Strawberry in cultivation. In front of some pits is an open temporary frame full of Rose cuttings put in last October. They have had no glass over them, but a sprinkling of rather rough leaf manure has been scattered over them for the purpose of protecting them from changes of temperature and to maintain the material in which they are growing in an even state as to moisture. This material consists of old Mushroom beds and fresh loam and some leaf-mould. Some of the cuttings were examined, and it was found that they had made in every case roots, some of the white tender fibres being half-an-inch long; and it is only reasonable to suppose that nearly every cutting will make a flowering plant next season. Near the Rose frame was a very useful kind of span-roofed frame supplied by a Norwich firm. It was strongly constructed, and the lights were all made to open, being hinged at the top. It was 26 feet long, 6 feet wide, and I should think somewhere about 3 feet high, but I am speaking from memory as to the height.

The orchard—about 2 acres—is divided and sub-divided by fences of galvanised wire to suit the breeds of poultry. The young trees of standard Apples and pyramid Pears have not made much progress. Whoever plants an orchard should, if possible, cultivate the surface of the ground for half-a-dozen years at least in order to give the young trees a fair start; but I suppose in this case the poultry, of which Sir Henry Thompson is very fond, had to be considered. It was intended to cover the wire fences with climbers of various kinds, but nearly everything that comes in contact with the galvanised wire dies during winter; even the Virginian Creeper makes no progress, and looks unhappy. A coat of paint would alter this, but the expense of painting all these lengths of fencing would be considerable, and, besides, it ought not to be necessary if the galvanising had been properly done. ADAM.

To protect iron from rust.—A new process for preserving iron is described in *Les Mondes*. It consists of treating the casting with dilute hydrochloric acid, which dissolves a little of the metal, and leaves a skin of homogeneous graphite, holding well to the iron. The article is then washed in a receiver with hot or cold water, or cooked in steam, so as to remove completely the chloride of iron that has been formed. Finally, the piece is allowed to dry in the empty receiver, and a solution of caoutchouc, gutta percha, or gum resin in essence of petroleum is injected, and the solvent, afterwards evaporating, leaves a hard and solid enamel on the surface of the ironwork. Another plan is to keep the chloride of iron on the metal instead of washing it off, and to plunge the piece into a bath of silicate and borate of soda.

Thus is formed a silicoborate of iron, very hard and brilliant, which fills the pores of the metal skin. As for the chlorine disengaged, it combines with the soda to form chloride of sodium, which remains in the pickle.

GARDEN FLORA.

PLATE CCCLXXIV.

ROSE CHARLES LEFEBVRE.

CHARLES LEFEBVRE is a name that is familiar to every grower of Roses, for if not the very best Rose of its colour, it certainly stands in the very front rank of Roses of any colour. Not only is the flower large, full, solid, and well shaped, but the habit of the plant is robust and the foliage excellent. It is, therefore, equally prized by exhibitors and those who grow for garden and house decoration only. It was raised by M. Lacharme, of Lyons, and introduced to public notice by him in the year 1861. To those of us who can look back to the first Hybrid Perpetuals, what a fine example of the improvement of Roses does this group present. The break from other groups was so gradual, that it is not easy to say when the first Hybrid Perpetual Rose appeared, but De Neuilly in 1835 and Princesse Hélène in 1837 were the first striking varieties obtained. These were quickly followed by Comte de Paris, Duchess of Sutherland, and Madame Laffay in 1839, Mrs. Elliot and others in 1840, La Reine in 1843, and since then the number of novelties has gone on increasing year by year with but few interruptions.

The great improver, if not the originator, of this group was M. Laffay, of Bellevue, near Paris. All but one of the early kinds mentioned above were his, and he continued adding others for many years. If we proceed to analyse the group we shall find at the least four distinct lines of character: 1, the "Bourbon Perpetual," apparently a cross between the Bourbon and Hybrid Perpetual, compact-growing kinds with small, round flowers; 2, the "Rose de Rosomane," probably between the Gloire de Rosomane and the Bourbon and Chinese Rose; 3, the "Rose de Trianon," principally raised by the most scientific rosarian of his time, M. Vibert, but which, though embracing some distinct and lovely blush and pink Roses, were neither exact enough in form for show Roses, nor of a habit to be prized as decorative Roses, and are now lost; and 4, "Hybrid Perpetual." The last-named has outrun all the others in popular favour, and is chiefly descended from a cross between the hybrid Chinese or hybrid Bourbon and the Damask Perpetual. It is to this last line that Charles Lefebvre and a host of others of varied character and matchless beauty belong.

So much has been written and published on the cultivation of Roses of late, that we shall in this instance confine ourselves to a few remarks on this particular line. Given a good soil (strong loam) and good plants, good flowers can only be obtained by liberal manuring and skilful pruning. No manure seems more suitable than a mixture of decayed stable manure and night soil. In pruning the shoots should be regulated during the summer's growth by pinching out supernumeraries, so that when the plants are pruned in March little or no thinning out is required. It is unnecessary to give

Growers or introducers of new plants will oblige us much by early intimation of the flowering of new or rare species, with a view to their representation in our "Garden Flora," the aim of which is the illustration in colour, and in all cases where possible life size, of distinct plants of high value for our gardens.

ROSE CHARLES LEFEBVRE

instructions on pruning to those who understand Roses, and difficult to instruct those who do not; but to the latter we may say, the shoots of the small-growing kinds should be shortened back to two or three good eyes, the moderate-growing ones to four or five, and the very strong growers to six or seven, rubbing out intermediate eyes along the shoots should a greater number show signs of development than can find convenient room when they arrive at the stage of flowering.

Waltham Cross.

WM. PAUL.

THE CHRYSANTHEMUM AND ITS CULTURE.

The points of perfection, as set forth by the late Mr. George Glenny in his remarks on the Chrysanthemum, are the following: 1. The plant should be dwarf, shrubby, well covered with green foliage to the bottom, the leaves broad and bright, the flowers well displayed at the end of each branch, produced in abundant quantity, and well supported by the stems. 2. The flowers should be round, double, high in the crown, perfect in the centre, without disk or confusion, and of the form of half a ball. 3. The individual petals should be thick, smooth, broad, circular at the ends, according with the circle of the flower, the indentations where they meet hardly perceptible. 4. The petals must not show their undersides by quilling, and should be of such firm texture as will retain them in their places. 5. Size of bloom to be large in proportion to the foliage, but the size only to be considered when plants are in all other respects equal.

The canons here laid down agree with the ideas of modern florists so far as exhibition varieties are concerned, but there are artistic and tasteful people of all kinds to please, and now-a-days all the varieties of the Chrysanthemum have their admirers.

Properties of the Chrysanthemum.—

It is a curious circumstance in the character of the Chrysanthemum that, however nearly some of the flowers may approach the general form required, there are scarcely two of the same construction. One globular flower is formed of long petals reflexing, another by a succession of cupped petals, one row above another to the centre; a third may be formed by a mass of incurved petals, whose spoon-like ends, showing the backs only, curl over and form an almost solid surface by their closeness; others again have petals broad and flat, but towering one above another, forming a fine symmetrical flower to the centre; and we have only spoken now of the varieties fit to show because of their approach to the desirable form of half a ball. But for those who grow a general collection for the sake of variety in form and colour, there are many more forms—some throwing out their quill-like petals like so many diverging rays, and scarcely opening even the ends of these quills at all; others again have quilled petals, but open at the ends a tolerably broad surface of the inner side; then some have long ragged tassel-like flowers in the form of a loose mop—but the most fanciful of these varied forms, and perhaps the prettiest of all, is that of a round disk formed with broad flat petals, and a globular mass of quilly florets nearly filling it. It is this variety of construction running through the whole family that perplexes the judges at a show; but they should look to the main point first: no matter what the construction, whichever flower makes up the best and closest half of a globe is the best flower, while those which are open and loose are the worst.

The properties of the Pomponé varieties do not vary much from those of the larger family; but as their diminutive size is their chief distinction, it is the more necessary that they should be compact and symmetrical. They must not show a disk. If the centre be not covered well, they must be discarded as soon as their colour can be got with a sound close centre. They should be as perfect as the *Ranunculus* or double Crow-foot, and as double as a double Primrose of the better kind. The flowers should be

abundant at the end of all the shoots in bunches, with footstalks sufficiently long to prevent the blooms covering each other. They should not be larger than 1½ inches in diameter, nor smaller than an inch, and the habit of the plant should be short-jointed and shrubby. At an exhibition they must be shown on the plants. These should not be more than 18 inches high, nor less than 12 inches, with one or more flowers perfectly open at the end of every shoot. The style of flower in all the family of *Chrysanthemums* should rank thus: Flowers forming a half ball, *Ranunculus* fashion; flowers forming a half ball by incurving; flowers forming a half ball by reflexing; *Anemone* flowers; tasseled flowers; quilled flowers; flowers showing a disk. Of these the first three alone are showable in an open class; the *Anemone* flowers form a class by themselves; the tasseled and quilled sorts are not showable except on the plant in collection.

I. For ordinary decorative purposes.

The first object in the culture of *Chrysanthemums* for this purpose is to obtain dwarf specimens, and to preserve all the foliage near the base of their stems. To effect this, the cuttings should be taken from the old stools in March or early in April, striking them in a shaded part of a cold frame under a hand-glass, and, as soon as rooted, the young plants should be potted singly into small pots filled with sandy loam, to induce them to emit an abundance of roots. A cool airy situation out of doors or a cold pit should be selected for them, and constant attention be given to the supply of water. After standing two or three weeks in this position, they should be shifted into the large pots they are intended to bloom in, one plant in an 8-inch pot or three in a 12-inch one, using as compost a mixture of equal parts loam and rotten manure, and at the same time the top of the plant should be taken off, which will cause it to protrude branches, and these again may be stopped if they have grown strongly and it can be done before the end of June. The old stools from which the cuttings were taken in March may be planted out under warm walls, or near palings, and will then afford strong tops for rooting in August. Five cuttings should be placed in a 7-inch pot, and these, if grown on freely, make useful little plants. During the whole of the time the plants are out of doors, which will be till the approach of frost, they should stand quite clear from each other, that each one may have the full influence of the air, and being carefully watered every day with pure water, and occasionally with diluted liquid manure, the new growth is vigorously developed, and the blooming consequently satisfactory. The plants may stand on a sunny vine border or beside walks in sheltered, but not in shaded positions; stake early and secure the plants from being blown over and damaged by high winds. If the points of the shoots which are last taken off can be induced to root quickly, they make pretty little plants of a few inches in height, surmounted with flowers nearly as fine as those on the larger specimens, and they are useful for the fronts of shelves or to stand before the large pots. On the removal of the plants to the greenhouse crowding should be avoided, and a full supply of both air and water given daily until the flowering season is past, when they may be removed to a shed or placed in the open ground, and protected at first from severe frosts by means of a mat or two thrown over them.

II. For large blooms.—In the culture of standard and trained dwarf *Chrysanthemums* judicious stopping and careful tying into shape is a main feature in their production. Now, on the contrary, when large blooms are desired, stopping the growths is reduced to a minimum, and success depends in a great measure on the judicious application of suitable manurial stimulants, on thorough maturation of the stout main shoots which are restricted in number from one to three on each plant, all axillary shoots being removed almost before they appear, and all the training the plants ever receive is securing them to upright stakes to prevent injury from wind. On the

plants being grown on from the cutting or rooted-sucker stage in December or January to the blooming stage in November without any check or other injury the production of really fine blooms may be said to depend. The stoutest of rooted suckers are preferable, but if suckers be weakly or drawn by the overcrowding of the plants when housed for blooming, then it is best to depend on the most solid and vigorous cuttings obtainable. Place each carefully in a small pot of sandy loam in a cold pit or frame, taking care that they are as near the glass as is possible in order to prevent their becoming drawn up in a weakly manner. Give air freely, drawing the lights off entirely during bright warm days. Repot from time to time in good loamy soil, keeping a sharp eye on the state of the roots, as plants which are allowed to become rootbound or checked in their early stages rarely if ever give satisfactory blooms. As soon as all danger from spring frosts is over the plants may be placed outside near a wall or fence, or in any position fully exposed to sunshine where they may be sheltered and secured from injury by rough winds. Temporary lath or other light fences, formed of upright stakes and wires not less than 5 feet in height, serve admirably, as the plants may be safely secured to them, and the light framework of slender sticks, with stouter supports here and there, does not prevent their obtaining the full benefit of air and light, both so essential during all stages of growth. The production of all growth from first to last without artificial heat of any kind, and in full exposure to sun and air, is the secret of proper growth maturation. Ripening up the growth in August and September means but little unless the previous growth has been well nourished by applications of soot water, and now and then a dose of liquid manure or soap-suds. An occasional syringing with soot water improves the leafage, and serves as a simple preventive to insect and mildew ravages. About the end of August or early in September is a critical time with growers of large blooms. Flower-buds will be showing at the ends of the strong upper branches or shoots, and it is now imperatively necessary that the buds in the leaf axils below be removed with the points of scissors or penknife. This causes all the flower-producing power of the shoot to become concentrated in the terminal bud, and the result is a bouncing big bloom early in November, just in time for the exhibition stands. This operation is called

"Setting the bud," and unless it be duly performed in the nick of time, the two or three axillary buds immediately below it take advantage of the slackening of growth which takes place while this terminal flower-bud is forming, to push forth on their own account, and, after growing away for 6 inches or 1 foot, these also each form what are called "terminal crown buds," but which are more properly "secondary" or axillary ones as opposed to the terminal or primary buds which form a few weeks earlier at the apex of the un-stopped main stem, and which are pinched out as soon as seen. Enormous blooms are thus obtained by this system of growth—force concentration. Some growers take out the primary bud as soon as it appears, and thin out the secondary shoots which protrude below it to one or two at the most, and so treated, aided by careful attention to feeding, noble blooms are obtained, and one has the choice of two or three flowers instead of limiting one's chances to one bud and its future development, as is the case when the terminal bud only is retained. Strong-growing kinds flower best from the third branching, that is to say, the flower-buds which are first seen are pinched out, and the strongest shoot is selected from just below them to lead away. Weak-habited kinds are not easily overgrown, and the second bud which shows is allowed to bloom. Messrs. Dixon give the following directions as to the culture of *Chrysanthemums* for larger blooms. They are clear and to the point: "The stands of cut blooms to be seen at exhibitions show to what perfection this flower can be brought by skilful treatment. In the early stages of growth the same soil and treatment are necessary as those

already described, except that the plants are not stopped, but allowed to grow naturally, and it will be found that as the season advances the crown will branch into three or four leaders, which should be allowed to grow, but all laterals should be removed as soon as they appear. When the flower-buds show themselves in September, the centre bud must be the one retained, as it produces the largest bloom. All the others must be carefully removed without bruising the stem, except when the centre one is imperfect, in which case one of the others must be left instead. If possible stand the plants in single rows, with room enough to get between each row, putting in a good stake at each end and one in the centre; then stretching wire to each stake, you can tie the stick by which the plant is supported to the wire, and prevent the wind from blowing them about; it also exposes them thoroughly to sun and air. Some growers for exhibition put two plants in a 10-inch pot, but we prefer only one in an 8-inch. Use manure water liberally until the flowers show colour, taking care not to give it when the plants are dry, but water first and then apply it." Since the above was prepared for press I have been so fortunate as to obtain the practical experience of a successful cultivator of the *Chrysanthemum* near Liverpool. I think I may fairly say that better or more comprehensive directions were never before given on this point.

Striking and stopping.—I strike at the end of February or early in March. If rooted in February in gentle warmth and then hardened to cool treatment as quickly as possible, the plants can be placed in their flowering pots (10-inch) in May. One flower and only one stem should be encouraged from the Mrs. G. Rundle type to produce large flowers, while three or more shoots should be encouraged from Queen of England, Empress of India, Golden Empress, and others. These should be stopped as soon as rooted, and the number of shoots required encouraged to lead upright. These with those not stopped will produce a small bud during May; the points of the shoots should be taken out at once to prevent this bud forming, and all the side shoots taken out with the point of a knife as soon as they can be seen except one nearest the top, which must be encouraged to extend. If you allow the bud to form and the plants to stop themselves, time is lost, and the next bud is late. The plants should be hurried out of this stage as quickly as possible. The next bud will appear about the middle of July, known as the July bud. Many leave or rely on this bud, but it is too early, and it will only produce rough, badly-shaped flowers. Do not allow this bud to form; remove all side shoots but one, as in the case of the earlier bud, as soon as they can be seen. The shoot you allow to grow will produce another bud about the last week in August after the plants have grown about a foot or little more. The August bud is the one to be selected, and will produce fine flowers. This bud appears at the end of the shoot, and is known as the crown bud. The moment it can be seen, the three that will be found nestling round it must be carefully taken out with the point of a knife, and every shoot that shows from the base of the leaves below, as the whole strength of the plants will be concentrated into the buds. If the growths around the bud are allowed to grow an inch or two the bud often afterwards will not swell, so you will see the necessity of removing them as soon as they can be seen. These three shoots to which I allude would grow about 9 inches long and produce other flowers known in *Chrysanthemum* circles as the terminal bud. If you wish a flower from the terminal bud only one growth should be allowed to grow. From this bud some of our finest flowers are obtained—I mean best shaped and most even, not the largest—from varieties inclined to grow rough or coarse. It is possible to overgrow some of the incurved varieties when one flower only is taken from a plant. This is not the case with the Japanese; the stronger they are grown the longer are their florets generally, and their curious character is better displayed.

Large-flowered or Incurved varieties are so many and so good that it is difficult to make a

selection. The following kinds, however, more often occupy a place on the first prize stands than others: Mrs. G. Rundle, George Glenny, Mrs. Dixon, Prince Alfred, White Globe, Queen of England, John Salter, Princess Teck, Barbara, White Venus, Mrs. Halliburton, Golden Beverley, Lady Hardinge, Nil Desperandum, Hero of Stoke Newington, Yellow Beverley, Princess of Wales, General Bainbridge, Peach Venus and Jardin des Plantes.

III. For trained standards.—In order to grow good standards select the strongest and stoutest of the root-suckers which can be found on the old plants after blooming in January or February at the latest. Carefully separate them from the old stools with as many roots as is possible, and pot them at once in 4-inch pots. Be careful as to names, as any neglect of this kind proves a fertile source of disappointment. Place them in a cold pit or deep frame on a bed of coal ashes, and sprinkle with water from a fine rose. Keep the lights down close for a week, so as to induce the protrusion of new roots, after which air should be freely given (except during hard frost), and on fine warm days the lights should be entirely removed. If lateral buds show themselves in any way prominently, carefully remove them with the point of a pair of scissors, or with a sharp penknife, until the required height is attained. As growth proceeds, secure the growth to a slender stake, so as to prevent its being accidentally broken. Pot on as may be required, taking care that the young plants never become root-bound in the pots. In April, or early in May, all danger from cold being over, the plants may be placed on a bed of coal ashes in the open air where they will be fully exposed to sunshine and air, but sheltered from rough winds. On no account must they be allowed to suffer from want of water. When the carefully nurtured single stem has reached the height desired, take out the upright stake which has hitherto supported it, and add one having a semi-hemispherical wire trellis at the top of this shape, and 10 inches or 12 inches in diameter. Bend the shoot around the outer rim of the framework. The plants should now be placed in their blooming pots. Now for the first time the axillary buds (hitherto carefully removed) may be encouraged to develop, which they will do speedily after the main shoot or stem of the proposed standard has been coiled round the frame. Judicious pinching now and then and syringing morning and evening with clear soot water will be conducive to the formation of strong shoots covered with healthy clean foliage. In cold districts it is not safe to stop or pinch off the growing points after about the last week in June. If pinched too late, the wood does not become thoroughly matured ere the flower buds form and the production of fine flowers solely depends on strong and well ripened growths. In warm localities, as in the south of England, pinching may go on as requisite until about the second week in July. As the pots become filled with roots, manure water and soot water may be given on alternate days. The best varieties for making good standards are the following: Large flowered—Mrs. Rundle, George Glenny, Mrs. Dixon, Anreum multiflorum, Empress of India, Eve, Venus, Lady Slade, Lady Hardinge, and White Venus. Annie Salter well grown makes a telling specimen, as also do most of the varieties of the Pomponne and Pomponne Anemone race under liberal culture. Mr. Brunlees, Brilliant, Faust, Julia Lagravère, Calliope, Elaine, Mrs. Halliburton, and Peter the Great also make effective standards.

IV. Fan-trained dwarfs.—*Chrysanthemums* of the Mrs. Rundle (Incurved) and Annie Salter (Reflexed) types make very attractive specimens when trained in a mushroom or pancake shaped manner on a trellis work of bamboo sticks and wire. As to tying and training directions are fully given at page 34. The following directions are those supplied by Messrs. Dixon. The practical notes on stopping are especially valuable and must be carefully followed. "In the choice of plants for specimens great care should be taken to select only those varieties possessing the follow-

ing qualities—viz., free blooming, clear and distinct colour, fine foliage, and graceful habit. Every attention has been paid by us to select only those sorts which contain the above properties, and which will be found the best. The soil should consist of two-thirds loam, and one-third rotted stable manure, with a liberal admixture of sand. Two inches of broken potsherds should be placed in the bottoms of the pots for drainage. If large specimens are required for exhibition, it is essential that cuttings should be made in the autumn, and only such as are healthy and robust selected (or a strong sucker with roots). These should be potted into 2½-inch pots, and when rooted shifted to a large 3-inch size. As soon as they are established in these, they must be stopped, being careful to take out only the extreme point of the shoot, containing the unexpanded leaves, as the plant then continues to lengthen, and it also encourages the growth of the laterals, of which five or six will be found sufficient. These, as they increase in length, should be pegged down, and great care taken that they are not injured or broken. Place them in a cold frame near the glass, giving air on all favourable occasions; continue to shift, and as soon as the laterals are 6 inches long, they must be stopped. Do this until the second week in July. In the last week of June the plants should be shifted into their blooming pots, which are 11 inches in diameter. Never shift and stop at the same time. Fourteen days should always be allowed between these operations. The shift then strengthens the laterals. (For exhibition specimens this should never be departed from.) When in their blooming pots, we stand them on three small pots in a good open piece of ground; this enables the water to escape freely, and prevents the plants rooting into the ground. As soon as the roots get to the sides of the pots we commence giving liquid manure. For the first three weeks, once a week; the next three weeks, twice a week; after that until they show colour, every other day. The foliage should be well syringed, and constant and well watering is necessary during hot weather to ensure green and healthy foliage. Nothing spoils the *Chrysanthemum* sooner than want of water. They will now require more care in regulating the shoots, which should be kept down as near the edge of the pots as possible. About the middle of September train the plants into the shape you want them, by neatly staking each shoot, leaving the stick longer than the shoots, as they continue to lengthen until they come into flower. As soon as the flower buds appear, dishud. This is done by removing all buds except the one in the centre of each branch; for if the plant be vigorous, these will be quite enough to insure a fine head of bloom, but if a quantity of bloom is preferred to large flowers, little (if any) disbudding need be done. They should be housed about the middle of October; but in this be guided by the state of the weather, as they are better outside whilst the weather is open, and the buds do not show colour; the foliage improves by remaining in the open air. When housed, avoid fire heat, except when absolutely necessary, but give them as much air as possible.

"Pompones are cultivated in the same manner as the large-flowering varieties, but it is not necessary that disbudding should be carried on to the same extent. Another style of plant which has become very popular lately is the standard. Either Pompones or the large varieties will do, if care is taken to grow only the suitable varieties—of which now-a-days there is no scarcity. Vigorous autumn cuttings or suckers should be selected, shifting as already described, and staking the plant to the height you want the stem, which for exhibition is not generally less than 2 feet 6 inches. After they are a little beyond the required height, stop them, trying to get as many breaks as possible from the first stopping to form the head. Be particular in keeping all side shoots pinched off. A small framework of laths erected under the head is the handiest for training them on. The sorts selected are early varieties, which enable us to stop them a fortnight later than

the others, which is necessary to obtain a good head." F. W. B.

FLOWER GARDEN.

COMMON AND SWEET-SCENTED COLTSFOOTS.

THERE is such a resemblance between these two plants as regards foliage and style of growth that one may be easily mistaken for the other, but while one is a desirable plant to have a little of in a garden, the other is a troublesome weed, difficult to extirpate when once a foothold has been obtained. Everybody knows the common Coltsfoot (*Tussilago Farfara*) met with on roadsides and in waste places, but the sweet-scented Coltsfoot, or, to use its more appropriate name, Winter Heliotrope, is not so well known, though just at the present time there is not a more fragrant plant in the outdoor garden, or one that is better able to brave our worst winters. It is chiefly for the delightful vanilla-like perfume of its flowers that it is desirable, a few cut heads of its bloom being sufficient to scent a good-sized room. Though its foliage so much resembles that of the common wayside Coltsfoot, its bloom is quite different, as may be seen by the annexed illustrations. In the common kind the flowers are Daisy-like and bright yellow, while in the scented one several flower-heads are gathered into a dense cluster, which is pale lilac and purple. This floral arrangement is common to the genus *Petasites*, to which the plant belongs, though besides being known botanically as *P. fragrans*, it is synonymous with *Tussilago fragrans* and *Nardosmia fragrans*. Like the common Coltsfoot, it has creeping underground stems, but the plant may otherwise be distinguished by its much deeper green than that of *T. Farfara*. It is, moreover, evergreen, while the common Coltsfoot is deciduous. It is a native plant, but, as already remarked, its flowers are so welcome in the depth

stems spreading rapidly and widely. A dry bank where little else would grow might profitably be devoted to the Winter Heliotrope, and if the soil is of a strong loamy character, it will produce luxuriant foliage by no means unhandsome throughout the year. G.

CHRISTMAS ROSES.

I SEND you, from my collection of many years' standing, a few specimens of distinct species, and a few also of pretty hybrids. The former are by far the more interesting to me, but as garden flowers the hybrids are invaluable; and at this season of the year two-year-old seedlings are daily producing new forms according to the peculiarities of their parentage, and from these my selection is made. My plants are treated strictly as hardy plants, not in cold frames, and the unusual amount of rain has greatly injured the blooms. I may mention also that in this season, not less than last, the field mouse (*Mus sylvaticus*), and I suspect the bank vole also (*Arvicola riparia*), have been most destructive, eating off the blooms by hundreds in a few nights. This would interfere with me the more had I any intention of sending a perfect collection, but such is not my object. The species sent are:—

Persistent foliage.	Non-persistent foliage.
<i>H. niger</i>	<i>H. viridis</i>
<i>n. maximus</i> = <i>altifolius</i>	<i>foetidus</i>
<i>argutifolius</i>	<i>cupreus</i>
<i>kantschatkensis</i>	<i>intermedius</i>
<i>abchasicus</i> = <i>atrorubens</i>	<i>purpurascens</i>
<i>a. albus</i>	<i>graveolens</i>
<i>olympicus</i>	<i>pedatus</i>
<i>o. major</i>	<i>Torquatus</i>
<i>orientalis</i>	<i>dumetorum</i>
<i>antiquorum</i>	<i>Bocconi</i>
<i>lividescens</i>	<i>odoratus</i>
<i>Semi-persistent foliage.</i>	<i>Sambuc-odorus</i>
<i>H. odorus</i>	

And I should wish to direct special attention to *graveolens*, because of its extreme rarity; to *cupreus* and *intermedius*, because their names have been reversed; to *purpurascens*, because it has been called *graveolens*; to *olympicus*, which (true) is rare, and quite unlike what is sold under that name; it is white, shaded green, well represented in *Botanical Register*, vol. xxviii., pl. 58; to *antiquorum*, white, delicately shaded pink, and well represented in *Botanical Register*, vol. xxviii., pl. 34, under the name of *orientalis*, from which, as may be seen by the *orientalis* enclosed, it differs much, being more delicate, less cupped, and with more pointed sepals than the latter. Although *antiquorum* and *olympicus* inhabit the same locality, the latter is never tinted with the pink shade, which is always more or less present in *antiquorum*. Observe also *dumetorum* difficult to distinguish, and *Bocconi* with others which, I believe to be true species, though with unauthorised names—viz, *odoratus* and *Sambuc-odorus* much more powerfully scented than *odorus*, but with non-persistent instead of semi-persistent foliage. *Pedatus* also and *lividescens*, *Torquatus*, and *olympicus major*. Many of

The hybrids are much spotted after the manner of *guttatus*, which last, if really found wild, is, I suspect, only a hybrid, not a species. In *THE GARDEN* of Jan. 20 (p. 49) there is a notice of *niger angustifolius* and *altifolius*, which latter has a prior claim to the name *maximus*. It is not, so far as is known, a true species, but a permanent variety, exceeding all others in size and substance, and particularly and constantly in its red pistil. In the year 1878 a beautiful representation of this variety was given in *THE GARDEN*, but I think the colouring was misleading. When in perfection it is a pure white flower, without of necessity any pink whatever, except in the pistil; the sepals in their later stages are always more or less pink with perhaps some green; but if, as is occasionally the case, this plant, white one year, opens out its sepals even in perfection pink the next season, the change is not permanent in the old plant, nor capable of being continued in its parts by sub-division, but seems to have arisen either from some check given to its roots or from exposure to a cold draught or some peculiarity of atmospheric influence. I do not know, certainly, the plant to which your correspondent applies

the term *niger angustifolius*; this is not usually spoken of as a large variety, but rather the contrary, but it may be major or some other form of *niger*, of which so many varieties come from seed, but all distinct from *altifolius*—all without the red pistil. T. H. ARCHER-HIND.

South Devon.

LILIUM POMPONIUM (VERUM).

IN reply to the remarks made in *THE GARDEN* (p. 58) by the Rev. Wolley Dod, I must say that

Winter Heliotrope (*Petasites fragrans*).

I have not grown this Lily for ten years in the same spot, nor do I believe that it would be possible to grow it for so long a time without renewing it either by seeds, division, or scales. This Lily seeds very freely, and my experience is that all Lilies that do that invariably require renewing every few years, say from four to six years. I have grown this Lily for some years past, and my experience is that it is one of the easiest of all to grow. When collected the bulbs are very small, and if planted early in autumn a few flower the first season, all flower well the second, and the third they are at their best, forming handsome bulbs weighing from 6 oz. to 7 oz., and from 9 inches to 11 inches in circumference; the fourth year they split into two or three bulbs, and must be taken up, divided, and replanted, and I think if this were done no one would have any difficulty in growing this, one of the most beautiful of all known Lilies. With regard to

Lilium Browni, bulbs of this increase naturally at a very fair rate; after they get about 10 inches or 12 inches in circumference they can be divided, usually into three or four bulbs each, and the stems produce annually a few small bulbs just above the ground, varying from three to six according to the strength of the bulb; the loose scales, too, planted form in three or four years nice bulbs. *L. Browni* does best in sandy peat, *L. pomponium* in sandy loam, giving them plenty of manure below the bulbs, and a good annual top-dressing of the same material. I always give every Lily I plant abundance of good old rotten manure; I have been told repeatedly that it would kill them, but they grow splendidly, and increase every year in size, proving that Lilies, like most other things, are fond of good living. P.

Godetia Whitneyi var. *Duchess of Albany*.—This is described by its introducers as growing about 1 foot in height in a branched pyramidal form, and producing in clusters very large

Common Coltsfoot (*Tussilago Farfara*).

of winter that an odd corner should be allotted to it where convenient, so that a few of its sweet-scented blossoms may be cut to mix with other flowers. Care must, however, be taken not to allow it to take root in any choice border, for it is a difficult plant to eradicate, its underground

flowers of a fine glossy white colour, each flower being 4 inches across when fully expanded. This probably is one of the finest of varieties which have originated from the *Godetia Whitneyi* introduced by me some years since.—W. THOMPSON.

VARIEGATED TREE MALLOW.
(*LAVATERA ARBOREA VARIEGATA*.)

LEAVING the question as to whether variegation in plants is a sign of depauperation or not to be settled elsewhere, it is a fact that during recent years the list of variegated garden plants has been considerably swelled by additions to both the hardy and tender classes. In the former we have here a fine example in the way of variegated foliage in our native Tree Mallow, which may be found in various parts of the British Isles, chiefly in seaside localities. We first saw this plant when it was exhibited last year at the Royal Horticultural Society's summer show, where it was awarded a first-class certificate. We then thought it a handsomely variegated plant, perfectly hardy and desirable. The variegation is well shown in the annexed illustration, the light portions being a creamy white. The following account of it from the raiser, Mr. Smith, we extract from Mr. Bull's catalogue: "I have (says Mr. Smith) propagated many plants of it, and I have not yet seen one that was not beautifully variegated. I have proved that it comes true from seed, but it must be understood that, like the variegated Maize, it does not

desirable, for in the spring of the second year the beauty of such plants is beyond description."

DWARF ASTERS FOR CUTTING FROM.

THERE are several useful sections of these, not only useful for cutting from, but well adapted for small gardens, owing to their being capable of cultivation in a smaller space than that required for such robust growing types as Truffaut's *Pæony*—

averaging from 12 inches to 15 inches in height, and which are specially adapted for bedding or ribbon borders. Of these the dwarf *Chrysanthemum* flowered is deserving of all praise, and it is one of the best and most useful types in cultivation, the flowers being large and so abundantly produced as to almost hide the foliage. The average height is 10 inches, and it is one of the characteristics of this Aster to throw out a large number of side blossoms that are very useful to

Lavatera arborea variegata.

cut from. The Schiller Aster is a most useful form also. This, like the foregoing, belongs to the flat-petalled type, growing about 12 inches in height, of robust constitution, and symmetrical growth, yielding a large quantity of flowers. As many as from 60 to 80 blossoms have been counted on a single plant, and of which there are several varieties. A more useful type cannot find a place in gardens. The large flowered Rose Aster is a dwarf strain of Truffaut's *Pæony*-flowered *Perfection*, and this also is robust and very fine, and of great value in the garden. The dwarf *Victoria* also comes into the flat-petalled group, and is a valuable acquisition. Though distinct, it is often confounded with the dwarf *Chrysanthemum*-flowered, and the latter is substituted for it. All the above are well worth attention for the purpose named, viz., cultivation in pots for cutting.

R. D.

Narcissus monophyllus.—Mr. Wolley Dod has (p. 84) misunderstood me. I certainly said that this plant was a desideratum in most English gardens, but I

show much variegation in a young state. Plants from seed sown last spring are now beautifully variegated. There is not the least doubt that it will be one of the finest and most effective plants for large beds and borders ever introduced. I find the leaves to be useful for garnishing late Grapes when Vine leaves are not to be had. It withstood last winter without injury; it is best, however, to pot some up, keep them in a cool house, and turn them out in spring, but a slight protection outside would be sufficient to keep the plants undisturbed in beds or borders, which is

flowered, the *Victoria*, or *Betteridge's Prize Quilled*. Looking over a collection of Asters last August, I was much struck with a dwarf type known as *Sutton's Miniature*, a profuse flowering variety, very useful indeed for growing in pots. This is valuable for getting into bloom early. Dwarf *Bouquet* is a little taller, and this and a good strain of the ordinary dwarf German Aster are both good types to cut from, because so profuse blooming. For growing in pots they are invaluable. There is a section of dwarf Asters which might be denominated intermediate types,

was far from wishing to imply that it had not long since been introduced into our gardens. I should be sorry to say (what anyone who consults old numbers of the *Botanical Magazine* and other periodicals may see for himself) how many good things have been introduced into and since lost to our gardens where they would now be thoroughly appreciated. Of such losses the genus *Pelargonium* is a notable example; and of the *Proteaceæ*, once numerous in our green-houses, how many do we now see? I find *Narcissus monophyllus* in the *Lesser Atlas* in full bloom

in March (not midwinter), and I feel satisfied that newly-imported bulbs, planted whilst dormant on a warm, sunny bank in turf, would have a good chance of success.—R. MILNE-REDHEAD.

I am surprised to read in Mr. Wolley Dod's article on *Narcissus monophyllus* that he has difficulty with the common Hoop-petticoat. With us it is no trouble at all, and I did not even know it was considered difficult. Our soil is a warm, peaty sand, the very opposite to his, and we are 400 feet above the sea level. It never fails to flower strongly, and increases satisfactorily. In 1877 I had a dozen bulbs; in 1879 I gave away one dozen, in 1880 two dozen, in 1881 one dozen, in 1882 four dozen, and I have seventy remaining. Perhaps Mr. Dod will do the sum, and say how many there would have been if none had been given away; later I will ask him to try a dozen from the same stock. It is a large vigorous kind, with strong, dark green leaves now a foot long; a woodcut prepared from some of the flowers appeared last year in THE GARDEN. The white Hoop-petticoat of Algiers I am trying in a warm bank of short turf and in other positions, and hope to be able to record some success next year. Our difficulty is with Jonquils. Some 300 planted in 1878 had dwindled to about fifty when taken up last summer; these were replanted in stiff clay, with us a scarce and precious commodity. They grow strongly and increase with our neighbours a few miles off on stiff soil on the edge of the weald of Sussex, where the sulphur and yellow wild Daffodil grows in damp meadows. Mr. Barr accounts for our failure with Jonquils by considering that the warm soil forces the foliage into premature growth, which is then injured by frost.—G. J., Surrey.

Mr. Wolley Dod's notes on *Narcissus Bulbocodium* are valuable, interesting, and inspiring. I observed some time since that my own bulbs, planted early last autumn, which in October last were making grass, had gone under again, and as I strongly suspect they have now gone altogether, I had concluded that I had not made the soil light enough, but it looks as if the evil lay deeper. Perhaps some of your readers may be able to give us a little further information on this matter derived from their experience. Such would be useful to me and probably to others, as although this is, I think, almost the most beautiful of the whole tribe of *Narcissus*, I am coming to the conclusion, in the matter of bulbs especially, that it is better to accept the defeat, and not to throw good money after bad. There are many beautiful Daffodils that will grow. There was an extremely fine display of *N. Bulbocodium* on the rockery at the Tottenham Nurseries last spring. I did not ask how long the plants had been there, but such things in nursery gardens are seldom left long enough to become established. *N. Bulbocodium* grew and flourished fairly well in my grandfather's garden in Devon in a very unlikely soil, but attempts to move it or give it away I believe always failed.—T. C. L.

I suppose that Mr. Wolley Dod considers that I live out of England (*vide* p. 84), and therefore his remarks about *Narcissus monophyllus* do not apply here. But it may interest him to know that in this favoured isle this beautiful bulb quite finds itself at home. It can certainly bear 17° or 18° of frost, and it blossoms in the open with ease, only its time of flowering is later than Mr. Dod imagines, viz., about the beginning of March. I sent you a blossom last spring from the open ground. Several pansful of *Narcissus monophyllus* have been at their best in the greenhouse for some weeks.—HENRY EWBANK, *St. John's, Ryde, Isle of Wight*.

Six-sepaled Hellebores.—Mr. J. Wood (p. 80) requests notice of this abnormal form. I send one specimen of *H. niger* and one of *H. olympicus major*, the latter a beautifully formed flower; each has six sepals or converted bracts. Amongst seedlings of *H. niger* I find very great variety of foliage and bract peculiarity; these seem purely accidental, for though in some cases the spotted stems would seem to point to inter-

mixture with *Helleborus maximus*, this would not lead to alteration in the sepals; it might, however change the character of the foliage, &c. In *argutifolius* we find in the same plant simple, bi-rid, tri-rid, and quadri-rid leaves.—T. H. ARCHER-HIND, *South Devon*.

BANKS OF SEDUMS, SAXIFRAGES, AND SEMPERVIVUMS.

IN the Botanic Gardens, Birmingham, a bank devoted to these plants is one of the most pleasing features of these well furnished gardens. It is placed near the fernery, a quiet, secluded dell devoted chiefly to Ferns enlivened with Foxgloves the first sight of which no one is likely to forget. The collection, as will be seen from the following list, is extensive and varied:—

<i>Saxifraga aizoides</i>	<i>Sedum Anacampseros</i>
<i>Alzoon</i>	<i>arborescens</i>
<i>aretioidea</i>	<i>brevifolium</i>
<i>a. primulina</i>	<i>carneum variegatum</i>
<i>aspera</i>	<i>cruciatum</i>
<i>atropurpurea</i>	<i>dasyphyllum</i>
<i>bryoides</i>	<i>Ewersi</i>
<i>Burseriana</i>	<i>monregalense</i>
<i>caesia</i>	<i>Nevii</i>
<i>Cotyledon</i>	<i>obtusatum</i>
<i>crustata</i>	<i>populifolium</i>
<i>flagellaris</i>	<i>spathulifolium</i>
<i>geranioides</i>	<i>Sempervivum arachnoideum</i>
<i>Hosti</i>	<i>arenarium</i>
<i>juniperina</i>	<i>barbatulum</i>
<i>lantoscana</i>	<i>Brauni</i>
<i>longifolia</i>	<i>ciliatum</i>
<i>mansuetudo purpurea</i>	<i>cornutum</i>
<i>oppositifolia</i>	<i>heterotrichum</i>
<i>rotundifolia</i>	<i>Neitreichi</i>
<i>sedoides</i>	<i>petrifolium</i>
<i>stellaris</i>	<i>ruthenicum</i>
<i>Tazetta</i>	<i>Regina-Amalie</i>
<i>tricuspidata</i>	<i>Verloti</i>
<i>valdensis</i>	<i>violaceum</i>
<i>Wallacei</i>	<i>Wulfeni</i>

Such plants have a special interest in themselves, but no one seeing them at Birmingham can doubt that their interest and beauty are greatly heightened by their disposal on a sloping bank. The bank virtually enlarges the patches or groups by bringing them nearer to the eye as well as presenting them to us at what may be called an enlarging angle of vision. The line of beauty, it is generally agreed, is a curved one; but to render it most beautiful it must curve towards the sky as well as meander out of a straight course. One of the chief attractions of the Birmingham Botanic Gardens consists in their beautiful undulations.

D. T. FISH.

COLOUR IN THE FLOWER GARDEN.

THERE are only one or two points in "R. A. H. G.'s" article on this subject which call for any remark on my part. The original idea to which I objected as fallacious was that taking all colours as composed of red, blue, and yellow in various proportions and combinations to find the correct harmony for any colour, all that was necessary was to combine the remaining colours. This I have already shown to be untenable. "R. A. H. G." now claims that all combinations of colour are harmonious which contain what he calls the three primary colours; assuming as he does that these form all the others, combinations which contain these primaries include nearly all the combinations of colour which can be made, and this brings us to the conclusion that there is scarcely such a thing as discord. The flaw in "R. A. H. G.'s" argument is in assuming as true what I have already shown to be false.

The only further reply I need make is one which will enable readers of THE GARDEN to judge of the comparative value of my remarks on colour harmony. I should not have considered it desirable to reply to "R. A. H. G.'s" first article had not twenty-five years' experience in teaching in schools of art, and in the practice of just those branches of art which bring one into intimate relation with the tastes and ideas of the general body of the public, and in which bad colouring immediately receives practical punishment in loss of cash, given me ample opportunity of judging of those matters, and especially of what is most likely to meet with general acceptance. The

theory of colour "R. A. H. G." propounded owes its publication to the schools of art, and having been found useless in those schools, it is only fair to the public that it should be contradicted from the same source. I hope "R. A. H. G." will see that as my alma mater must bear the lion's share of the blame in misleading him, I have only been doing my duty by her in endeavouring to set him right again. I need only add, in conclusion, that we should consider ourselves lucky in having such pupils as "R. A. H. G.," who take everything we taught them as infallible, and defend it as tenaciously as he has done in this instance. J. D.

PROPERTIES AND CULTURE OF THE POLYANTHUS.

AN enthusiastic amateur, and one having a good knowledge of flowers and plants, writing on this early spring flower forty years ago, says it is "one of the loveliest gems in all the wide kingdom of Flora." At that time when people spoke or wrote of the Polyanthus they meant what we now call the gold-laced form. The type of Polyanthus of the mottled or border kind, which in recent years has been so much improved, did not seem to be known in those days, nor were choice forms of the Polyanthus grown as border flowers. Showy border Polyanthuses are admirable subjects to grow for the adornment of the spring garden, but when compared with the laced varieties they are as "moonshine unto sunshine," so far are they behind them in refinement. It may be desirable to give the following description of

The properties of a first-class laced Polyanthus, approved and published by the Metropolitan Society of Florists about forty-five years ago, and the best I have met with. "The pip should be large, and the nearer the outline approaches a circle the better; it should be free from any unevenness and lie perfectly flat; the edge must be smooth, and the divisions in the corolla, which form it into heart-shaped segments, should reach the eye, but not cut into it. The segments should be well rounded, making the divisions between them small and shallow. The tube must be of a fine yellow colour, round and clearly defined, well filled with anthers, and terminating in a narrow ridge, raised slightly above the surface of the eye. The eye should be bright rich yellow of an uniform width round the tube. The ground colour must be entire, free from specks and blemishes, of a dark and rich crimson, not paler at the edges, and uniform in every division. The edge should form a narrow and well defined rim of yellow, perfectly regular, bordering each segment, and passing down the centre of each division to the eye. It is essential that the edge and the eye be of a uniform yellow. These qualities in the pips, and the flower forming a compact truss, standing well above the foliage, on a firm, upright stem, will constitute perfection in the Polyanthus."

Culture.—Now, when the Polyanthuses are bursting into life and beauty, it may be well to make a few remarks on their cultural requirements. The finer forms do not grow very freely. Indeed, they must be classed amongst what may be termed difficult plants to manage; and it is only by importing plants occasionally from a northern district that collections in the south can be maintained intact. What is most trying is the hot, dry weather that generally occurs in June, July, and August. Our plants are put out into the open ground early in May, or as soon as the flowering period is over. They are planted in a shady place, and in good rich yellow turfy loam, brought from Primrose districts, but with all our care their most desperate enemy, red spider, makes sad havoc amongst them—many varieties being so debilitated by it, that they succumb altogether during the following autumn and winter. At present our plants are in their flowering pots and pushing satisfactorily; they must be kept in frames and well aired, the lights being drawn off whenever the weather is at all favourable. They are generally in flower before the Auriculas, and in order

to maintain them in beauty as long as possible they must be shaded from bright sunshine; but as soon as the sun passes off them the shading should be removed. They also succeed best when the frames in which they are growing have their backs placed to the south. If there is any trace of greenfly upon the leaves it ought to be removed now by fumigating the frames, as it injures the flowers to fumigate when they are in full beauty.

The Polyanthus lasts in flower longer than the *Auricula*, for, besides the centre truss, there are usually three or four side trusses which come in later, causing the plants to last in flower for six weeks at least. It is usual for those who make a fancy flower of the *Polyanthus* to remove the side trusses, allowing the centre one to remain, and also to thin out the pips to five or seven of the best only; but to treat a *Polyanthus* in this way destroys the natural character of the plant. One of the best amateur growers in the north of England told me that he never grew *Polyanthuses* two years in succession in pots. His plan was to plant them out in borders as soon as the flowering period was over, and they were not potted again until they had made two seasons' growth. His time for potting was the first week in August, and I have also potted them at that time and found them to succeed admirably. The potting material should contain more loam in proportion to the other ingredients than the compost recommended for *Auriculas*. When they are potted the north side of a wall or fence seems to be the best place for them; they may be protected with glass lights until they are established, but they are best in the open air until frosts set in. They should also be aired very freely during the winter months.

J. DOUGLAS.

HARDY PRIMULAS.

THE interesting note, with list of *Primulas*, contributed by M. Gusmus, of Villach, to your last number (p. 83) suggests to my mind a pleasant train of thought as to the future of this interesting class of plants from a florist's point of view. M. Gusmus enumerates about thirty-six species of European origin and thirty-eight of Asian and American. To the Asian we must add the twenty-four new Indian species described by Mr. George Watt in the *Transactions of the Linnean Society* (December 18, vol. xx., No. 123). From the European series M. Gusmus gives a list of about forty-nine hybrid varieties, a great portion of which are practically unknown in England; but there are several forms known to us which are not in his enumeration, and there are also a number of interesting hybrids from the Asiatic section. What an interesting field for culture will be opened out to the florist when these new Indian forms come to hand!

The Continental florists know very little of our English *Auriculas*, which have all sprung from their mountain *Primula Auricula*, or perhaps from *P. pubescens*. What a troop of lovely forms are included in an array of show *Auriculas*—white edge, grey edge, green edge, selfs, and alpinas, which have been carefully cultivated from the parent stock. It is the same with *P. elatior* and the lovely progeny raised therefrom, our *Polyanthuses* of every colour and of such perfect forms, and with *P. acaulis* and all its lovely varieties, single and double.

M. Gusmus gives the hybrid *P. intermedia* as arising from *P. minima* × *P. Clusiana*, but we have also a *P. intermedia* from *P. Auricula* × *P. viscosa*, which is likely to become a favourite garden flower. Mr. Harry Brownhill, of Sale, had a large batch of seedlings from show *Auriculas*, selfs and fancies, the seed of which had been set in a frame which had a plant of *P. viscosa* in bloom at the same time, the pollen from which seemed to have been carried to every flower of the *Auriculas*. The seedlings from this accident proved to be of great beauty, the blooms showing the dwarf, compact habit of *P. viscosa* with the lovely colours of the show *Auricula*, and the plants when in bloom were literally one mass of flower. No doubt there are many such hybrids

to be obtained from alpine varieties in this way. It is the same with the Asian species. What lovely forms have sprung from *P. cortusoides*, *P. denticulata*, and *P. japonica*! and we may look for many more from *P. rosea*, *P. capitata*, *P. luteola*, and *P. cashmeriana*.

Of the new Indian species described by Mr. Watt, many appear likely to be of great value. There are several forms of *P. Stuarti* varying from 6 inches to 1 foot in height, reminding one of large varieties of our own *P. farinosa*. *P. Watti* is a good deal like *P. capitata*, of a rich purple-violet colour. *P. Kingi* has looser and more drooping umbels of a rich claret colour. All these have the leafage of the *P. farinosa*. Then come a number with leaves like our *Violets*, *P. Gambeliana* having these leaves, with a purple flower like *P. cashmeriana* and *P. Clarki*, and *P. philipes* having tiny *Violet*-like flower-stalks and small flowers, clustered and single. But there are still smaller varieties. *P. sapphirina* is like a tiny *Saxifrage* with bright blue flowers; *P. reptans* has a creeping stalk, from which it throws up flower-stalks an inch high; and *P. Stirtoniana* and *P. muscoides* are dwarfer still. There is another tiny form called *P. soldanelloides*, from its resemblance to that flower. Another dwarf variety, *P. tenella*, has large bluish white flowers; and there is a tall yellow variety, *P. elongata*, which is likely to be most welcome of all. It will be seen from this brief description of a few of the new *Primulas* introduced to us by Mr. Watt, how interesting a lot they are, and one longs to hear of the seed or plants being obtainable for our gardens.

Brockhurst, Didsbury.

WM. BROCKBANK.

White long-spurred Columbine (*Aquilegia cœrulea alba*).—This has disappeared from the catalogues of the best hardy plant nurserymen, and, as far as I recollect, "the commentators" were ominously silent about it last summer. It would be a pity if so beautiful a plant were lost; it is, I fear, less hardy than *A. cœrulea*. The only plant of it I ever came across, itself a "come-hy-chance," has long gone over to the majority.—T. C. L.

Hint for raisers of Dahlias.—Some years ago I brought from Bahia seeds of *Bidens atrosanguinea*, which I have grown ever since. I now see this plant in the catalogues under the name of *Dahlia Zimapani*; it has the advantage of being very dwarf and compact in habit, and although the flowers are small they are well shaped, and of such a depth of colour that when opened on a fine dry day they appear almost black. Surely by fertilising the flowers of a good single *Dahlia* with the pollen of *D. Zimapani* excellent results might be obtained.—R. MILNE-REDHEAD.

Hypericum empetrifolium.—Can anyone who has established this tell me if it is particular as to soil—for instance, is peat (as seems not improbable from the apparent affinities of the plant) a *sine qua non*? I had a nice specimen of it planted last spring, growing and flourishing on my rockery in common soil, but, without giving any previous warning of its intentions, it has suddenly "put its ears back and cut it," as sporting writers say when describing the defeat of the favourite for "the Oaks." I should be sorry not to have it, for it is a really good thing; indeed, I do not think I know a more beautiful dwarf shrub for rockery purposes.—T. C. L.

Aponogeton distachyon and mice.—I can fully confirm what your correspondent says (p. 50) as to the destruction of this plant by some small animals, but are they mice or rats? I have attributed my loss of the plant to the latter; it threw with me in a shallow pool, but as soon as it came into flower it was attacked, first in the leaves, then in the flower-stalks, and finally the root itself absolutely disappeared. I then planted another good root in a deeper pool, say 2 feet deep (the water never freezes in either pool). Here again it bloomed freely in midwinter, but whilst so blooming most provokingly disappeared, not a fragment being left to show where its

curious and deliciously-scented flowers had been a day or two before.—R. MILNE-REDHEAD.

NEW HARDY PLANTS.

Abronia villosa.—To the two species of this genus already introduced to cultivation by me, viz., *A. arenaria* and *A. fragrans*, I now have the gratification of adding another of no less interest, which has the considerable advantage of being annual. *Abronia villosa* resembles in its general characteristics the well-known *A. umbellata*, but is more robust in growth, and is remarkable for the shaggy hairs with which its trailing succulent stems, foot-stalks, and peduncles are clothed. The flowers are produced in axillary umbels in great abundance, each consisting of from ten to fifteen flowers of a lilac-purple colour, surrounded by an involucre of several small lanceolate scales or leaflets. The individual florets are larger than in *A. umbellata* and of a deeper colour. It luxuriates in warm dry soils with a sunny exposure. The seeds vegetate with great facility, and preserve their vitality for a considerable period.

Layia elegans.—This is a pretty Californian annual composite, resembling the well-known *Callichroa platyglossa* and *Oxyura chrysanthemoides* from the same region, but differing from the former in having the broad deep yellow ray-florets margined with white, and from the latter in its larger flower-heads and more branching habit. It grows from 1½ feet to 1½ feet high, with numerous spreading branches and linear-lanceolate foliage, somewhat hirsute, more or less incised at the margins near the tips, but often quite entire. The flower-heads are about 1½ inches to 1½ inches across, having from ten to twelve wedge-shaped ray-florets of a bright full yellow, tipped with white, and three-toothed at the extremity. It continues in flower for a month or six weeks, and is very showy when cultivated in a mass. The seeds are very distinct in character, being quite dissimilar to those of the *Callichroa* and *Oxyura*, though these are now both classed in the same genus with the *Layia elegans*. It may be treated either as a half-hardy annual, sowing in March in a slight hot-bed, and planting the seedlings out in May, or as a hardy annual, in which case the seeds should be sown thinly in the open ground in April where they are to bloom.

Eriogonum cardiophyllum.—If not one of the showiest or largest flowered, this is undoubtedly one of the most remarkable and distinct of all the Californian *Eriogonums*. From a perennial root it throws up several stems nearly a foot high, furnished with heart-shaped leaves an inch or less long, hoary beneath, the margin sinuately and conspicuously toothed. The flowers, which are yellow, are produced in loose terminal racemes of ten to twelve blossoms, each flower being, inclusive of the funnel-shaped tube, about 2 inches long, and the limb an inch across, the petals somewhat rhomboidal in form. It is described by the collector as being an elegant little species, and likely to flower in the first year from seed. The seed is very small, being scarcely larger than that of the *Lobelias*.

Pentstemon Eatoni.—Of the numerous scarlet-flowered species of *Pentstemon*, this is described by Prof. A. Gray to be the finest. It is allied to the well-known *P. centranthifolius*, but is dwarfer in habit and less glaucous; the corolla tube is wider, and its colour a deeper scarlet, verging on crimson. It grows about 1½ feet high, producing several stems from the same root, the foliage being all entire, broadly ovate below to lanceolate upwards. The flowers are produced in a terminal panicle, a foot in length, the corolla gradually widening towards the mouth, the limb with five rounded nearly equal lobes. This handsome species is almost certain to prove quite hardy in England, seed having been collected at an elevation of 8000 feet in the sierras of California, where it is exposed to frost and snow.

Haplocarpha Leichtlini.—This is a handsome new composite from that "home for flowers,"

the Cape of Good Hope, with showy *Gazania*-like capitules. It is a stemless perennial plant, producing from a woody rhizome numerous lyrate-pinnatifidly-cut leaves, from 3 inches to 6 inches in length, smooth and cobwebbed above, densely white tomentose beneath. The flower-heads are borne singly on long scapes, and are from 2 inches to 2½ inches across, with bright yellow ray florets and a disk of deeper yellow. Seeds of it have been received from M. Max Leichtlin under the name of *Gorteria acaulis*, but it is believed to be a new species of the genus *Haplocarpha*, and has been named by Mr. N. E. Brown, of the Kew herbarium, in compliment to the amiable and enthusiastic horticulturist whose name it bears. Seedlings may possibly flower the first season, but no guarantee can be given on that point. It will, of course, need protection during the winter months, but will doubtless prove a very ornamental border or bedding plant in warm, sunny situations.

Acroclinium roseum fl.-pl.—This interesting novelty affords another illustration of the tendency manifested by many composite plants under cultivation to redundant growth, as exhibited in the transformation of the yellow tubular disk florets either into strap-shaped corollas, resembling those of the ray both in form and colour, of which we have an example in the *Pæony*-flowered *Aster* and double *Pyrethrum*; or into largely-developed tubular florets, as in the *Anemone*-flowered *Chrysanthemum* and quilled *Aster*. In the new so-called double *Acroclinium roseum*, the original type of which was introduced some twenty years ago from Western Australia (not from Texas, as recently stated by the raiser, Mr. J. C. Schmidt, of Erfurt), this duplication of parts takes place in the involucre scales which surround the disk, simulating the ray, their number being largely increased, the disk itself undergoing little change; in fact, if one may judge merely by the published figures, the scales are multiplied at the expense of the disk, which is apparently diminished in size. In any case the beauty of this popular *Everlasting* is greatly enhanced, and its utility both for border decoration and for use in a dried state much increased. It may be grown in pots for winter or spring flowering, in which case plants should be kept as near the glass as possible. The pappus of the disk florets is an interesting object under a half-inch lens, consisting of about fifteen to twenty densely plumose scales, united at the base, and tipped with a yellow club-shaped brush, to which, and not to the florets themselves, the colour of the disk of the flower is due. The plant is said to be a little taller and more branched than the older form.

Convolvulus tricolor roseus.—From the description given of this Bindweed it should prove a great acquisition, and will doubtless initiate a series of new varieties. The habit of the plant appears to be that of the older varieties of this popular annual, the only difference consisting in the colours of the flower. These are described by the raiser as being pure white in the centre, encircled by a band of purplish violet rays, intermixed with five broad golden-yellow stripes from the throat, the margin being of a lovely rose colour. It is said to be reproduced freely by seed, and requires only the treatment of the common varieties.

New double-flowered Godetia (*G. rubicunda splendens*).—This is represented to be a very fine plant, growing about 1½ feet high, or even 2 feet when sown in autumn, with the oblong-lanceolate foliage common to most of the species, and producing handsome double or semi-double flowers from the axils, about 2 inches across, each petal having a large bright purple blotch, which gives them a very striking and showy appearance. It is said to come perfectly true from seed, and will require only the treatment usually given to the hardy annuals. It may be sown either in spring or autumn.

Hesperocallis undulata.—This is a very interesting new Lilywort, the more so that it is likely to prove hardy in this country. From an

ovate tunicated bulb it produces fleshy, linear, keeled leaves about a foot long and nearly half an inch wide, with a more or less undulate margin, the flower-stem being from 1 foot to 2 feet high, with a few small leaves, and bearing from five to eight large white funnel-shaped flowers on short pedicels in a simple raceme. Each flower is about 2 inches long, having beneath it a conspicuous scarious bract. A native of California, where it blooms in March and April. The seeds are comparatively large, resembling those of many *Yuccas*.

Mimulus maculatus nobilis.—Few plants are more attractive than a well-grown specimen of the large-flowered blotched *Mimulus*, and the addition of a richly-coloured calyx, scarcely inferior in size to the corolla, must obviously lend an additional charm to its beauty. What are known as hose-in-hose *Mimuli* have been cultivated for some years, but *M. m. nobilis* produces flowers considerably larger and more conspicuously marked than any before introduced. The habit of the plant is remarkably compact, the flowers are abundant, and both corolla and calyx are handsomely spotted in a variety of patterns. It is said to be very hardy, and may be grown either in pots or the open border. Requires only the treatment of the ordinary kind; seeds being very small, should be but slightly covered with soil.

Oenothera albicaulis.—This species is widely diffused in the North American continent, but does not appear to have been introduced to cultivation, or if so has been long lost from gardens. It is a variable plant, but its best forms are well deserving cultivation. The present variety forms a compact branching bush from 12 inches to 15 inches high, with a glistening white slender stem, linear to oblong lanceolate foliage, sinuately toothed or even pinnatifid near the base, of greyish green colour. The flowers are pure white, and are produced from the upper axils of the stems and branches, each blossom being about 2½ inches across, the petals obcordate or inversely heart-shaped and assuming a purplish tint in fading. It flowers the first year from seed, but it is really a perennial with a creeping root-stock. It should be sown early in a greenhouse or on a mild hot-bed, and requires only ordinary garden soil.

Oenothera crassicaulis.—This species is allied to the preceding, but differs from it in having larger flowers and in being apparently of annual duration only. It grows about a foot high, with stouter stems and larger foliage than in the *O. albicaulis*, and produces a succession of large white flowers nearly 3 inches in diameter, tinged with pale yellow around the throat, and fading, as most of the white flowered species of this genus do, to a pale reddish purple. It requires the treatment of half-hardy annuals, and will probably succeed in most soils. The seeds are very distinct, being fusiform or spindle-shaped and nearly quarter of an inch in length.

Omphalodes Luciliae.—Of this small genus only two species have been hitherto cultivated in gardens, viz., the neat little white-flowered annual *O. linifolia*, long known as *Venus's Navelwort*, and the pretty *O. verna*, a perennial species with bright blue flowers. The present introduction is also perennial, but differs considerably from the species just named both in foliage and flowers, and is more strictly alpine in habit. Like *O. verna*, it is a very dwarf plant, and apparently more restricted in its growth, having slender rhizome-like stems, furnished with glaucous entire ovate leaves, and producing its flowers on short few-flowered racemes, the corolla being of a delicate pale blue. The plant requires the treatment of alpinists, and demands partial shade; it is well suited to pot culture, and may also be grown successfully on rockwork. The seeds are best sown as soon as gathered, but will germinate in spring after an interval of a few weeks; no artificial heat should be employed to hasten their growth.

Papaver somniferum var. Danebrog.—This promises to be an interesting addition to the group of ornamental Poppies. It is a single

flowered variety of the *Opium Poppy*, from which it differs in its dwarfier growth and in its flowers being of a bright scarlet, each petal bearing a large silvery white blotch, the four spots thus forming a white cross on a scarlet ground, and suggesting a resemblance to the Danish or Swiss national banner. It is a hardy annual, requiring the same treatment as the other varieties of the same section.

Primula obconica.—This very neat little Primrose is a recent introduction of Messrs. Veitch & Sons from China, where it was discovered in the neighbourhood of Ichun. In habit and foliage it resembles the beautiful *P. cortusoides*, but differs in flowering continuously and profusely from spring till autumn. The foliage is oval-cordate with crenate margins, and forms a spreading rosette, from which the scapes arise in succession. The flowers are about 1 inch in diameter, with a flat limb of a pale lilac or purplish tint, in umbels consisting of from twelve to sixteen or eighteen blossoms each, the pedicels very unequal in length. It has been distributed by Messrs. Veitch under the name of *P. obconica*, but has been recently described and figured by Sir J. D. Hooker in the *Botanical Magazine* under the name of *P. poculiformis*.

Salvia carduacea.—This pretty and very distinct Californian species first appeared in my catalogue two years ago, but as it is being offered this season as a novelty I again direct attention to it. From a cluster of oblong, sinuate, and spinulose-toothed Thistle-like leaves clothed with white, cobwebbed hairs it produces a stout, almost naked stem 1 foot to 2 feet high. The flowers form dense clusters around the stem at intervals, the bracts beneath the whorls being very spiny and pectinately toothed. The corolla is about 1 inch long, of a pleasing lilac-blue, and is remarkable for having its lower lip fimbriately cut or fringed, which gives it an elegant appearance. The reddish anthers contrast effectively with the colour of the flower. It should be treated as a half-hardy annual, sowing early and potting off the young plants singly prior to planting out in some sunny exposure, in light sandy loam, in May.

Muscari Argæi.—The Grape Hyacinths are among the prettiest of spring-flowering Liliaceæ, and *M. Argæi* is one of the finest of the genus. It produces an abundance of flowers of the brightest blue in large spikes, and is a worthy associate of the *M. Szovitzianum* and *M. armeniacum*, two other similar and very ornamental species. The plants of this genus are among the easiest to raise of all hardy bulbs, the seeds vegetating freely after lying dormant a few weeks, and producing flowering bulbs in two or three years.

Calochortus Kennedyi.—The species of this genus of Californian Liliaceæ are among the most beautiful ornaments of our gardens, and *C. Kennedyi* is not surpassed by any previously introduced. Its flowers are of a rich deep orange colour resembling that of *Eschscholtzia crocea*, but scarcely as large as those of that plant. It is a rather tall species, the stem growing nearly 18 inches high with a few distant lanceolate leaves, 2 inches or 3 inches in length, each stem bearing from two to four erect flowers. The sepals are nearly as long as the petals, orange within, with purple spot at the base; the petals are from 1 inch to 1½ inches long, of a uniform clear reddish orange, the glandular pit near the base being densely hairy, and surrounded by a broad, deep purple spot. It belongs to the *Mariposa* section of the genus, which includes *C. luteus*, *C. venustus*, *C. splendens*, *C. macrocarpus*, and a few other less known species. The seeds should be sown in light soil, and will be best left to vegetate without the aid of artificial heat; a greenhouse shelf will do well as a station for the pot. The first season the bulbils will attain but a small size, and care must be taken that the soil never becomes quite dry after the foliage has withered, or the tiny bulbils will shrivel up and perish. They may be expected to attain a flowering size in three or four years, when they may be treated like the rest of the species, that is, as half-hardy bulbs, to be planted

in warm light soil in April, and removed from the border in the autumn when foliage has decayed.

New double white Sweet William.—

The ordinary forms of double white Sweet William have usually a purple centre; this is said to be pure white, and to be very constant from seed. It must, therefore, prove useful for cutting, as well as for border decoration, from the contrast it affords.

W. THOMPSON.

Ipswich.

SEASONABLE WORK.

INDOOR PLANTS.

Æschynanthus and Torenias.—Such plants as possess a drooping habit of growth are much more suitable for hanging baskets than erect growers. Most of the kinds of *Æschynanthus* are particularly adapted for the purpose as well as *Torenia asiatica* and *T. pulcherrima*. If cuttings of either are at once put in they will, as a rule, root quickly, and should then be transferred to the baskets, using a sufficient number of the *Æschynanthus* to make them effective with a single season's growth.

Tuberous-rooted Begonias.—A portion of the stock of these may now be started by placing them in a house where they can have an intermediate temperature. These plants are so accommodating that they will succeed in either a hot or greenhouse; still, if grown too warm they make weak growth that produces comparatively few flowers, the plants in addition having an indifferent appearance. They may be shook out of the old soil and at once potted in new. Such of these *Begonias* as are now started in heat will be found very useful to precede the latter portion that will come on with greenhouse treatment. They do best with moderately light soil, fairly enriched with manure and a little leaf-mould.

Caladiums.—Although a few large specimens of these are suitable for use in large houses, still small examples, consisting of a single crown each, are generally preferable. Where large old plants are available they may be divided, retaining a portion of root to each piece. When so treated they must immediately be started in a brisk heat, and should not be placed in soil that is over moist, or they will be liable to decay. The small growing *C. argyrites*, if well managed by keeping it close to the glass, where it will get plenty of light with a moderate amount of air so as to secure stout growth, is one of the most useful stove plants in cultivation, for in such condition it will bear using in a lower temperature along with flowering subjects for some weeks when the weather gets warmer, and the leaves are alike available for cutting to use in bouquets and other combinations of flowers.

Peperomias, Fittonias, and Panicum variegatum.—These small-growing handsome-leaved plants are alike suitable for cultivation in either large or small houses, adding much to the appearance of the stages when used in quantity so as to act as a setting for larger growers, and where the side stages are composed of slate, stone, or other imperishable material, a carpet of such plants, with a moderate number of other things possessing larger growth stood about on them, produces a much better effect than is attainable by the ordinary arrangement of crowding all sorts of plants indiscriminately together. Where a considerable stock of the above plants are to be used, a sufficient number of cuttings should at once be put in, as by having them rooted thus early the plants should be in a position to get established early in the season.

Sonerilas and Bertolonias.—These pretty handsome-leaved subjects, although not able to bear the rough usage and shade inseparable from use in the way advised for the *Fittonias*, &c., ought to have a place in all collections of stove plants where a good amount of heat is available, without which it is useless attempting their cultivation. They root freely from cuttings which may be put in now, giving them a brisk heat,

and keeping them moist and close under propagating glasses.

FLOWER GARDEN.

Pruning shrubs.—So far as most parts of the country are concerned, better weather for the prosecution of outdoor work could not be than that which we have lately had, and if it has been taken advantage of, much of the rough work connected with alterations and all planting of trees and shrubs will now be finished, or if not, should be so as early as practicable, after which the next most pressing work will be hedge clipping and shrub pruning. All hedges, lines, belts, and screens of Privet, Beech, Holly, Yew, &c., to be kept thick must be cut annually; such work we usually reserve for frosty weather, which may perhaps not be the best for shearing them, but having from necessity done it in such weather for many years without perceiving any ill effects, we can safely recommend it to be done now no matter what the weather is. In the majority of gardens shrub pruning is but a secondary consideration, and in some never attempted at all; consequently Hollies, Laurels, Bays, and all similar habited shrubs soon get naked stemmed, a condition that can only be effectually prevented by timely cutting back the leading shoots, an operation which conduces to lateral extension of growth, and keeps the plants equably furnished with shoots. Moreover, we have an impression that such timely curtailment contributes to longevity, for all surely must have noted the wholesale destruction of unpruned Hollies and Laurels during the past few winters, whilst those that have been kept trimmed are as healthy as evergreens of any kind could be. That it may not be inferred from the importance here attached to shrub pruning that formal trimming is advocated, we would add that, from our point of view, trees never look handsomer than in their natural forms, the only aid here advocated being simply the restriction of the stronger branchlets to, as it were, aid the weaker to keep pace with them. Many kinds of trees, Conifers in particular, by the pinching out of the point of a strong shoot or shoots, as the case may be, can be made to grow of even proportions throughout. Of course these remarks refer more particularly to young trees; to influence or direct the growth of old-established Conifers is obviously out of the question.

General work.—This now consists in the completion of the turning or re-gravelling of walks to get them well consolidated by frequent rolling whilst the ground is still wet. Verge cutting and levelling of turf are also important works that should be completed as early as possible; as should also new edgings of Box or repairs to the same. Where turf would be in bad taste, not to mention the bother of mowing or clipping *Sedum glaucum* makes an excellent boundary line for walks in rockeries and ferneries, and when planted virtually requires no attention, except to be kept free from weeds. Sweeping and rolling are still a necessity as regards the preservation of neatness, worm casts, owing to the mildness of the weather, being still thrown up in abundance.

FRUIT.

Pines.—To meet the demand for early fruit, see that the bottom-heat in which the first batch of Queens are plunged does not fall below 80°, and let the top-heat range from 70° at night to 80° through the early part of the day, and 85° to 90° after, closing with sun-heat. Keep the evaporating pans filled with stimulating liquid, pay particular attention to root watering with the same in a diluted form, and reduce the necessity of overhead syringing by damping all available spaces, including the surface of the bed, when the house is closed for the day. If the bed in which winter fruit is swelling shows signs of declining, take advantage of a mild day for renovating it with fresh fermenting leaves or tan, and replunge the plants, keeping the Cayennes and Rothschilds which

started late in October and November together in the lightest and best part of the house, where they can receive heat and moisture with stimulating food, as recommended for the early Queens. If well rooted and not overpotted, these plants will give excellent Pines at a time when good English fruit is in great demand and not too plentiful.

Successions.—Strong plants intended to make a growth before their fruit should be examined, and if found very dry at the root a little tepid water may be given to prevent them from receiving too decided a check, which might cause them to throw up prematurely. In light, airy houses an occasional dewing over with the syringe may also be indulged in, but in close pits atmospheric moisture will be quite sufficient for the present. If the bottom-heat valves have been kept shut through the dead months of November and December, and the heat has declined below 70°, it will be necessary to admit a gentle circulation until the thermometer indicates a move upwards, but great caution must be observed, as the application of water to the fermenting material combined with increasing solar heat often produces the desired effect without having recourse to the hot-water pipes. Gradually increase the top and bottom-heat in pits containing suckers, which require shifting into fruiting pots. Give a little water from time to time to bring the soil into a growing state, and shift as soon as the roots show signs of moving. Meantime push on the usual preliminaries as opportunity offers by getting crocks, pots, and soil ready for use before a single plant is disturbed.

Peaches.—Do not neglect the fertilisation of the later kinds of Peaches in the early house, and when all the fruit is set resume syringing with tepid water a few degrees warmer than the house. In mild weather give air at 60°, and raise the temperature to 70° or 75°, under gleams of sunshine; close early, and aim at 50° to 55° by night. Disbudding must now receive attention, and in the event of a single fly having gained a footing fumigate lightly once or twice at short intervals as soon as the young fruit shows signs of swelling. When fairly on the move rub off a few of the smallest and worst-placed fruit, in order to give strength to those intended to ripen, always bearing in mind that Peaches nearest the base of the shoot and on the upper side are the most promising to leave for the crop. Examine the borders, and if old trees show signs of weakness top-dress with short manure and water with clear diluted liquid. To vigorous young trees give plenty of water, and defer the application of stimulants until they begin to feel the strain of the crop. Get all pruning and training finished, and retard trees in late houses by throwing open the ventilators when the weather is not very severe.

Figs.—While the weather is cold run down the blinds at night, and counteract the drying influence of fire-heat by introducing additional supplies of fermenting leaves. Syringe the trees twice a day to keep down spider; stop all gross shoots at the sixth leaf; thin out useless spray to give young spurs and fruit the benefit of light and air as the season advances, and feed the roots with liquid manure. Encourage the trees in succession houses by giving fire-heat and moisture through the day. Mulch inside borders and water with tepid liquid, but avoid an excess of moisture or high temperatures by night until the terminal buds show signs of pushing into growth. Trees struck from eyes last year may be encouraged with warmth and moisture. Remove all ground suckers. Pinch the points of the strongest side shoots and train the leaders to straight sticks.

Cherries.—Be guided by the state of the weather in the management of early-started trees now approaching the blooming period. When fire-heat is needed for the maintenance of the night temperature, 40° to 45°, with a little air, should not be exceeded, and in the event of a continuance of severe weather a few degrees lower will be preferable to sharp firing. As Cherries cannot be fumigated or syringed when in flower, see that the trees are quite free from insects when the blossoms

begin to open. Pay daily attention to fertilisation. Ventilate freely without causing a draught, and avoid damping in dull weather. The past autumn having been so fine, we may assume that lifting and planting were performed at the proper time. If still in arrear, choose the first dry day for the completion of this work in late houses, using good turfy loam and old lime rubble. Drain well, and mulch with manure.

Orchard house.—Owing to the mildness of the season, the buds on Peach and Nectarine trees still standing out-doors have got very forward, and altogether unfit to be exposed to moderate severity should this extraordinary weather be succeeded by frost. In many places the orchard house is used for other purposes in winter, and early housing of the trees is often attended with inconvenience; but steps of some kind should be taken for getting them under glass, as they may be placed closely together for a time, provided the house is fully ventilated at all times, unless frost is very severe. In years gone by it was the practice to pot and top-dress trees quite up to the time of housing, but this remarkable season fully confirms the sound advice to get all work of this kind performed before, if possible, or immediately after the fall of the leaf. When all the trees are under glass keep them well supplied with water, as dryness at the root after this date is sure to settle the crop for this season. Also look to trees established in inside borders, mulch well, and give them repeated waterings until the soil is as moist as it will be found in a well-drained Peach border out-of-doors.

Early houses.—After the fruit is all set on the early forced pot trees, syringing must not be neglected to keep insects down and to wash off the remains of the flowers. If fly has gained a footing, fumigate when the trees are dry, and repeat if necessary. Allow a night temperature of 50° to 55°, and 60° to 65° in the daytime, with a slight increase after closing on sunny afternoons. Where the young fruit is too thickly set relieve the trees by removing a few of the small and badly placed ones, and at the same time gradually carry on disbudding and shortening back, when the shape of the trees can be improved without detriment to the crop of fruit. Water well with tepid liquid and give the roots a little more fresh top-dressing when they show upon the surface.

Cucumbers.—Winter fruiting plants renovated with fresh top-dressing and fermenting Oak leaves, as formerly directed, will now be in the best possible condition for passing through the present trying period. Counteract the ill effects of incessant firing by covering the roof at night. Keep the glass clean. Syringe all available spaces to keep down spider and remove old leaves to make room for young growths, which must not be stopped until we have more light and solar heat. The change to weather of a colder character will not admit of more than the maintenance of minimum temperatures, but there will be short periods of sunshine which will raise the house to the maximum degree of heat, and this, combined with cleanliness and light cropping, will keep them progressing until we have brighter weather. Put in cuttings of Telegraph, sow seeds and pot on young plants if the hills or fruiting pots are not ready for them. Follow former directions with regard to making hotbeds. Where a good nursing pit is at command do not be in a hurry to turn out young plants until the soil in manure pits and frames is in good order and danger from rank steam has passed away.

KITCHEN GARDEN.

WE have been employed during the week digging and manuring quarters left vacant by Brussels Sprouts, Savoy, and early Broccoli, also in salting and liming vacant Celery quarters, in order to get rid of slugs; this land we intend for spring Onions. We are planting Tripoli Onions from seed beds into rich land, and at this season we plant a large breadth of small Onions for very early use. We are likewise planting early Cauliflowers out of seed beds in cold pits into three-light boxes, in

order to make them stocky and strong for planting out in April and May. Small sowings of Lettuce and Cauliflower may be made at once. Radishes now up should be aired regularly and thinned timely, so that they may grow with little top and good bulbs. Wood's Frame ranks among the best. As the days lengthen all things indoors strengthen. Kidney Beans are looking and bearing like May Beans, and once again we say to all, use Osborn's; it is the king of Beans for forcing. Asparagus we force in old Pine stoves, and with very little trouble. See that old stools are taken out and replaced at once, a remark which also applies to Seakale and Rhubarb. Outside Mushrooms are now bearing well, and the quality far in advance of those indoors. We have finished making beds for this season, and doubtless shall have a full supply until next June.

KITCHEN GARDEN.

CULINARY AND SALAD HERBS.

ALTHOUGH herbs of a medicinal character have gradually been losing ground in public favour, there are many culinary herbs that are still indispensable; and as the best season for replanting herb beds and making provision for the coming year's supply is at hand, a few notes on the culture of such as are really useful may not be unacceptable. Herbs are mostly plants of easy culture, and only fail when cutting off the tops is carried to excess during the dormant season, when fresh growth cannot be made to keep the roots from perishing. Amongst those of a permanent character, of which I have found it advisable to have a good supply ready, must be named the

COMMON AND LEMON THYME.—These are what may be termed all-the-year-round herbs, as they enter into the wants of the culinary department both in winter and summer. They are readily increased by means of cuttings inserted under hand or bell glasses, also by seed; but, if taken in time, division of the roots is the readiest way of making good beds quickly, and during the month of February, or just as fresh growth is starting, is the best time to replant, as they strike fresh roots directly, and soon make fine clumps. The best position for herb beds is a border close to one of the main kitchen garden walks, where they are within ready access at all times and seasons. Beds from 5 feet to 6 feet wide, with alleys between, and rows of plants 1 foot apart will suit both common and Lemon Thyme.

SAGE, although not so frequently in request as the preceding, is a most useful herb, but, being of coarser growth, requires more space between the rows and plants. It will grow freely in any good kitchen garden soil, and is readily increased by slips or side branches taken off with a heel of the old wood attached to them, and dibbled deeply and firmly into the soil at this time of the year, so as to get rooted before the sun shines too brightly; or later in the season a shaded position must be selected for cuttings, or some glass covering must be used to check too rapid evaporation. Sage may be readily increased by seed that ripens freely in fine seasons; the broad and narrow leafed green varieties are those most largely grown, but the red leafed Sage is preferred by some, and it is very hardy.

MINT is a useful herb, being liked both in a green and dried state; the young shoots are especially valued for mint sauce in early spring, and, in addition to the requirements of the kitchen necessitating constant picking of the tops as long as procurable, both early and late out of doors, there is a considerable space of time when the supply of green shoots has to be made good from the forcing pits. A large stock of roots is necessary in order to insure a supply, and, the plant being of a true herbaceous character, its roots must have some rest before it starts readily into growth again. The best way I have found in order to have a good supply all the year round is to annually transplant a portion of the stock, as the underground roots or stems of the plant

need fresh feeding grounds, or they soon perish. The central portion will usually be barren, while a crowd of young growths will be found round the edge of the beds, an indication that the plants are seeking fresh soil. I find Mint to do best in rather light well-drained land, and the addition of road scrapings or old mortar rubbish is better than manure in stiff adhesive soils. It will now be starting naturally into growth, and, if pieces of the roots are laid in drills and just covered with soil, they will make fine clumps for next year's forcing. Dried Mint is useful in winter. It should be cut when the stalks are in flower, and carefully dried in a cool airy shed, well ventilated, to preserve it from mouldiness. Plants cut down will yield a supply of green shoots late in the season, while those left to mature their growth will be in the best condition for early forcing. They must be lifted carefully, so as not to break the growing points, and, if covered with light soil in boxes, and introduced to gentle heat, a supply of green shoots is readily produced.

TARRAGON is of very similar growth to Mint, and not only in great request in the kitchen, but especially for mixing with salads. It is rather capricious as to soil; but when it does not succeed in the ordinary kitchen garden soil, I have found a mixture of old potting material, finely powdered brick rubbish and coarse sand, never fail to grow it well. If treated exactly the same as Mint in respect to cutting, drying, and forcing, a supply of both green and dried shoots may be secured at all times.

SORREL is frequently used as a substitute for Spinach. It should be transplanted annually or the leaves get very small. The best way, in order to secure a continuous supply in summer, is to cut off the tops of a portion of the stock at intervals of a week, to prevent their running to seed, as when this takes place, the supply of succulent leaves soon fails.

SWEET MARJORUM, Winter Savory, Horehound, Hyssop, Rue, and Fennel should be grown in limited quantities. When once established, they are not fastidious as to soil or special attention. If the beds for them are well prepared at first, they will yield a supply for three or four years without renewal; merely keep them free from weeds in summer, and lightly fork in some old hot-bed manure at this time of year.

Annual or biennial herbs are of quite equal merit to those of a more permanent character. First on the list is that daily want of the kitchen,

CURLED PARSLEY.—It is, in fact, only when the supply fails that the importance of this useful herb is realised. This is the time to make preparation by thoroughly cultivating the soil intended for its growth. It is a strong rooter and gross feeder, and one good plant will cover a square yard of soil, and yield a large supply of fine leaves. Single rows in an open sunny position in rich soil yield the best results for summer and autumn, if sown at once; for winter, sow in July, under the friendly shelter of bush fruits or at the base of a wall, where the young plants can be easily protected by means of straw-thatched hurdles, evergreen branches, or similar protections.

CHERVIL is a valuable biennial or annual herb according to the time at which it is sown, the most important being the autumn for the winter and spring supply. It is much in request for salading, and, in order to keep up a supply in summer, frequent sowing is necessary, as in hot weather it soon runs to seed. A partially shaded position and good soil are the best antidotes to premature seeding.

SWEET BASIL is, perhaps, the most important of the true annual herbs. The first sowing should be made in pots or boxes in heated pits or houses, as it is tender, and a supply of it can only be relied on from the open air during the warmest summer months. A bed should be sown on a warm border in April, and another in May, for summer use; but, as soon as the nights get cold, the supply must be again procured from under

glass. This herb is highly prized in a dried state, and the first sowing out-of-doors, when in full bloom, in July or August, should be pulled up and carefully dried and preserved.

BORAGE is much prized for flavouring wines, &c. It is of easy culture, and its pretty blue flowers make it worth growing, even if not required for domestic use, especially where bees are kept, as they are especially fond of it. A sowing in spring, and another in August, will yield a constant succession.

CORN SALAD is a useful annual herb. If sown in drills 1 foot apart once a month, from February to September, it will yield a daily supply. A shaded cool border is the best position for it in summer, and a dry sloping border for the winter supply. Small sowings and often should be the rule with this, as with other herbs of rapid growth.

BUSH BASIL, pot Marigold, pot Majoram, Caraway, and many other useful herbs may be easily raised from seed; but, as they are only in request in special cases, I need not allude to them further than to say that, if sown in March or April in seed beds such as are annually made for the Brassica family, they will yield a good supply without further trouble than that of weeding or thinning.

WATERCRESS is a much valued herb, and, although it can hardly be said to be improved by cultivation—for the produce of a clear brook of spring water can hardly be excelled—yet there are many places in which these natural conditions are not at command. In that case it has to be cultivated, and very good Watercress may be obtained by sowing the seed in pans or boxes, and when large enough, planting out in cool shaded positions, such as the north side of a wall, where, if kept constantly moist by copious watering, very good cresses are obtainable.

THE DANDELION, I may add, has of late become very popular as a salad herb. It requires the same routine in the way of culture as Chicory, viz., sow in April in drills, take up the roots when fully grown in autumn, and plant in a dark warm cellar or Mushroom house. The young blanched leaves are excellent for making up winter salads, and they come in at a time when the ordinary supply of out-door materials for salading is at its lowest ebb.—*Field*.

GARLIC AND SHALLOTS.

THESE are grown in almost every garden, and in some even on a large scale. Both are frequently asked for, and with many Shallots are preferred to small Onions for pickling. Garlic, with very little attention, will produce a crop almost anywhere. When we first began to grow it we bought 2 lbs. of it from a seedsman, and in a few years we might have had several hundredweights from this small quantity, so quickly does it increase. At first the bulbs were planted singly, but by the end of the season they appeared in large clusters, and it is these offsets which are kept for use in the kitchen, or part of them may be reserved for planting again the following spring. About this time the ground for the reception of the bulbs should be moderately rich and free in texture. We never make a special plantation of this, but put in 100 or so of roots between the fruit trees on the border which edges our walks in the vegetable department. Here we never fail to get a full crop, and we consider such a position suitable for Garlic culture. The bulbs are put in 9 inches apart each way, and as each one is put in the soil with a blunt-pointed dibble, a little river sand is placed round to prevent it from decaying should the soil be very wet after planting. Hoeing is all the after culture given until fresh bulbs have been formed and are fully grown, when they are all taken up and harvested like Onions. During the growing season we have had to take up some for use, but as a rule we avoid doing this by always having a few bulbs in store. In planting now we do not insert every one, but keep as many as we can in reserve, and these keep the kitchen supplied until those that are growing are almost ripe.

Shallots are treated throughout in almost the same way. We plant them on the same day as the Garlic and on the same piece of ground. The Russian Mammoth is the best variety we possess, and by selecting the finest bulbs for planting the crop is much better than taking any size or kind for this purpose. As Shallots require more space in which to develop themselves than the Garlic, the roots should not be put in closer than 1 foot apart, and for very fine bulbs we have sometimes given more space than even that. In planting, the crowns of the bulbs are left above ground, and a handful of sand is put round every one of them. When planted about this time they will be well forward in growth in March, and all will be ready for harvesting in June or July. We have always found them to keep best when drawn up from the soil spread out on the surface for a week or ten days in the sun, and then stored away in a dry, airy loft, room, or shed. After that, as time may allow, the withered tops are drawn from them, the clusters are divided, and each bulb has all the dry, rough material removed when they are ready for use.

CAMBRIAN.

CELERY IN FRAMES.

HAVING grown this esculent to the weight of 6½ lbs., I thought I had obtained something above mediocrity. I had not, however, paid much attention to the weight of Celery, but, judging from appearances, I felt sure I had not seen anything in Covent Garden to equal it. The late Mr. Parsons, of Welwyn, thought he had done well when he grew some weighing 3 lbs.; and having exceeded that weight, I named the matter to an acquaintance, who, noticing my semi-exulting tone, retorted that the weight was nothing extraordinary, for he had seen some 9 lbs. in weight grown by weavers. This was a great blow, and my friend, I think, meant it to be so. All praise for all that to the Lancashire mill hands for their horticultural skill. It is pleasant to see them gliding home from their allotments with Celery sticks 3 feet long, Cauliflowers 10 in. or 12 in. over, and Onions more in circumference. Celery shows are a speciality in many parts of Lancashire. They may be counted by the dozen in an area of four miles in this district. Many are the devices resorted to to get the plants on without check and as early as possible. They do not all raise their own plants. One of our village mill hands who had to procure his plants some miles off arranged for them to be potted some time beforehand. Knowing how Celery succumbs, if of any size, when disturbed, one would have thought he had caught hold of an excellent idea, but for some cause or other (probably being in the pots too long) they "piped" or bolted.

Sowing.—We sow the first week in February, thinly in pans containing light rich soil, securing a position near the glass in a temperature varying from 50° to 55°. If too thick, we thin out as soon as the plants are large enough to lay hold of. When large enough we prick them out in boxes 3 inches apart. Last year we made up a gentle hotbed, and I fancy they were more at home managed in that way than any other. We kept them close and shaded them when required for three or four days. At the bottom of our framing ground, which has a slight declivity, we placed a quantity of half decayed manure, levelled it down 2 feet thick, and put it into shape to receive some frames. Some decayed manure was thrown in, and 8 inches of old Cucumber and Melon soil was laid on that, leaving 8 inches of space between the glass and the plants, and as they progressed the frame was raised, packing at the same time decayed manure round to keep the materials in the interior of the frame in their place. We planted six varieties 1 foot by 1 foot 6 inches apart. As they advanced they were top-dressed with decayed manure, kept well watered, attended to as regards ventilation, and by the first week in September they were ready for use.

Blanching.—When the plants are 2 feet high we tie them round loosely; this gives more air space between them. A month before the heads

are required for use these ties are cut and a portion is bandaged round with sheets of brown paper from 1 foot to 1 foot 6 inches wide drawn moderately tight. Each strip is tied and placed so as to well overlap the one below it. All the strips should go round three times at least. In wet weather we put one as a capping on the top. I have omitted to state that we remove the frames as soon as the weather permits us to do so, as top-dressing and watering can be more readily performed and ultimately the bandaging. We sow in a one-light frame on a slight hotbed for our earliest crop in the kitchen garden. This is usually done the first week in March, and as soon as the plants are large enough they are pricked out in the usual way in frames. I will not at present go over the usual routine of cultivation out-of-doors, but I may just add that, taking it on the whole, the best and decidedly the cleanest looking Celery I have seen has been growing in bog earth.

W. P. R.

Potato culture.—There is nothing new in what "E. B." calls his system of planting Potatoes. He must be placed in a cool district indeed if he can prevent his seed tubers—early ones especially—from sprouting without actually rubbing off the young shoots. It is better to recommend seed tubers not to be stored where the shoots get drawn, and if they be kept during such a soft winter as this where there is plenty of light and air, there will be no fear that the shoots will be unduly drawn. Then, ordinary observation shows that all properly-housed seed tubers at first break a less number of shoots than if these are rubbed off and a second break takes place. These first shoots are the most robust, and one, as the germ of a plant, is worth half-a-dozen weak ones. Then it may also be noticed that a seed tuber, let it be ever so big, has no power of itself to push shoots beyond 1 inch in length if the tuber be kept in full light and air. That is a most interesting fact, and it is correct. It is not till the tuber is put either into a moist temperature or in the dark, or else is brought into contact with soil or moisture that the shoots lengthen; but these shoots, even though not more than 1 inch in length, will be found to have several rootlets, each, perhaps, half an inch in length, thrown out as feeders, ready at once to take up moisture and nutriment, and thus promote growth. Until such moisture or nutriment is found the shoot remains stationary, if the atmosphere be dry, until the tubers shrivel and decay. This growth of shoots and roots is exactly what would take place in the soil, but being done out of it admits of later planting, when risks are fewer and success far more certain.—A. D.

DRAINAGE AND VENTILATION OF HOUSES.*

THREE sanitary principles govern house drainage: 1. All refuse matter must be completely and rapidly removed from the house. 2. There must never be any passage of air from the drains or waste pipes into the house. 3. There must be no connection between the drains and the domestic water supply. These, although so simple, are very frequently neglected. The first goes absolutely to the root of sanitation, for were it strictly complied with, there would be no leaky drains, no polluted subsoil, and no production of foul gases in the drains from decomposing organic matter. There cannot be a greater mistake than to assume, as is commonly done in investigating drainage, that if water runs away with freedom this is all that is required. Numerous cases are on record where the sewage from houses has apparently run away freely for years, but where the greater portion of it has really been leaking out of the drains into the ground under or close to the house. In illustration of this point two cases may be mentioned—one in which the connection with the sewer was actually found to be blocked with shavings, which had been left in when the house was built three years before; the other, that of a

* From a paper recently read before the Medical Officers of Health by Mr. Rogers Field.

school in which the drainage from the lavatories had leaked through disused drains under the floor of a large portion of the building, and where, although there was a mass of filth in some places 7 feet deep, no leakage had been suspected. If the drains are exposed and found clean and jointed with cement, this is not sufficient; the tops of the joints may be good and the bottoms bad. The only safe method is to actually test the drains by plugging them at the lower end and filling them with water. Very few house drains stand this test. Even if the drains are outside the house it is a mistake to assume that it is unimportant whether they are sound, for not only may sewage leak out of faulty joints and percolate under the house, but foul air may be drawn into the house. It is important to realise how small an amount of deposit will create mischief by decomposing and generating foul gases; a mere irregularity of the joints, even when the drain has a good fall, is sufficient to cause this. There is no better test of the condition of the drains than the amount of smell emitted from a ventilated opening, for if drains be properly laid and in thorough working order, practically no smell should exist. The principle that there should never be any

Passage of air from the drains or waste pipes is most essential, and the means of isolating the house drains from the public sewer, the necessity of keeping the drains outside the house, their ventilation, as well as that of the soil pipes, the position of the water-closets, the disconnection of the sanitary fittings inside the house from the drains are each and all highly important. The danger should be guarded against of trusting too much to those parts of the drainage of a house which are visible as an index of the condition of other and important parts which are concealed; the drainage of a house which had recently been constructed, and where all the sanitary arrangements appeared at first sight to be perfect, but where a subsequent examination of the drains which were under the house showed that the joints were in many places defective, and at one point the pipes were not jointed at all, but a space left large enough to put a hand in, though it was stated that special care had been taken to make the drains watertight. Old drains, which had no outlet connected with gullies, were found beneath the passages and rooms; the housemaid nearly died of typhoid fever, and beneath the room she occupied was found an old drain with a large amount of foul deposit. In another instance a lady and her cook were attacked with erysipelas and blood-poisoning shortly after occupying a house. An examination of the house showed that an old stoneware drain in the scullery, into which the sink discharged before it was disconnected, had not been removed, and though stopped with cement the stopping was imperfect, thus allowing the air of the drain to enter the house. There are various ways in which foul air from faulty drainage inside the house passes to different parts, windows and fires being the chief, the latter mainly acting by drawing the air through passages, staircases, and doors. But other channels must also be borne in mind; in one instance the passage of foul air was found to be along bell-wire tubes, the proximity of the bell pull to the fireplace giving an increased opportunity for air to be drawn from a distance to this part of the room. Channels for gas-pipes and for hot-water pipes also not uncommonly give facility for the admission of

Foul air.—Another remarkable instance in connection with this subject was a particular bed in a school, the occupants of which were constantly the subjects of slight attacks of pneumonia with tendency to typhoid. In this case the foul air was conducted from a lavatory, where there was defective drainage up a staircase, and, impinging on the ceiling of the dormitory, was reflected on the bed where the sickness occurred. In the recent illness of the Duchess of Connaught defective drainage was found in the basement of the house, and after numerous experiments the means by which the foul air entered the Duchess's bedroom was discovered. These showed that it was only

when occupying certain positions in the room that she would be exposed to the influence of the foul air, while in bed she would escape. In twenty-four hours after sitting on a sofa in one of these exposed positions her Royal Highness's symptoms fully developed themselves. T. C. W.

TREES AND SHRUBS.

CONSERVATION OF OLD AND REMARKABLE TREES.

IN considering the question of the conservation of large trees, the subject naturally divides itself into two heads, each of which in its mode of treatment is entirely distinct from the other. First, conservation may be directed towards the maintenance and development of trees in progressive vigour—two old large timber trees still enjoying health, and whose grateful shade, or graceful outline, in sweeping arms, it may be desirable to foster for amenity or picturesque effect in the landscape or park. Or, again, second, it may be requisite that steps be taken for the conservation of some old gnarled bare trunk, whose hollow stem and blasted head bear witness to the flight of many centuries, and around whose venerable form cluster memories and associations of historical or family interest or traditional lore, which it is well to keep alive in the minds of a countryside by the preservation of the trees themselves, whose very names refer to the events their presence commemorates. The steps to be recommended for the conservation of old trees, under either of the foregoing heads, are naturally much alike, and simply embrace measures of a remedial character, taking in both instances due cognisance of the elementary principles of vegetable life in the tree. If trees were, in the early stages of their growth, to receive that care and attention which their importance demands, and which their ultimate value will show to have been necessary, there would be little need for the adoption, in later years, of measures to promote their progressive vigour and ultimate recovery from premature decay or decline. Early and fearless thinning, so that the young tree may find ample scope and free air for the development of its youthful form, is one essential requisite too often neglected, and the oversight of which is one of the most fruitful sources of early decline in old trees. In trees, as in the animal kingdom, the true secret of success in promoting a full physiological development, and maintaining a healthy frame, consists in prompt attention to early habits and appearances, and in checking in youth what might prove baneful to the constitution of the plant in later years. This may be called the prophetic or active treatment for the maintenance of progressive vigour in trees. The other treatment involves the arrestment of decay or decline in individuals already evincing symptoms more or less defined; and, while the measures to be adopted are based on the same principles of the growth of vegetable tissues, they can never be so satisfactory, nor so remedial, as the same steps would be if taken in the case of younger and more vigorous subjects. The method of treatment in regard to such trees may be styled the retrospective or passive. In attempting to

Conserve old timber trees, attention must be directed, in the case of large trees still vigorous, though evincing incipient signs of decay, to the prolongation of the growing period of the tree, and efforts must be directed to stimulating the formation of additional cell tissue, and thus keeping the health of the tree in a progressively vigorous condition. On the other hand, should the subject of treatment be in a declining state, whether from accidental or natural causes, efforts must be used to arrest the decline by stimulating the growth of young wood, branchlets, and leaves, so as to aid in the elaboration of sap throughout the head of the tree. The causes of what may be styled, for the want of a better epithet, "backwardness" in large or old trees, are frequently obscure and puzzling. It may arise from many sources, such as exposure to sudden extremes of temperature in spring, chilling the young foliage,

and stunting its development to such an extent as seriously to interfere with the leaf functions for the season. The penetration of the rootlets into an ungenial substratum or subsoil, inimical to the further progress of the tree, is another cause of backwardness in large trees, and this is one of the most difficult and fruitful sources of mischief with which the arborist has to contend. Defective root action, arising from bad drainage, or from a water-logged state of the young spongioles and rootlets, also frequently tends to incipient stagnation of wood formation and to a hide-bound, unhealthy appearance of bark, resulting shortly in a stag-headed condition of the upper branchlets. Recently transplanted trees of a large size are peculiarly prone to suffer from this last form of backwardness, through the interference with the rootlets in the process of removal and subsequent drought. One of the first symptoms of a check having been sustained in the continued progressive vigour of any tree is an appearance of scanty foliage during the summer months along the very top of the upper branches and at their extremities. If this is allowed to go on, in another season these outer and upper branches present a bare, dead appearance, appropriately called "stag-headedness," from the resemblance of these denuded branches to the antlers of a deer. Trees in exposed situations are most liable to suffer from this evil, especially if the subsoil be shallow and of a cold, damp nature. The remedy therefore lies in stimulating, by such artificial means as suggest themselves, according to soil and situation and nature of the tree, the action of its vegetative powers, and the formation of cellular tissue at such extremities of the branches as have become bare and dead-like. This will be found to be almost invariably attained by giving the tree, around its trunk and for a space outwards as far as the outer tiers of branches overshadow, a

Liberal mulching of fresh loam or soil of a friable nature. By such an application to the soil, increased energy is imparted to the more fibrous roots, which are always situated nearest the surface of the ground, and any lack of chemical food agents in which the site of the tree may be deficient, from long occupation and consequent exhaustion, will be supplied. The application of such fresh soil may be made at any season of the year. Autumn is probably the most advantageous period, and it may consist of road scrapings in a loose, well-turned-over, friable condition, mixed with lime, or applied alone, or of old well decomposed leaf-mould mixed with peat soil; the scourgings of ponds or ditches, which have been allowed to dry, and been well turned over and aerated by the frequent use of fork or spade; or, indeed, of any good clean fresh earth of open texture. The surface of the ground about the tree should be lightly forked over previous to its application. The depth to which this compost or top-dressing should be laid depends upon the situation of the tree to be operated upon, but it should be deposited round the trunk to a depth of not less than 2 feet (in some cases, when the trunk is exposed at the neck, to a depth of 3 feet or 4 feet), and be gradually tapered off, so as not to offend the eye, from the stem outwards to a final depth, at the extremity of the circumference of the branches, of 1 foot of fresh soil. In the following season all the dead branchlets in the head of the tree should be cut back to where young wood will have formed, and it is a considerable assistance to the formation of young wood to thin out the head of the tree carefully, by cutting off several of the side shoots springing from the main branches, thus admitting light and air, and promoting a condition favourable to the development of young wood and foliage. In some cases Ash trees, from 60 feet to 70 feet in height, and growing in strong loam with a clayey subsoil, thus treated after they had shown evident signs of incipient decline, have been known to recover their former vigour. Horse Chestnut and Lime trees, in the same situation, and from 200 to 250 years of age, have been also successfully treated by the same process after having been allowed to remain "stag-headed" for fully three years. Hollies injured in the memorable winter of 1860-61, and

from 20 feet to 30 feet in height, after presenting an almost dead appearance, were treated in this manner, and the dead branches cut back to the very stem, in some instances leaving almost nothing but the quasi-dead trunk above, and are now fully furnished with dense masses of foliage of the most healthy hue of glossy brightness; and although now lacking the large wide-spread arms, they have been by this treatment saved, and their height, as tall evergreens, secured, where absence would have created an unsightly blank.

The growth of young wood under this treatment is sometimes so thick that it is necessary, after the first season, to thin it out, removing superfluous shoots, and singling out leading twigs into which the force of the resuscitated action may be directed for the formation and development of new cellular tissue. It may sometimes be necessary, where the natural soil in which the tree is placed is inimical to its habits and nature, to use as a compost or top-dressing a mixture of earths of various kinds, and the reverse in their chemical composition, of the soil in which the tree has begun to wane. In cold, clay, damp, or wet tilly soils, for example, in which few hard-woods will thrive for any long time or acquire large dimensions, it will be found advantageous to use a mixture of coal ashes or wood ashes (the cinders having been removed) compounded with road scrapings (silicious) or well-decayed peat in the proportion of one part of coal ash to three of road scrapings, or mould of peat or decayed leaves. A compost of this description need not be laid on thicker than about 1 foot at the tree neck, gradually tapering off to about 4 inches thick at the outer circumference of the circle. It should be applied in autumn and during the fall of the leaf, and carefully stirred into the soil in which the tree is growing. The use of ash-pit refuse from dwelling-houses from which all cinders have been carefully removed is not so generally appreciated as it ought to be for the promotion of vigour and healthy foliage in trees. If administered to young specimens and dug into the soil in which they are intended to be placed its effects very soon become apparent in the increased root action and consequent improved health and appearance of the plants. In cases of large trees whose condition seems to be stationary, although not positively backward, it will be found beneficial to use

A top-dressing of rich loam mixed with leaf-mould or house coal ashes, in the proportion of one cartload of the latter to four or five of the former, and to lay the compost "barrow thick" upon the roots under the drip of the branches, without levelling the surface during the first winter. In this way the rains and snows of winter wash in the various chemical agents of which this compound is made up, and carry down to the roots fresh supplies of food along with the quantity of carbonic acid gas derived from the atmosphere; and in this way the powers of exhausted soil in which trees have been too thickly planted are renewed, and the dormant functions of Nature in the tree itself receive a revivifying impulse. The application of street sweepings as a medium for increasing and intensifying tree life was first suggested by the appearance of several Beech trees of large dimensions standing in rows in the centre of a field which, after long remaining in pasture, had been broken up for cropping. During the earlier years of the rotation no difference in the progress or appearance of the Beeches was apparent. They had previously exhibited symptoms of decay and stationary existence for many years; but one season, after an unusually liberal application to the soil of rich, well-turned manure for a Turnip crop, the Beech trees suddenly appeared to have taken a new start—a fresh lease of life, as it were,—and their unusually strong growths of young wood quite apparent, while the colour of their leaves lost that sickly hue which had for years distinguished them.

Manure for Conifers.—To younger specimens, and chiefly to some of the more recently introduced Coniferæ and evergreens, the application of liquid manure has long been known, and its use has been in many instances of much

benefit. It requires, of course, to be presented in a highly diluted form, and either in the autumn or winter months after rain, and while the ground is well saturated with moisture. It is of considerable benefit to the progress of *Araucaria imbricata* and to many of the *Cupressus* and *Juniperus* families, but it requires careful use in the case of those Pines (*Abies* or *Piceas*) which are of themselves prone to throw out early buds in spring, for any undue stimulant of growth during the cold, frosty winds of March or April must be attended with corresponding failure and disappointment. In using liquid manure, therefore, in such cases it is better to apply it, well diluted, in May than at an earlier or later period of the year. To stimulate such species either into too early vigorous growth in spring or to prolong their active vitality into late autumn, and thereby retard the proper ripening of their young wood is alike a mistake, and necessary to be guarded against. When in any particular instance it is deemed proper to administer diluted liquid manure to cure stagnant energy in tree life it must be applied very slowly and gradually, for the principal object in the application of any manure is to supply as much soluble matter as possible to the roots for their absorption into the system of the plant or tree, and if it be administered slowly and gradually it must necessarily be more thoroughly assimilated in the gradual formation of sap and the various tissues. A mulching of short cut grass has sometimes been found beneficial for top-dressing the soil around and over the roots of choice or rare specimen trees and shrubs, and it has often proved of much advantage to the *Araucaria*, *Deodar*, and others in many places acting not only as a manure, but also as a preventive against evaporation, and as an important agent for retaining moisture in the soil. Such an application plays a double part, and is worthy of more general adoption than at present is accorded to it. If the covering be neatly laid on, and closely and evenly spread, there is nothing unsightly in this mulching, and it is of very great advantage in many other ways. Another fertile source of incipient decline, and a means of accelerating decay and death in old trees, is the practice of leaving dead wood, and allowing Nature to rid herself, by the intervention of wind or storm, of many a useless dead bare limb or branch which should have been skilfully removed when death became apparent. The rugged wound which a gale of wind causes in wrenching off dead branches from the heavy limbs of a tree is the source of much ultimate evil. Weather works down into the scar so created, and the dry woody tissues of the stump aid the further spread of decay. Old timber trees should, as regularly as young plantations, be gone over carefully every year, and have all dead or dying big branches and twigs sawn over, the wounds being at the time covered with a good coating of strong oil paint. This leads us to consider

The other process of conservation of large trees, referred to in the early part of this paper, viz., to the cases of those in which all progressive vigour is beyond recall, but whose picturesque and gnarled trunks or hollow stems, from historical associations or traditional legends attaching to them, it may be desirable to use every possible means to preserve. The appliances in such cases are mainly mechanical. Painting the shattered wound caused by the livid thunderbolt, so as to exclude the destructive ravages of the wind and rain; roofing over with zinc or lead the hollow decaying stem of some historical memorial; girding with iron hoop or rod to its parent stem some giant limb, whose swaying from the hurricane has well-nigh wrenched from the old trunk, are remedies too well known and generally practised to call for further notice.—*Scottish Arboricultural Society's Transactions.*

Variegated Oak tree.—Like the Fulham, Lucombe, and other hybrid Oaks, grafting is the only sure mode of increasing this variegated form, for although in most cases acorns are produced abundantly, the seedlings are found to sport or vary so much that they cannot be relied upon.

Grafts take freely upon healthy stocks of the common Oak. The scions should be taken from the tree before or about the time the sap commences to rise in spring, and inserted in moist earth or sand in a shady position. The stock will be all the better if cut over about the same time. Judging from the description given by "E. B." of his variegated Oak, it is certainly uncommon and well worth the trouble of perpetuating.—A. D. WEBSTER, *Penrhyn Castle, North Wales.*

Propagating Mistletoe.—The best method is first to take the skin and part of the viscous matter away from the seed, then to place the latter on the ball of the thumb, lay it on the smooth bark, and gently move the thumb backwards and forwards until it is felt that the seed is firmly fixed in its place. Nothing more is required except protection from birds, &c. I have grown bushes 2 feet in diameter on Apple trees in the course of fifteen years. Though ornamental, it is not desirable to have Mistletoe in an orchard, as when once established it is difficult to eradicate it. I have an old Apple tree on which it was placed some twenty-six years ago, and though cut off at different times, the tree still continues to produce young plants in an apparently spontaneous manner.—J. G. N.

Spiræa flagelliformis.—I have admired the fine illustration of this *Spiræa*, given in THE GARDEN (p. 81), and have perused with much pleasure the account of the shrub which accompanied it. On looking at the illustration it occurred to me that I had seen a shrub somewhere which very much resembled it, and on referring to my notes, I find that on the 25th of June, 1879, I attended a meeting of the Berwickshire Naturalists' Club, held at Kelso and Morebattle, and in the course of our day's rambles we visited Marfield, in the parish of Eckford, Roxburghshire, formerly the residence of Sir William Bennet, of Grubbert, the well-known patron of Allan Ramsay, and of whose hospitable mansion, Thomson, the author of "The Seasons," is said to have frequently been an inmate. The public road passes near Marfield House, and in the hedge along the west side of the road we found growing a number of flowering shrubs, which were said to have been planted by Sir William Bennet, and which seemed to have become naturalised. Amongst these there was one which particularly attracted our attention. This was a profuse flowering slender-stalked shrubby *Spiræa*, the small branches of which were wreathed with beautiful white flowers like the illustration. Mr. James Hardy, of Oldcumbus, our secretary, in the report of the meetings of the Berwickshire Naturalists' Club for 1879, mentions that the *Spiræa* which we found at Marfield "has obovate wedge-shaped leaves, which have an apiculus, and are slightly puberulent, and the racemes of white blossoms, which are very delicate and graceful, are sessile. The twigs bend readily, as if adapted to form a garland, and of this the name "*Spiræa*" is said to be significant. The species appears to be *S. acutifolia*—*S. hypericifolia* var. *acutifolia* of De Candolle.—GEORGE MUIRHEAD, *Paxton, Berwickshire.*

Planting waste land in Ireland.—Mr. D. S. Scott, writing in the *Journal of Forestry*, says: "The most discouraging feature in planting is the expense of enclosing the ground. Certainly this incurs expense when the piece of ground is of elongated shape, with two parallel fences. To obviate this latter difficulty, the ground should be as broad as possible. A slight addition to the breadth forms a considerable acquisition to the area enclosed, and, of course, diminishes the expense. This is an important point to study when laying off a plantation. In this county (Tipperary) sod ditches are very common, and if Furze seed is sown on the top, this fence in two years will make excellent protection. The cost of erection ranges from 2s. 6d. to 6s. per pole of 21 feet. Draining comes next to fencing. Nothing excels open drains, 26 inches wide at the top and 18 inches deep, sloped on both sides to 9 inches wide at the bottom. Unless on cold, sour, wet

flats, catch water drains, slanting diagonally, are most economical, and usually effective. Estimate of cost, 2d. to 3d. per pole. For ground covered with stubby heath or waste land generally, I recommend two-year-old plants, notched in with the spade. Scotch Fir and Larch are the most profitable of all our timber trees. The hitherto promiscuous mixing of all sorts of trees in general planting ought to be abandoned, and a system more in accordance with practical arboricultural science adopted. The following table may be taken as an approximate estimate of the cost of planting:—

2000 Larch, one year seedling	£	s.	d.
2000 Scotch, two year do.	0	7	0
Carriage of plants per rail	0	12	0
Planting in home nursery	0	2	6
Weeding and cleaning	0	2	0
Removing at planting season	0	4	0
Three men and one boy	0	2	0
Draining 60 p. on average per acre ..	0	6	0
Fencing, 4s. 6d. per pole do.	1	0	0
Rent (many districts <i>nil</i>)	0	2	0
Rent of nursery	0	3	0
Rent of ground, 15 years	£1	10	0
Rates and taxes	0	5	0
	1	15	0
	£5	5	6
Allow for interest	2	14	6
	£8	0	0

As will be seen, nothing is allowed for replacing failures, but where such occur there is some mismanagement. I shall now leave owners of waste lands to judge for themselves what a plantation of Larch and Scotch Fir is worth at fifteen years' growth; also what it would be worth to the nation if the whole of the 4,253,400 acres of waste lands in Ireland were planted. The above estimate of cost refers to an acre. The cost, as will be seen, is, at fifteen years, £8. I can vouch for land not worth more than the keep of one snipe before being planted bringing a return of above 30s. per acre ground rent for fifty years after deducting all expenses.

QUESTIONS.

Tuberosees.—Can anyone give me full instructions how to treat these, which I have just procured? and which are best, African or Italian bulbs?—A. B.

Mertensia maritima, alias "the Oyster Plant."—Is this to be had at a reasonable price anywhere nearer than Zurich? and is it exclusively a maritime plant?—T. C. L.

Birds and Wellingtonias.—Its there any reason why birds should not build in the Wellingtonia? I have a fine specimen over 50 feet high and twenty-five years old, yet I never saw a bird's nest in it, though they build freely in other Conifers; nor do they seem to come to it much by day or roost in it at night. I should like to know whether this is the case elsewhere.—HENRY N. ELLACOMBE, *Bitton Vicarage*.

Freeing orchards from Lichen.—Is there any plan known of freeing orchard trees from Lichen without the expense and trouble of scraping the branches? Probably someone may have tried a decoction that has proved successful. If there is a liquid that could be thrown over the trees with the garden engine and would prove effectual it would be a great boon to many of us who suffer from the rapid growth of this troublesome parasite. Advice that would recommend me to cleanse the trees annually and to cultivate the ground under them (the orchard is in Grass and well drained) would be useless to me, as I am one of those who have a large place to manage and not enough labour at command to do all that is essential as regards good cultivation; therefore, some things do not get the attention and labour bestowed on them that they require and what they would have under more favourable conditions.—CONSTANT READER.

* * * Our readers will greatly oblige by replying, so far as their knowledge and observation permit, to these questions. The title of each query answered should be prefixed to each answer, and replies will be printed in the department of the paper under which the subject falls. The questions that arise and must be solved are so many in these days, that it is only by a general interchange of ideas and experiences among practical men that we can hope to answer them satisfactorily.

BOOKS.

RATIONAL BEE-KEEPING.*

DR. DZIERZON has long been known as the author of various articles and books relating to apiculture published in Germany, but hitherto none of his works have been translated into English, and therefore they have not been read by the majority of bee masters in this country. Thanks, however, to the translators, Messrs. H. Dick and S. Stutterd, and the editor, Mr. C. N. Abbott, the last work by Dr. Dzierzon has been published in English, in a small octavo form, well printed, and illustrated with woodcuts wherever necessary; these woodcuts are very coarse, but they serve the purpose for which they are intended. "Rational Bee-keeping" expresses fully the views of those who manage their bees according to the German system, and anyone who is interested in the welfare of bees has now a good opportunity of learning how apiculturists manage their favourites in Germany, and we feel certain that all who read this book will derive both pleasure and instruction from it, and that it will be much appreciated by those for whom it is written. In this work is given in the fullest manner every detail of how each operation that has to be carried out is effected, and the reason why it should be performed. If, however, all the author's instructions and suggestions are followed, anyone possessing many hives will find their time during the greater part of the year quite occupied. Some one hundred pages are devoted to descriptions of the various hives in use in Germany, and to directions for making them before discussing the merits of the different hives. The author says at page 41: The spot where the hives are placed, and which is generally in the garden attached to the house, is called

A bee garden, bee stand (apiary), or bee house, the latter name being given to it if the hives are placed in a separate building, which, however, is not necessary or desirable. He then mentions various reasons why hives are better placed apart; yet at page 124 he recommends what he terms a pavilion, which may contain as many as sixteen hives, and is formed by placing four piles of rectangular hives in such a manner that their backs form the sides of a hollow square (so that if one faces north the others will face south-east and west respectively), and then roofing and casing the whole. Why this has not the disadvantages of the other apiaries already condemned we cannot discover. After describing the various forms of hives, some of which are very different from those generally used in this country, different methods of bee culture are discussed, and the various operations connected therewith fully described. Whether bees communicate with one another by sounds or not is not at present clearly proved, but it seems most probable at any rate that they cannot hear sounds which are audible to us. Sir John Lubbock, who has made many experiments to solve this question, says, "I have never succeeded in satisfying myself that my ants, bees, or wasps heard any of the sounds with which I tried them. I have over and over again tested them with the loudest and shrillest noises I could make, using a penny pipe, dog whistle, and violin, as well as the most piercing noises I could produce with my voice, but all without effect." Linnæus and Bonnet were of the opinion that bees could not hear, and Huber thought that if bees possessed the sense of hearing it differed from the same sense among the higher animals. But Dr. Dzierzon is very positive on this point. Speaking of the meeting of the queens and drones, he says: "It is certainly the sound which both emit in their flight and which may be even distinguished by the human ear, whereby they communicate with one another, and by which they are attracted." We wish the author had given some proofs of the correctness of this statement. He also mentions the well-known distinct notes of the queen as expressive of jealousy and

anxiety; and, again, speaking of a queenless stock, that, "when smoked, or even without this provocation, the bees raise a continuous wail, a genuine cry of distress, that can be heard at some distance from the hive." How can the author know what meaning the bees attach to these sounds? when the bees are smoked, why should not the sounds if more than mechanical and unintentional on the bees' part mean anger or pleasure? A chapter is devoted to

The diseases of bees, in speaking of foul brood and the great difficulty of eradicating it from hives when once infected is alluded to, and leaving the hives empty in the fresh air for two years is mentioned as the only certain method of preventing the re-appearance of the disease. This plan, surely, as Mr. Abbott points out, is very likely to contaminate other hives, unless all bees are denied access to the infected hives. The author states that even boiling the hive is of no use. This must be a mistake, for we believe that all organisms are killed by the heat of boiling water. Following a chapter describing the various implements used in apiculture is a bee calendar, from which it is easy to find out in what months certain operations should be performed. A very full index concludes the volume. Mr. Abbott's notes will be found very useful, explaining what might otherwise be misunderstood, and pointing out where the German practice differs from the English. G. S. S.

* "Dzierzon's Rational Bee-keeping." Edited and revised by Charles Nash Abbott, editor of the "British Bee Journal." Houlston and Sons, Paternoster Row, London.

NOTES OF THE WEEK.

THE APPLE CROP must have been poor in America, for very little is coming now to Covent Garden from that country. A good many Apples have lately come from Bordeaux.

STREET TREES IN CARLISLE.—The trees presented to this city by Messrs. Little & Ballantyne, Knowfield Nurseries, are now being planted in Warwick Road. Sycamores and black Italian Poplars are being planted alternately along both sides of the road at distances of eleven yards apart; and at corners of streets Limes will be planted. Messrs. Little & Ballantyne have also presented trees to be planted in Earl Street.

"THE MINISTER'S GARDEN."—"A. C." writes thus to the *Times*: "It may interest some to know that the original studies for Mr. Cecil Lawson's great picture of 'The Minister's Garden' were taken from the curate's cottage at Sandhurst, in Berkshire. The foreground of the picture represents the cottage garden; in the middle distance, below the spectator, lies the village of Sandhurst, indicated, however (if I rightly remember), by a single cottage roof; and beyond the landscape extends over the Blackwater Valley to Aldershot Camp and Farnham."

STREPTOSOLEN JAMESONI.—M. Lemoine, of Nancy, sends us a coloured plate of this new plant which he intends to put in commerce during the ensuing spring. The illustration shows a branched stem about 8 inches high, each twig being terminated by a dense cluster of blossoms. These resemble those of a *Browallia*, being about 1 inch long, tubular, with an expanding corolla. The tube is represented as bright yellow, while the limb is a rich red. This variety of colouring and the profusion in which the flowers are borne render it a showy and welcome greenhouse plant.

SOUTHAMPTON HORTICULTURAL SOCIETY.—The annual report just issued by this society shows it to be in a flourishing condition. The proposal to establish horticultural gardens having collapsed, the committee, feeling that the existence of the society depends upon some place being secured for the society's shows, have entered into a provisional agreement to rent 10 acres of Westwood Park for the purpose on a lease for fourteen years. It is proposed, in addition to holding the shows on this ground, to make provision for lawn tennis, athletic clubs, football, cricket, &c. The site possesses great advantage as to position, and is one of considerable beauty, being well wooded. It is also proposed, as far as the means placed at the committee's disposal will allow, to add to the ornamental appearance of the park.

THE ARNOLD ARBORETUM.—Mr. C. S. Sargent, the director of this arboretum, which is attached to the Harvard University, Cambridge, Mass., has issued his annual report concerning it. From this we learn that arrangements are in progress to open the arboretum as a public park under certain restrictions. This, the director states, will not interfere with the scientific aims of the arboretum. Pending this arrangement all permanent planting is in abeyance. The report further says that—"Various experiments in book-keeping have been tried from time to time, with the view of preserving an accurate record of every plant in the collection; they have not, however, hitherto been satisfactory, and have been abandoned, as either too complicated or too expensive for practical working. The future value of the arboretum would, however, be greatly increased if the history of each tree could be preserved as a record of the hardiness and rate of growth of the species or of different individuals of the same species raised under different conditions or descended from ancestors long subjected to different climatic conditions. An attempt, which promises to be successful, to preserve such records by means of a card catalogue similar to that now in general use in public libraries has been made during the year, and a complete catalogue of the collection has been prepared. A numbered card represents each species in the col-

lection; and a card with the same number with an additional sub-number represents each distinct lot of plants of the species raised at different times or obtained in a different manner from the lot represented by the first card. The card contains the name of the species, the source from which the plant is derived, and, if raised in the arboretum, the date at which the seed was sown, space being left for correcting the name when necessary, and for future records, such as the date of final planting, or any notes upon the rate of growth, hardiness, &c., of the species, which may seem desirable. This plan offers many advantages, and it is hoped that it will bear the test of continuous use. The collection is now represented by some 2250 cards."

EPHING FOREST.—At a meeting of the Essex Field Club, held on January 27, the following resolution, condemning the proposed extension of the Great Eastern Railway from Chingford to High Beach, was passed: "That this society, on behalf of the large section of the population of London interested in the pursuit of natural history, desires to record an emphatic protest against the proposal of the Great Eastern Railway Company to carry a line across a part of Epping Forest, believing that it is wholly unnecessary for the railway to take the route projected, and that it would not fail to prejudicially affect the advantages secured by the Epping Forest Act, which directs that the forest is to be preserved as far as possible in its natural aspect, and the society hereby authorises the council to petition Parliament against the project."

FLOWERS BY POST.—A correspondent writes: "Having frequently observed paragraphs in THE GARDEN respecting the difficulty of sending flower safely by post, I am sure I ought no longer to keep to myself the knowledge and use of Mr. Salter's (of Hemel Hempstead) excellent wicker baskets for this purpose. They are about 10 inches or 12 inches long, and 4 inches high or wide. In June, 1881, I received nine of these baskets in excellent order, five of which were given away and four have done duty ever since, constantly to and fro to Dublin, filled with choice flowers of all kinds, and once I sent Grapes in the same way. When filled with Grapes the postage was 4½d.; with flowers almost always 3½d. The baskets get a little crushed in returning, but still they are useable, and with a damp, small-sized old pocket-handkerchief to protect the flowers, they go as fresh as possible and last for days."

PLANT LABELS.—An extensive assortment of these reaches us from Mr. H. Bradley's Saw Mills, Southwell. They are made of various kinds of wood and are of different shapes and sizes, from the ordinary flat peg to the elaborated mounted tablets for trees. Most of the superior kinds are made of Pear wood, which has been found to be the best of all ordinary woods for this purpose, and Beech the next best. Boxwood, though good, is difficult to manipulate and liable to become discoloured unless well varnished. The collection includes some neat little tablets of Pear wood steeped in oil for suspending to Rose bushes, the name being stamped deeply in the wood. The same form is made also in Beech, Lancelwood, Apple wood, Ash, Box, steamed Beech, and Maple, all of which have the appearance of being very durable. Oak and Spanish Chestnut have been found good enough for all ordinary purposes. For printed labels, for pots, and borders, when anything extremely durable is required, Yew, Acacia, and several foreign durable woods are used. A capital flat peg label is made out of Quebec Pine, covered with two coats of paint. The best white Pine well painted also makes a good label, said to last from five years to seven years. Pitch Pine is not recommended for being painted to be written upon. The wood is too hard to absorb sufficient of any composition to render the writing legible and durable. White Willow makes a good peg label, and is written upon with ease. Oak pegs steeped in oil make a capital label for Orchids and other plants in hot moist stoves. The larger labels are T shaped, the standards being made of Oak, Yew, Acacia, and other durable woods, as well as galvanised iron, while the tablets

are made of the hard woods, such as Pear, Apple, and Box. It will thus be seen that Mr. Bradley has tested every available kind of wood thought to be suitable for plant labels, and that he has succeeded in proving by the many who have adopted his labels, which have been in existence for the last thirty years.

NEW CLEMATISES.—M. Lemoine sends us a coloured plate of three new varieties of Clematis which he has raised in his nursery at Nancy. They all have affinity with *C. Viticella*, and are named as varieties of that species. No. 1, *kermesina*, has blooms measuring 2½ inches across, with four broad sepals of a rich carmine-crimson, a colour we have never seen in a Clematis. No. 2, *venosa violacea*, is about a third larger than the preceding. The six sepals, about 1½ inches long, are violet, with three longitudinal bars of deep purple; the whole surface is netted with deep hues, and the margins are much deeper than the other parts. No. 3, *grandiflora*, has flowers over 4 inches across, with six broad sepals of a deep mauve-purple barred and netted with a deeper hue. These fine varieties will be sent out by M. Lemoine in spring.

Lawn weeds.—There can be no doubt that the Daisy killer is a powerful agent in the destruction of Daisies. But it must be remembered that besides the plants operated on seeds shed by them are continually coming up; therefore anyone who has once allowed weeds to get ahead must be prepared for a little trouble in getting rid of them, whether he adopts the plan of burying the turf or burning it, or of making one or two applications of the Daisy and weed destroyer.—JAMES CARTER & Co.

Dipping mixture for green-fly.—In cultivating Cinerarias, Calceolarias, Pelargoniums, and hosts of other things subject to green-fly, constant care has to be exercised in order to keep that pest off if possible, sometimes not an easy matter, especially in winter, when fire-heat has to be so often used to battle with frost and damp. Fumigating is a good preventive, but when once settled under the large leaves of Cinerarias or Calceolarias, the enemy is difficult to dislodge, and fumigating has to be repeated week after week until the Tobacco paper bill becomes really more than the worth of the plants, leaving the labour required in attending to them out of the question. The most effective and cheapest way I know of in regard to dealing with aphides is dipping the plants in a solution of hot water with which is mixed a little soft soap and Tobacco juice. This not only kills them altogether, but leaves the foliage distasteful to them afterwards. With a good tub and two men—one to hold the plant and see that it is put carefully in the water, and another to hold the pot—it is wonderful how quick a few hundred plants can be dipped. Plants that cannot be operated on in this way may be syringed with the mixture with equally good results.—A. MACKIE, Woodlands, Darlington.

Single Dahlias (A.).—Try Messrs. Camell, Swanley, Kent, or Mr. Ware, Tottenham.

Names of plants.—*Nemo*.—*Cœlogyne cristata*.—*Ferns*.—1, *Asplenium marinum imbricatum*; 2, *A. marinum*; 3, *Polystichum lentum*.—*G. S.*—*Allium neapolitanum*.—*W. H. W.*—1, *Sempervivum* (species); 2, *Veronica elliptica*; 3, apparently a *Euonymus*; send better specimens; also of No. 4, which is a *Gasteria*.—*J. M.*—*Senecio Ghiesbreghtii*.—*O. R.*—*Cœlogyne cristata*.—*A. T. H.*—*Rhododendron davuricum*.—*O. R.*—*Cœlogyne cristata*.—*A. J. H.*—*Rhododendron davuricum*.—*Beta*.—*Sparmannia africana*.—*O. V.*—*Eupatorium riparium*.—*L. B.*—Send better specimens later in the season.—*J. C. K.*—1, *Santolina incana*; 2, *Cotoneaster Simonsi*.—*A. Widdowson*.—*Gasteria verrucosa*.—*E. A. V.*—Species of *Iberis*.—*A. S. Little*.—The large bulb is a kind of *Narcissus*.

"This is an Art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FRUIT GARDEN.

PEACHES AND NECTARINES.

THESE are rightly becoming more popular, proprietors of comparatively small gardens especially becoming alive to the fact that these delicious fruits can be both easily and profitably grown. It is a general complaint that mid-season Grapes have of late years greatly decreased in value, and that those who have been in the habit of selling their superfluous bunches find a material falling off in the income thus derived. On the other hand, Peaches and Nectarines, whether they ripen early, mid-season, or late, still realise remunerative prices—at least such is my experience, and that, too, in a provincial town; a few trees may, therefore, well replace some of the Grape Vines where these are grown to excess. It will be found they may be grown with or without fire heat, in any shape and in almost any form of house. They will succeed trained to the back walls of lean-to and half-span houses, while more may be trained to semi-circular trellises in the front of the house; or a trellis may be dispensed with and the trees grown as standards or bush-shaped. They will thrive admirably and ripen fruit in abundance when trained to trellises fixed at right angles with the front or across the house, and are equally satisfactory grown under widely planted Grape Vines; in fact, I should say, and I do not speak without experience, that the most profitable fruit house would be a combination of vinery and Peach house. At the same time too much must not be expected of them, and a little judgment should be exercised when planting. I was recently consulted as to what was the matter with some Peach and Nectarine trees on the back wall of a vinery, and I had to insist upon the necessity of growing fewer Vines, or the growth of the Peaches could not possibly ripen. Strong rods furnished with spurs about 6 inches apart and disposed 3 feet asunder are too close even for Grapes alone, but by thinning out the rods and the spurs so as to bring the former about 5 feet apart the weight of Grapes grown need not be greatly diminished, while the quality would be much improved, and a good crop of Peaches and Nectarines might thus be easily secured.

Planting Peaches and Nectarines in houses at present, unless exclusively devoted to them, is not advisable, especially if the trees have to be purchased. We usually plant the young trees when first received against an open south wall, and encourage them by mulching, syringing, and watering, as required, to form handsome trees well furnished with bearing wood. They are transplanted into the houses in autumn when in full leaf. At this time root action is most vigorous, and moving, when carefully performed, only interrupts this for a time. Our trees are thus well established before the fall of the leaf, while the growth ripens thoroughly under glass. Young trees brought in from the open walls last autumn are now in full bloom, and we shall crop them rather heavily, or they will grow more luxuriantly than is required. If I wished to rapidly cover a wall or trellis in a heated house I should unhesitatingly lay in the requisite amount of lateral growth which the strong early shoots inevitably develop, as these would ripen and fruit freely the following season. Houses have been filled in an extraordinarily short time by simply avoiding the use of the knife.

Artificial fertilisation, in the case of early and second early Peaches and Nectarines, I have always thought advisable, and since the introduction of the new and very early large-flowered varieties, such as Early Beatrice,

Hale's Early, and Early Alexander Peaches, and Lord Napier and Pine-apple Nectarines it has become absolutely necessary. Botanists rightly inform us that the more showy the bloom the greater the certainty of indifferent fructification, and that is really the case with regard to large-flowering Peaches and Nectarines which under glass must be artificially assisted, and where at this time of year is assistance to come from if not from those to whose care the trees are entrusted? Such good old varieties as Royal George, Violette Hâtive, and Bellegarde Peaches and Elruge, Balgown, and Downton Nectarines, with their closely-packed and pollen-laden stamens, might be set by means of the air circulated by the heated pipes or a breath of wind, and probably a smart tap of the branches is oftentimes sufficient to secure a set; but the case is different where the stamens are widely apart, as in the large-flowered kinds. Even, however, with the free setters we ought always to feel assured of a good even set, and if the result is great quantities of small fruit to remove, that is better than an insufficiency or perhaps a sufficiency disposed in inconvenient positions. A worse season than this for setting early Peaches and Nectarines we could not have, yet I find we have abundance of fruit swelling on all the above-mentioned large-flowering varieties. This was effected by simply passing a rabbit's tail, tied to a stick, lightly over all the fully expanded blossoms about the middle of each day. By fully expanded blossoms I mean those with anthers covered with golden pollen, and this, being in a dry state, is easily passed on to the moist stigma of the pistil. Varieties deficient in pollen are fertilised with that of those abundantly laden, and by these means a generally good set is secured. I am aware that the use of the rabbit's tail is not original, but of the many methods which I have tried, including the introduction of a hive of bees, it proves the simplest, and on the whole the most satisfactory way of doing what is desired. A camel's-hair brush was at one time preferred for the purpose, but though sure in effect, it is slow in operation. As a rule we only fertilise those flowers that are placed in a position favourable for the production of large-sized highly-coloured fruit. All other flowers are rubbed off. I am an advocate of and practise

Disbudding early, and follow this up carefully in order to dispense with the knife as much as possible. To defer disbudding till the fruits are as large as Peas I consider altogether a mistake. Peaches and Nectarines break freely throughout any length of young growth, and by disbudding early, leaving those buds only where we require a shoot to lay in for fruiting next season, and those where a fruit is to swell we naturally insure for ourselves a good start. The latter I term "fruit swellers," and they are stopped early, leaving about six good leaves. When disbudding, should the fruiting wood be weakly, with probably a wood bud at each extremity, the growth from the latter is allowed to extend for a short time, when it is stopped at about the fourth joint, and this is sufficient to swell the fruit, while the stopping strengthens the otherwise weakly shoot starting from the base. In the case of medium-sized and well ripened growth, this being shortened to about 12 inches and at a triple bud, the leading shoot is allowed to extend, while another is preserved at the base and eventually laid in. Long, well ripened shoots we frequently lay in to a length of 30 inches, and these are disbudded so as to have three branches to lay in—one at each end and one in the middle. It will be seen we do not lay in much growth—in fact, crowding is avoided—nothing, to say the least, being gained by it. Most of our young growth is laid in on the upper side of the main branches, thus much simplifying the training, but occasionally it is advisable to depart from this rule rather than have a blank. Hard and fast rules, as regards training, are not now-a-days so strictly observed as they used to be. What little pruning we find necessary is completed in the autumn, and before the foliage is off.

FRUIT GROWER.

SHELTER FOR FRUIT TREES.

MR. GROOM (p. 74) does well in calling attention to the importance of having plenty of shelter for fruit trees, as we seldom get a season without much cold frosty wind, which cuts off or destroys blossoms wholesale. This was seen everywhere last year after the storm of April the 29th. The trees, however, recovered in a marvellous manner, and at this moment are looking perhaps all the better for being relieved of their burden. Having nothing to carry, they were able to repair the mischief done, and now they are crowded with flower-buds. Although it is too late to plant Apples and Pears at this season, it is not too late to partly surround orchards with shelter trees; the best for the purpose are quick growing Firs, such as Spruce, Scotch, and Pinus Laricio, all of which are very hardy, and run up in a few years to a height that will keep off the wind and make many degrees' difference in the warmth of the air over the land they partly surround. The belt or plantation should face the north, east, and west, but should be well away from the fruit trees, so as not to overshadow or rob the ground. Evergreen Oaks, where they succeed, are capital shelter plants, and come in admirably for inner lines, as they are dense and clothe well down to the ground, and break up and smother a storm. The secret at starting is to break up the soil well where the trees are to go, and to plant thickly, as then they act as nurses to each other, and as soon as they begin to crowd it is an easy matter to cut out and thin, when the stems will come in for posts or rails and pay well for the growing. Before planting it is as well to get the March winds over, as sometimes they are very searching and exceedingly trying to fresh moved Firs, out of which drying blasts take the sap, and leave them to wither and die. April showers keep them plump and fresh, and under their influence they start quickly, and soon get fresh hold of the ground, when if this suits them they make vigorous shoots, varying from 2 feet to 3 feet in length. S. D.

Fruits in season.—The table given last week under this heading is an example of a worse than useless kind of table which would be clever people are apt to indulge in. It tells in a round-about way, troublesome to both teller and learner, what could be told more simply in words, such as "Brazil Nuts, May to December." It is, moreover, inexact in several of its items.—J. H.

Pear tree in bloom.—As an instance of the mildness of the season I may mention that a pyramid Pear (Fondante d'Automne) which I moved in 1881 had some flowers all but out early in December. There are now three or four flowers out on it, and the tree will be well in flower in a few days should this weather continue. Also another rather singular thing—a Laburnum, which I moved at the same time, and which almost died, broke out into leaf at the middle or end of October, and has retained such foliage as it made up to the present.—E. H. EYLES, *Enfield.*

Fruit prospects and retarding the flowers.—Notwithstanding the gale of the 29th of April, 1882, which swept with devastating force over the whole of the country and stripped many trees of most of their leaves, the promise of fruit this year is nevertheless great, Apples, Pears, Plums, and Cherries being, wherever I have seen them, well set with bud. This augurs well for the forthcoming summer, but what is to be feared is that the plump fat buds, now so abundant, will get too forward, as they are fast swelling, and a continuance of the present mild weather, if accompanied by sunshine, will bring them more rapidly on. Unfortunately, there is not much help for this, although it has been stated that they may be retarded by a certain system of pruning, a fallacious statement, as may be proved by leaving half a tree unpruned, when it will be seen that the flowers on that part will be open quite as soon as those on the other. In a small way trees may be retarded by keeping the sun off them, which may be done by tying evergreen branches or mats to stakes placed on the south sides, where a screen

so formed by keeping the solar rays from the branches and ground may be made to lower the temperature. Although this shading cannot be carried out to any great extent with Pears and Apples, it may be made to render good service to trees on walls, especially Peaches and Nectarines, or Apricots, which are so quickly excited. With canvas blinds or anything of that kind in front, the fruit trees just named may be kept back a week or two.—S. D.

Josephine de Malines Pear.—I find by referring to memoranda that this really excellent Pear ripened with me for three years in the early part of December, once in January, and three times in November, but that was always after very warm dry Septembers. The tree is planted on the north side of a wall and trained over the coping on the south side. I had a tree of this variety on an east wall, but in cold, wet seasons the fruits were comparatively worthless; not so, however, on the south wall. There they always ripened, and being planted in a cold, wet north border, they never became mealy. There is no doubt that a tree of this Pear planted against a south wall will answer the purpose and pay much better than Peaches or Nectarines, or even Apricots.—E. SENDALL, *Thorpe Hamlet, Norwich.*

QUESTIONS

Begonia Froebeli.—Will someone kindly say when this Begonia should be potted to grow in a cold frame for exhibition about the end of August? what sized pot and what sort of soil should be used?—BEGINNER.

Enothera eximia.—Will any reader of THE GARDEN kindly tell me where I can obtain a plant of this Enothera? I lost mine some four years ago, and have not been able to meet with it since.—E. H. EYLES, *Enfield.*

Budding Roses.—Being desirous of budding some Briers this season with a special Rose, grown by a friend at a distance, I wish to know if buds posted to me for that purpose will "take" two days after removal from the trees, or whether the time taken between cutting and budding will prevent growth.—R.

Vegetables for exhibition.—Will some one kindly tell me when to sow the following to come in for exhibition about the end of August, viz., Peas, Broad Beans, French Beans, Cos and Cabbage Lettuces, Autumn Giant Cauliflower, and early Cabbage?—the two last named can be sown in a frame.—BEGINNER.

Woodlice.—Can any of the readers of THE GARDEN advise me as to the best plan of getting rid of woodlice in a Mushroom house? They have kept their ground in it for many years in spite of all endeavours to dislodge them, and they have now got so numerous that they devour almost the whole of the Mushrooms as soon as they appear.—C. F.

Perle des Jardins.—Will some of your readers who have grown this Rose kindly answer the following questions: 1. Have they ever known it to have an orange centre with a slight purplish tinge on the back of the outer petals? 2. My catalogue says that it is a deep canary yellow. Would open-air culture change it to the colour stated in question No. 1? 3. Would not a Rose of that description be *Perle de Lyon*?—DISPUTE.

Japanese plants.—A young Scotchman, a clever professor, is leaving Japan next autumn, and I have the chance of asking him to bring plants home. Can any of your correspondents tell me what deciduous trees (such as the Maples) and shrubs there are, natives of Japan and not yet common in English nurseries, which it would be worth while to ask my friend to bring home? Would the evergreen and deciduous Oaks live here? Fortune speaks of seeing fine Oaks of both kinds. I suppose Messrs. Veitch would know best what plants have been acclimatized and could be safely brought to England? Will they assist me? I live on loamy clay in Bucks, but the *Retinosporas* and *Acer polymorphum* do fairly well.—E. H.

* * Our readers will greatly oblige by replying so far as their knowledge and observation permit, to these questions. The title of each query answered should be prefixed to each answer, and replies will be printed in the department of the paper under which the subject falls. The questions that arise and must be solved are so many in these days, that it is only by a general interchange of ideas and experiences among practical men that we can hope to answer them satisfactorily.

GARDEN IN THE HOUSE.

CEPHALOTUS FOLLICULARIS AS A WINDOW PLANT.

AMONG the small gems of the vegetable kingdom few are more attractive or interesting than this little Australian Pitcher plant. If it cannot vie with many other plants during their flowering period, it at least has this advantage over them that its beauty never fades throughout the year. At this dull season it is just at its best; all the pitchers are fully developed and in their brightest stage of colouring. It is a plant seldom seen in private gardens, unless the proprietor has a more than usual knowledge of and admiration for singular rather than beautiful plants. My object, however, in writing thus concerning its merits is not to recommend it for greenhouse culture, but to the many who are on the look out for plants out of the ordinary type suitable for room decoration. Anyone possessing a sunny window may grow it as successfully as in the best appointed greenhouse; and as it requires to be always covered with a bell-glass, it is independent of gas fumes, dust, and other exhalations that make such havoc among plants generally used for that purpose. Those who are accustomed to grow Filmy Ferns will have no difficulty in growing this Pitcher plant; it requires to be kept very moist at the root at all seasons of the year, and the case or bell-glass in which it must be grown need never be opened except for the purpose of watering it. The soil most suitable to grow it in is a compost consisting of equal parts fibry peat and Sphagnum Moss, with the addition of a very little fibry loam and silver sand. The pot must be well drained to prevent the water from stagnating about the roots. When well established it will not require repotting oftener than every other year, and care must be taken never to give a larger shift than is really necessary; in transferring it from one pot to another the roots should never be mutilated. A good plant of it can be purchased for 5s., and those who succeed in growing it are sure to be pleased with it. J. R. G.

FOLIAGE FOR INDOOR DECORATION.

WE have been experimenting of late with different varieties of foliage for various kinds of indoor decoration, finding that Maiden-hair Fern is not in many cases so satisfactory as we could desire. In a cut state it fades quickly in rooms kept somewhat unusually warm by fire heat, likewise where a considerable quantity of gas is burnt, and a sharp draught is also detrimental to it. I am aware that hard growth increases its lasting properties, but this cannot always be obtained, surrounding circumstances not being favourable to such growth. The house in which it is grown may be either too warm or too moist to develop a lasting growth for cut purposes. Under such circumstances fronds of a deeper shade as regards colour and with larger pinnae would be obtained, but fronds of this description do not keep well. To produce fronds of good lasting quality, the plants should have an abundance of light during the spring, autumn, and winter months, with a fair amount of air, and a cool stove temperature. Growth made by plants in baskets we have found to last well when cut, a circumstance doubtless attributable to the large amount of air to which they are subjected. But to our subject. We have of late tried fronds of *Gleichenia flabellata* cut from a plant in luxuriant health and too large for the position it occupies. In a cut state this Fern has given us every satisfaction, lasting well for ten days at a time in most cases. The pleasing colour of its fronds, and their distinct growth and character, have given us quite a change of greenery. We have also tried *Gleichenia Mendelli*, but this did not give satisfaction, quickly drying up and looking as if it had been cut many days. This variety belongs to a section of the *Gleichenia* family, quite different from that to which the first named kind belongs. I have no doubt that *G. dichotoma* would keep well, this being nearer

to *G. flabellata*, both being members of the *Mertensia* group. Another useful Fern for cutting from at this time of the year is *Davallia Tyermani*, the deep green fronds of which keep good a long time. Having a tall stem of *Aralia Veitchii gracillima* which we eventually intended to cut hard down, it occurred to me that the foliage in a cut form might be useful. We have found it to last fresh an unusually long time, and when used in association with other foliage and appropriate flowers the result was very effective. The leaves of *A. elegantissima* would no doubt be as durable as those of this kind. Growths of *Pandanus graminifolius* have also done good service on several occasions. This Pandanus can be grown under the shade of other stove plants, and will prove useful for what is called furnishing. The plant, however, that has given us the greatest amount of satisfaction in a cut state for some time past is the newly introduced *Asparagus plumosus nanus*. If ever the Maiden-hair Fern has a rival, this, in my opinion, is the plant that will be it. For button-hole bouquets, for sprays for the hair or the dress, it is simply first-rate, keeping fresh out of water almost as well as in it. It is an accepted favourite here, and will be so in many places when better known. Our plant of it is growing away most freely under ordinary stove treatment. Some time back we cut some of the smallest growths, and new shoots have now, to our surprise, pushed again from the joint just below the cut, whilst young ones from the base are breaking away in quantity. I can with confidence recommend this useful addition to our ornamental foliaged plants; whosoever may take it in hand for decorative work will, I feel sure, be pleased with it. Other kinds, such as *A. tennis-sinus* and *A. virgatus* are likewise useful, but to my mind the palm must be given to *A. plumosus nanus*. JAMES HUDSON.

Gunnorsbury House, Acton.

BOUQUET OF EVERLASTING FLOWERS.

DURING winter when blossoms in a fresh state are scarce, dried flowers, or Everlastings as they are generally called, form a good substitute, and are very acceptable for room decoration. If they lack the brisk sweetness of newly gathered flowers they have the advantage of being permanent, and when tastefully arranged amongst Grasses and Fern fronds have a really pretty effect—better by far than tawdry imitation flowers of unnatural shape and colour now made so largely to take the place of fresh flowers. Our Continental neighbours seem to have a wider appreciation of dried flowers than we have, and, besides, they appear to have a better way as regards manipulating them, especially in Germany. Moreover, they do not confine themselves to Everlastings in the general sense of the term, but extend the drying process to plants which we never hear of being dried for ornament, a fact fully represented in the annexed illustration. Those shown in this case are mostly all mountain flowers. At the top is *Astrantia minor*, an umbelliferous plant with pinkish bracts. Below it is *Gnaphalium margaritaceum* in company with its ally the *Edelweiss* (*Leontopodium alpinum*), which, as every alpine tourist knows, dries capitally. The other flowers in the bouquet are the alpine *Eryngium*, of which the big flower in the centre is a good illustration. The Cornflower-like bloom appears to be *Centaurea montana*, and that immediately below it *Senecio Balbisianus*; while the lowest flower of all is a little mountain Milfoil (*Achillea*). To many these flowers would appear to be very unlikely subjects to select for Everlastings, but such indeed they are if carefully dried.

Garrya elliptica.—This is certainly one of the most ornamental as well as curious shrubs sent home by Douglas. When in bloom it presents a striking and beautiful appearance, with its delicate, pendulous catkins, many of which are from 8 inches to 12 inches in length. It is a capital wall plant, of easy culture, and readily increased by layers or cuttings.—A. D. WEBSTER.

BOUQUET OF EVERLASTING FLOWERS.

TREES AND SHRUBS.

TREES AND SHRUBS FOR TOWN GARDENS.

HAVING lately been desired to prepare a list of trees and wall shrubs suitable for a town garden, it has occurred to me to submit it to the readers of *THE GARDEN*, some of whom may throw further light on the matter and thus benefit myself and others. The garden, or rather small park, in question is in a mild locality near the sea. Although quite a variety of things is recommended in this list, the most reliance will be placed on Hollies, Aucubas, Ivies, and Yuccas, in bold beds and masses. Low Ivy edgings will also be employed near the grass verges with advantage. What is especially desired is the use of perfectly hardy, free-growing plants, which when once well planted will give but little further trouble as to keeping, and increase in effect year by year. To this end good bold beds and groups or masses of Yuccas, Ivies, Hollies, Aucubas, &c., are recommended rather than mixed beds or borders of shrubs of the usual kind, in which all things do not grow well alike, and the stronger eventually overcome the weaker. It is proposed to cover existing dead tree trunks each with some one distinct kind of green or golden Ivy. Bare walls are likewise to be covered with Ivies of various kinds—Cotoneasters, golden winter Jasmine, and Ampelopsis Veitchi, the more sunny and sheltered nooks being reserved for a Magnolia or two, Wistaria, Aristolochia Siphon, Clematis, Almonds, Cydonia japonica, Colletias, common Passion Flower, and other wall shrubs and plants.

Ephemeral floral effects, being most costly in all ways and least satisfying, are not desired. It is particularly recommended that the plants be selected from some bleak, cold northern nursery, as experience proves that those grown in warm, sheltered country places in the best of soil and climate rarely grow well, even if they exist, when brought into town gardens; reared in adverse circumstances, they acquire a robust constitution, which enables them to hold their own amid town smoke and dust.

In shrub culture one must ever bear in mind that by their permanently occupying the same spot for years the principle of crop rotation is suspended, so that manure is often needful, especially when the plant has to contend with smoke and dust. A good top-dressing of well-rotted manure and burnt rubbish—better still leaf-mould—is beneficial applied in autumn. This forms a substitute for Nature's own leaf-dressing in their native woods. During hot summer weather also all newly planted shrubs and trees are the better for a mulching of rotten manure or leaf-soil over their roots. This serves a double purpose; the rains wash down its manurial elements, and it mechanically acts as a wet blanket, thus preventing the evaporation of earth moisture.

Lime dressings (not magnesian) are beneficial to all newly dug ground, that is unplanted, especially in towns. It may be crushed and applied to bare ground fresh from the kiln and at once dug in. Apart from its direct manurial value it also aids in the liberation of organic matter, which lies crude and useless in old plots of uncultivated soil. Old mortar and lime rubbish mixed with calcined rubbish of all kinds and a small proportion of agricultural salt form a valuable manure, and easily prepared. A broadcast sprinkling of freshly burnt lime, applied at night or on wet evenings, is death to all slugs on which it falls. On plots occupied by shrubs or flowers the plan is to slake the lime, applying it when cool after pulverisation.

Shrubs for walls.—Ivy in variety.—There are about twenty good distinct varieties of Ivy of the green-leaved type invaluable for bare walls in town gardens. *Nedera algeriensis*, *H. palmata*, *H. cordata*, *H. pedata*, *H. canariensis*, *H. Helix aurea* (golden Ivy), *H. digitata*, *H. Rægnieriana*, *H. dentata*, *H. nepalensis*. The common Irish Ivy (*H. canariensis*) makes very nice low edgings on grass near walks, and is often so used with good

effect in the public gardens of Paris. After the common golden few variegated kinds are effective in towns. *Magnolia grandiflora* (Exmouth variety) is in sheltered places a noble wall shrub, even if so be that it does not bloom. The Exmouth variety, known by the under surface of its leaves, being densely covered with red tomentum, is the best. *Wistaria sinensis*.—Deciduous, but still a noble wall shrub effective from April until November. *Ampelopsis Veitchi* (Japan Creeper).—Deciduous; during summer and autumn one of the neatest and most effective of wall plants. A great advantage it possesses over the Virginian Creeper is that it requires no nailing, clinging lightly and flatly to the wall surface by its own tendrils. Good for bare walls and sunny gables. *A. hederacea* (Virginian Creeper) is good for walls in summer and autumn, when it becomes highly coloured. *Jasminum nudiflorum* (golden Japan, or Winter Jasmine), on walls near Ivies, or near the red-berried *Cotoneaster Simonsi*, produces its golden flowers through the winter months, one of the best and brightest of all winter blooming shrubs, and it does well in towns if well planted in good rich soil. *Cydonia japonica* (Japan Quince) on a sunny wall bears a profusion of scarlet flowers during winter and spring. It is nearly evergreen. *Colletia cruciata* and *C. ferox* are singular hardy wall shrubs worth trial. *Pyracantha japonica* (Fire Thorn).—This species and also its variety, *P. crenulata*, from the Himalayas, are red-berried evergreen shrubs, well suited for bare walls in town gardens. *Escallonia macrantha*.—Bright and cheerful in winter, dark glossy leaves, and clusters of red flowers. Although perfectly hardy in exposed places near the sea, it well deserves wall shelter in town. *Aristolochia Siphon*.—Large cordate leaves, effective foliage on a wall. *Cotoneaster microphylla* is a good wall shrub, evergreen, with white flowers and red berries. *Clematis Jackmani* (purple Clematis).—For sunny walls a good hardy free-blooming variety. Poultry netting of galvanised wire nailed to the wall affords a ready base on which to train and tie its growing shoots. *C. montana* is a white flowered species, blooming in spring.

Evergreen shrubs.—Hollies, green, gold, and silver variegated.—Of all town shrubs these are the hardiest and best, and by no means slow growing if manured with rotten leaf earth every year, as they soon exhaust the ground near their boles. *Aucuba japonica*, one of the most cheerful of all town shrubs in winter. Apart from the glossy foliage, if male plants be planted here and there among the common female kinds, their red berries are an additional attraction. *Euonymus japonicus*, *E. j. var. aureus*, *E. j. latifolius*.—All fresh glossy-leaved shrubs of dense habit. Of town shrubs they are of the best. *Garrya elliptica*, a grey-green shrub bearing catkins during the winter months, well worth trial in a sheltered position, or even the protection of a wall. *Portugal Laurel*, gloomy leafage. Common Holly, far more bright and effective. *Quercus Ilex* (Evergreen Oak).—Good for shelter belts or as isolated specimens. *Laurustinus*.—The best form is a shining-leaved variety, with pure white flowers. 30° of frost kills this. *Berberis fascicularis* hybrida. Good *Berberis* for walls in sheltered positions.

Yuccas.—Most distinct and effective in leafage and blossom. These plants make handsome clumps on the turf in sheltered positions, or as isolated specimens near angles or corners of grass plots. Perhaps they show best, however, massed together in large beds or groups in sheltered positions on grass. *Y. gloriosa* and *Y. recurva* are both noble large growing kinds. *Y. flaccida* is a dwarf, but extremely free blooming species. *Rhododendrons*, planted in peat and leaf mould, are effective, but they often require renewal in town gardens.

Deciduous shrubs, &c.—*Clematis Vitalba* (the common Traveller's Joy) may well be used for draping tree trunks, fences, railings, &c., and is a rampant grower. *Pyrus floribunda*, a free-flowering species, bearing rosy clusters of Apple blossoms in spring. *Crataegus Oxyacantha* var.

Paul's Crimmon (double red Thorn).—Both this and the common Hawthorn flower well in towns. *Almond*.—The white, blush, pink, and rosy varieties of the common Almond are perhaps the best and most satisfactory of all early blooming town trees. *Cherry*.—The double-blossomed Cherry is also well worth a place. *Lilac* (*Syringa vulgaris*).—A showy flowering bush in spring. Its bare and dark-coloured wintry aspect is a drawback. *Laburnum* (*Cytisus Laburnum*).—The Scotch variety is the best and flowers well in open town spaces. *Beech*.—The purple or copper-leaved varieties may well be planted, their young leaves contrasting well with the Laburnum when it is in bloom. *Forsythia suspensa* and *F. viridissima*.—Yellow flowered wall shrubs, deciduous. *Magnolia conspicua* and *M. Lenné*.—Two showy species, apt to suffer from late spring frosts, but very effective in mild seasons, and worth the shelter of a wall. *Sambucus niger* var. *aureus* (golden-leaved Elder).—Quick growing golden-leaved bush, producing bright effects during summer. Contrasts well with dark Hollies. *Buddleia globosa*.—A distinct and effective deciduous flowering shrub, sometimes called the Orange Bush from its golden ball-like flower-heads. *Willows*.—Some kinds do well, especially the silver-leaved; the golden shoots also of the golden Willow are most effective in winter sunshine, and there is a variety with crimson tinted shoots which is far more striking than the common Dogwood as a plant for winter colour effect. *Salisburia adiantifolia* (Ginkgo or Maiden-hair Tree); either as a standard tree on the turf or on a wall, this plant is most effective and distinct from anything else, leaves like those of a gigantic Maiden-hair Fern. A good specimen has existed for many years in the Chelsea Botanic Gardens. W. F. B.

RED-BERRIED MISTLETOE.

INFORMATION is asked (p. 75) respecting "a red-berried variety of Mistletoe, mentioned by Loudon as occurring in the vicinity of Jerusalem." Of such a variety I know nothing, but I have found a lovely red flowered parasite, *Loranthus indicus*, growing in profusion in Nubk trees (*Zizyphus Lotus*), near the fountain Ain Sultân, in the plain of Riha, the ancient Jericho, and I think this must be the plant to which your correspondent alludes. Canon Tristram says ("Land of Israel," p. 202): "The most conspicuous was a beautiful parasite, *Loranthus indicus*, with graceful red blossoms studding its branches as it climbed up the topmost boughs of the Thorn trees." This plant is one of a genus closely allied to *Viscum*, and its propagation is thus described by Mr. Griffith (Linn. Transactions, vol. xviii., p. 71): "In *Loranthus* the ripe seeds adhere firmly to the substance on which they are applied by means of their viscid coating, which hardens into a transparent glue. In two or three days after application, the radicle curves towards its support, and as soon as it reaches it, becomes enlarged and flattened. By degrees a union is formed between the woody system of the parasite and the stock." Unlike our English *Viscum*, however, the *Loranthus* has the power of attaching itself to the branches of the tree on which it grows by means of suckers proceeding from its own shoots. It has been suggested that *Loranthus europæus* was once a native of Great Britain, but that all vestiges of their religion having been extirpated with the Druids, the *Loranthus* has disappeared wherever that religion formerly held its sway. R. MILNE-REDHEAD.

Tree planting on the Northern Pacific.

—A railway running along hundreds of miles between rows of shade trees will soon be one of the novel characteristics of the Northern Pacific. This extensive tree planting is being carried out to protect the line from storms and snowdrifts. In addition to having a large force of men engaged at this work between Fargo and Bismarck and Dakota, the officers of the company have distributed large quantities of seedlings and cuttings to cultivators settled on the land, and have offered prizes for skill in forestry.—T. C. W.

Flowering shrubs.—It has often occurred to me that more descriptions of that hitherto neglected class of plants, viz., flowering shrubs, accompanied by coloured illustrations, would be most acceptable to readers of THE GARDEN. I constantly now hear persons inquiring about them, and think that the tide of opinion is setting in that way. There is no book that I know of which treats on them thoroughly. Mongredien's book is out of print, and Hemsley generally dismisses them by not describing any of the rarer kinds, and by saying that it is unnecessary to speak further, as "they are very uncommon in gardens," which seems to me to be the very best reason for describing them fully. No doubt many of the so-called tender shrubs will be found hardy enough to withstand our winters, at all events against a wall, and if you would give us illustrations and descriptions of some of the best and rarer kinds it would, I am sure, be a great boon to all lovers of what I consider the best kind of gardening. At present it is very difficult to procure the rarer kinds from nurserymen, or at least I cannot find any nurseryman who supplies them; but if once a demand was created the supply would soon follow, and we should be relieved from the eternal monotony to be seen everywhere in the modern shrubbery.—OXON. [We have figured many beautiful shrubs, and hope to do many more.—ED.]

FERNS.

BEST CULTIVATED SORTS.

Anemia.—This genus is composed of mostly dwarf growing Ferns forming part of a section which is commonly known under the denomination of "Flowering Ferns," on account of their fertile segments being wholly contacted, a peculiarity which gives them the appearance of flower-spikes. Although several interesting species have been at different times introduced from tropical countries, a few only have survived the ordeal of acclimatisation, or the effects of the treatment first received after their importation. Provided heat and plenty of light are at the disposal of the cultivator, they are not difficult to manage, and will be found to do best in a mixture of two parts of good fibrous peat to one of sharp silver sand, the plants being either kept on a shelf if in a spacious house, or near the glass if in a warm pit or low house. Watering overhead is very injurious to them. They prefer being grown in small pots to being planted out in the fernery, and although they are not what may be thought the ideal of decorative Ferns, as they cannot be used for general purposes on account of their vegetation being too slow, still, when Anemias and Anemidietyons are grouped together, they present a very striking appearance.

A. adiantifolia.—A pretty little species from Jamaica, rarely exceeding 12 inches to 15 inches high. The fronds, produced from a succulent crown, are bipinnate when sterile and triangular in shape; from the base of the sterile pinnae come the fertile segments, generally produced in pairs; these grow to the height of 6 inches to 8 inches, and are completely covered with sporangia. Stove.

A. cheilanthoides (tomentosa).—This Brazilian species, perhaps the most elegantly cut of the genus, bears beautiful fronds of about 12 inches high; they are tripinnatifid with pinnae finely cut, but closely set, and of a dark green colour, their stalks and rachis covered with ferruginous brown short hairs. The fertile segments, also of the same reddish brown colour, are produced in pairs from the base of the lower pinnae, and grow about 8 inches high. Stove.

A. mandioccana.—A comparatively strong growing Brazilian species, producing fronds 15 inches high, the sterile part of which is pinnate and acuminate; the pinnae, auriculate at their base, are about 1½ inches long and entire; the fertile segments, in pairs and bipartite, grow to about 6 inches; the stalks and rachis are densely clothed with long hairs of a reddish brown colour. Stove.

A. Phyllitidis (Anemidietyon Phyllitidis).—This species and its several varieties form a separate section of the genus Anemia, from which they are readily distinguished by having their veins reticulated; they are besides stronger growers than any of the above described species. A. phyllitidis produces fronds often reaching 30 inches high, and borne on green stout stalks; the sterile part is pinnate, with pinnae entire, somewhat distant, of which each frond bears about ten pairs besides the terminal one; they are about 4 inches long, 1 inch in breadth, of a bright green, and of a tolerably tough texture. The fertile parts of the fronds, as in Anemia proper, are bipartite, dense, and wholly covered with sporangia. Stove.

A. Phyllitidis fraxinifolia (Anemidietyon fraxinifolium).—This species, from Tropical America, is very distinct; the fronds grow to about 18 inches in height; their sterile part is pinnate and made up of nine pairs of pinnae besides the terminal one; these are entire, ovate in shape, about 2½ inches long and 1 inch in breadth and closely set together; the fertile segments, produced in pairs from the base of the lower pinnae, grow to about 9 inches high, and are very dense, green in their young stage, turning light brown when mature. Stove.

A. Phyllitidis tessellata.—This peculiar and handsome variety is distinct from all the others on account of its fronds, which grow to about 18 inches high, having the pinnae of a dark green ground mottled with transparent greenish yellow blotches and veins on the upper surface, which marking and netting gives the fronds all the appearance of a charmingly attractive piece of mosaic. As in the parent plant, from which it is issue, the pinnae are produced in nine or ten pairs besides the terminal one, but smaller in dimension, and measuring only 2 inches long by hardly 1 inch in width. Another peculiarity of this variety is its tendency to often produce from the base of the lower pinnae three fertile segments instead of a pair. Stove.

Angiopteris evecta.—This, I believe the only species comprised in the genus, is closely related to the Marattias, and belongs to a family of gigantic growing Ferns, which are totally deprived of stems, and which are altogether very unlike Ferns in general appearance. Its immensely large fronds, reaching 18 feet high by 10 feet in width, and which give to a fernery of sufficient size to accommodate them a noble and tropical appearance, are produced from a thick fleshy crown, rising a little above the surface of the ground, and are borne on stout blackish, fleshy stalks, clubbed at their base, where they often measure 8 inches in circumference. They are bipinnate with pinnales of a coriaceous texture and bright shining green in colour; they are generally from 4 inches to 5 inches long and about 2 inches wide. Being found in swampy places all over Ceylon, Java, and the Pacific Islands, this Fern will grow luxuriantly if potted in a compost of two parts fibrous loam, two parts rough peat, and one part chopped Sphagnum, and kept partially in water in the stove fernery, although it will also do very well in an intermediate house. There exists also a very pretty variety found in Java resembling the species in general appearance, but with pinnales rather larger and of a fine glaucous colour on the underside, and bearing the name of A. pruinosa.

Aspidium.—Most of the plants in this genus are strong, erect-growing, highly ornamental Ferns, having broad, massive fronds with netted veins. Although very accommodating plants and of easy growth, they are not so well adapted for pot culture as for planting in the rock fernery, where they will prove most effective, their bold foliage being shown off to much advantage by the finer cut nature of the other kinds surrounding them. A mixture of two parts of peat, one of loam, and one of silver sand will suit them very well. They will also benefit by being now and then syringed overhead.

A. conifolium.—This Asiatic species produces from a thick underground rhizome and in

great abundance beautiful tripinnatifid fronds almost triangular in shape, of a dark glossy green colour, and of very leathery texture; the pinnales, which are overlapping each other, have their edges rather rough and slightly ciliated. Greenhouse.

A. coadnutum.—A very fine East Indian species of large dimensions, with fronds from 3 feet to 4 feet high, and light green in colour; they are subpinnatifid, and the pinnae very broad. It is one of the easiest to grow, and most distinct in habit. Greenhouse.

A. lepidocaulon.—An interesting Japanese species of drooping habit, particularly adapted for basket, bracket, or suspension of any kind, in which it thrives well and shows itself off to advantage. Its fronds grow from 18 inches to 24 inches long; they are pinnate, dark shining green, and of a very coriaceous texture. The most remarkable peculiarity of this plant is that the upper part of the frond is naked, and, being totally unprovided with pinnae, it terminates in a long tail-like process, producing at the far end a bulbil, developing into a young plant later on. Greenhouse.

A. macrophyllum.—This grand and most distinct species from Tropical America requires a great deal of space to develop properly its beautiful pinnate fronds, which grow to about 4 feet high; the basal pair of pinnae are auriculate on the lower margin, whereas the terminal pair are broad and decurrent; the whole plant of a light green colour. Stove.

A. trifoliatum (A. heracleifolium).—A very free-growing Brazilian Fern of very peculiar appearance. Its fronds, produced from a succulent crown, are trifoliate, the lower pair of pinnae lobed on their margins, and all deeply crenate; they are of a bright green colour, and grow from 12 inches to 18 inches long. Although it will do fairly well in a greenhouse, it grows finer in a stove.

PELLSEA.

BOOKS.

VINES AT LONGLEAT.*

THE author of this treatise professes to take the reader "into his confidence" and to relate his "failures and successes" with equal candour, but from one end of the book to the other an assumption of superiority and originality, not borne out by the contents, is plainly visible. It is amusing to read of the "punishments" the author has had to endure "for venturing on originality," which "originality" consisted, so far as one can make out, in attempting to grow his Vines in a soil destitute of lime. While he was yet only young and a learner he was quite ahead, by his own account, of authors of mature age and experience. At that time a treatise on Vine culture "was placed in his hands, and when he had time to open its pages he saw the contents did not agree with what he had found out for himself, and, well—he closed the book again." To sustain the claim to originality of thought and practice, we are told, not far from the beginning, that the author "had never yet read an essay on Vine culture." That his system of culture "is something like the plan we should probably follow if we had never heard of any other, and perhaps that will account for his following it." In short, Mr. Taylor is anxious to persuade the reader that he has had a "revelation" on the subject of Vine culture, but as we proceed we discover that he has been very faithfully guided in the path which others have trodden before him, while no doubt those conversant with Vine literature will rise from a perusal of the book with the conviction that its author has been a more than usually diligent student of the writings and practice of other authors. For example, the following passage betrays a wonderfully accurate knowledge of "the old school of Grape growers" (p 42), a term which appears to include all who have written before Mr. Taylor:

* "Vines at Longleat: their History and Management." By Wm. Taylor, 171, Fleet Street.

"He makes up his mixture everywhere in the same way—so much turf, so much manure, so many bones, so much lime rubbish, and special quantities of certain other ingredients, &c." Passages like this and references to what "many of our teachers" say, the practices "followed by most of our leading men of the present day," "the rules laid down by many of our acknowledged teachers," and similar sentences and coincidences of expression scattered broadcast throughout the book tell in plain language of the author's familiarity with other essays and writings. Practices in Vine culture which have been rung in the ears of gardeners till they are nearly tired of hearing them are, in the book before us, explained and discussed with an affectation of unconsciousness and originality that is truly entertaining. In fact, the author appears to be an expert at sifting the records of other people's experiences, as the following remarkably candid piece of advice to *such people as are capable of doing it* will show (p. 45): In reading "controverted questions" and discussions on Vine culture, they are told to *need out all superfluous verbiage, get at the points made by each side, balance them, and work out the proofs for themselves*. Evidently our author is "capable" of doing this to some purpose. Our remarks on these matters are made in no carping spirit. If Mr. Taylor did not choose to acknowledge his indebtedness to other writers—so transparent in his book—he need not have repudiated by anticipation, and so ostentatiously, the suspicions of his readers on that point. No fault whatever is found with Mr. Taylor, or anyone else, for utilising to the utmost the recorded experiences of others; but when, as in the present instance, an author has been benefited by the writings of one and all who have preceded him, something better than a studied attempt at ignoring them might be expected in return.

The main features of Mr. Taylor's essay are his advocacy of the "extension system" and low night temperature. He appears to have successfully and accurately carried out extension on the spur principle, as described and figured in *THE GARDEN* of January 16, 1875, and put in practice by Mr. Taylor the year following when he found his Vines to need more room. On the subject of temperature he quite rightly condemns running to extremes, but few have diverged further or more successfully from the beaten track than himself in respect of temperatures. For Vines in flower he recommends a night temperature from 15° to 18° lower than the high temperature advocates recommend, and a lower day temperature than any other authority on Vine culture we know. None, so far as we are aware, have ever recommended so low a temperature by sun heat as from 75° to 80° for Muscats in flower. A large portion of the book treats on matters unconnected with the Vines at Longleat, and some very doubtful vegetable physiology is advanced and questionable theories and opinions. Every subject connected with Vine culture is, however, touched upon, but the value of the record of the author's experiences, whether the system be his own or other people's, rests on the fact that Mr. Taylor is a successful cultivator of the Grape. His crops of Grapes have, lately at least, been quite first class, we believe, and that portion of his essay devoted to his practice at Longleat cannot fail to be of value to all who seek information on Vine culture. He has proved in the most conclusive fashion that first class Grapes can be grown on the "cool temperature system," as it is called, and about which there has been so much discussion, and done much to set that point at rest and lessen our coal bills. Many matters connected with ventilation, borders, training, watering, &c., are treated very fully, and points discussed which writers are too often apt to overlook, but which learners want to know all about. Mr. Taylor has forgotten nothing, in short.

Should another edition be called for, the author will do well to alter the headings of some of the chapters, which savour more of the "Salvation Army" vocabulary than that of the gardener. For example, "Under a Cloud" is a rather unintelligible title for a chapter on the character of soil for

a Vine border, and a "Gleam of Light" does not forecast the author's discovery of a deficiency of lime in his Vine borders, while such phrases tend to make the reader think Mr. Taylor is himself one of those "enthusiasts" against whom he cautions his readers in one part of his book.

J. S. W.

NOTES.

Cornus Mas.—One of the prettiest of hardy shrubs now in bloom is *Cornus Mas*, the *Cornel* tree, so commonly found in the vicinity of old religious buildings. Report hath it that its fruits were eaten long ago as a substitute for the imported green Almonds of our own day. Its fresh, golden green flowers brighten up its dark twigs, and even make some pleasant effect in the sunshine. It is not showy, but then the colour is unique, and one may look a long time at a *Cornel* bush at this dull season without tiring of it.

Narcissus monophyllus.—We must ask Mr. Peter Barr to let us into the little secret which he seems to possess as to the best way of blooming this "gem of all the Daffodils." Mr. Ferme, of

Flower of *Narcissus monophyllus*.

Haddington, must also have the secret at his fingers' ends, for does he not bloom it with two flowers on a scape? This fact betokens much vigour, albeit that pot or frame culture is resorted to. The Rev. Mr. Rawson when at Bromley was one of the first of cultivators who in recent years bloomed it satisfactorily, although, as Mr. W. Dod says, Parkinson described it in his "Paradisus," p. 106, two centuries and a half ago. Then, after his time, in 1588, "a Master Nicholas Belson, some time of ye Kinge's College, Cambridge," cultivated it, as noted by Gerard, and hence comes the name of *Corbularia cantabrica*. Mrs. London, in her "Bulbous Plants," says it is a native of Biscay, and is found in great abundance among the mountain passes of the Pyrenees, a statement sufficiently vague. That there are sulphur (citrinus) and pale, if not white, forms of Hooped Petticoat Daffodil (*N. Graellsii*) found in Europe, I was well aware, but is *N. monophyllus* really found at Bayonne, or in Europe? One of its names, *C. Clusi*, would seem to point to its having been at some time supposed to be European, even if not actually known to be so. A botanist who

has travelled in Europe and in Algeria, and who knows plants well in both continents, doubts the statement, although of course he is open to conviction on the point. No matter where it may be found, it is a little gem of a flower, and its headquarters, according to the late Mr. Munby, is in Algeria, particularly near Oran, and at Baghar, on the borders of the desert to the south of Algiers.

Bulbs on Grass.—Some of my friends write to say that they have failed to naturalise bulbs on the grass of their lawns and pleasure grounds in the way they had hoped to do. This is disappointing, and the failure may result from the wrong bulbous plants having been selected for the purpose, or from some error in the planting. Snowdrops of all kinds rarely fail; so too *Crocus biflorus* and all the Daffodils. *Eranthis hyemalis* rarely fails under trees, or where the grass is thin and spare; so also Bluebells; and where the grass is mossy in the shade Primroses do well. Then *Anemone apennina* roots chopped up into mince-meat about July or August and dibbled into the turf especially where it is just a little thin on the top as under trees rarely fail. This

Dibbling plan is generally successful, but the best way is to plant the bulbs thoroughly well at the time lawns are being made or renovated, as the case may be. Another plan is to dig out holes a foot or more in diameter and plant the bulbs, adding good rich compost for them, after which inoculate the bare patches with bits of turf only, or sow them with new lawn grass seeds, which is even better. The Snowdrops are turf-piercers as well as snow-piercers; so too the Daffodils "gin to peer" oblivious of any resistance which a dense mat of grass roots may offer.

Snowdrops on Grass.—The other day I went to see a garden which belongeth to a "learned clerk" who had told me of the beauty of his Snowdrops on the grass, fancying, indeed, that they came larger as they certainly retain their fresh purity and pearly beauty longer when so grown. On dry grassy knolls around the boles of some large trees—Ash, I fancy they were—Cyclamens of the *hederæfolium* or Ivy-leaved section were quite "at home," their marbled leaves nestling very cosily in the withered grass, and adding quite a fresh charm to the wintry herbage. On dry grass-covered banks facing the sun even the "miffy" (a gardener's word for delicate or hard to grow) *Narcissus Bulbocodium* (yellow Hooped Petticoat) will often establish itself permanently. Not very long ago, indeed, I was speaking to a gentleman who had dug up roots of this plant, and also of the sulphur variety of Hooped Petticoat Daffodil from near the lighthouse at Biarritz, and, he informed me, he was quite surprised at the network of grass and shrub roots which enveloped the little black-coated bulbs. As the terrestrial Orchids object to the bareness of earth around them, so too, many bulbous plants seem to like a little root-fellowship or society of their own kind down below the ground-line. Speaking on the subject of

Lilium auratum failures one day with an old cultivator, he suggested "planting them in amongst Rose bushes" (a wedding of the Roses with the Lilies is an idea I beg to recommend to the author of a "Book about Roses"), "or even," continued this old prophet, "put them in at the foot of a Privet hedge, and on the sunny side." Perhaps he is right. In such a place the bulbs would never be too wet, since the hedge—be it of

Privet or of Roses—would shelter their bulbs from the direct action of rain and sun alike. I sometimes think that the idea that every plant must have a separate plot of ground all to itself is mistaken kindness on our part. Perhaps, after all, genial society is best for plants sometimes, as well as for those who grow them. Those articles in *THE GARDEN* the other day on

Mistletoe propagation would interest many people. I think that April or May is the best time to sow the berries on the smooth, clean branches of either Apples, Pears, or Limes, as they are then thoroughly ripened, and begin to germinate promptly. We all know that the plant is rarely found on the Oak—how rarely the following extract will show: "In our Christmas stories and fancies the Mistletoe is often connected with the

The blossoms are of snowy whiteness, and exhale a delicious perfume similar to that of *J. Sambac*. It is exceedingly floriferous, bearing clusters of blossoms the whole length of its slender branches, which droop very gracefully on all sides. In addition to these good qualities, it continues to flower throughout the winter, a circumstance which cannot fail to render it popular and invaluable, particularly for cutting. Why are the really

Hardy Bamboos so seldom seen, even in good gardens? As fresh and graceful foliaged plants they have few equals in their own elegant, reed-like way. *B. Metake* is one of the safest to plant largely, and as I write I am looking at a graceful cluster of wand-like stems 8 feet high, of an ash or pale straw colour, with deep green leafage daintily poised up towards their tips in a really

Other good kinds are *B. nigra*, with black stems arching over gracefully, and 4 feet or 5 feet in height. *B. Mazelli* is likewise good. Then *B. viridi-glaucescens* resists frost well likewise, and of the dwarfier kinds which are fresh and green in winter, one of the most effective is *Arundinaria bambusoides*, and *B. Ragamowski*, of similarly dwarf spreading habit, is equally good in its way. For sheltered nooks, or among natural rocks in low-lying places, these are very effective and distinct. Dry winds seem to injure them more than actual frost, but planted in sheltered places on grass, or in deep, rich earth under the lee of walls or buildings, they succeed well. A plant with much of a Bamboo-like grace about it, and even more than a Bamboo-like freshness and glossiness of leafage is

Ruscus racemosus, which by some is supposed to be the Victor's Laurel of Mount Olympus. Be that as it may, those may be accounted "gainers of a good thing" who, having well planted it, have induced it to luxuriate in their gardens. For cutting its shining-leaved stems are unique amongst foliage plants, hardy and otherwise. I saw some wand-like sprays of it the other day sent from Shankbill Castle, Ireland, and alone in large vases nothing could have been finer in a decorative way. Of the four or five species of *Ruscus* in cultivation all are hardy, if we except the greater Alexandrian Laurel (*R. androgynus*), which groweth rampant up a lofty pillar at the Crystal Palace, likewise groweth gracefully near a stair in the great temperate house at Kew. All the hardy kinds enjoy shelter; a wood or plantation on deep, rich well-drained soil suits them admirably. I hope there are plenty of Bamboos and *Ruscus racemosus* also in that classical wood at Wistley? Lovers of

Rock and wall gardens will enjoy this peep at a few of the plants which at one time grew on and near the Colosseum at Rome. "And what be the shrubs and kinds of flowers that act the part of the robins in the 'Babes of the Wood?'" Shiny-leaved *Laurustinus*, Ivy, Cypress, *Acanthus*—looking more beautiful than ever I saw it; it makes a glorious old wall plant. Then Wallflowers, a beautiful purple Anemone, and a great variety of smaller plants, many unknown to me. But I have omitted one of which there is a great abundance under the arches—*Adiantum Capillus-veneris*—which makes a most lovely drapery. With such softening as these plants give to the decayed walls, the unsightliness of ruin completely vanishes, and one heartily subscribes to Byron's idea of "ruinous perfection."

Orchids at home.—We can never know too much of the precise conditions under which Orchids are found luxuriating at home in their native wilds; so I make the following extract from a letter written from Cape Town to Mr. N. B. Ward (inventor of Wardian cases) by the late Prof. W. H. Harvey, the celebrated algologist, relating to the natural conditions under which he found *Disa grandiflora* growing on Table Mountain at the Cape: "First, as all the world knows, it grows on the summit of Table Mountain, and nowhere else. This summit is very frequently enveloped in mist, especially at the season when the *Disa* blossoms, but it is very cold also, and the mist comes accompanied by a strong south-east wind. After this succeeds the scorching sun of latitude 33°. So much for general circumstances. The particular ones are, that the plant

Jasminum gracillimum.

Oak, but its connection with the Oak is a common error; it is more rarely found upon that tree than any other. There are only twelve known Mistletoe Oaks in England and Wales. The following is a list of them: Oak at Eastnor, Herefordshire; Oak at Tedstone Delamere, Herefordshire, discovered in 1851; Oak at Sunbury Park, near Chepstow; Oak at Dunsfold, Surrey; Oak in Wackwood Park, near Basingstoke; Oak near Plymouth, on the South Devon Railway; Oak at Frampton Severn, Gloucestershire; Oak at Haven, Herefordshire, first known in 1869; Oak at Plas Newydd, Anglesea; Oak at Llangattock Lingoed, Monmouthshire, discovered in 1870; Oak at Predwardine, Herefordshire, discovered in 1871; Oak near Knightwick Church, Gloucestershire. Can any of our friends extend this little list of Mistletoe Oaks? Among winter flowering stove plants few are so white or so fragrant as

Jasminum gracillimum.—This is an excellent plant sent out by Messrs. Veitch & Sons last year. The clusters are larger than here shown.

pretty way. In a good clump or mass these wands are of all heights, and so the plant has not a bare or naked appearance at the base. I like to see them rising fresh and fair from bronze-leaved Brambles, or from a breadth of common Brake Fern, itself now a pretty object, warm and dry looking, and tinted like dead Beech leaves.

The golden winter or Japan Jasmine, with its bending wreaths of golden buds and yellow blossoms, is very showy. When newly planted it embroiders old walls very effectively, and when older and well established it hangs like a thick golden fleece upon them in the cold January days; 25° of frost, with a bitter blast blowing—a frost that has in many places cut down *Euonymus japonicus*—has been insufficient to stay the flowering of this Jasmine. Alone on a sunny wall it is very effective, still more so when peeping out and drooping from a mass of fresh green Ivy, or when its golden buds are contrasted with the coral red berries of Simon's Cotoneaster.

only grows along the steep, boggy, spongy margins of a stream which has water in it at all seasons, but which in winter must be so swollen as to cover the plant. Here the margin is completely clothed with the Disa to the exclusion of other plants, but immediately beyond the Disa is a margin of *Restias*, which, growing taller than the Disa and bending over the stream, afford considerable shade to the roots and leaves, at the same time that they leave the flower-stalks room to peep out at the sun and exhibit their large blossoms. All these, except the cold wind, can be easily managed in a Wardian case, and I should hope that our plant will have the good taste to forgive us that part. The shade, moist atmosphere, and soil seem the chief things to provide."

White Tiger flower (*Tigridia Pavonia alba*) must be a lovely plant in its own deliciously fugitive way, reminding one of those pearl-toothed Eastern beauties, who laugh at you one moment and then closely veil their faces the next, as if blushing repentant of so bold a sin. "Creamy white, marked with chestnut-red, on a yellowish ground;" yes, that sounds pretty enough, and having obtained a few of its bulbs, I am on the tip-toe of expectancy, seeing that its congeners are so strikingly lovely in the summer's sun. It would be a great pleasure to see those rapidly extending

Flower farms in New Jersey, where *Tigridias*, *Tuberoses*, *Ixias*, *Sparaxis*, and many other beautiful bulbous flowers are grown by the acre. Who knows but that those Pine barrens of the sunny west will not one day be a very paradise of bulb and seed farming. Already American capital and energy have done much in this way; and to-day I hear whispers that American amateurs have mastered that little secret of saving *Chrysanthemum* seed, so that we may expect them to rival France and the Channel Isles in the way of new seedling *Chrysanthemums* as well as in bulb and fruit culture. *Vive l'Amérique!* Speaking of

The Chrysanthemum reminds me of "F. W. B.'s" papers on its history and culture now appearing in *THE GARDEN*. Lest they should escape him, here are a few extracts which may be of interest. Mr. Fortune told us long ago that the Chinese made life-sized images of their blossoms, but who would suspect the "moon-faced celestial" of liquor. And yet we are told that "in China a liquor is distilled from the flowers of the *Chrysanthemum*, which is regarded as an elixir-vite, and in the Chinese pharmacopœa a powder of the flowers or florets dried is prescribed as a cure for drunkenness." Can anyone tell us more of the history of the *Chrysanthemum* here alluded to? It would seem to be an uncommon and highly interesting species. "One of the most singular of all the species of *Chrysanthemum* is *C. anciatum*, a perfectly hardy succulent species, which looks not unlike a delicate mass of green coral. Its leaves are like fleshy hooks (*ancia*), and give the plant a unique appearance. It is a good rock plant."

Grafting two or three varieties of *Chrysanthemum* which bloom simultaneously on one stock, if not as yet a general practice, is sufficiently so to warrant some notice. In 1876 and 1877 Mr. Charles Turner adopted this mode of culture, and in the latter year (as we learn from *THE GARDEN*, Vol. XII., p. 175) he had over 200 fine plants worked as standards on 3 feet high stems, several sorts which bloom at the same time being

grafted into one head. At Oxford also this grafting practice is pretty general, as we learn from a visitor at the *Chrysanthemum* show recently held in that city. Long ago, indeed, Mr. Fortune found Chinese gardeners employing *Artemisia indica* as a stock on which they engrafted their *Chrysanthemums*.

The General Index for the first twenty volumes of *THE GARDEN* may be called "a good idea well carried out," and it will be a boon to all those who have wisely filed and bound up their copies, thus forming a complete and valuable series in more senses than one. Much labour and worry will now be saved in making references to the volumes by the use of this handy index. The convenience now experienced makes one wonder how we did without such an index so long. This index, moreover, is one of those "good examples" which the "copy book" headings of long ago used to say were "better than precept." So the author of "*Proserpine*" has again been elected to the

Sladian Professorship of Fine Arts at Oxford. He is a remarkable man in many ways is this John Ruskin, who, while criticising pictures severely betimes, has ever preached the great gospel of plant beauty to us all. "When all other service is vain from plant and tree, the soft Moss and grey Lichen take up their watch by the headstone. The woods, the blossoms, the gift-bearing Grasses have done their work for a time, but these do service for ever. Trees for the builder's yard, flowers for the bride's chamber, corn for the granary, Moss for the grave—Kismet!"

VERONICA.

THE CHRYSANTHEMUM AND ITS CULTURE.

Chrysanthemums for small green-houses.—Anyone who has a greenhouse, a well-lighted porch, or even a large bay window or two should grow a few *Chrysanthemums* in pots outside during the summer, as they may be well bloomed even in a window if moved inside after the buds show colour and before sharp frosts set in in October. In country places every artisan or intelligent labourer might build a rough greenhouse with a few old lights for the roof, five shillings' worth of timber for supports, and some pieces of canvas or bast mats for the front and sides. No flower is better worth attention, and amateur growers should encourage garden-loving workmen by giving them spare plants or cuttings. The following directions from *Gardening Illustrated* are specially suitable for beginners.

There are three distinct objects for which *Chrysanthemums* are grown, viz.: First, specimen plants in which the beauty of the individual flower is subordinated to the training of the plant to some particular shape; second, for conservatory decoration where the object is to get a brilliant mass of colour, irrespective of individual flowers or shape of plant; and third, for the beauty of individual flowers only, without regard to number of flowers or shape of plant. Each of these ends requires a distinct system of culture, and the great number of failures in growing *Chrysanthemums* are probably owing to mixing all three systems together and keeping no definite object in view. In small greenhouses there is neither room nor need for specimen plants and great masses of colour, so we shall confine our remarks to the culture for individual flowers, which is by far the most interesting of the three.

Propagating.—Cuttings should be put in round the edge of the pots in the usual way during the last week of January, not sooner, for we do not wish the plants to be drawn up under glass before we can venture them outside. The pots of cuttings should be put near the glass on a shelf in the greenhouse; there is no need for

either bell-glasses or bottom-heat; indeed, both are hurtful.

Potting.—When the cuttings are rooted put them into 4-inch pots, keeping them still near the glass. When the roots come through the soil to the side of the pot shift into 6-inch pots, and as soon thereafter as the weather will permit stand them outside, tying each plant to a light stick to prevent its being broken by the wind. From the time the cuttings are put in until now, and, indeed, to the end of the chapter, never pinch; let the plants grow up to one single stem. Place the pots on slates to prevent the ingress of worms, in such a situation that they may get sun the most of the day. Do not plunge the pots, nor protect them from sunshine in any way; this, doubtless, entails far more labour in watering, but it will be amply repaid by a dwarf plant, well-ripened wood, and consequently fine flowers. When the roots come through to the sides of the 6-inch pots, probably about the end of May, give a final shift into 9-inch ones.

Staking.—When the plants are 1 foot high put a light stake 4 feet long in the centre of each pot, and tie the stems to this as they lengthen out. Towards the end of September we may expect gales of wind, so put three more light stakes at equal distances apart round the pot, bend them over, and tie all the points to the centre stake; this will be found far more effective than one thick stake.

Watering.—While the plants are in the open air water them frequently over head through a fine rose, as well as attend to watering at the roots. If you have a command of hot water, make the water, for both purposes, perceptibly warm to the hand; this greatly tends to keep the plants in health, and takes but little extra time.

Insects.—Towards the end of summer two insects will probably give some trouble, viz., earwigs and green-fly. The former show themselves by the leaves being eaten at the edges. Insert small rolls of paper between the stem and the stake and examine them in the morning, destroying the intruders. The green-fly will be found to attack the points of the shoots; choose a dry, still evening, and thickly dust them over with Tobacco powder, washing it off with the rose or syringe the following day. All shoots which spring from the roots must be carefully rubbed off until flowering is over.

Feeding.—By the beginning of October the flower buds will form; then you must feed with manure; up till now you have not done so, and turn a deaf ear to those who advise you so to continue. Any good manure will do, but one of the many made-up ones, now in the market, will be the easiest applied. Standen's is as good as any; a small dessert-spoonful, sprinkled over and stirred into the top soil, constitutes a feed; let a week intervene between the first two feeds, after that fortnight between each, until the flowers are past.

Best varieties: INCURVED.—Mrs. G. Rundle, white; Mr. G. Glenny, sulphur; Mrs. Dixon, yellow; Lady Hardinge, rose; Peach Venus, peach; Jardin des Plantes, golden; General Bainbridge, bronze; Empress of India, white.

POMPONES.—Bob, crimson; General Canrobert, yellow; Cedo Nulli, white, lilac, and yellow and brown forms; Madame Marthé, white and golden yellow.

JAPANESE.—Elaine, white; Ethel, late white; Fair Maid of Gherney, late white; Peter the Great, yellow; Filton, gold; Cossack, brown; Tokio, red; James Salter, lilac.

ANEMONE-FLOWERED.—Large: Fleur de Marie, white; Glück, yellow; King of Anemones, purple; Princess Louise, lilac. Small: Madame Montels, silvery lilac; Calliope, red; Dick Turpin, red and yellow.

MISCELLANEOUS OR REFLEXED.—Progne, crimson-purple; Crimson Velvet, velvety crimson; Annie Salter, yellow; Dr. Sharpe, magenta-red.

Disbudding.—When the buds are quite set and standing apart from each other is the time to

disbud; this can usually be done at the time of housing for the winter. Leave only one bud to each shoot. If any green-fly be found round the base of the bud left, remove it with a small brush dipped in water; there will probably be no further annoyance from these pests.

Housing.—Choose a dry day for housing, and the plants may be put close together, leaving only as much room as will keep the shoots from touching each other. About the time the flowers are expanding mildew will probably make its appearance on the foliage. This is the result of a number of plants being housed in a small space, and the temperature kept at 45° or thereabouts, for the sake of the other inmates of the house. Nothing need be done; the flowers will win the race and then the plants can be cut back.

Treatment after blooming.—When the flowers are over, cut back the main stem, so as only to leave one or two of the small side-shoots which have now formed; these are left to keep the sap flowing until shoots spring from the roots. These shoots from the base of the plant form the cuttings, which should be taken at the end of January, as directed at the commencement of this article. When you cut back the stems do not remove the stakes, for the pots by this time are so crammed with roots there is a danger of all the water running through the holes left and the plant perishing from want of it. You need not be very choice as to soil; perhaps the best is two parts rotted turf to one of well-decayed manure, mixed with a good deal of sand, riddled for the first potting, and rough for the other two. Under this system of

Single stem culture, leaving one bloom to each shoot, you will only get from three to nine blooms on each plant, but then they will all be good. Now suppose you pinch until you have ten stems round a 9-inch pot, the writer's experience is that if you have to flower your plants in a small house you will only have one or two good blooms on each plant, and these one or two will not compare either in size or finish with those on the single stem. Then you can easily house half as many again plants with single stems as you can those with ten. When we say that all the blooms on the single stem system are good; of course we do not mean that all are up to the exhibition standard, but simply that they are of good size and form. With fair luck about one bloom out of twenty should be fit for the exhibition table; it is the old story that under the same culture the man with 100 plants can beat him who has only ten. Another advantage of single stem culture is that you can successfully flower the incurved varieties with long petals. As for what varieties to choose for a small house, the only limit is that none should be chosen that do not set their flower-buds by the time you have to house them, for under the confinement of a small house there is a danger of the plants making new wood and never forming flower-buds.

For those who have not time for this careful treatment, there is a simpler style of single stem culture, which gives fair results. Put in cuttings and treat them as directed above, but keep them in the 4-inch pots till you can trust them outside. Select a sunny border; the soil should be in fair heart, but not enriched with fresh manure; turn the plants out of the pots and plant them 2 feet apart. Attend to staking, watering overhead, and at the roots if the weather is very dry, rubbing off shoots from the roots, and keep a lookout for earwigs and green-fly. Nothing more is needed until the flower-buds are set, then lift the plants and pot into 7-inch pots. Use light soil passed through a fine riddle. Keep the foliage damp, and shade the pots by placing them on the floor of the greenhouse. In a week or ten days the pots may be lifted on to the stage, disbudding attended to, and liberal feeds of manure given. The blooms will come deficient in size, but well shaped and finished, and very much better than the average Chrysanthemums seen in small houses.

Open-air culture.—The introduction of early blooming races of the Chrysanthemum must

of necessity give a great impetus to its culture in the open air. Some of the more hardy of the kinds long ago introduced, such as the quilled yellow and old tasseled purple, flowered fairly well on sunny walls during mild Novembers. I have seen the cottage fronts and little gardens in the suburbs of London quite gay with these old kinds during mild seasons, but as a rule the Chrysanthemum was scarcely into flower before the severe frosts of November cut them off. Now all this is changed, and there are two distinct and satisfactory ways of growing the Chrysanthemum in the open air. The easiest way is to grow the modern kinds now known as summer bloomers, which begin to bloom early in August, and continue quite floriferous and gay until the frosts cut them down. Another highly satisfactory plan when large blooms are desired is to plant out strong rooted cuttings in March in a well prepared bed or border at the foot of a sunny wall. Of course the cuttings if struck in heat must have been carefully established in pots and hardened off gradually before planting. As nights and mornings in March are often very frosty some slight protective covering must be given to the young plants until fully established. After the end of April this will be unnecessary. Plant 15 inches to 18 inches apart, and as soon as they are established stop them for the first time, merely nipping out the point of the shoot. If a Chrysanthemum be stopped by breaking back a shoot to the hard or hardening wood, it is fatal to its ever producing a good bloom. Shoots so stopped, or broken off accidentally, are better removed at once, as they always break weakly and badly afterwards. After stopping, leave the two strongest growths that make their appearance, and lead these up straight, nailing them to the wall at intervals, as may be necessary for safety. Carefully pick out all other growths as they appear. After-treatment is simply that recommended as applicable when large blooms are desired from pot plants. Keep off green-fly and red-spider by frequent syringing, and in all cases remove lateral growths and damaged or weakly growths. Even although planted out in a deep rich border, occasional soakings with soot water or liquid manure will greatly assist growth and future flowers if given during the hot, dry weather. Take off the "July bud" and thin out blooming laterals in August or September, as recommended for pot plants, and very fine flowers will be the result. In the beginning of October run up a light timber framework, being careful to allow sufficient head-room for the plants when in bloom. This may be roofed with any odd spare lights or sashes, and the sides and ends may be closed up on cold nights with either strong canvas or bast mats. This protection will be sufficient to ensure the safe development of the flowers. During fine sunny days abundance of air should be admitted, closing up early if symptoms of frosty nights appear. Even plants grown in pots especially for large flowers—or for decorative uses may be protected in this way should no other convenience for housing them exist. The fine show Chrysanthemums inaugurated at the Inner Temple Gardens by the late Mr. Samuel Broome were protected with old lights and matting supported on a rough timber framework as above described. It is precisely this capacity for growth and floral perfection under difficulties that makes the Chrysanthemum above all others the winter flower for cultivators of all descriptions.

Early flowering Chrysanthemums.

These early blooming Pompones or summer lili-pution varieties are a great gain; even under ordinary hardy herbaceous plant culture in the open border they are invaluable for cut flowers or outdoor decorative uses. They are yearly being more and more improved in size and in colour and have a great future before them. No garden, however small, should be without a few of the best varieties. "A good mode of culture is as follows: Four cuttings are inserted in a 3-inch pot in a compost of Cocoa fibre, a little light soil, and plenty of silver sand. I always use plenty of fibre in my cutting pots, as I find that the cuttings root

in it quickly. The pots are then watered with a fine rose and plunged up to their rims in Cocoa fibre in a cold frame and kept shut up close, which keeps them from flagging. In the time of frost the frames are banked up outside with short litter, and the glass is covered with matting. When the plants are rooted they are potted singly in 3-inch pots in soil made up of a mixture of loam and leaf-mould, instead of the Cocoa fibre, with enough silver sand to keep the whole porous. When the plants are about 5 inches or 6 inches high the extreme point is taken off; this will cause them to throw out some shoots, which in their turn must be pinched when about 4 inches long. As soon as the roots feel the sides of the pots they should be potted into 4½-inch pots, and when established in these pots they should be again pinched. As to the time for final potting and the size of pot for flowering the plants in, all depends upon the size of plant required and also the time when they are wanted in bloom. If the plants are wanted in bloom about the end of June, they should be finally potted not later than the beginning of May, and 6-inch pots will suffice, but of course the plants will not be so large as those that are potted into 8-inch or 9-inch pots, and kept pinched till the end of June. In the spring, after all danger of frost is past, the plants should be placed in an open situation out-of-doors, and carefully attended to as to watering, for if they are allowed to get too dry and flag, they will lose their foliage and look unsightly. After the bloom buds appear, an occasional watering with liquid manure will be of benefit. Care should be taken to keep the plants free from insects, and they should be syringed overhead in the summer at least twice a day. Good plants for window or conservatory decoration can be obtained from cuttings struck from February till April, and grown on as above described. Madame C. Desgrange, sulphur and white, and La Petite Marie, dwarf white, should be grown, both being distinct and good. The following will be found a good collection: Adrastrae, reddish purple; Casey, rosy lilac; Chromatella, orange tipped red; Delphine Caboché, reddish mauve; Durham, yellow; Frederick Pelé, bronze red; Golden Button, small, canary yellow; Golden Madame Damage, golden yellow; Hendersoni, yellow; Illustration, fine light pink changing to white; Jardin des Plantes, white; Jardin des Plantes, yellow; Little Bob, maroon-red; Mme. Pecaul, fine deep rose; Nanum, creamy blush; Précocité, orange-yellow; Souvenir d'un Ami, fine large white, and the different varieties of Cedo Nulli.*

Late blooming Chrysanthemums.

Early blooming varieties of Pompones are a great gain, but scarcely more so than are certain of the large flowered and Japanese Chrysanthemums which bloom any time after Christmas. Special culture and late pinching may alike be made to favour late blooming, but it is necessary to select the varieties best and most naturally fitted for producing a supply of flowers during January, when flowers, as a rule, are scarce, and so more highly to be prized. If once practical cultivators and those who rear seedling varieties will but turn their attention to the production [and special culture of varieties for the purpose here indicated, I see no reason why the season of Chrysanthemums should not last from the end of July until the end of March, even if we do not succeed in engirdling the year with their favourite blossoms.

Among the kinds which have been especially alluded to as suitable for late flowering are the following: Nelly, Bouquet Parfait, Princess Teck, Incurved white; Mr. Gladstone, dark red; Ethel, white Japanese; Saul, The Czar, Julia Lagravère, dark red-brown. Splendens [may be had good up to February. Hero of Stoke Newington, a pink sport from Princess Teck; Grandiflorum, yellow Japanese; Virginalis is a good late white Anemone; and old Fleur de Marie is also good; Meg Merrilies is a lemon yellow or straw-coloured Japanese variety having long tubular florets gashed open at their apices; this variety gives

* An article by Mr. W. E. Boyce, of Holloway, in "Gardening Illustrated."

enormous flowers when well grown, and only opens its blooms about the middle of January; even the small flowers are nice and fringing bits of colour for bouquet work or for vases. Harlequin and Lady Margaret, the former nankeen-yellow, and the latter, a white-flowered Anemone flowered variety, are both of considerable merit for late bloom. Miss Marechaux, a pure white Incurved variety, with thick, waxy-looking petals, is to be recommended as a January blooming kind. So also Khedive and Lamia and Late Duchess, the latter an intermediate form between the Anemone flowered and the Pompon sections, having pure white flowers, suffused with lemon-yellow in the centre. Grandiflorum, a bright canary-coloured Japanese variety, carries on the flowering season well into February. Mrs. Charles Carey, a variety sent out by Cannell in 1880-1, is an excellent late white, somewhat after the style of James Salter. It is most valuable as a Christmas flower.

Late propagation is one way of obtaining late flowers. Cuttings may be rooted in March, April, or even in May. These may be either planted out on the Celery trench system of culture, or arranged outside in pots in May or June. If decorative flowers only are desired, pinching or stopping may go on every two or three weeks until the end of July. As soon as the flower-buds are formed, feed liberally and mulch with rotten manure. By placing them in a north aspect in October and November (protecting from frost with canvas or mats), and so keeping them outside until the buds actually show colour, they may be much retarded. After the blooms actually open, a little fire-heat with plenty of ventilation night and day preserves the flowers for a much longer period than does subjecting them to cold treatment indoors, which often induces mildew or damping off.

AURICULAS AND POLYANTHUSES.

THE annual meeting of the northern section of the National Auricula Society was held at Manchester on the 31st ult. There was a large attendance, Mr. Barlow being in the chair, and the Rev. F. D. Horner, secretary. The finances of the society are in a sound position, but a few new subscribers are needed to supply the vacancies by death, and to furnish some additional prizes for the present year. The proceedings were of much interest, showing the favour in which these flowers are still held in Lancashire and Yorkshire. The officers remain the same as last year, with the exception of three new names added to the committee.

The prize list is also the same as for 1882, with the exception of the prizes for alpine Auriculas. These are to be divided into two classes, shaded and unshaded, the latter for the first time being acknowledged as a class. The funds for the extra prizes for unshaded alpine are to be raised by special subscription.

A warm discussion took place upon Rule 11, which has hitherto been as follows: "All plants to have been the *bona-fide* property of the exhibitor for two months;" it was shown that in this form the rule admitted of plants being exhibited which had neither been grown by the exhibitor nor in his possession; in fact, that plants might be purchased and left with others to be grown for the exhibitions. A strong feeling was expressed that all plants shown should not only be *bona-fide* the property of the exhibitor, but that they must also be of his own growing, and have been in his possession for two months. The rule was amended accordingly.

It transpired in the discussion that there is no rule whatever on this point at the London shows, and that an exhibitor may show there any plants he can borrow for the purpose—a most mistaken license, and not calculated to foster honourable competition. It is to be hoped that the southern section will amend this rule and insist upon its observance for the future.

The Manchester Auricula Show is fixed for May 1, and that for Rochdale the day following.

It is unfortunate that these shows and that for Newcastle-on-Tyne all come upon the same days this year.

GARDEN FLORA.

PLATE CCCLXXV.

DR. PATERSON'S VANDA.

(VANDA TRICOLOR PATERSONI.*)

THE artist has not given one a fair chance of displaying any descriptive ability in regard to this Vanda. The oldest of all writing, we are told now, was simply rude drawing; and, verily, in our own time the brush is in some ways more potent

Vanda tricolor, showing habit of growth.

in its powers of teaching than the pen. *Vanda tricolor* is one of the most common of all of what are popularly known as East Indian Orchids, and its variations are many, but in beauty none surpasses this one, which years ago was called *V. Patersoni* by the genial Provost of Falkirk, the late Mr. Russel, himself one of the most thorough and skilful of all the Orchid-growing amateurs of our day; indeed, Provost Russel was generally

* Drawn from a specimen kindly sent to us by Dr. Paterson from his collection at Fernfield, Bridge of Allan, N.B.

Growers or introducers of new plants will oblige us much by early intimation of the flowering of new or rare species, with a view to their representation in our "Garden Flora," the aim of which is the illustration in colour, and in all cases where possible life size, of distinct plants of high value for our gardens.

allowed to have been the "Rucker of Scotland," so rich was his collection and so well cultivated withal. For the "true, full, and particular" account of this beautiful *Vanda* I am indebted to Dr. Paterson himself, he having kindly given me the following history of it at my own request:—

"*Vanda tricolor Patersoni* was imported by me from Singapore about fifteen years ago along with other good things, including *Aerides Reichenbachianum*, *A. suavisissimum* (original varieties, according to Reichenbach), and I understand that my plants are the only ones in this country of this beautiful and most fragrant Orchid. My warmest house during the last two months (October and November) has averaged 50° in the morning, and sometimes 45°, and I find that *Vandas*, *Aerides*, *Saccolabiums*, &c., grow and flower splendidly, and *Phalaenopsis Schilleriana* and *P. Luddeemanniana* do well with the same treatment. Whenever the outside temperature is at 50° I always give plenty of air. At all times the air of an Orchid house should be fresh and sweet, not stuffy, dry, and burning, as we too often find it in many places; such an unnatural atmosphere offers facilities to all sorts of insect pests and disease, and in the end kills many valuable and rare plants."

The good effects of this treatment is corroborated by all who have had the privilege of inspecting Dr. Paterson's now famous collection, for all agree that his plants are unsurpassed in health, vigour, and floriferous tendencies. Another fact not so generally known is, that this success is due to the personal care of the worthy doctor and his son Mr. Charles Paterson, with the aid of a lady assistant. So much for Dr. Paterson's superb *Vanda*, of which he may well be proud. There will henceforth be no great difficulty in determining exactly what *Vanda Patersoni* really is; we have only to compare flowers with this coloured plate and trust to the evidence of our own eyes. But at my elbow sits an old Orchid grower, who asks all sorts of pertinent questions, and now he has perplexed me a little by asking me what the type

V. tricolor really is. This is not easy to define at once; it is not very clear indeed where *V. suavis* ends or where *V. tricolor* begins. Here, again, mere descriptions fail us, and we must trust to the pencil rather than to the pen. Let us look at the plate in the "Botanical Register" for the year 1847; that, I think, no doubt represents what Lindley meant for *V. tricolor* pure and simple; but I fancy no one seriously imagines that *V. suavis* and *V. tricolor* are really distinct except in colour, for even Mr. Bateman acknowledges as much in his "Second Century of Orchidaceous Plants" (t. 125), where in describing *V. suavis*, he says: "*V. suavis* is an extremely lovely Orchid, the flowers richly blotched and spotted with blood purple on a pure white ground so clear and distinct that they look as if made of porcelain. There are innumerable varieties, some of which have a good deal of brownish yellow in their sepals and petals, and to these the name of *V. tricolor* is usually given." A reference to the many figures published of these two quondam species will show the most marked variety, but for all practical purposes it is convenient to retain the specific names, *V. suavis* being pure white in the ground colour of the sepals and petals, and *V. tricolor* yellow instead of white. As Bateman truly says, the varieties are innumerable. Mr. Rand, in his "Orchid Book," p. 407, says he knows of fifteen varieties of *V. tricolor* all well defined, and specially mentions

V. tricolor Corningiana, Dodgsoniana, insignis, Russeliana, and multiflora. Then of

Vanda suavis have we not Veitchi, Rollisoni, the superb Dalkeith form, and our own beautiful Dublin variety, to say nothing of many others?

When at Clovenfords some years ago I saw a noble variety with, I believe, over twenty fine blooms on a stout spike nearly as long as one's arm. It seems as if the pure brisk air from the northern hills suits these Javanese Vandas admirably. I not long ago received a set of some nine or ten distinct varieties of our old friend *Cypripedium insigne* from Mr. Wm. Thomson, jun., and in the letter which accompanied them he remarks on the great variety to be found now in these and nearly all other plants, adding, "of *Vanda tricolor* we have also some very fine varieties; I should think we have eight or nine quite distinct, and about six of *V. suavis*." All this variety in habit, form, and colour, so bewildering to the "descriptive" botanist, is so much added joy to the cultivator, and especially so to the artist. Variety is to them the one great thing hoped for, and we are glad of importations of old Orchids from new localities mainly because, until they bloom, we are, like the respected Mr. Micawber, on the tip-toe of expectancy, anxiously looking out for something new to "turn up."

Then, again, we were told in old text-books of botany that colour, like the round O of our cricketing days, "stood for nothing," but Darwin and Lubbock and Mr. Grant Allan have taught us that colour is as potent in the history of all vegetable life as is structure even, if not the direct cause of all the variety of form observable in the wild plants of the "great wild garden." In the coming by-and-by we shall doubtless become learned enough to go back to first principles, and then scent and flavour will become "characters" as important in determining those "shifting indices" we call "species" as structure and colour are in this our own time. F. W. B.

SEASONABLE WORK.

FLORAL DECORATIONS.

CAMELLIAS in varied colours will now give an abundant supply of bloom, by means of which many distinct arrangements may be made. Unless the plants are very large, a great length of stem cannot consistently be cut with these showy and beautiful flowers, or the plants will be deprived of valuable growth. Stems a few inches in length may, in many cases, be secured without doing much injury to the plants if due regard is paid to cut only those growths that can be spared, selecting such as may be straggling or any that are taking the lead in strength of wood to the detriment of weaker shoots. Camellia flowers always look best when at least two or three leaves are retained. Wiring should only be resorted to in cases of necessity—not adopted as a general rule. Florist's gum (liquid gum arabic) is always useful in the case of these flowers; a little of this placed around the base of the blooms will oftentimes hold them together longer than they otherwise would be. A somewhat flat receptacle is the best in which to arrange them, or one with a trumpet arising from its centre. Sand well moistened and covered over with either good green common moss or some tufts of *Lycopodium* would give a very good base on which to arrange the blooms. This keeps them better in position than water. A few small seedling Ferns might be dotted here and there to relieve the otherwise somewhat formal look of the Camellias. Where a trumpet-shaped glass rises from the centre a piece or two of *Myrsiphyllum* twined around the stem look well. A spray or two of *Chorozema Chandleri*, in blossom now, might also be used in conjunction with or independently of the *Myrsiphyllum*. This is a good lasting flower in a cut state. As a finish to the top, white Roman Hyacinths or *Spiraea japonica* would be useful with a few pieces of *Epacris*, or even the latter by themselves would be sufficient, using two or three distinct colours. The sweet-scented Carnation Miss Joliffe is one of the best of its class at this season as a cut flower. Small spikes of Paper-white Narcissus are also extremely useful for the same purpose. Lily of the Valley will also be valuable in this direction, and can now be better depended on than earlier in the year, the spikes being altogether stouter and more lasting.

FLOWER GARDEN.

Aralias, at least some half-a-dozen of them, are in every way well suited for summer decoration out-of-doors, and two have proved to be perfectly hardy, having stood unprotected in the open ground in Hants during the two last winters; these are A. Sieboldi and A. Sieboldi variegata, both of them introductions from Japan, and presumably therefore natives of that country. The large bright glossy-green and finely-cut foliage of Sieboldi stands out conspicuously at any season of the year, but particularly so in winter when deciduous trees are leafless, and if this were its only merit it would be ample to justify the recommendation of it to extended culture, but it is also one of our most effective summer-flowering plants, being especially well suited for lawns, either as a centre or terminal plant, or to break up the formality of stiff geometrical arrangements of bedding plants. The variegated kind, alternated with the green, makes a fine bed, but they should not be planted closer together than 4 feet; therefore the bed should be large and preferably round in shape, and an appropriate undergrowth for the same is *Salvia argentea* or *Gnaphalium lanatum*, and for winter *Sedum glaucum*. The other varieties that do well for summer planting only are A. papyrifera, A. heterophylla, A. macrophylla, and A. sambucifolia, all of which are well adapted for use as single specimens, the foliage being displayed to best advantage when so used. If whole beds of these are planted they should be at such a distance apart that the foliage of each plant stands clear of that of its neighbour; of course this long distance planting necessitates the ground being furnished

with low-growing plants of suitable kinds, of which there is no lack. The varieties here named propagate readily from cuttings made of ripened wood, taken off with a "heel," inserted in sandy loam, and placed in heat. A. Sieboldi we have propagated by cutting up the stems as vines are propagated. Plunged in a bottom heat of 70° and covered with a bell-glass, they strike root as quickly and successfully as Vines.

Bedding succulents.—The uses to which these have been lately put in our flower gardens have undoubtedly contributed to the refinement of taste that has taken place in that department, and by a judicious selection of varieties, and using them in reasonable proportion to other kinds of bedding plants, there can be no doubt that they will long continue to exercise the same favourable influence. The kinds that are most valued here are those that produce the best effects and are the easiest wintered and propagated, as, for instance, *Agave americana* variegata, propagated by root suckers which are thrown up freely when planted out; *Echeverias*, many varieties, the best being *secunda glauca*, *glauca metallica*, *pumila*, and *sanguinea*, all of which produce offsets freely, which quickly root in any dry atmosphere and in any temperature short of actual frost. *Echeveria metallica*, *E. farinosa*, and *E. Peacocki* are extra choice kinds which, though somewhat tender, cannot be dispensed with; these varieties are most readily increased by seeds. *Kleinia repens* and *K. tomentosa* are invaluable for marginal lines in succulent arrangements; they are propagated by division of the roots in spring, and may be wintered safely in a cold pit. Several kinds of *Mesembryanthemum* are indispensable for clothing the ground beneath the taller succulents, by far the best being *M. cordifolium* variegatum; other good kinds are *cordifolium*, *caulescens*, and *incladens*, all easily propagated by cuttings in warmth. *Pachyphytum bracteatum* and *P. pulverulentum* are amongst the most curious of succulents, and being of small growth are well suited for dotting over the outer lines of beds; they are propagated by offsets and cuttings. Of *Sempervivums* the best for edgings and groundwork are *calcareum*, *montanum*, and *arachnoideum*, all hardy, producing offsets freely. *S. canariense*, *Donkelaari*, and *cuneatum* are three very fine low, dense growing kinds, propagated by offsets and seeds. *S. arboreum*, *arboreum* variegatum, and *arboreum atropurpureum* are generally termed Tree *Sempervivums*; they are of a branching habit of growth and attain a height of from 18 inches to 2 feet. They are propagated by cuttings. Perhaps *Sedums* and *Saxifrages* should not be classed as succulents; but as many of the low-growing varieties of these are seen to best advantage when serving as a cushion or setting for many of the succulents just mentioned, I name them, not their least recommendation being that they are quite hardy, and that they continue effective the year round. This latter advantage has tended to strengthen our partiality for succulent bedding, seeing that the only thing to be done when winter approaches is simply to remove the tender and half hardy succulents and substitute small shrubs, and the beds are at once furnished for the winter. Those who wish to adopt this kind of bedding in the coming summer should now set about the preparation of the plants by one or other of the ways indicated. On how to arrange them to the best advantage suggestions will be offered as the planting-out season approaches.

Sowing.—A first sowing of Sweet Peas should now be made, and to ensure continuous flowering a rich, deep soil is essential. Some make the earliest sowings in pots, and place them in warmth to germinate, transplanting to the open ground when the young plants are 2 inches high, but our experience is that the check caused by such transplantation is greater than any advantages gained by thus sowing them; we therefore prefer to sow them at once in their permanent positions. The following may also now be sown for cutting purposes in any warm nook in the open ground, viz., *Mignonette*, *Clarkias*, *Collinsias*, and *Larkspurs*. As soon as they are well through the

Hybrid Orchids and their culture.—So much is often said and written as to the supposed difficulties of Orchid culture, that anything on the other side seems worth recording. It is barely five years since I bought my first lot of about a score of Orchids, principally *Cypripeds*; neither I nor my gardener had had any previous experience of Orchids in any way, much less of growing them, yet we are now flowering the first batch of our own hybrids (two different crops). In addition to these we have many hundreds of a number of different crosses in earlier stages of development. Our latest addition is a fine lot of *Odontoglossums*, of which the pollen parent is one of the finest varieties of *crispum* (var. *Chester-toni*) ever seen; the seedparent is either *gloriosum* or *Uro-Skinneri* (extra fine variety), which we are not yet sure, but one or other it is for certain. As our first purchase of Orchids (from Messrs. Veitch) did well they were rapidly increased, till now I have over three houses full. Plenty of light, air, pure rain water, with stages well up to the glass, combined with an extra amount of hot-water pipes (to avoid forcing), makes success comparatively easy; but all this would be useless without the attention such as only one whose heart is in his work constantly gives, and I am of opinion our want of experience in our early start was an advantage, inasmuch as we escaped many of the prejudices of old-fashioned orchidists. I have certain reverses, e.g., I cannot grow *Cypripedium Fairieanum* well; in fact, it only exists with me. Can anyone tell me how to grow it?—N. C. C., Oakwood, Wylam-on-Tyne.

ground they will need guarding against the attacks of slugs, but besides thinning out this is about all the attention which they will require. Every kind of sub-tropical annual that it is intended to use this season should now be sown in warmth. Castor-oil plants suffer so much through transplantation from seed pans, that it is best to sow the seeds singly in small pots. The same remark applies to Maize. Of Cannas, put two seeds in a pot. Solanums, Wigandias, Ferulas, and all other kinds do quite well when sown under ordinary conditions, *i.e.*, in pans placed on a gentle bottom-heat, and covered with glass till germination takes place. After that and till the seedlings have got a firm hold of the soil water must be sparingly applied, or damping off will be the result. All stock plants of whatever kind kept over from last year ought now to be potted. Dahlias, Salvias, Cannas, and Marvel of Peru are among the more important of the kinds alluded to.

General work.—Prune Roses, shrubs, and trees, and complete any planting of these that has yet to be done, tying up or placing supports to the same. Dig and maure all vacant beds and borders. Cut back and nail in climbers. Keep spring flowers well firmed in the ground, protect them from vermin, and the tender and more highly prized kinds when necessary from injury by frost by covering the beds with tiffany or mats resting on hooped sticks. Turn gravel walks, mend Box edgings, roll lawns, and prepare any new additions to the same for sowing with Grass seeds by working the soil fine and level. A rich soil is not desirable, but if very poor a dressing of soot, or wood ashes, or both mixed, will be found to be an excellent manure.

INDOOR PLANTS.

Potting.—Preparations should now be made for potting stove plants. Plants grown in heat need warm soil, and on no account should potting be carried out with soil that is in an over-moist condition. When so used it becomes a close, compact mass, wholly unsuited to the healthy formation of roots. It is, however, possible to err in the opposite direction, the result of which is that in watering afterwards the whole does not get equally moistened. The best way is to keep all potting soils in the open air, getting as much as is likely to be required under cover a sufficient time before it is used to admit of its getting in proper condition. Therefore, enough loam, peat, leaf-mould, and rotten manure to meet the demand for the general potting of stove plants should now be placed where it will be secure from wet, yet exposed to the air. In order to warm it sufficiently for use it may be spread out on the brickwork over a boiler or on a flue; where it is inconvenient to do that, it may be warmed in the baskets set on the pipes in the house wherein are grown the plants to be potted. The time for the general spring potting will to some extent be ruled in the case of stove plants by the amount of heat kept up. The advantage of being able to use a brisk heat early in the season is that many plants of an almost continuous blooming habit, such as Gardenias, Allamandas, Ixoras, Dipladenias, Anthuriums, Scutellaria mocciniana, and others can be regularly brought on to give a lengthened succession. In this way Clerodendrons, Stephanotis, Bougainvilleas, and Eucharis can be had quite double the length of time in bloom that is possible where only a low temperature is maintained, the season being far advanced before such plants can come into flower.

Pitcher plants.—Unless there is a brisk heat at command it is useless to attempt the cultivation of *Nepenthes*; but where they are grown whatever they require in the way of additional pot room should be given at once before active growth commences. *Nepenthes* are spare rooters, and the roots, being brittle and black in colour, are easily hurt unseen. In potting, even so much as removing the drainage material is as well avoided, but if the soil has got into a decomposed, pasty condition it should be washed from the roots

by syringing it with warm water. If this is done carefully, the old material can be got rid of without so much as a root being broken; a 2-inch shift is usually enough for plants that are in vigorous health. Fill the pots half full of drainage, using nothing but the fibrous matter from good Orchid peat with all the earth removed, and an equal portion of chopped Sphagnum, with a few crocks intermixed; pot lightly and soak with tepid water immediately. In the case of *Sarracenia*, it is important that they should have the whole of the soil removed every year, as from the quantity of water which they require, it is certain to get unfit for the roots, which are not so brittle as those of the *Nepenthes*. They should be potted without delay, as if not done before growth commences the destruction of the roots is certain to cause the young pitchers that are coming on to be deformed. We have found this time of the year to be the best for potting all *Sarracenia*s, except *S. Drummondii* and its varieties, which should be done about July or August. One-half good fibrous Orchid peat to an equal part of chopped living Sphagnum, with a liberal addition of sand and some crocks, is the material these plants require, and plenty of water to saturate the soil at once. This condition must also be regularly maintained afterwards, as they are true swamp plants, and dislike their roots being dry. *Sarracenia*s increase readily by division of the crowns, and in the case of the taller growers that form rhizome-like stems, the latter may be cut into pieces 1 inch or 2 inches long. These will form crowns and in time make good plants, but it is not well to make these stem cuttings too small, or they will take several years afterwards to acquire their full strength. See that the plants are free from brown scale before potting; sponging with clean water is the best plan we have met with for removing the scale. *Cephalotus follicularis* succeeds best in a warm greenhouse temperature. Like most other plants that grow in continuously moist places, it cannot bear to be dry at the roots. It thrives in equal parts of fibrous peat and Sphagnum, with the addition of sand and crocks broken fine, filling the pots half full of drainage. It requires a bell-glass over it in order to grow it well.

Alocasias.—These should be potted before growth begins, especially if any division of the crowns is to be made. They bear dividing freely, the extent to which this is to be carried depending on the size of the plants required. Single crowns are very useful, the distinct form and colour of such kinds as *A. metallica*, *A. Veitchii*, *A. Lowi*, *A. intermedia*, and others of like character having a good effect when dispersed amongst the other occupants of the stove. Most of the species when strong produce young bulb-like offsets that should at the time of potting be taken off and placed singly in small pots. They mostly require soil similar to that which is used for Orchids, *viz.*, fibrous peat, Sphagnum, crocks, and in addition some sand. They are surface rooters; consequently the pots may be filled from one-third to one-half with crocks, according to the size of pots used.

Myosotis dissitiflora.—This Forget-me-not makes a pretty pot plant, and will bear a little warmth without becoming drawn. Even if the plants were not potted in autumn they may be taken up now. Seedlings that have had plenty of room to enable their getting strong may be put singly in 4-inch or 5-inch pots, securing good balls of earth so that their roots are not much broken in removal. Give them plenty of water and a light position.

Ferns.—The more compact growing species of *Adiantum*, including *A. cuneatum*, *A. assimile*, *A. gracillimum*, and for large baskets *A. farleyense* along with some of the *Davallias*, such as *D. bullata*, *D. elegans*, and most of the tasselled varieties of *Pteris serrulata*, all make excellent basket plants, and where employed alternately with flowering subjects have a much better effect than is obtainable by the use of blooming plants alone.

Hyacinths, Narcissi, and Tulips.—More of these should be placed in heat to come in late; they will now require little forcing, and

usually flower the best through coming in nearer their natural time. Still keep such plants near the glass, as by this means only can the leaves be prevented from attaining an unduolength, in which state they never look well.

Zonal Pelargoniums.—Easily managed as these are, they are often seen in indifferent condition in winter, producing much more leaf than flower. If the plants have been well prepared, they will bear a temperature of 58° or 60° in the night if located in a light house and kept close to the glass. Some of the double varieties, such as Wonderful, scarlet, and Madame Thibaut, pink, are the most durable, but they do not open freely with less heat than that just named.

Achimenes.—When well grown *Achimenes* are second to none for the dense masses of colour which they present. In hanging baskets suspended over the paths in a cool stove or intermediate house there are no flowering subjects equal to them, and in no way can the often bare, unfurnished appearance of the roof of a plant house be so well altered for the better and with a minimum of interference with the growth of the plants underneath as by the use of such baskets. But when employed a little forethought should be exercised so as to see that the size of the baskets bears some proportion to the dimensions of the house in which they are to be used. Large baskets are very effective when well filled, but they look out of character in a small structure. Baskets to be so used should be made of either copper or galvanised wire; if the latter be painted it improves their appearance, and the wires should not be too far apart, or the Moss with which they need to be lined protrudes in a way that looks untidy. Green Moss, such as is to be met with on the ground in woods, we have found to be the best. A couple of inches of this should be used, as less will not keep the soil within from washing through when water is given. After the baskets are thus well lined, they want filling with ordinary potting soil, moderately light, and the plants should be dibbled in about 2 inches or three inches apart over the whole surface bottom as well as top. Previous to this the roots ought to be started by putting them closely in shallow pans in a mixture of sandy loam and leaf-mould, giving them ordinary stove treatment; after the shoots are about 2 inches high they should be placed in the baskets as above, keeping them well up to the glass and in not too moist an atmosphere, for upon their making close, compact growth will depend their after appearance. A portion of the roots for pot culture should now be similarly started, with others kept dormant for a time yet, so as to give a succession of bloom.

PROPAGATING.

This is a good time for propagating *Dracænas*, both by means of roots and stems, where required in quantity; if struck now they will be sufficiently advanced for the bright sunny weather of the summer months to assist in colouring the foliage, which will not be the case if struck late, as then it will be necessary to push growth on as rapidly as possible to get fair sized plants before winter. For propagating purposes choose plants that have grown tall and leggy—the taller, indeed, the better, as the stem will then cut up into a greater number of pieces. In the first place cut off the top of the plant, and put it in as an ordinary cutting, leaving sufficient stem attached to it to form a base, and do not remove too many leaves, or when rooted it will have to be grown on for some time before it becomes effective; whereas if struck with as many leaves as possible as soon as it is potted it becomes a good dwarf plant. The tops should be put in small, well drained pots in a soil composed of sandy peat, with just a slight amount of loam well mixed up together. It will be necessary to stake any of them that may be top-heavy. After potting they should be kept in a close case in the stove and plunged in a bottom heat of from 80° to 85°, in which they will soon root. After that they should be hardened off without delay and shifted into larger pots.

Another way, and one often followed, is to put new Cocoa-nut fibre in the case, and in it insert the cuttings instead of putting them in pots, but where this is done they should be kept close for a few days after being rooted and potted, just to give the roots a start in the new compost. When the tops are taken off they should be thoroughly cleaned before putting them in the case, as if there be but a few insects on them in the confined atmosphere in the case, they will increase rapidly. Cuttings of the stem may be put either in a close case or in a house without any extra covering, provided a good growing atmosphere and a bottom-heat of about 85° are maintained. In either case the same principle is carried out, viz., to cut the stems up into lengths of about 3 inches or 4 inches, and the thick fleshy roots into pieces about half that length; this done, lay them in rows in Cocoa-nut fibre, leaving about half an inch between each row of stems, and when so placed cover them to a depth of 1 inch with fibre, levelling it down, when all will be finished. Except in a very dry place, no water need be given, as excess of moisture causes many of the pieces to rot. The young plants will soon push up freely from every joint, and when they have made four or five leaves they should be removed from the parent stems. Most of them root quite independently of the old stem, and if cut off carefully can be at once potted, when if kept close for a few days they soon become established. The old stems can be laid in again as before, when they will push into growth, but only weakly and irregularly compared with the first effort.

Stem cuttings of *Dracæna Goldieana* will not grow, but it may be propagated in this way: When the plant has attained a sufficient height, take off the top and put it in as a cutting; after a time the old plant will push out another shoot from the bud immediately below the cut part, which when strong enough may be taken off and treated as the top. The rate of increase by this method is slow compared with stem propagation, but is useful in the case of kinds that grow, but with difficulty, from eyes, such as *D. congesta*, *gracilis*, *excelsa*, &c. Where a plant has a fine crown of leaves, and it is desired to strike the top with as little risk as possible of losing them, two or three incisions should be made in the stem at the height required, and some Moss should be bound around, which must always be kept moist. If done in this way, the top need not be separated from the parent plant till it pushes roots into the Moss, when it should be taken off and potted.

FRUIT.

Peaches.—After the fruit is all set in the early house, the daily syringing of the trees may be resumed on fine mornings when the temperature begins to rise, and again after the house is closed for the day. If the inside borders have not been watered since the trees were started, a good supply of diluted liquid a few degrees warmer than the mean temperature of the house will be beneficial, and old trees which invariably set more fruit than they can carry may have a light mulching of good rotten manure placed over the roots at the earliest convenience. When the young fruit has been relieved of the remains of the decaying flowers, all the small and least promising may be removed as disbudding is proceeded with, but these operations will require great care and judgment, as anything approaching severity, particularly where the trees are weak, may produce a check which will affect the size if it does not cause the fruit to drop. The best and safest plan is to commence with the upper parts of the most vigorous trees, by taking off the foreright shoots first, and pinching others for spurs or ultimate removal, as space is wanted, and to work gradually down to the horizontal branches through which the sap flows less freely. Airing will now require constant attention, as sudden changes from a high temperature to cutting draughts often do much injury. In bright sunny weather it will be well to shut off fire heat early in the day and to close a little earlier in the afternoon when 70°

to 75° from solar heat alone will be quite safe, and the pipes being cold, a night temperature of 50° to 55° will be secured with gentle firing, and a chink of air on the front ventilators.

Succession houses.—Keep these well syringed and give just enough fire heat to admit of forcing with a circulation of air by night and day. Aim at a minimum temperature of 45° to 50° and a day temperature of 55° to 60° when artificial heat is required, and 5° more when the weather is bright or very mild. Fumigate with tobacco paper before the first blossoms open. Thin the latter where thickly placed by drawing the finger down the undersides of the shoots, and impregnate with a brush when in flower. By this time all late houses should be cleansed, tied in, and ready for syringing when the blossoms can be no longer kept back. Owing to the mildness of the season the buds are getting very forward, and unless we have a change the trees will be much earlier than they were last year, but much may be done by judicious retarding up to a certain stage, when a different course must be followed.

Figs.—The last few days being bright and warm early trees have made considerable progress, and many of the most forward Figs have reached a size which will not increase until the flowering process is complete, but this apparent stand need not cause alarm, as very important work is going on inwardly, and hard forcing will not help them. If the weather continues favourable a steady night temperature of 60°, with a rise of 10° by day and 5° more after shutting up will be quite high enough for a considerable time, but in the event of a change to wintry weather, 5° lower will form a safe working standard. Pay particular attention to the maintenance of a steady bottom-heat of 70° to 75°, and keep the roots well supplied with tepid liquid and guano water alternately, as the Fig when in growth is a gross feeder, and soon resents a falling off in quantity or quality. Be careful to keep the young growths and foliage firm and stout by means of liberal ventilation and clean by a vigorous use of the syringe, particularly when the house is closed for the day, with plenty of solar heat. Guard against overcrowding by pinching side shoots to form spurs, and remove weak growths entirely where there is not room for full development of the foliage and exposure of the fruit when it begins to ripen. Repeat former directions in the management of the succession house, always bearing in mind that a steady supply of heat, air, and moisture, combined with liberal feeding to well ripened trees which are not over-cropped, are cardinal points in the production of high-class fruit worth eating. Get trees in late houses pruned or thinned, washed and tied in as opportunity offers, as the time is near at hand when a multitude of pressing matters will require prompt attention.

Grape room.—Now all the late keeping Grapes are in their places, and doubtful berries have been removed, it will be necessary to keep the room dark, dry, and well ventilated. A temperature of 40° to 45° is quite high enough for Lady Downes, still the best and most profitable kind for keeping until new Hamburgs are ripe; and as the above figures can be maintained without the aid of fire-heat, all that is needed is just sufficient warmth on fine mornings to expel moisture. If Lady Downes are started early, perfectly fertilised, and well ripened early in the autumn, they will keep fresh and plump until May, but all stoneless berries which show signs of shrivelling after the leaves fall invariably shrink and perish first; hence the importance of taking time by the forelock in the spring, and the removal of all doubtful berries in the autumn before the bunches are removed from the Vines. To insure the perfect keeping of Muscats for any length of time after Christmas they should be quite ripe by the end of August, and slightly shaded from the autumn sun until the time arrives for cutting. To preserve their rich colour the Grape room should be kept at a temperature of 50° to 55°.

Melons.—To maintain a steady supply of Melons throughout the season another sowing should at once be made to succeed the first batch

now coming into rough leaf. If the bed intended for these is not ready, give them a small shift and replunge in bottom heat near the glass. Meantime prepare the fruiting pots, and plunge them where they are to remain until the fruit is ripe. Prepare the soil (stiff calcareous loam, which has been stacked for some months in an open shed) by breaking it up with the hand. Place it loosely in the pots, to admit of the heat passing freely through it, then ram firmly and turn out the young plants before they become pot-bound. If the soil is poor add a 6-in. potful of bone dust, or twice that quantity of dry rotten cow manure to a bushel of loam. Mix thoroughly some time before it is wanted, and see that a few of the roughest lumps are placed over the drainage. Give water sparingly until the roots reach the sides of the pots, and defer feeding until the fruit begins to swell, when the highest culture that can be given will be needful. If planting out on hills or ridges is preferred, make them small at first, using thin sods of turf, Grass side downwards, for a foundation. Turn out the plants, a pair on each hill, and 2 feet apart on continuous ridges, water sparingly, and then train to sticks when they begin to grow. Prolific kinds, now too numerous to mention, from which the earliest fruit is to be cut, may run over two-thirds of the trellis before the points are pinched out. The first set of side shoots will then show and set freely, and the plants being clean and vigorous they will finish Melons of the finest size and quality. For growing over paths in Pine stoves and other places where the pots cannot be plunged, free-bearing scarlet-fleshed kinds like Turner's Gem, Read's and Blenheim Orange are well adapted, and often succeed over dry hot-water pipes where the green-fleshed varieties fail, or become badly infested with red spider. We generally get plants of the above kinds established in the fruiting pots ready to succeed winter Cucumbers. They take up but little room, and the rapidity with which the superfluous moisture can be forced out of the soil without lowering the temperature when the Melons begin to ripen prevents cracking, and gives them a flavour they do not often attain when planted out on hills, when the roots are not so completely under control. Where pit or frame culture is contemplated and fermenting material is plentiful, the latter must be well worked and fermented to be ready for making up a bed early in February. Plants for this kind of culture are usually pinched at the third or fourth leaf.

Vines.—Follow up disbudding and tying down in the early house. Stop the shoots at the second or third joint beyond the bunches, and lay in the first set of laterals where there is trellis room for extension. Direct syringing may be considerably lightened in dark, dull weather, but the daily application of tepid water to strong stems, walls, and floors must be followed up until the bunches come into flower, and even then a soft atmosphere with a free circulation of air will be preferable to extreme aridity. From this time forward airing will require careful attention, particularly in cold, windy weather; but so important is a constant change, that steady firing must be pursued every morning until a little air can be admitted at the apex of the house. Close early at 75°, and run up to 80° for a short time on bright afternoons. When the bunches come into flower maintain a steady night heat of 60° to 65° for Hamburgs and 70° for Muscats and shy-setting kinds. Run up 10° after closing, and re-open the ventilators, if only half an inch, from the close of day until the following morning. Fertilisation is, of course, an important matter, and almost every grower has a method of his own, from a dash with the syringe to a draw over with the hand; but this rough usage being often injurious to the delicate organs, a camel's-hair brush well charged with Hamburg pollen will best perform this operation.

Late houses now ready for starting may be well watered with cold water from the tanks to bring the inside borders into a growing state, and to fill up the buds before forcing is commenced. If the Vines carry heavy crops annually, and the Grapes are kept hanging until Christmas, a good

surfacing of rotten manure may be laid on forthwith and well washed in with tepid liquid, as late hanging is quite as severe a tax as early forcing. Get all pruning and cutting down finished for the season, and dress the wounds with styptic, as there is now danger of bleeding; also put on grafts when the sap in the stocks begins to swell up the buds. An excellent kind for the late house will be found in Mrs. Pearson, as it is a good grower, and is greatly improved by being allowed to hang after the leaves fall; moreover, it can be grown and finished in a much shorter time than its fickle sister, the second-rate Golden Queen.

KITCHEN GARDEN.

WE commenced the other day to stick our early border of Peas, and we may hear remark that we like new stakes in preference to old ones, always thinking the Peas take to them more kindly; we shall not at present use any Fir tops to protect them, the weather being so mild. But all will be in readiness for the cutting March winds, which do them far more harm than frost. Take advantage of all fine dry, open weather to run the hoe through all growing crops, Lettuces, Cabbages, &c. Although no advocate for earthing up the latter, still the firmer the soil is round the neck the better. In windy weather Cabbages often blow about and get loose at the neck, which is anything but a good condition. Planting out Tripoli Onions between rows of young Strawberries is a system which we always adopt, and generally they turn out fine bulbs, doing the young Strawberries no harm whatever; also planting a quarter of Hawke's Champion Rhubarb. We use Rhubarb in quantity for forcing purposes, and also for preserving. Turning over our store of Potatoes has occupied a long time, but is now drawing to a close. They are in capital condition, the eyes in most of them being now visible; the greater part are stored in a good dry room on shelves. Gardeners will now begin to order their seeds—nothing like being in time in this matter. Young Tomato plants should now be in 3-inch pots, singly. Keep them close to the glass in order to get them stubby and robust. In February we plant ours out in not too rich soil. Winter Tomatoes have done well with us, having had a full supply all through the autumn and winter. The best forcing varieties are Criterion and a selection of Hathaway's of our own. None of these are giants in size, but queens in flavour.

KITCHEN GARDEN.

SPRING TREATMENT OF AUTUMN-SOWN ONIONS.

WHERE new Onions are wanted earlier in spring than can be had from seed sown now or during the next two months, there is no better way of securing them than by sowing seed in the autumn, getting a good batch of young plants up then and cultivating them well in spring. It is the Tripoli and Rocca varieties which we prefer for this work. The seed is sown early in September, the plants are about 3 inches or 4 inches in height in November, and they do not grow much more until now. We have had them larger than the sizes just named at this time, but we do not like them too tall, as if we have a mild winter and spring and the plants very forward, many of them are almost sure to run to flower, and that spoils the bulbs. When of medium size the weather has no influence on them; they transplant well, start off in a free growing state, and not five per cent. of them will fail to produce fine bulbs. The white ones always bulb first, then the yellow ones, and lastly the red ones. While sowing in autumn we always study to do so in good, well manured soil, and as we sow in rows we allow one plant to remain every 10 inches or so apart, and lift all the others for transplanting at this time. Those that are undisturbed bulb first as a rule, but those which are taken up and replanted make the finest specimens. For this reason I would always transplant those

intended for exhibition, or any which I wanted to be of an extra large size.

Deeply dug, well manured land is the only kind which will produce a really fine crop. Liquid manure or other artificial feeding may be given when the bulbs are forming, and this assists their development, but properly prepared land is the main secret of success, and as this should be seen to before any planting takes place, it will be understood that this is an important operation in connection with Onion culture at the present time. The best autumn-sown Onions I have ever seen were grown on a piece of ground which was trenched 2 feet deep in January, and just before planting early in February another trench was taken out at one end. This was 18 inches wide and 8 inches deep. Into this a quantity of manure was emptied and spread out in a solid layer 6 inches deep. The soil from the next trench was thrown on the top of this, levelled and trodden down, and the whole piece was gone over in the same way, when it was ready for planting, and the crop was an unusually heavy one. It may be remarked that the manure came from a closet, and was mixed up previously to being dug in with a quantity of old Mushroom bed manure. This mixture suits Onions admirably, and all anxious to excel with their Onion crop should use it. Probably it might not be convenient to treat all the Onion ground in this way, but part of it for any special purpose might be done so.

Another way which applies to all Onion ground at this time is to have it trenched as before, and then dig in a heavy coating of manure in the ordinary way. A dressing of soot may also be given at the same time to kill or ward off worms, but lime and manure should never be put on together. Salt is useful for the same purpose, and I often put a thin sprinkling of it over the manure before turning it on to the Onion ground. It is a bad plan to dig the soil when very wet, and it is a still worse practice to plant under such conditions. A dry day, and when the soil will not adhere to the feet, are the best conditions for getting in Onions. The ground being ready, the next thing is to plant. No drills or anything should be drawn for this crop; on the contrary, the plants should be merely put in on the level surface. Fifteen inches between the rows and 10 inches between the plants is a suitable distance at which to put them in. In taking the plants up from the seed rows they should be very carefully drawn out, and if this cannot be done without breaking the small roots, especially those close to the base, a fork should be used for easing them out of the soil. In planting we use a dibble, and the roots are let well into the ground, but the bottom of the plant is not covered more than 1 inch with soil. This is made very firm to prevent shaking, and planting is completed. Under favourable weather growth soon recommences, and the Dutch hoe is run through them from time to time. If planted now many of the bulbs will be of fair size by May, and then the worst of them may be drawn up for use, allowing the strongest and best formed to remain for later use or exhibition. Where the latter object is in view large quantities of liquid manure should be given during drought, and if the weather is too wet to apply this, a little guano may be put round each bulb, to be washed to the roots by the rain. Altogether the autumn-sown Onion crop is a most profitable one in spring.

CAMBRIAN.

SHODDY MANURE.—WOOL V. COTTON.

A PORTION of Mr. Wood's remarks on this subject (p. 72) is, I think, somewhat misleading. He says, "The extracting process consists in soaking the rags in oil of vitriol, diluted of course. That destroys the vegetable fibre, which falls to dust when passing through the machinery," adding, "and so shoddy is made." Yes, but which is the shoddy? Surely not the burnt cotton dust which falls in the process, as Mr. Wood's assertion would, I think, lead us to infer, but the wool thus extracted, which, unless one is mistaken, is sent to the mill to be again worked up with other wool or cotton

into yarn and cloth. Quite a distinct article this from that sold as "woollen shoddy manure," of which large quantities have been for many years, and still are, sent to the farming districts from Yorkshire. That which I use comes almost entirely from the woollen mills, where it drops under the machinery. Most of it being heavily saturated with oil, is then sent to the oil extractor, who, by hydraulic pressure, and with the aid of boiling water only, extracts the oil, which he refines. The residue is then sold as "shoddy manure," being chiefly woollen refuse, with a small percentage of cotton, which is so often worked in with woollen goods. Good wool shoddy contains say 7 to 8½ per cent. of nitrate of ammonia, this being its test of value. I know nothing of cotton shoddy, but doubt from its nature whether it possesses any ammonia worth naming. If some user of it who has taken an analysis would give us the result it would be interesting. X.

DECIDUOUS FLOWERING WALL PLANTS.

Magnolia conspicua.—When trained to walls on any other but a north aspect this Magnolia is quite hardy, and when a plant of it has attained a good age and covers a large space, I know of nothing that is so striking, flowering as

Magnolia conspicua.

it does in a most profuse manner. It is the earliest to flower of all hardy wall plants. With us it flowers generally about the beginning of April. Before the leaves appear more than 3000 flowers have been counted, more or less open at one time, on a fine specimen which we have here trained to a wall with an east aspect. All that it requires is a good deep soil, and it is not very particular as to its character, provided it is strong and holding. Our tree has reached to the top of a wall 14 feet high, and the branches have extended to a proportionate width. Fan training appears to suit it best if the branches are trained from 12 inches to 20 inches apart; flowering spurs are formed in just the same way as in the case of a Pear tree, and these spurs will go on almost an indefinite time, producing a crop of flowers every year. The regularity with which these spurs are distributed over the branches is not the least of its many valuable qualities, as they not only furnish flowers regularly every year, but they are so placed that when the tree is in blossom it presents quite a sheet of bloom. We have to secure the branches to the wall by means of long nails and strong tar cord. In order to do this work well it must be done during the winter when the leaves are down. This and the cutting away of a stray shoot now and then is all the trouble it gives us, and for this we get regularly every year a grand display of flowers.

Chimonanthus fragrans and grandiflorus.—I do not claim for these any effective features further than when in leaf they have a very pleasing appearance, and that they will grow

well in any position and in almost any kind of soil, but we must not altogether ignore their curiously formed and fragrant flowers that appear in the dead of winter, for their flowers alone make them favourites, and if a garden is to be interesting at all times of the year, these plants should find a home in it. In a good soil these *Chimonanthus* grow freely, and are not at all difficult subjects to train against a wall. The proper time to prune them is in the end of February when out of flower. If pruned in autumn there is danger of cutting away some of the growths that, if left untouched, would flower. Strong plants in good soil will in a few years reach to a height of 12 feet.

Large yellow-flowered Jasminum.—This very vigorous-growing plant will often reach a height of from 12 feet to 14 feet. In mild winters it sometimes retains a portion of its foliage. In a warm position it commences to flower in June, and continues in that condition until the autumn. The flowers are clear yellow in colour, and larger than those of other hardy *Jasmines*. The white, sweet-scented *Jasmine* is so well known that I need only say it should always be planted where hardy creepers are required.

Aristolochia Sipho.—This is in many respects a distinct form of climber; the foliage is striking and the flowers different in form and colour from those of any other hardy creeper. It is also a rapid grower, and in a good soil with plenty of space for its roots it is capable of covering a large area of wall; for clothing the fronts of dwelling-houses it is admirably adapted, but it requires time and space to show it off to the best advantage. I once saw the front of a large house covered with it, and when in full flower it made an impression which I shall not soon forget. It requires more attention when growing fast than some other subjects, or the young growth soon gets entangled, but when the space has once been covered it does not grow so unruly. The pruning should be done in the winter time or early in spring, and when judiciously done it will flower from the spurs formed by cutting away the shoots that grow outwards from the large branches. Sometimes it is desirable to thin out a few of the old branches to make room for the young growths in order to keep up a supply of flowering wood.

Buddleia globosa.—As this plant does not always retain its foliage in winter, it may be admissible in this list, but it is not recommended as a choice wall plant. Anyone who may have a high wall to cover or the gable end of a building may, however, plant it with every prospect of its covering a large space as quickly as any plant that I know. When practicable, a sheltered situation should be selected for it, as rough winds are liable to injure the young growth, which is easily broken. It will thrive in any moderately light soil, and, as regards the roots, when once established they will take care of themselves, but the branches require more attention; they must be firmly secured to the wall by strong shreds or ties. Let the leading shoots be secured close to the wall, and a good portion of the lateral growth should be tied in to hide the naked branches. It flowers on the young wood during the summer months, and its globular-shaped, dark yellow blossoms are both curious and handsome. What pruning it requires should be done in February or March.

Calycanthus floridus (Allspice tree).—This is only suitable for walls of medium height. With us it is quite hardy in the form of a shrub in the open borders, but in colder districts it may require the shelter of a wall, where it will grow and flower freely. It is not a striking plant, being more curious than beautiful, but its highly aromatic flowers are much esteemed by some. A rather light soil is necessary for it, and it needs very little pruning.

Wistaria sinensis.—This is so well known that any lengthy notice of it is unnecessary. I may, however, mention that where there are large spaces to cover, the *Wistaria* will cover them sooner than any other flowering plant of equal merit.

Jasminum nudiflorum.—This is another winter flowering plant, no doubt well known, but as it is quite hardy and grows freely in any kind of soil, it deserves a place wherever there is room for it. It begins to open its blossoms in November, and in mild winters will keep flowering for several weeks. As it grows fast during the early

Jasminum nudiflorum.

summer months, it requires some attention during that time to keep it in good order. When overcrowded some of the old exhausted wood should be cut out early in March to make room for young shoots, for it is on these the largest flowers are produced. The blossoms being bright in colour, a few twigs thickly studded with them are acceptable in January to mix with other flowers, and a reasonable amount of cutting does not injure the tree.

Honeysuckles.—Of these there are several that are fast growing and thoroughly hardy. The common Dutch variety is perhaps as useful as any, but for the choicest positions the variety known as *flava*, which has, as its name implies, yellow flowers, and the scarlet trumpet kind are very suitable plants. The sorts here named will grow from 10 feet to 15 feet high. A good deep soil, careful training, and judicious pruning during winter are the principal details needing attention. On the merits of Honeysuckles as fragrant flowers I need not dwell, that being a feature they are widely known to possess.

Bignonia radicans.—This is a vigorous and somewhat unruly subject, its greatest value being that in a suitable climate it will cover a large

Bignonia radicans.

space in a few years. In the west of England it may be seen sometimes in good condition, its large trumpet-shaped flowers, pretty freely produced on a vigorous plant, being very handsome in the late summer months.

Double-flowered Kerria.—This is better known as *Corchorus japonicus*, and although not now grown so much as in times past, it is not

without merit; it is thoroughly hardy and will grow in any kind of soil. The neglected condition in which it is generally found gives one no conception of its true value when properly managed. It is just the plant to cultivate where more tender subjects fail. In a good soil it will reach a height of 10 feet. To get it to flower freely it should have some of the old wood cut out of it early in spring, and the young growths must be nailed into the wall, especially the strong growing shoots, for it is these that furnish the principal flowering wood. It commences to open its blossoms in June, and a vigorous plant will continue flowering all the summer. There is a single kind as well as a variegated form with single flowers, but in my opinion as a wall plant the double-flowered variety is the best.

Weigela rosea.—As a fast growing, free flowering plant this can be highly recommended for walls or trellises from 6 feet to 10 feet high. The profuse manner in which it flowers is sufficient to recommend it for positions where a hardy plant is required.

Clematises.—Although many of the new sorts of *Clematis* are very beautiful when in blossom, there are not many of them that can be recommended for the covering of walls, &c., unless the cultivator is prepared to devote a good deal of time to training them when in active growth. I shall, therefore, only name a few, selecting them from the different types, and mentioning only the most suitable that will thrive with ordinary attention. To produce a mass of white flowers over a large space there is not one to beat *montana*, the blossoms of which put one in mind of those of the *Wood Anemone*. This is an old variety, and well known to thrive in any position. The *patens* type consists principally of spring bloomers, with medium sized flowers borne in clusters on the old or ripened wood; *Standishi* has light purple flowers, and is one of the oldest of this section; *Stella* is a very distinct sort, with pale violet flowers; *Miss Bateman* is a well-known white kind, and well worthy of any extra care that may be devoted to training it; the *lanuginosa* type contains large-flowered summer and autumn bloomers, flowering principally on short, summer shoots; they require but little pruning. The best are *Lady Caroline Neville* (French white) and *lanuginosa* (lavender). The *Jackmani* type is probably the best of the whole family, containing, as it does, plants that grow vigorously and flower in the most profuse manner for several weeks continuously towards the end of the summer. In its particular line of colour *Jackmani* is undoubtedly the best, and *Prince of Wales*, also a deep purple, grows and flowers well from August to September. The old and familiar sweet-scented variety named *Flammula* is probably the best white flowered sort in this section, as it thrives in any kind of soil and position. All in this section flower on the wood of the current year; therefore all the old wood should be reduced considerably at the winter pruning. J. C. C.

Lawn weeds.—During the last thirty years I have tried every mode of eradicating these suggested by every published correspondence, and, taking the result and cost of time into consideration, I have come to the conclusion that the best method of proceeding is, after the first cutting in the spring, to put as much salt on each weed through the palm of the hand as will distinctly cover it. In two or three days, depending on the weather, they will turn brown. Those weeds that have escaped can be distinctly seen and the operation repeated. The weeds thus treated die, and in about three weeks the grass will have grown, and there will not be a vestige of disturbance left. Two years ago I converted a rough pasture into a tennis ground for six courts. Naturally, the turf was a mass of rough weeds. It took three days to salt them, and the result was curiously successful. I had one lawn with more Daisies than grass, and on Sept. 2, 1881, I took up the turf, scratched the ground, relaid the turf upside down, scratched this also, well seeded it,

sprinkled it with soil, and in one month it was green and hardly distinguishable from the other parts of the lawn. Similar trials had been made in each month from March, and as late as August 12, but the earth gaped or cracked.—BERKSHIRE.

FLOWER GARDEN.

THE GLADIOLUS FAILURE.

I AM very glad that this subject is being well ventilated, and hope that all growers of the flower will be as explicit in their statements as your two correspondents, "J. C. C." and "W. J. M." (although I am not over sanguine that any very practical results will accrue), for the first thing in arriving at any conclusion upon any given subject is to have a full and clear statement. How many a client has lost his cause from keeping back from his lawyer, through shame or some false motive or other, some material point in the history of it which has come out in court afterwards! Not long ago a friend of mine took up a case of a disputed property. His client made out a very clear statement, and he thought all would go well; but when the case came on it oozed out that there was another relative in the matter who was on the male side, my friend's client suing for the female side, a fact perfectly well known to the client, but which he concealed from his lawyer. I would be the very last person to discourage anyone from growing florist's flowers, and especially a flower from which I have had so much pleasure as the Gladiolus; but I think that it is only fair that the difficulties which surround its culture should be well known, and then persons entering on it may try their hand at overcoming its difficulties. In speaking plainly, of course, one is liable to the charge of damaging the sale of the roots, but if my ideas are as wrong as some would imagine, they cannot have much weight in influencing others. But even were it otherwise, a suppressed truth is often as much a falsehood as a direct misstatement, and one who writes for the benefit of others has no right to conceal what he knows on any given subject.

Your correspondent "J. C. C." claims to know something about the Gladiolus, and I do not dispute his claim. A grower of 2000 roots ought to know a good deal, unless he has entered on their cultivation with some preconceived theory which blinds his eyes. I know something also of the Gladiolus in the localities he alludes to. For the last dozen years or more I have had the pleasure of judging Mr. Dobree's Gladioli at Taunton, and exceedingly fine they have been, but of late years I have noticed that there are larger numbers of seedlings amongst his exhibits than there used to be taking the place of the named varieties, and I should not at all wonder if his experience very much coincided with that of another gentleman in the same county who possesses a garden known far and wide, and spares no expense in carrying out his cultures. I mean Mr. Marshall, of Belmont, Taunton. I once or twice saw his exhibits, and, knowing that he grew them, I wrote to ask him his opinion. I cannot, perhaps, do better than transcribe his words, as they bear so strongly on what I have always stated concerning the flower. "I shall be most willing," he says, "to give you my experience of the growing of the named Gladioli. I am sorry to say it is very unsatisfactory. I used to get from Messrs. Kelway their collection of new ones for the year. My luck was this: generally three bulbs out of the lot would not germinate at all. My gardener has just told me that I have underrated the number. Quite an equal number would grow, but would wither away and die before flowering; the others would flower, but the second year the flowers were not at all equal to the first, and the third year they were of no use at all, even if they lived. I then got quite tired of the failures and mixed all the bulbs I had to plant in clumps, but the result was the same. It is a great pity there is such a failure, for it is a most beautiful flower." This letter is most interesting on two points. It is often said that these failures are the result of ignorance. Well, here

that cannot apply; and secondly, Mr. Kelway asserts that this failure is occasioned by exhaustion; but surely his own seedlings are not exhausted. And yet what Mr. Marshall writes of are his best and newest varieties. Moreover, as he lives not more than twenty miles from Langport, his climate must be very nearly the same. With regard to Mr. Dobree, I think your correspondent is in error in saying that he has been a successful exhibitor at the Crystal Palace. I never recollect seeing his flowers there, and I think I have seen every exhibition at which Gladioli have been shown there. Since this was written I have received a letter from Mr. Dobree which entirely bears out my view. In it he says, "I fear my knowledge of Gladioli is too small to be of much use to you. I have, like others, experienced many losses. Out of £20 worth bought in 1881 I only flowered a few, and I have hardly any of that lot left." He speaks of it as on account of disease, and says "seedling bulbs are not free with me from the disease, and this year some beds which showed signs of it in September were half gone by November. I have now a large lot of mixed and numbered seedlings, and have not therefore been so anxious after new varieties." My statement as to the loss of 50,000 bulbs in two years may seem astounding, but is none the less a fact. As to the planting of Gladioli, I can only say that I have frequently planted at 6 inches in depth, but that I have found no advantage in so doing. I am somewhat astonished that "J. C. C." should say that Mr. Kelway uses no manure; whatever he may do now, I know that I have seen very heavy mulchings of rotten manure on his principal beds. I should not have called Mr. Kelway's soil alluvial, at least a considerable portion of it, nor do I see why Somerset should be more favourable for the growth of the flower than any other of the southern counties.

The observations of "W. J. M." of Clonmel, are to me very interesting, as everything horticultural in a country where my first gardening tastes were developed must be, and also because he has been somewhat confident of his methods of cultivation. I notice indeed in his last notes a somewhat less confident tone, a confession of failure which I do not recollect in his earlier communications on the subject, and a consciousness that there is a good deal of difference between cultivating highly-bred varieties and seedlings or the common varieties. He, too, seems to have been startled at my report of my friend Mr. Banks' failures, and seems rather to have misunderstood my statement as to seedlings. What I meant was that there was as little likelihood of retaining a good seedling as a good named variety and hence as little satisfaction in them, for surely in seedling raising of any flower, the prospect of retaining it as of one's own raising is a great inducement; and as to the question of seedling raising, which I have done myself for years, it is very pleasant doubtless, and the fondness of a parent will often see beauties of surpassing excellence in one's own progeny which a stranger fails to see; but, after all, one rarely sees, except with Mr. Kelway's seedlings, anything at all equal to the named varieties. I cannot say that I see the advantage of his plan of storing, even if one had room for it, for I do not find that the disease—for such I must call it—develops itself after the bulbs are raised, but if it is present at that time it goes on until the whole bulb is destroyed. As to not cutting the stems when they are green, I can only say that this is always done at Fontainebleau and elsewhere in France, the bulbs are dried off on shelves in the house, and the good condition in which these bulbs reach us over here is the admiration of all who grow Gladioli. A relative of mine who has just received a lot from France writes in glowing terms of them, and says how different they are from the bulbs of English growth bought last year.

Mr. Douglas says I have accepted at last the inevitable, but I have never differed from him as to the losses which I have from year to year deplored, although we entirely differ (perhaps more in words than anything else) as to the cause. He calls it degeneration; I call it disease. By dege-

neration, as I have frequently said, I understand the falling off of a variety—not of a bulb; and I maintain that by growing the spawn of any one of the named varieties you can get as good blooms of them as in the year in which they were first sent out, but that the individual bulb does not improve—rather the reverse—is, I think, undeniable, and it is in this direction that I can alone see any way out of the difficulty. Many of the most valuable kinds spawn freely, and by careful management of them one is able to keep up a stock of varieties which would otherwise perish. Some kinds on the other hand spawn very sparsely. Our other help is the diminished price of good varieties. I have before me a list which a friend of mine has just obtained from France of 100 bulbs in twenty-five varieties of the *crème de la crème* of the French varieties, and for which he had to pay less than £5.

I know not to what we are to attribute the fine condition of the French bulbs but to their drier autumns, and it will be curious to see what will be the character this year, for the incessant rains with which we have been visited have reached them also, and Messrs. Souillard & Brunelet inform me that they have had the greatest difficulty in securing their harvest.

Altogether, I fear the growing of named varieties is on the decrease; people do not like giving, as Mr. Dobree did, £20, or as a relative did £15, and then in two years to have none of them left. I have known almost every one in the south of England at any rate who has attempted their cultivation, and they are nowhere. For two years I was the only exhibitor amongst amateurs at the Crystal Palace, and at last they shut the amateur classes out altogether; and I fear, with Mr. Douglas, we shall never again see the exhibitions we used to see some years ago of this grand, but very disappointing flower. DELTA.

CHRISTMAS ROSES.

WE have all to thank the Rev. C. Wolley Dod for raising a discussion upon *Helleborus niger maximus*, as it has led some of us to a right nomenclature for the varieties we grow under the above name. "Veronica" (p. 49) calls the great white Christmas Rose *H. niger angustifolius*, and describes it as having pale green scapes and large snowy flowers covered by the glossy green leaflets borne aloft. I had omitted to notice this paragraph when my friend Mr. Wolley Dod drew my attention to it, as it accurately described the variety we grow here, and which I had sent him.

Through the kindness of the editor, who forwarded my request to "Veronica," I received a flower and leaf, and they proved to agree exactly with our variety, and so, I suppose, we may consider that point settled. It also agreed, I find, with Miss Hope's description of *H. niger angustifolius* ("Gardens and Woodlands," by the late Frances-J. Hope, p. 26). I believe this to be by far the best Christmas Rose. It is also the most purely beautiful, the centre tuft of anthers being golden yellow, and it is also the most floriferous. We have lots of plants here which have yielded fifty flowers apiece from December to February. Truly a Christmas Rose. Next, as to *H. niger maximus*, "Veronica" makes Miss Hope call it also *H. altifolius*, but I cannot find this to be so. Miss Hope quotes the three synonyms, *H. niger major*, *maximus*, and *grandiflorus*, but I cannot find *altifolius* mentioned, nor do we need the name, as far as I know, although the plant is so called in florist catalogues. The true *H. niger maximus* is also accurately described by Miss Hope. It blooms two months earlier than *angustifolius*, and has its flower and leaf-stalks spotted with red, has a small tuft of pink in the centre of the flower on the tops of the pistils, and it is altogether a larger and more sturdy plant, easily distinguished by stalk, leaf, and flower. This variety I always look upon as Miss Hope's memorial; she discovered it in Aberdeenshire, where it abounds to this day, and whence all the true plants of it originate. I have again to thank Mr. Wolley Dod for putting me right on this point also, and for helping me to a

supply of the correct sort, which I thought I had already, but which I found I lacked when put to the proof.

I find Hellebores of all sorts thrive best with a west aspect. They like to be perched on a sloping bank, sheltered from every wind. Only last week during the cold westerly gales every leaf of Hellebores on the rockery that showed above the stones were withered up by the cold wind. They like a light soil with a large admixture of leaf-mould, and they are all the better for a liberal top-dressing of manure in August when the buds are setting. I buy a dozen large plants of *H. niger angustifolius* every autumn for flowering at Christmas in a cool fernery; these yield 50 or 60 flowers each, and are afterwards planted out, when, after a year's rest, they are as vigorous as ever.

WM. BROCKBANK.

Brockhurst, Didsbury.

WINTERING FLORISTS' FLOWERS.

SEVERE frosts and heavy snowstorms have prevailed in some districts, and disastrous floods in others. About London, however, we have had what may be termed an open winter, one that has been upon the whole favourable to florists' flowers. Nevertheless, let the winter be what it may, there are always some who cannot steer their collections of florists' flowers through it without heavy losses in the way of Auriculas, Pinks, Carnations, Pansies, and some other flowers. May I be allowed to state that we have scarcely any losses amongst our florists' flowers during winter? It may therefore be of service to those who cultivate these plants to know how we keep our collections intact.

THE AURICULA is still stated to be a difficult plant to keep through the winter, and difficult to manage even in summer. Nothing can be further from the truth. If the plants receive water when they ought to be dry, or suffer from lack of water when they require it, and withal are allowed to become a prey to green-fly they will die, as any other class of plants would do. During November, December, and January very little water is required. They should be placed in frames in an open, airy position early in October, but before placing them there, the frames and pots should be made clean, and air ought to be freely admitted both by night and day, unless very severe frosts should set in. Remove dead and decaying leaves once in ten days. Water merely to prevent the plants from becoming dust-dry, but never during frosty weather.

CARNATIONS AND PICOTEEES.—Of these we have wintered a large collection this year out of doors exposed to all the vicissitudes of the weather, but this is not the treatment which they ought to receive. All the choice varieties ought to be planted in small pots about the month of October, so that they may be wintered in cold frames and be freely exposed to the air like Auriculas. Here, again, cleanliness is a matter of vital importance. Green-fly does them much mischief, and if not destroyed will cripple them, so that they will not produce any full-sized well-marked blooms. We look over our plants about twice during the winter months to remove decayed leaves, and, if necessary, to stir up the soil in the pots. It is a good plan to fumigate them two or three times during winter whether there is green-fly on them or not. They require rather more water at the roots than Auriculas. Carnations and Picotees, I need scarcely say, are quite hardy during the severest frosts. We never cover the glass; keeping the frames close in winter, covering with mats during frost, and watering when the plants do not require any is the cause of disease and weak, spindly growths. The pots in which the plants are wintered had better be too small than too large.

PINKS.—In ordinary well drained garden soil these pretty sweet-scented flowers will stand the winter in the open ground, and require very little attention. They must, however, be well established before severe winter weather sets in; it is necessary, therefore, to plant them in September. I

generally prepare the ground early in that month by trenching it about 18 inches deep, and if the plants can be set out 6 inches apart from the middle to the end of the month they will succeed admirably. The beds should be raised, say, from 3 inches to 6 inches above the level of the paths. The plants root firmly into the ground before cold winter weather sets in, and they are not so easily thrown out by alternate frosts and thaws, as late planted ones are. Pinks are sometimes eaten off in winter, and one is sometimes puzzled whether it is rabbits or the leather-coated grub that does the mischief. Both feed after dark, and a few turns round at night with a good lamp will discover the depredators. Although the plants are comparatively safe in the open ground, a cautious florist will not trust all his plants there; and besides, some varieties are of a more delicate constitution than others. It is a good plan to pot one or two pairs of each variety. A single pair should occupy a 3 inch-pot, so that they may be wintered in a cold frame the same as Carnations. Those wintered in frames may be planted out in the open ground in March. I fancy, however, that those planted in autumn produce the most perfectly laced flowers.

PANSIES.—These require treatment very similar to that usually given to the Pink, but they do not seem to winter in the open borders quite so well, although the losses are unimportant if the plants are put out early; still, as a matter of precaution, it is best to place a plant or two of each variety in pots and winter them in frames. It is a good plan to cover the surface of the beds after the plants are established with dry, fine soil, to which a liberal portion of powdered charcoal has been added. Let this be spread thinly and evenly over the surface, and the plants should be pegged down to it to prevent their being injured by wind. Seedlings, in the shape of strong autumn plants, make a grand display, and not 1 per cent. of them are injured by severe winter weather. Wireworm will sometimes do much damage both to Pansies, Pinks, Carnations, and Picotees. The Pansy also likes rich soil, and prefers cow manure to all others.

HOLLYHOCKS.—It is earnestly to be hoped that this noble autumn-blooming plant may again be brought into prominence. The choicest varieties in some instances are not so easily propagated as Dahlias and Roses; but in general there is not a great deal of labour required to keep the collection intact. The plants should be potted into 6, 7, or 8-inch pots in autumn or be planted out in cold frames. The main thing is to protect them from too much wet. Early in February cuttings should be taken from the stools and potted in sandy soil, placing them in a gentle bottom heat in the forcing house. Autumn-struck cuttings ought to be wintered either in a cold frame or near the glass in a cool greenhouse, or in any house from which frost is excluded. They may be potted on into larger pots any time during this month. Strong seedlings planted in the open ground in September generally stand well during the winter in the open ground. If planted about 3 feet apart they will flower very strongly during the ensuing season.

J. DOUGLAS.

Loxford Hall, Ilford.

Shortia californica.—Owing to a misconception of the statements in the American paper from which the account was taken by M. Sisley, when writing to the *Révue Horticole* for January 16, the above named plant was said to be identical with *S. galacifolia*, which it seems is not correct, as the two plants are entirely distinct and different the one from the other; and as this error was unwittingly reproduced in the last issue of THE GARDEN (p. 100), I think it but right that it should now be corrected. The *Shortia galacifolia* is an excessively scarce plant, of, I should think, little, save botanical, interest, and closely allied to the family of Pyrola; a single plant of it growing in the garden of the Paris Museum of Natural History is believed to be the only one now in Europe. *Shortia californica* is a synonym for *Hymenoxys californica*, and is a composite allied to *Bæria chrysostoma*. It is of this plant the wood-

cut is given in the *Révue*, and of which seed is offered by Messrs. Vilmorin.—W. E. G.

SNOWDROPS AND RAIN.

THESE seem fairer and purer from the constant floodings to which they have been subjected this winter. The rains have neither washed the pearly whiteness out of the flowers, nor the pleasing and deep verdure out of the leaves. Some of the finest patches I have ever seen were clothing the surface of flooded lawns about the 20th of January. This shows that the Snowdrop is equally at home in hot soils and cold, heavy soils, and light, wet soils, and in dry. It often looks best and grows most vigorously contiguous to running or standing water. In early seasons it is sometimes practicable to have early Forget-me-not (*Myosotis dissitiflora*) in flower with the Snowdrop. But this is rarely the case, and the best companion plants are some of the earlier flowering blue Squills. But indeed the Snowdrop needs no support to render it the fairest and most pleasing flower of the spring. Its immunity from insect enemies and the attacks of rodents and birds, and the wonderful rapidity of its increasing alike by seeds and offsets if simply left alone, renders the Snowdrop the easiest and most desirable flower to grow by thousands and hundreds of thousands. And yet we seldom see a garden sufficiently full of Snowdrops. Even in those filled to repletion there is still room enough in wooded copse, shrubbery, lawn, mead, and hedgerow to hold myriads more Snowdrops are seldom seen in hedgerows, though no plant, not even excepting the Primrose, that claims and clothes these by right, looks more chaste and beautiful in such positions. In ferneries the Snowdrops look and do their best before the fresh fronds of the Ferns begin to creep forth at the bidding of warm weather. By the way, can anyone inform me what preys on the tiny roots of the golden Aconite when planted among Ferns as a companion plant to the Snowdrop? Having a taste for grouping plants in pairs, I thought the patches of gold in close proximity to drooping masses of silver would produce a charming effect, and therefore planted them pretty extensively. But the little Aconite has nearly disappeared, while the Snowdrops continue to spread and colonise among the Ferns. Possibly the situation is too shaded for the former, though I have seen great masses of gold even under the overhanging boughs of trees. One more question. Has anyone succeeded in having good Snowdrops at Christmas? and if so, will they kindly describe in THE GARDEN how they forced them?

D. T. FISH.

Hypericum empetrifolium.—"T. C. L." (p. 116) complains that this plant has died, and asks a question about the soil it ought to have. It is more likely that frost killed it than soil, as it is no more hardy than its near relation, *H. Coris*, though both of them are included in many catalogues of hardy plants; but it must be recollected that hardy is a relative term, and that different standards of hardiness apply to the climate of the Isle of Wight, and Kew, and Yorkshire. All the plants of *H. empetrifolium* were killed on my rockery by the frosts of the second week of December, but I had taken care to provide a stock for next year under glass. It is a pity that so many of the prettiest St. John's Worts are tender, but the best of all the genus for rockeries, *H. reptans*, seems able to stand ordinary winters. If "T. C. L." will send me his address, I think I can give him *Mertensia maritima*, which does fairly without sea air, though it is troublesome to keep, but I rescued several seedlings from slugs last summer.—C. WOLLEY DOD.

The Oyster plant (*Mertensia maritima*) used to be grown for sale by Mr. Stark, of Edinburgh. I have seen the plant growing on the coast near Balbriggan, and in flower. I believe it is exclusively a maritime plant in a wild state.—CHARLES McDONALD.

INDOOR GARDEN.

LACHENALIAS AND THEIR CULTURE.

The annexed woodcut represents an unusually fine *Lachenalia* recently sent to THE GARDEN office by Mr. Smith, of the Caledonian Nursery, Guernsey, under whose care this and several other pretty kinds of *Lachenalia* are exceedingly well grown. No doubt the plant figured is what has been called *L. pendula* var. *splendens*, though I am inclined to think that good cultivation and not any distinct varietal character has given rise to the last mentioned name. *L. pendula* is the best of the known *Lachenalias*, though some of the varieties of *L. tricolor* are not far behind it either in richness of colour or size of bloom. The late Mr. Nelson produced what is really a handsome and quite distinct addition to cultivated kinds, viz., *L. Nelsoni*, a seedling, I believe, from *L. aurea* and *L. luteola*, both of which, according to Mr. Baker, are varieties of *L. tricolor*, as is also what is known in gardens as *L. quadricolor*. For garden purposes, however, they are all sufficiently distinct to warrant us in retaining the old names, names, too, which are specially serviceable in distinguishing the one from the other, as they are descriptive of the colours of each kind. *L. pallida* and some of its varieties, of which several rather attractive ones have lately been in flower at Kew, and *L. orchioides*, a prettily marked species, are others of the genus deserving of cultivation.

Like a good many bulbous plants from the Cape, *Lachenalias* are winter flowering. They are so easily grown and flowered, and require so little fire heat, that no one possessing a cool greenhouse or even a frame need hesitate to add a few of them to their collection. Grown in pots, they look well in the front row on a stage or on a shelf, while planted in suspended wire baskets they make effective objects when in flower for hanging in conservatories. In Vol. XIX., p. 286, a few notes on the requirements of these plants will be found which are sufficient to enable would-be cultivators to succeed with them. *Lachenalias* have not inaptly been compared to our own Bluebell (*Scilla nutans*);—they suggest such a comparison from their habit and time of flowering. Indeed, the Cape colonists look upon them with the same affection as we do on our woodland pet. *Scillas*, *Chionodoxas*, *Muscari*, *Hyacinthus*, and *Lachenalias* are all of them among the most choice of our small herbaceous Liliaceous plants. It would be interesting to try whether the improvement effected through attention and skill in the case of *Hyacinthus orientalis* could not be brought to bear on the *Lachenalias*. We know that our now magnificent garden *Hyacinths* have all been worked out of the comparatively insignificant little species just mentioned, a plant with a flower-spike 3 inches long and about half that across. Compare this with some of the giant *Hyacinths* which we now see at our exhibitions, such as Lord Macaulay, Gigantea, or Grand Lilas, and it will seem almost incredible that such great improvements should have been achieved. Of course we must remember that some plants do not yield so readily to the inducements of the cultivator and hybridiser, and “break” into something better as others do, but Mr. Nelson has proved that in the case of *Lachenalias*, at all events, better varieties may be obtained than those we now possess. It would be worth while trying to get better still. Does any reader of THE GARDEN, let me ask, know anything of *L. stolonifera*? It is a narrow, long-bulbed species with green leaves; the flowers I do not know. I have had it several years now, but cannot get it to bloom. Our plants came from Messrs. Henderson, Maida Vale, and probably Mr. O'Brien knows something of it. I may mention that Mr. Baker does not include the name in his monograph of Liliaceae.

In reference to *Lachenalias* generally, Mr. Smith says: “Were I growing a few of the most distinct for decorative purposes only, I should select the following, viz., *L. aurea* (Mr. Nelson's form), *L. luteola*, *L. Nelsoni*, *L. pendula*, *L. quadricolor*, and *L. tricolor*. In one of Mr. Nelson's letters to me he says, ‘There are many views about the nomenclature of *Lachenalias*’—a

statement, alas, too true, as all who have attempted to form a collection have found to their annoyance. *L. Nelsoni* is certainly the finest all-round yellow. As to treatment, we pot during September and October, six bulbs in a 6-inch pot in soil consisting of two parts loam, one part well decomposed manure (that from an old hotbed answers well), one part sand, and a dash of dry wood ashes. This compost should be used in a fairly dry condition; the bulbs should be placed

Flower-spike of *Lachenalia pendula*.

about 2½ inches below the surface on a little layer of perfectly dry sand; they may then be left in the potting shed or any convenient place without water for about three weeks; by that time root action will have commenced, after which gradual watering should begin. A good plan is to examine a pot or two previous to using water in order to see if rooting has taken place. After that an abundance of light and air is the most important requisite; when the flower-spike can be first seen nestling down amid the foliage an occasional watering with weak liquid manure will be beneficial. After flowering let them still enjoy full sunlight, and as the foliage turns yellow gradually withhold water; thus by the time the bulbs are ripe the soil will be dust dry. They should then

be turned out of their pots and placed in a dry cupboard or drawer, there to be left till the potting season comes round again.”

FORCING IN FRAMES.

It is surprising what may be done in frames in the way of forcing, especially where plenty of leaves, stable manure, or tan can be got, as by the aid of either heat highly congenial to vegetation may be obtained at a trifling cost. The great thing in starting is to see that the manure, or whatever is used, is well sweetened, i.e., freed from rank steam, fiery gases, and its fermentation moderated before the bed is formed. When ready for use, the bed must be staked out according to the size of the frame, allowing about a foot larger all round, so as to insure plenty of base for it to stand on. The height will depend on what is intended to be forced. If for Cucumbers, or anything of that kind where strong heat is required, 4 feet will not be too much, as the bed subsides a good deal unless trodden firmly when made up, which is not a good plan, as it often prevents the material from beating in the regular manner it does when put more lightly together. Although many like a solid hotbed, I prefer one made up with a foundation of faggots or bushes, as then it is an easy matter by applying linings around to send fresh warmth under whenever there is any decline, which cannot be done so quickly and certainly when the manure and leaves get closely compressed by the weight of the frame and soil constantly bearing them down. For beds that have not to last any great length of time, and are only required for Carrots or Potatoes, from 2 feet to 3 feet is quite high enough if the material they are made with is good, as all Carrots and Potatoes require is just heat enough to start them well on their way. In the growing of either

Carrots or Potatoes light soil should be used; for the former a good deal of sand is beneficial, and the latter like leaf-mould. To save time while the frame is being made up and got ready Potatoes may be forwarded in small pots or boxes, and then planted out in the bed, where to economise space, Radishes and Mustard and Cress may be sown between the rows, or young Cauliflower or Lettuces raised, as any or all of these will be off before the Potatoes require the room. The distance at which to plant Potatoes is about a foot from row to row, and 9 inches from set to set, which is quite enough for Ashleaf or Myatt's, the two best sorts for growing in frames. If

Cucumbers are to be grown, some half rotten leaves should be scattered over the bed, and then a ridge of soil laid along the middle to warm. What suits Cucumbers best is fresh cut loam, just the thin top spit with plenty of fibre. This should be chopped up roughly, and laid in the frame lightly, as the more loose and open it is, the more freely will the roots of the Cucumbers be able to ramify. Unless the frame is very large, one plant to a light is quite enough, as by training a branch back and front the ground may soon be covered with fruit-bearing shoots. The bottom heat necessary to grow Cucumbers quickly and well is about 85°, and if kept steadily at this, with a temperature inside of 65° by night to 75° by day, the progress of the plants will be rapid and the stems strong. In giving air, which should not be done till the thermometer runs up to 75°, great care is requisite, or cold, cutting winds will rush in. To prevent this the lights should only be just tilted behind, so as to open them about half an inch, as with that much the glass may be allowed to rise 10° or 15° by the aid of the sun without any danger of burning or injuring the leaves. Cucumbers in frames so early in the season require but little water, either at the roots or over the foliage, as the steam from the manure supplies moisture, but on hot days it may be necessary now and then to sprinkle the foliage, but this should never be done unless the water is warm, as it would otherwise cause a chill and stunt the plant's growth. Some think Cucumbers only set by being impregnated, which is a most mistaken notion, as the setting is quite unnecessary,

unless seed is required, for the fruits swell just as well when there are no male flowers near, and the plants do much better without them. This being so, they should be pinched or rubbed out as they show, and the shoots stopped one joint above the young fruit, which will prevent the frame becoming too crowded with foliage. Besides Cucumbers, Potatoes and Carrots, Asparagus forces well in manure frames at this season, and if roots are taken up and put in on a gentle heat, heads will soon be fit to cut. To get these stout and well coloured and of good flavour, air should be given on sunny days and whenever the weather is favourable. S. D.

ERYTHRINAS AND THEIR CULTURE.

OF this gorgeously flowered genus, which in tropical forests is represented by many richly flowered species, both in the large tree and bush forms, we have at least one useful and very ornamental kind in cultivation, as well as several others more or less known and remarkable either for handsome foliage or richly coloured flowers. *E. Crista-galli*, or the Cockscomb Coral tree, as it is called—which is rather a long name, although perhaps with some, at least, preferable to the Latin name of which it is a literal translation—is one of our most useful greenhouse plants, as well as being one of the most gorgeously flowering subjects for outdoor summer bedding. In some of the London parks one may see beds of this plant in the autumn which are a glowing picture of scarlet and deep green, something to talk about, as one might say, while in some gardens the fitness of this species for greenhouse and conservatory decoration is amply testified to by the fine, profusely flowered specimens sometimes met with. Being an old-fashioned plant, we nearly always find this *Erythrina* in old-fashioned gardens. But, like many other antiquated fashions and ideas, some of these old-fashioned garden plants often find their way back to favour; as George Elliot says, they are just old enough to come into popular favour again. I do not mean to say that this *Erythrina* has ever quite gone out of favour in some quarters, but as we often find occasion to say of similar plants, it is not nearly so much in favour as it deserves to be. We grow this species in quantity for conservatory work, and as the season for working up a stock of such plants is just commencing, a note or two on *Erythras* may be seasonable just now. Old stools of

E. CRISTA-GALLI should at once be placed in a warm, genial temperature and well watered and syringed. This treatment causes them to break freely. On the young shoots becoming 4 inches or 6 inches long they may be taken off with a little of the old wood attached—a heel, as we say—and placed in a sandy soil in a propagating frame, where they will soon emit roots. Pot them on as they grow, using a mixture of loam and cow manure, and keeping them in a humid stove temperature until they are strong plants, when they may be gradually hardened off preparatory to their being placed out-of-doors if in the warmer parts of this country, or they may be grown on for indoor work. Abundance of water at the roots as well as overhead are necessary to the well-doing of this plant. As I have already hinted, it prefers a mixture of loam and cow manure, quite one-third of the latter to two of the former being not a bit too rich for it. As winter advances the plants should be potted up, and after becoming established dried off, that is, should they have been planted out of doors. They may be kept in any warm greenhouse under the stage until the time arrives for starting them again.

E. BIDWILLI is a hybrid between the above and *E. herbacea*, and combines the characters of its two parents. The shoots are annual, as in the above, and the flowers are borne in the axils of the leaves as well as on a terminal spike. This kind may be treated as advised for *E. Crista-galli*, and it is quite as useful a plant.

E. HERBACEA is a pretty dwarf-growing kind, deciduous like the two last, and bearing its flowers

on leafless axillary spikes at the base of the leafy shoots. It is a lover of a little warmer treatment than those above mentioned require; in other respects the treatment may be the same. Coming now to the ornamental foliaged kinds, we have in

E. MARMORATA a handsome stove plant worthy of a place in every collection where variegated leaves are desired. It is a large broad-leaved species of compact, yet elegant, appearance, and is remarkable for the beautiful marbling of its foliage, which is often blotched and spotted with more white than it has green. Being evergreen, too, it may be grown into a very handsome specimen. One of Messrs. Veitch & Sons' introductions, and in my opinion one of the best of variegated stove plants. It is a tropical species, being a native of the South Sea Islands.

E. PARCELLI is a tall-growing stove plant, very elegant, with trifoliate leaves, the leaflets being marked with a yellow variegation which spreads from the costa and veins almost to the margin. Treated liberally, it soon grows into a tall and beautiful plant, also a native of the South Sea Islands. Like the stocky-stemmed hardier kinds, these stove species delight in liberal treatment as regards soil and water. Other species, such as *E. indica*, are sometimes met with in botanic gardens, but as they are not free flowering under cultivation, at least they need not be mentioned here. There are several varieties of the Cockscomb species, some of which are superior to the type, such as *E. compacta*, *E. laurifolia*, &c.

B.

Simplex glazing.—This method consists of small neatly-made deal rafters, about 2½ inches by 1½ inches in size, upon the uppermost surface of which is fixed a double layer of thin lead strips, the two even ends of which terminate along the centre of and about 1 inch above the rafter. The squares, in width according to the distance of rafters apart, are then laid on the flat part of the lead, and the two projecting ends are then pressed closely over the squares on either side of the rafter. The simplicity of this arrangement, and the comparative ease with which the squares may be fixed by even unskilful hands, highly commend it to notice. At the same time there are one or two faults in connection with it which cannot be overlooked by practical men. Lead is unfortunately easily affected by heat, and when fully exposed to the sun on glass roofs in summer, the edges quickly curl upwards, and the rain in this case would then be freely admitted inside the house. Also as the pressure of the lead on the glass decreases from the same cause, the squares would have a tendency to slide out of position, unless secured by other means. Again lead by the action of soft water upon it leaves an unsightly deposit on the glass, which cannot be easily cleansed, and in time becomes highly objectionable. If these faults can, however, be overcome, the Simplex method of glazing may have a prosperous and profitable future.—T. C. W.

Tuberose culture (see p. 123).—Tuberose may be potted from January to June, but only a few should be reserved for the last-named period. From those potted in June we have had flowers at Christmas, but from some cause or other we lost more than half of them in consequence of the buds turning yellow; but as one flower at that season is worth half a dozen in September, the time at which we had the bulk of the plants in flower, we had to be content. Anyone wishing to secure a few flowers at Christmas should place the bulbs, after being potted, in a frame, covering them over with 2 inches or 3 inches of ashes or Cocoa-nut fibre; a wooden shutter over them will be better than glass. Glass must be heavily shaded and well ventilated, the object being to retard them as well as to protect them from rain. When they start into growth raise them out of the material in which they are plunged, but they may remain in the glass-covered frame until the temperature falls below 50° at night. When once started they must be pushed briskly on. They will require a temperature of from 55° to 60° to enable them to expand their

flowers in November and December. It is best to place one bulb in a 4-inch pot, using soil consisting of three parts loam and one leaf-soil, with a sprinkling of sand, pressing it firmly round the bulb, which should be inserted half its depth in the soil. It is seldom that Tuberose require watering until they start into growth; even then it must be judiciously applied. Over-watering has been productive of more failures than anything else. When once the flower-spikes are visible the plants must not be allowed to get dry, and they will be benefited by applying stimulants in a liquid form, which I prefer to using organic matter in the compost. It is seldom they all flower; one or two out of every dozen invariably fail with me as well as with others who have grown them largely. Bottom heat of from 60° to 70° will assist in reducing failures to a minimum, and it should be applied in the shape of a hotbed; thus the top heat can be kept comparatively low, say from 50° to 60°, and the bottom heat can be regulated by renewing the linings. Plunged in a moist hotbed, they seldom require water until they have grown 4 inches to 6 inches. As regards sorts, I have no partiality for one more than the other, and your correspondent will find both Italian and American good, *i.e.*, if he procures his bulbs from a reliable source. Tuberose are subject to red spider, but in some houses they may be grown without a trace of it. When it makes its appearance water is the best remedy, applied by means of a syringe. The surface of the leaves being smooth, the insects are readily washed off. —W. P. R.

RECENT PLANT PORTRAITS.

THE number of the *Botanical Magazine* for February contains coloured portraits of the following plants:—

BILLEBERGIA (HELICODIA) PORTEANA (a double plate, No. 6670).—This plant is a native of Brazil, and is a member of the family of the Bromeliaceæ; it produces long pendulous spikes of curious purple and green flowers, surmounted at top of stem by numerous brilliant rose-coloured bracts or involucres, and is said to be one of the most striking of all cultivated Bromeliaceæ. It flowered at Kew for the first time in summer of 1878, and again in June, 1882, when the present drawing was made.

POGONIA GAMMIEANA (Plate 6671).—A curious and handsome foliaged Orchid from India, where it is found in hot valleys below Darjeeling, and also in the Western Himalayas about Bagesar. It produces spikes of pendulous and rather pretty pink flowers, and is said to be extremely difficult to cultivate. It flowered at Kew in May, 1881.

MICROGLOSSA ALBESCENTES (Plate 6672).—Native of the Himalaya. This plant was introduced so long as 1842, but is still very rare and comparatively unknown in gardens. It is described as a very handsome hardy flowering shrub, with bunches of small starry purple blossoms. It bloomed for the first time in the gardens of the Royal Horticultural Society at Chiswick, and has been described under no fewer than nine different names.

PSEUDODRACONTIUM (AMORPHOPHALLUS) LA-COURI (Plate 6673).—A singular Aroid from Cochin China, whence it was introduced by M. Liuden, who sent it to Kew, where it flowered in May of last year. Its foliage is distinctly spotted with white; it was discovered by a French collector, M. Contest Lacour, after whom it was named. Its flower-scapes are of a greenish colour, and probably when fully developed attain a much larger size than here figured.

PLEUROPETALUM COSTARICENSE (Plate 6674).—Native of Central America. A very handsome half-shrubby plant bearing bunches of brilliant red fruit about the size of a small pea; well adapted for pot culture in a moderately warm house, where it is said to retain its beauty for several months. This plant was sent to Kew by Dr. Wendland. It flowers in the Palm house in the autumn and ripens its fruit in winter.

The last number of *La Belgique Horticole* contains a fine triple plate of a very curious Bromeliad named *Vriesia tessellata*, the foliage of which is veined over with cross lines somewhat resembling the structure of that curious aquatic known as the Lattice plant; also a plate of *Masdevallia Chimæra*, the best representation of this curious species that I have yet seen. The *Revue de l'horticulture Belge* for February contains a pretty group of four *Masdevallias*, representing the following varieties of this showy family—*M. Lindeni*, *M. Veitchiana*, *M. amabilis lineata*, and *M. tovarensis*, with three flowers open simultaneously on same stem. The last number of Regel's *Gartenflora*, completing the volume for 1882, contains coloured plates of *Odontoglossum Murellianum* var. *cinctum* (plate 1101), a very pretty Orchid with white flowers margined with light purple and a distinct golden centre with handsome markings. *Ethionema grandiflorum* (plate 1102), a very ornamental low growing herbaceous plant, producing quantities of bright rose-coloured flowers resembling those of a Ten-week Stock, also woodcuts of *Crinum australe pedunculatum* and *Trichocentrum Pfaui*, apparently a very handsome Orchid. W. E. G.

PLANTS IN FLOWER.

A SEEDLING PRIMROSE of the duplex or hose-in-hose class comes from Mr. Dean's seed grounds at Bedford, where at present Primroses of every type and hue abound. This seedling has flowers of a rich rosy mauve colour, and the corolla being duplicated makes it a very showy variety.

FLOWERS of CHOICE BULBOUS PLANTS sent us by Mr. Barr remind us pleasantly of the return of spring. Among them are the *Galanthus Elwesi*, the handsome Snowdrop noticed last week; *Iris reticulata Krelagei*, the early form of this lovely netted Iris, with flowers of a more violet tinge than the type; and the Spring Snowflake (*Leucojum vernum*) with its snow-white bells so prettily tipped with green.

EUPHARIS AMAZONICA.—Will you kindly note that we have here (Roseneath) two plants of this *Eupharis* in flower—one with twenty-four spikes, the other with eleven, each spike producing from four to seven flowers, numbering altogether 186 blooms. I may add that both plants were in flower last October, and that each then produced from eight to twelve spikes.—CHARLES MAY, London Road, Enfield.

PRIMULA FLORIBUNDA is quite a little gem among Primroses. It is not much to look at, but the colour of the tiny flowers is such a rich golden yellow as is seen in but few if any of the other species. It grows but 4 inches or 5 inches high, at least in the case of the specimens which we saw in the Chiswick garden; from a tuft of leaves it produces a slender flower-stem terminated by whorls of flowers as big, say, as a threepenny-piece. It was exhibited at the last meeting at South Kensington from Messrs. J. Dickson's nursery at Chester. It is a Himalayan species.

HABROTHAMNUS NEWELLI, a seedling raised by Mr. Newell, of Ryston Hall, Downham Market, is a fine greenhouse shrub, suitable for draping pillars or hiding rafters. It is an improvement on such as *H. elegans* and *fasciculatus*, inasmuch as the colour is brighter, being a carmine-crimson and more floriferous. Flowering throughout the winter, it is very useful for cutting from, and it affords plenty of material for the flower basket when most required. In the Horticultural Gardens at Chiswick there is a fine plant of it in flower under the roof of one of the houses.

MILLA LEICHTLINI, a little Chilian bulbous plant, gives one the impression at this season that it is trying to flower and cannot, the flower-stalks being so short that the half-grown leaves and numerous flowers are mixed together. A plant in the open border at Kew is just now in this condition, and were it not that it has so very few rivals it would be unnoticed. The flowers are about the size of those of the favourite *Triteleia uniflora*

(which by the way is also, strictly speaking, a *Milla*), and are paper white, lined with green. We have known *Leichtlini's Milla* for about eight years, but we have never seen it much better than we have just described it; therefore it can be only recommended to one specially interested in bulbous plants. After all, perhaps it is our own climate and not the plant that is at fault. It may be quite a gem in a Chilian autumn.

STAPHYLEA COLCHICA.—Quite out of the ordinary run of forced flowering shrubs is this pretty plant which we saw the other day so beautifully in bloom in the garden at Gunnersbury Park. The flowers, which are pure white, are produced in clusters on the end of each twig, and are sufficiently numerous even on small plants to be effective. A pleasing set-off to the delicacy of the blossoms is the tender green of the foliage, which begins to unfold just about the same time as the flowers. Mr. Roberts speaks highly of it as a decorative plant at this season, and forces it pretty extensively. Pretty as it is, it does not seem to be much known, though Messrs. Veitch introduced it, we believe, some ten years ago or more. It needs the same treatment in forcing as shrubs of a like character, such as *Lilac*, *Deutzia*, and *Azalea*.

THE YELLOW COLCHICUM (*C. luteum*) sent us by Mr. Barr has a peculiar interest, inasmuch as it is the only yellow flowered *Colchicum* known. The whole plant does not exceed 4 inches or 5 inches in height. It bears its bright yellow blossoms while yet the leaves are but half developed. The blossoms, usually two or three from each corm, are about 1½ inches across when expanded, and as bright a yellow as the Cloth of Gold Crocus. It is a native of the mountains in the extreme west of India, beyond the Indus in Hazara, at an elevation of 7000 feet, where it flowers in December and January. It seems to flower a little later in the country, but much depends on the state of the weather. It has been introduced some seven or eight years, but is even now a rarity. It is quite hardy and thrives well with other species in a deep loamy soil.

PURPLE SCABIOUS flowers are not as a rule seen in winter, but they are now to be found in Baroness Rothschild's garden at Gunnersbury Park, where Mr. Roberts grows this plant better and on a larger scale than we have seen it elsewhere. Spacious cold frames, leaning to the south, so as to catch every glimmer of a wintery sun, are filled to overflowing with them. The plants are in 6-inch pots, dwarf and bushy, and covered with flower-heads, notwithstanding that a supply of flowers has been cut from them since autumn. These Scabious are also useful for adorning a conservatory, but if for no other purpose than for producing an almost inexhaustible supply of beautiful cut blooms they are worth attention. The way in which Mr. Roberts specially prepares them for winter blooming has been told so often in THE GARDEN that repetition is needless.

CLEMATIS INDIVISA.—When greenhouse roofs are conspicuous by their bareness in the way of flowers, it is well to have at least one plant to rely on for winter bloom, and this New Zealand Clematis with its garlands of white blossoms embowered amid glossy evergreen foliage is the best one could recommend anybody to grow. It not only flowers in winter, but in spring and summer; in fact, it is somewhat erratic on that point. In the conservatory (No. 4) at Kew it is in bloom, and probably in a month or two hence the fine specimen of it that trails along the north side of the temperate house will be wreathed in white, and we have seen Mr. G. F. Wilson's fine plant of it in the garden at Gishurst Cottage in full bloom in summer. Its flowers are pure white, star-shaped, as big or bigger than a crown-piece, and produced in elegant loose clusters. It is little or no trouble to grow, and flowers well in an ordinary greenhouse with a good bed of soil to start with, and the usual treatment afterwards. It seems to have a liking for a shady part of the house, for the best flowered plants we have seen of it have been in partial shade.

AMERICAN NOTES.

Virescence in the Rose.—A specimen was lately shown to the Torrey Club by Mr. Braman of what is popularly called a "green Rose"—a condition of the flower in which chlorophyll is substituted in the petals for the usual colouring matter.

The tree flora of the foot hills in Eastern Colorado is said in the "Proceedings of the Torrey Club" to be much more abundant than that of Southern Wyoming. *Pinus ponderosa*, known as yellow Pine, was very plentiful, and attained there a height of 80 feet to 100 feet, and was a very valuable timber tree. *Pinus edulis*, the "piñon" of the Mexicans, was a small tree extending as far north as Colorado Springs; *Juniperus virginiana* was occasional; *Abies Douglassi* was quite plentiful at middle elevations, attaining a height of 75 feet, and known as Swamp Pine; the narrow-leaved Cottonwood (*Populus balsamifera* var. *angustifolia*) and also *P. angulata* were frequent along the streams; *Salix nigra* var. *amygdaloides* and *Negundo aceroides* were frequent along the Platte River. The most abundant shrubs were *Quercus alba* var. *Gunnisoni*, the only Oak of the foot hills, except *Q. Emoryi*, which was scarce and was a scrub Oak, seldom rising higher than 10 feet and occurring plentifully on the dry slopes; *Cercocarpus parvifolius*, *Spiræa dumosa*, *Prunus americana*, *Vitis riparia*, and *Acer glabrum*, the Mountain Maple, were also plentiful.

Select garden vegetables.—Among the finest Squashes recommended by the secretary of the Massachusetts Horticultural Society may be named the Butman, which is beautiful in colour, excellent in quality, a good keeper, desirable for amateurs, but not very productive. The Marblehead is like it, both better than the Hubbard, of which they are sub-varieties, and both moderately productive. The Essex was obtained by crossing the Turban and Hubbard, a remarkable sort, uniting the excellence of the Turban with the keeping quality of the Hubbard. It is a rapid grower, ripens early and may be planted as late as the 1st of July. Marshall Wilder said the Essex and Hubbard would fill the season. Mr. Gregory said the Marblehead Squash was brought from the West Indies, and he recommended raising only the best sorts, even if not the most productive. They would be worth more in the end. Mr. Ware said that Fottler's Improved Brunswick Cabbage is the best early variety, and that Mr. Fottler sold his seed for its weight in gold. It has now run some years and has gained in size and lost in earliness. In Marblehead, where the Cabbage is the most important of all crops, it was formerly preferred to the Stone Mason, but is now less reliable. The last named was introduced some forty years ago by Mr. Mason and afterwards improved by Mr. Stone. It makes solid heads of excellent quality. The American Improved Savoy is an improvement on the old Savoy, having smaller stumps and larger heads. Mr. Gregory said the Stone Mason Cabbage has one fault—a tendency to rot at the stump. As regards Tomatoes, Marshall Wilder said he had tried all the new sorts, and had settled on the Acme and Paragon. Mr. Ware thought these two superior to all others. As to Potatoes, Burbank was highly commended. Early Ohio is earlier than Early Rose and is of fine quality. The Bell is probably the best new sort. Among Peas, several had found the American Wonder the best early dwarf variety, and Champion of England was the general favourite for a late one. Mr. Gregory said the John Bull Pea has very stocky leaves; pods and Peas both very large, and it fills out well. Hancock's Early was the most satisfactory among the hard yellow sorts. Mr. Wilder said Breck's Excelsior is an excellent variety.

Mistakes in grafting.—Some of the supposed remarkable changes effected in fruits through the influence of the stocks employed in grafting have proved to be nothing more than mistakes made by the grafters. Mr. Hovey stated this year at a meeting of the Massachusetts Horticultural Society that many years ago, when the

Lewis Pear was first introduced, and was supposed to be valuable, he planted six or eight trees, but finding them to be small and unprofitable, he regrafted them with Beurré Bosc. Afterwards a Bosc tree, when it fruited, bore a small green Pear, inducing some persons to suppose it a striking case of graft hybridism, but it proved only that the man who cut the Bosc scions from one of the original Lewis trees had cut one of the shoots below the graft. Another curious instance was where a well-known fruit raiser had grafted a poor with an excellent sort; the graft, when it bore, gave fruit almost identical with the stock. But he found that in pruning the stock, a shoot had fallen and was mixed with the grafts, and this shoot was used instead of one of the good grafts. Sometimes shoots from the stock spring out so near the place of junction as to be mistaken for those of the graft. Mr. Peter Henderson has doubtless adopted a just view when he remarked that the only distinct change by grafting was where variegated or diseased leaves of the stock imparted the disease to the graft, and apparent and not radical changes are thus made.—*Country Gentleman*.

History of the Lombardy Poplar.—Names are often misleading. People have often endeavoured to trace some relationship between this variety of Poplar and some European species, on account of its name. But the Lombardy Poplar is only so called from its having been introduced to England from Lombardy. It has been traced from Persia, where it abounds, and from the Himalayas to the banks of the Po, and thence to the margin of our English streams.—*Gardeners' Monthly*.

The origin of treeless prairies seems to be referable to annual prairie fires by the growing consent of those who patiently investigate the matter, and thus one of the great philosophical questions of the past age is being finally set at rest. Up to, say, a couple of years ago the belief of Prof. Whitney prevailed that there was something in the finely comminuted soil of the prairies which so firmly enveloped the seed as to prevent the necessary action of the atmosphere in inducing germination. Other hypotheses—all, however, tending to the physical impossibilities of tree growths—were in favour. In the "Proceedings of the Academy of Natural Sciences of Philadelphia" for February, 1881, probably the first philosophic attempt to show the futility of all these hypotheses appeared. It was there shown that there was no reason why the seeds of strong herbaceous plants should not grow and form the well-known flora of the prairies than the seeds of ligneous plants; that herbaceous plants or annuals which could flower and commit their seeds to the earth before a fire flew over them could spread in spite of prairie fires; but that ligneous plants, which required several years of growth before seeding, could not spread when annually burned down; that, as a matter of fact, trees were being raised by the million on the prairies by nurserymen, and that wherever prairie fires were prevented from occurring, the woodlands did actually encroach on the grassy prairie. This view now receives all the confirmation that is necessary from a paper by Mr. Ridgway in the "Proceedings of the National Museum," wherein he shows that the forest area of the Wabash basin has extended to such an extent that numerous small grassy prairies which were common at the first settlement of the country have become transformed to woodland, and that, owing to this encroachment, the forest area of the valley is greater than it was fifty years ago. There are now huge trees of Oak and Hickory, 80 feet high, on what certainly was grassy prairies fifty years ago.—*Independent*.

Bad stoking.—Many garden lovers have suffered from this evil—the dense smoke, heavily laden with soot, so often emitted by the greenhouse chimney, wasting the fuel, fouling the air, spoiling the appearance of the surrounding garden, and by the deposit of soot on the glass robbing the inmates of the house of a considerable portion of the light so necessary to their well

being. As the fogs and clouds of an English winter leave so small an amount of light, it is of the greatest importance not to further curtail it. By a little care in the management of the fire, the evils just alluded to may to a great extent be avoided. The general rule in making up a fire is to pull it to the front of the furnace, and to throw the fresh fuel on the top and behind the clear fire, the heat of which drives off the gas, tar, and other volatile portions of the coal to pollute the air and blacken the neighbourhood, thus worse than wasting a most valuable part of the fuel. Instead of this the clear fire should be pushed back and the fresh fuel added in front; by doing so, the gas, &c., escaping from the fresh coal having to pass over the clear fire behind, is consumed. By attention to this simple matter we obtain the heat desired and burn the objectionable smoke.—*THOS. WOODFIELD*.

GARDEN DESTROYERS.

Mining insects (*G. L. J.*).—Your plants are attacked by the grubs of a small fly nearly allied to the Celery fly. The fly lays its eggs under the skin of the leaves from which the grubs are hatched; these feed on the juices of the leaves, which they obtain by burrowing about within the leaves. You will easily see where the grubs are if you hold the leaves up to the light, and a pinch kills them at once. Some of the grubs have become chrysalides, but the same treatment will kill them.—*G. S. S.*

Root-feeding insects (*C. B. and G.*).—The insects you forwarded are young specimens of a common millipede (*Polydesmus complanatus*); as they feed on the roots of plants any insecticide which would kill them would also injure the plants. The best way to catch them is to place pieces of Potatoes or some other vegetable scooped out with the hollow part downwards in their haunts; they will be sure to crawl under them; small garden pots filled with dry moss are also very successful traps.—*G. S. S.*

Mealy bug.—Young gardeners and amateurs should use "Cambrian's" remedy for destroying mealy bug on Vines with caution. Coal-tar, soil, and lime, made into paint, and every crevice in the Vines filled up, followed by the syringe or garden engine with sufficient force to wash off the bug, would not only dash the foliage to pieces, but would pretty well annihilate the tar mixture, which would wash off with less force than the bug. In the cultivation of all sorts of fruit under glass, make cleanliness the principal object; never heap dirt on to dirt, but with a sharp knife remove all loose bark, and follow with a stiff brush, soft soap, and hot water, and give the glass, woodwork, and walls a similar application; allow them to get quite dry, and then give the woodwork a coat of paint, and wash the walls with hot lime. If these annual cleansings are attended to and thoroughly done, the tar mixture and syringe may be dispensed with; in fact, the syringe should never be used on Vines after the buds break, for the least sediment in the water will injure the bloom. As soon as the Grapes are set, give strict attention to supplying the roots with water, and damp the floors and any available part, so as to create a genial atmosphere, when the finest fruit will be the result.—*JAMES SMITH, Waterdale*.

Complete Index to "The Garden."—*The general index, embracing the whole of the volumes from the commencement to the end of the twentieth, is now ready. It has been compiled, printed, and bound with much care, and will be very useful in making more accessible to all who possess the volumes the immense mass of practical gardening matter, plates, and woodcuts embodied in its pages. Those who intimated their willingness to subscribe for it will be supplied at the subscriber's price of 10s. 6d. per copy. As its production has been more expensive than was anticipated, the price has to be fixed at 12s. 6d. per copy. There will be no free copies, and no reduction to the trade on the published price.*

London suburban cemeteries.—The state of these may be judged of to some extent by an article in the last number of the *Saturday Review*. The following refers to the state of the Tower Hamlets Cemetery, which, be it remembered, is one of the cemeteries formed since the general closing of the intramural cemeteries scarcely a generation ago: "Portions of the available burial space were set apart for family vaults and brick graves; other portions for family graves marked by the usual head and foot stones; the remainder of the space being used for what are known as 'common interments,' arranged in two or more classes, in which a considerable number of coffins are placed one above another in graves dug to as great a depth as is consistent with safety. Out of the difficulty of providing ground sufficient for these interments the present complaints have arisen. The removal of excavated soil has involved the raising of the level of the ground in portions of the cemetery, and for some years past interments have been made in the ground so raised, which may probably have covered previous graves. But one especial complaint which is now made against the directors is that they are destroying the memorials, tablets, and ornaments which have been placed by relatives over the resting-places of their dead. These marks of affection have been very simple, and often very touching; commonly a framework of wood or other material has been placed round the grave-mound, and within have been set small wooden tablets, or frequently the large shells which seafaring men bring home, and which give a broad surface for an inscription. Sometimes a more special memorial would appear; and for several years over a child's grave near the southern gate of the cemetery a little glass case contained a pair of baby shoes, which no East-end passer-by ever thought of disturbing, till at last the case fell to pieces by decay. A more serious complaint which, in connexion with this destruction of memorials, is being made against the directors, consists in a charge of something approaching to pit-burial. It is said that instances have occurred in which the coffins of children have been removed after interment and placed, to the number of between fifty and sixty, in a single grave. If this statement, or anything approaching to it, can be substantiated, the pressure upon the ground still available for interment must have become so excessive as to call for immediate and perhaps legislative consideration. In the earlier days of the cemetery a practice of pit-burial was introduced for workhouse funerals; but on the attention of the directors being called to the matter, it was at once discontinued."

CATALOGUES RECEIVED.

- Wheeler's (Gloucester) Select Seed List.
- E. P. Dixon's (Hull) Garden and Farm Seeds.
- Parsons & Co.'s (Flushing, N.Y.) Ornamental Trees and Shrubs, with descriptive notes.
- Hiram Sibley's (Rochester, N.Y.) General Seed Catalogue.
- Downie & Laird's (Edinburgh) Garden, Flower, and Agricultural Seeds.

PROPAGATING.

PROPAGATING CLEMATISES.

THE usual method of propagating these is by grafting a young shoot on a piece of root of the common kind, that is so far as concerns the ligneous species, the herbaceous ones being of course increased by division. Those for which grafting is employed can also be multiplied by means of cuttings made of the half-ripened wood put in during the summer months; but the most successful way of striking them if the plants are in pots is to put them in a growing temperature about February, when the young shoots will push forth in abundance, but in a somewhat weakly condition. These shoots if taken off readily strike root. The principal thing to guard against is damping off; but when once they have formed roots the danger in this direction is then over. When struck the cuttings must be allowed to have more air than hitherto, and as soon as possible they should be potted off. The advantage of striking thus early is that a long season of growth is thereby secured, and for the same reason grafting should be performed with as little delay as possible. For stocks take strong fleshy roots of the common Traveller's Joy (*C. Vitalba*), or of *C. Flammula*, and cut them up into lengths of from 4 inches to 6 inches, leaving as many of the small fibres attached to them as possible. The scions must be young shoots of the current year, and should not be of too great a length; a couple of well-developed leaves and a pushing bud will be sufficient. Split the top of the stock, then cut the scion in the form of a wedge, and insert it in the cleft portion, being careful not to bruise the tender succulent scion, and also observe that the cut parts fit perfectly together. Then tie firmly and the operation is finished. The grafted root must now be potted in a small pot, sufficiently deep to cover the whole of the point of union. Then plunge the pots in a propagating case where there is a little bottom heat, but before doing this give a good watering to settle the soil. As the succulent shoots are very liable to damp off if moisture be allowed to condense too freely on them, a little air may be given when necessary, but on no account allow them to flag; indeed, if possible, it is better to dispense with the air except when the lights are taken off, which should be done every morning, in order to remove condensed moisture. As soon as a union has taken place, which will be perceived by the centre bud starting, air may with safety be given, and the plants quickly hardened off; when necessary they should be shifted into larger pots. Early propagation in the case of these plants is very desirable; if the cuttings are taken from plants grown under glass the roots should be taken under cover for a few days, just to put the sap in motion. After a time the scion frequently pushes forth roots of its own in addition to those of the stock upon which it is grafted. The greenhouse *C. indivisa* also does well grafted in this manner, besides which half ripened shoots are not difficult to strike.

T.

Propagating variegated Oaks.—The Oak mentioned in THE GARDEN (page 80) is, I presume, a variegated form of the common kind, in which case it must be grafted on young green-leaved plants of the same sort, and even if it be the Turkey Oak (*Quercus Cerris*), the same principle must be carried out, and as young seedlings have been raised from the tree, no better stock exists on which to graft the variegated shoots; cuttings of it will not strike, and variegation is seldom perpetuated by seed in the case of such trees. In grafting several methods may be employed, but in all cases it will be found that the Oak is rather a difficult subject to deal with. If fair-sized stocks are obtainable, cleft graft them after the manner of fruit trees in March, or if the stocks are small, say as large as a lead pencil, pot them and side-graft them about August, choosing for that purpose a half-ripened shoot of the current year's growth. In this latter case, which, in the hands of an ama-

teur, is more likely to be successful than the other, the plants, when grafted, must be kept in a close frame without artificial heat, and do not remove the head of the stock till spring, and then only by degrees. The Oak may also be inarched, but in the case of large trees that is a somewhat difficult matter. In all cases the point of union must be carefully covered with grafting wax to exclude air, besides which care must be taken to tie the graft in securely.—T.

MARKET PLANTS.

THE zonal Pelargonium, being grown largely during winter for cut bloom and in summer for market plants, is produced by our market plant growers in enormous quantities. Their production is, however, not so much a matter for wonder or surprise as the way in which they are got rid of. Out of the perhaps quarter of a million sent away from the nurseries yearly one-half may find their way into beds to make gardens gay for a month or two in summer; then they disappear. The other half, kept in pots, go into windows, and are used for other purposes in house decoration for a few weeks; then they are cast aside to make room for some new favourite that in its season will take their places. Still they have, in the estimation of the purchasers, played their part and all are content. There are few market plant establishments around London where zonal Pelargonium bloom is more largely grown than in that belonging to the Messrs. Hawkins & Bennett, of Twickenham, names well known in connection with the Lily of the Valley, which is so superbly grown by them. Nearly all the houses in this establishment are broad lean-tos, and have broad paths running through them, so that perambulation is easy and pleasant; the stages at this time of the year are crammed to the utmost with myriads of fine robust plants in 4½-inch pots which are just now producing bloom that as fast as ready is cut and bunched for market. The ranges are of great length, and being of good height and breadth, the eye can readily run over the whole of the contents. When, as is often the case, one length of three divisions is entirely filled with scarlet, white, and pink-flowered kinds, the vast bank of colour gives a very charming effect. So far the good old kinds of Vesuvius, Master Christine, and Madame Vaucher give the desired colours, but a visit on the part of the firm to Mr. Cannell's winter blooming Pelargoniums, at Swanley, has led to the introduction of several less known kinds, and there can be little doubt that in a short time some of these from being now but a plant or two will fill whole houses. Messrs. Hawkins and Bennett are fast erecting more large houses, and in these mean to introduce as an experiment

Mr. Cannell's system of top heating, which, as has so often been shown in the past, seems to be the great cause of such successful production of winter bloom at Swanley. Should the plan turn out at Twickenham all that is expected of it, it will not be a matter for surprise if some change is introduced into the existing houses that shall enable the top air in those to be both heated and dried also. It is, in fact, in the drying of the air more than in the heating of the house that the success in producing such beautiful bloom in the winter is found. A very gentle heat will suffice to keep any zonal Pelargonium growing, but the bloom needs something more than exciting—it needs a dry atmosphere and an entire absence from drip, and this is partly gained by the system of top-heating. At Swanley, it is true, there is a sharp pitch to the span-roofed houses that should be generally copied, because the drip is always less; but in all cases where there is top-heat the drip is less, because moisture does not gather on the glass. Some day, perhaps, Vine growers, and especially those who want to ripen early Muscats, may give a trial to the top-heating plan; in fact two or three 2-inch pipes, running along at regular intervals just beneath the rods, might be productive of marked success in securing not only a free set,

but rapid development of berries as well as rich colouring. Some of

The double-flowered Pelargoniums are grown at Twickenham, and notably Madame Thibaut, pink, and F. V. Raspail, a grand scarlet, with large pips. These are not gathered in trusses, as the waste would be excessive, but singly, and sent in small bags to market, where they are wired, and then made into bouquets. Considerable judgment is needed in getting plants in 48° to bloom well right through the winter, for whilst anyone may, with room, grow large quantities of plants fit for bedding, or even for market, in the spring and summer, it is by no means easy to have good plants to bloom not only early in the winter, but all through the winter, and to so effectively arrange the needful heat and general cultivation, as that whilst the plants are blooming they shall not get drawn or become weakly. Most gardeners who have grown collections of zonal Pelargoniums soon learn to admire the pretty, soft hues found in the salmon, rose-tinted varieties, and, not least, the beautiful violet-shaded flowers. The market grower, however, seldom favours these intermediate hues, let them be ever so beautiful. If he does not, his customers at least seem to prefer the decided colours such as are found in Henry Jacoby, Vesuvius, Master Christine, Mrs. Turner, or Madame Vaucher, so that the dominant colours in any market-growing establishment are scarlet, white, and deep pink.

The broad alleys that run through Messrs. Hawkins and Bennett's houses greatly facilitate the removal of the plants, as handbarrows may be carried right through them. Then they have the benefit of an admirably arranged supply of water, which, having a moderate pressure, can be utilised for watering the plants by means of hose and a tube far more rapidly and cleanly than can be the case when ordinary water-pots are used. It seems strange, having regard to the great saving of labour which results, that a similar plan is not more widely adopted, especially in large places. The elevation of a cistern, or, as is the case at Twickenham, a couple of huge wine casks, with pipes communicating with all the plant houses, gives all that can be desired. It is fair, however, to the firm I am writing of to say that their houses are all not only very roomy, but substantially built. They are intended not only for a year or two, but for a generation or two, and hence some little extra outlay in laying on a constant supply of water is not at all wasted capital. The huge trade done at this establishment is evidence that it is well for market plant growers to take but few things in hand and to do these well. Reputations for the cultivation of certain things are not made in a day, but when made cannot be too highly prized. Thus Messrs. Hawkins & Bennett trade almost exclusively in zonal Pelargoniums, Maiden-hair Fern fronds and blooms of Stephanotis, and their famous Lilies of the Valley.

A. D.

OBITUARY.

WE hear with regret of the death of Mr. CHARLES ALBERT PATERSON, at Edinburgh, at the early age of 22. He was the youngest son of Dr. Paterson, of Fernfield, Bridge of Allan, well known for his collection of Orchids, of which his late son was an enthusiastic lover, and assisted his father in their culture.

WE have also to record the death of Mr. ROCHFORD, of Tottenham, to whose excellent system of Vine growing allusion was only made the other day in THE GARDEN. His place as a market nursery is second to none in the neighbourhood of London.

Names of plants.—A. B. C.—1 and 2, *Viola odorata*, commonly called Violets; 3, *Azalea amona*; 4, *Salvia Heeri*.—P. Barlow.—*Zygopetalum Mackayi*.—A. C.—*Dendrobium fimbriatum*.—Lady K.—*Narcissus Tazetta floribunda*.—G. M.—*Dendrobium fimbriatum*, *Melanthus* species.

No. 587 SATURDAY, FEB. 17, 1883. Vol. XXIII.

"This is an Art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES AND READINGS.

SELF-HELP FOR GARDENERS.—The note on this subject, published some time ago, has brought a mass of correspondence from gardeners, all willing and even anxious to promote some such association as that mentioned. Some correspondents suggest that the Gardeners' Royal Benevolent Institution possesses the machinery, and to some extent the interest, for promoting such an undertaking, and predicts that were that society to take the matter up energetically it would at once meet with such a response from the gardening community as would set the scheme on a practical footing. I have no doubt whatever that the majority of gardeners would join any good society designed to help them in their old age, or their families in the event of their death. Numbers of gardeners are at present members of other friendly societies, for the gardening fraternity can as yet boast of no benefit association of its own.

MAGNUM BONUMS AND CHAMPIONS.—The most saleable and best paying Potatoes in the market just now are these two varieties. They are really only coming in season after this date. In the south Magnum Bonums are realising the highest prices going according to market lists, while in the north Champions are realising 90s. and 100s. per ton, with the probability of higher rates being reached very soon. Last year Champions in Scotland, owing to the abundant supply, were offered at 30s. per ton at the same season. The Champion is rapidly extending in cultivation both among farmers and cottagers. It has been a boon to the latter, affording them a good store till new Potatoes became plentiful. In many places last year, however, the disease attacked both sorts, especially the Magnum Bonum. Many, too, have failed to get good crops of either by growing them on too strong land and planting too thickly.

THE ORCHID CENTRE.—It is quite true, as a correspondent of THE GARDEN lately observed, that Orchid culture grows less general the further we travel from London. This is not to be wondered at. London is the great central dépôt for imported plants as well as of Orchid culture generally. The frequent auction sales that occur in London are a great advantage and convenience to growers living there and in the adjoining counties—the chances of investing with advantage are greater. We have, however, no doubt that occasional provincial sales, like those at Stevens's rooms, would succeed as well as those in London, if not better, as a few recent examples have shown. Many gardeners and growers would avail themselves of such opportunities of buying who would never think of going to the London sales, and auctioneers and dealers might avail themselves of the opportunities afforded by the more important provincial shows at such places as Manchester, Liverpool, York, Leeds, Glasgow, and other towns to promote their business. The experiment is at least worth trying.

THE RAINFALL.—Since October the rainfall in many parts of England, and especially in the midlands, has averaged fully 5 inches per month, with no present prospect of settled weather. This is an almost unprecedented quantity for the season, and the ground is in a thoroughly saturated condition, rendering all work on the farm or in the garden impracticable. We continue to read of early Primroses and other flowers, and of precocious fruit trees in the south, but in the north, owing to the comparatively low mean temperature that has been experienced, vegetation is not dangerously

forward. The cyclonic storms of wind and rain that we have had of late brought an abnormally low temperature from the west and south-west, with heavy and cold showers of rain and sleet, a thing people hardly remember before. Cold rains, by saturating the roots and reducing the general temperature, retard vegetation almost as much as frost. We hear of puttyless glass roofs have responded to the gale in a rather alarming manner in some places.

CANNELL'S SYSTEM OF HEATING.—It is difficult to see what benefit this method of heating houses from the roof downwards is going to confer. A buoyant and moving atmosphere in hot-houses is the main point, and we know that by placing the heating apparatus at the bottom of a column of air we set the whole body in motion, like smoke in a flue. Mr. Cannell's plan or principle is to place the fire at the top of the chimney instead of at the bottom. If we are to adopt the system of carrying hot-water pipes along the roof instead of on the floor, another system of ventilation than that in use will have to be adopted, otherwise the warm air will be expelled as fast as it is heated, and that is just the reverse of what hot-water engineers aim at. Besides, the plan presents many obstacles and practical objections, in the case of fruit houses especially.

REMARKABLE EXPERIMENTS.—Some remarks elsewhere on the effects of light in ripening Grapes must make practical Grape growers scratch their heads. Grapes in Algiers exposed to all the heat of an African summer never, it is said, ripen their berries (for want of sugar) under a trellis covered with Vines grown expressly for the shade of their foliage. It is a remarkable thing that under our duller skies in vineries the fruit can be ripened to tolerable perfection under a trellis, on which the leaves are crowded together as thickly as they will exist, and probably the Vines grown on a trellis in Africa were no worse crowded than these. It is to be regretted that anyone should bring such a tale as this all the way from Africa with plenty of evidence to the contrary at our own doors. One of the Vine growers near Fontainebleau has along tunnel—a trellis—covered so thickly with Frankenthal Vines that one can scarcely see outside anywhere, and yet the Vines bore an even crop fast approaching maturity when we saw them; this was out-of-doors. It was positively almost dark under the archway where all the bunches hung, but the leaves turned their surfaces outside to the sun. Another curious circumstance in connection with some experiments recorded by a certain M. Macagnolis that in Italy an umbrella has the effect of raising instead of diminishing the temperature. Three sets of Vines growing "side by side" out-doors, it would appear, were operated upon, one lot being covered by a black cloth, one by a white cloth, and the third left exposed, with the result that while during three months the mean natural temperature round the uncovered Vines was 70° Fahr. it rose to 82° under the white cloth, and to 92° under the black. Meteorologists have a maxim that no object can be warmer than that which heats it, but here we have the temperature raised and steadily maintained for three months 22° above the surrounding temperature by means of a black cloth only. In other words, the mean temperature was much higher in the shade than in the sun—a wholly abnormal condition of things. Of the result of this experiment nothing more need be said at present, but we commend the subject to the attention of manufacturers of frigi-domo and the like. The object of your contemporary is to prove that it is

LIGHT only and not heat or the two conjoined that turns fruit ripe or rather sweet. Gardeners have entertained the belief that it was the thorough exposure of the foliage to the light, in conjunction with the right temperature, which produced perfect maturity, and they point to the fact that no amount of light will ever render Grapes

or Gooseberries fit to eat either as regards sweetness or flavour, from trees that have from any cause lost their leaves before the fruit was ripe. If light only can convert the acids of fruit into sugar, how comes it that sour Apples and Pears grow sweet and excellent after being several weeks in a dark drawer or fruit room? and how is it Oranges gathered in a half green state ripen and become sweet in the packing cases in which they are shipped or stored for months afterwards? And how do Melons ripen in dark warm rooms? not to speak of other and similar examples. Scottish peasants gather Sloes from bushes when they are sour and rough, but put in a bag in a little oatmeal as a packing material, and allowed to hang in a warm kitchen, they turn out sweet and mild towards Christmas. What converts the tartaric acid in such a case as this? No; Lindley, though pooh-poohed by some now, said, "the production of sugar and certain flavours were the effects of a high temperature and exposure to bright light, and that under opposite circumstances acidity prevails," and his opinion has not yet been controverted.

QUICK RETURNS.—"T. B.'s" second note on this subject is more gratifying than the first. Our error respecting the length of the young rods originated in our estimating about 1 lb. to the foot run—the maximum allowance of all good growers of permanent Vines—and an average of 20 lbs. to each cane, as recorded by "T. B.," gives just 20 feet. That, it appears now, is the weight to 11-foot rods, or about 2 lbs. to the foot—an unprecedented feat in Grape culture, and one only to be accomplished by extension. Eight feet of wood in the season is the exact amount recommended for general practice by extensionists. Still, "T. B." and other physiologists will find it difficult to explain why the pruner should stop at 8 feet if he can ripen twice or three times that length of rod successfully, as has been done. The principle involved is that as much wood as can be ripened soundly is fit to leave and bear fruit discretely, and those who now sanction 8 feet cannot logically stop there. This is the way intelligent practitioners will look at and consider all such problems, and the difficulties of persuading gardeners of this are vanishing more quickly than "T. B." appears to be aware of. It is dangerous prophesying in these days. To simplify garden practice and accelerate results should be our aim. It is but a few years ago since we read in a calendar of operations that the way to propagate the Lapageria was to insert morsels of cuttings that required nearly a year to root and several years more to nurse to an adult state, but, thanks to discussion and argument on the subject, that practice is now superseded by a better, and we seem in a fair way of doing the same in the case of the Vine and Peach.

FOOD FOR GARDENERS.—The Crystal Palace School of Gardening presents a rich bill of fare for the "next course" of Wednesday lectures and demonstrations. The theme is "The Relation of Function to Structure in Flowering Plants"—a very substantial diet for gardeners most people will grant. Since this intimation appeared, the Crystal Palace authorities have advertised for "competent young men for flower garden work; also some for all kinds of plant growing, to work under a foreman," and a facetious acquaintance asks if the "syllabus" can have caused a dispersion of the staff. "Six lectures" on "the relation of function to structure in flowering plants," and on that alone, it may be conceived, would try the patience, not to say endurance, of most human beings.

DUTIES OF GARDENERS.—The Crystal Palace School should note the following extract from an otherwise excellent article on gardeners in a contemporary: "Gardening requires a man to be thoroughly in earnest. He must devote every moment he has to the study and practice of his calling; he must be a close and attentive observer of Nature and her wants; he must be able to grapple with many difficulties, and by assiduous

endeavours seek to comprehend the varied details in connection with the multitudinous subjects that come under his notice and require his attention." Dr. Guthrie used to tell moralists that their great mistake lay in attempting "to dam up human nature;" and the Queen's chaplain, the late Dr. McLeod, recommended dancing as an excellent recreation for all sorts of young people, but the author of the above paragraph evidently believes in "all work and no play" for gardeners. Considering the modest average prospects of the young gardener, a perusal of the above may well make him pause and ask if it would not be preferable at once to take the Queen's shilling. He certainly ought to strive to get on as a student, but working with the spade all day and studying with Spartan fortitude every spare minute at other times, in order to comprehend "multitudinous subjects," is expecting and asking too much from him. Besides, there is no need for such laborious study. Any man who is willing may master his business and have leisure to spare. The things he has got to master are neither so multitudinous nor so varied; and if he only chooses his subjects of study judiciously, and apportions out his time methodically, he may soon, while becoming at the same time a good workman, master the main branches of his profession. PEREGRINE.

NOTES OF THE WEEK.

GARDENER'S ROYAL BENEVOLENT INSTITUTION.—At a meeting numerously attended of the committee of this institution, held a few days ago, Mr Edward Tidswell, of the firm of Bollen & Tidswell, of Wood Street, Cheapside, was unanimously elected treasurer of this institution, in the room of Mr. Robert Wrench, deceased.

NEW BOOK ON VINES.—We learn that the book on "Vines and Vine Culture," by Mr. A. F. Barron, Royal Horticultural Gardens, Chiswick, will shortly be published. It is an illustrated treatise on the cultivation of the Grape Vine, with descriptions of the principal varieties, reprinted and enlarged from the *Florist*.

THE "SHAKSPEARE FLORA."—Messrs. Palmer & Howe, of Manchester, announce the early publication of a work, under this title, by Mr. Leo H. Grindon, in which every tree, plant, and flower alluded to by Shakespeare is to be dealt with briefly from the botanical point of view; every important passage in which the name occurs is then to be quoted, and all unusual and curious words and phrases which occur in those passages are to be explained. The work, it is said, is to be illustrated, and its size and general appearance is to be exactly those of "Country Rambles," by the same author, issued last spring.

THE QUEEN HAS PROMISED TO OPEN THE International Fisheries Exhibition at South Kensington, on May 1. The site is an area of 22 acres, in the Royal Horticultural Gardens, and the total area to be occupied by the exhibition will be 253,000 square feet. The buildings which are now in course of construction are of wood, with arched roofs, and are arranged in blocks with intercommunication through corridors. On the west, or Queen's Gate side, will be the tanks and aquaria, which will be supplied from a circulating reservoir, capable of holding between 30,000 and 40,000 gallons of water. There will be a lecture theatre seating 150 persons, several model cottages, and a fish-curing establishment.

HOT-WATER CURE FOR SICKLY PLANTS.—The *Florist* asks has anyone tried hot water as a restorative for sickly plants? and then proceeds to say that M. Willermoz some time since related that plants in pots may be restored to health by means of hot water; ill-health, he maintains, ensues from acid substances in the soil, which, being absorbed by the roots, act as poison. The small roots wither and cease to act, and the upper and younger shoots consequently turn yellow, or become spotted, indicative of their morbid state. In such cases the usual remedy is to transplant into fresh soil, in clean pots with good drainage,

and this often with the best results. But his experience of several years has proved the unfailing efficacy of the simpler treatment, which consists in watering abundantly with hot water at a temperature of about 145° Fahr., having previously stirred the soil of the pots so far as may be done without injury to the roots. Water is then given until it runs freely from the pots. In his experiments the water at first came out clear, afterwards it was sensibly tinged with brown, and gave an appreciable acid reaction. After this thorough washing, the pots were kept warm, and the plants very soon made new roots, immediately followed by vigorous growth.

HORTICULTURAL EXHIBITION AT PARIS.—An international exhibition of plants in flower, forced vegetables, fruit trees in pots (forced), and of coniferous and evergreen trees will be held in the Champs Elysée from the 28th March to the 1st April. A gold medal is offered for new or recently introduced plants either in or out of flower. Intending exhibitors must communicate before the 12th of March with the president of the society, 84, Rue de Grenelle, stating what they wish to exhibit and the amount of space they will be likely to require. Flowers, fruits, and vegetables will be received on March 26, and up to 3 o'clock p.m. on March 27.—J. C. B.

VEITCH MEMORIAL PRIZES.—The trustees of this fund intend to offer the following prizes to be competed for on May 22, at the summer show of the Royal Horticultural Society at South Kensington, a prize of five sovereigns and the Veitch Memorial Medal for—1. Best specimen stove or greenhouse plant, in flower, to be selected by the judges from the plant classes. 2. Best specimen Orchid, in flower, to be selected by the judges from the plant classes. 3. Best dish of three bunches of Grapes (one sort), to be selected by the judges from the fruit classes. To be awarded only to subjects of superior cultivation exhibited by *bonâ fide* gentlemen's gardeners.

PRIZES FOR PACKING FRUIT.—In order to show the best mode of packing fruit for the market, so as to realise the highest prices, Messrs. Webber, fruiterers, Covent Garden Market, will again offer the following prizes for the best packed three boxes of fruit, to be competed for on July 3 at South Kensington: 1st prize, £5 5s.; 2nd prize, £3 3s.; 3rd prize, £2 2s. To consist of one box of Grapes, not less than 14 lbs.; one box of Peaches, not less than 24; one box of Strawberries, not less than 2 lbs. The exhibits are to be booked, carriage paid, at any station irrespective of distance, and delivered by railway company, addressed to the Superintendent, Royal Horticultural Society, South Kensington.

CONGRESS OF HORTICULTURISTS IN BELGIUM.—The Syndical Chamber of Belgian horticulturists has issued the following notice: "In order to give to the representatives of horticultural industry of all countries an opportunity to extend mutually their commercial relations and discuss their common interests, an international meeting of horticulturists will take place at Ghent in April, 1883. The programme will be published in due time. As this meeting will coincide with the great quinquennial International Flower Show organised by the Royal Agricultural and Botanical Society, entertainments will be provided for the congress members, and excursions organised to the different horticultural centres in Belgium."—T. C. B.

NEW MODE OF KILLING THIRIPS AND RED SPIDER.—The *Garten Zeitung* points out an easy way to kill these pests, which is worth trying. The directions are to take a tub large enough to dip the largest show plants in, and fill it with clean water at a temperature of 130° Fahr. Into this the plants are plunged for four seconds, not longer; and it is averred that this will kill all the living insects, though a second immersion is, perhaps, necessary to completely destroy the young, undeveloped insects. The temperature of the water should not be allowed to fall below 122° Fahr. In this way a large collection of Azaleas was treated when they were taken out of doors in

spring, and again when they were taken in in autumn, and neither the young shoots in spring nor the flower-buds in autumn are said to have suffered in the least. Dracænas, Myrtles, Crotons, and other plants were also successfully treated in this way, the young, tender leaves not being in the least injured.

NEW PARK FOR NEWCASTLE.—At the Newcastle-on-Tyne Town Council meeting the other day a letter was read from Sir W. G. Armstrong, intimating his intention of presenting his estate in Jesmond Vale, in the eastern suburb of Newcastle, to the town for the purpose of adding it to the Armstrong Park, which he gave to the public a few years ago. Jesmond Vale is about a mile in length, and possesses some of the most lovely scenery to be found in the vicinity of Newcastle. A part of the gift consists of a handsome banqueting-hall and some houses in Jesmond Vale. The estate is given with the reservation that the control of the park shall remain in the hands of Sir William and Lady Armstrong during their lives. Heaton Park and Jesmond Vale together will make one of the finest parks in the country, and will be a great boon to the large population resident in the eastern portion of Newcastle.

THE BOTANICAL DEPARTMENT in the new Natural History Museum at South Kensington is being arranged with great success on a new plan by Mr. Carruthers. Dried samples of plants are not either instructive or amusing to any but the scientific eye, but the new arrangement undoubtedly is both one and the other. Types of families are selected, and exhibited in their dried state, and also by means of coloured drawings and diagrams are shown as they were alive, with all their peculiarities of structure fully developed. A series of maps also shows by varying intensity of colour the geographical distribution of the family upon the earth's surface, while a coloured scale tells whether the plants comprised in the family are found in the more ancient or recent strata of the earth's crust. Great strides have been made towards completing this valuable and interesting method of arrangement, and the difficult task of making botany popular and accessible without sacrificing direct scientific teaching appears in a fair way towards achievement.

A DISEASE FROM REEDS.—A curious affection has been occasionally met with in certain parts of France, especially in Provence, among Reed workers, chiefly those who manipulate the stems of *Arundo Donax*. A case at Frontignan (Hérault) has lately been very carefully studied by M. Baltus, of Lille. A man, aged forty-seven, and his son, aged seventeen, had been at work for several hours loading a cart with Reeds, which had been cut a year before, and kept in a damp trench. Both were seized with a painful irritation of the nose, eyes, and throat, followed by erythematous swelling in the same parts, which extended to the hands and trunk. An examination of the Reeds showed that they were covered with a mould consisting of the spores and mycelium of a fungus, *Sporotrichum dermatodes*, which had developed under the influence of the prolonged exposure to moisture. The spores had been shaken off as dust during the manipulation of the Reeds, and had irritated the exposed parts of the skin on which they had lodged. Although usually trifling, the malady may sometimes assume a severe form. It may apparently be prevented by the simple expedient of washing the Reeds before their manipulation.—*Lancet*.

PRIZES FOR ANARYLLISES.—An amateur, anxious to encourage the cultivation of this fine tribe of plants, again offers the following prizes to be competed for at the Royal Horticultural Society's meeting, on Tuesday, March 27, 1883. For the best seedling—1st prize, £2; 2nd prize, £1; 3rd prize, 15s. Fine form and substance are the points specially aimed at in offering the prizes in Class A. To be eligible, the flower must be smooth in the petal, of good firm substance, without the unevenness of the marginata conspicua type, and as little pointed in the petal as possible. Colours will not be considered unless two flowers

should be, in other points, considered equal in merit, the better coloured of the two would then receive the higher prize. For the best six *Amaryllis*, named, three to be dark and three light varieties—1st prize, £2; 2nd prize, £1. These prizes will be awarded only on condition that the exhibits are considered to be of sufficient merit. Form, substance, and breadth of petal are necessary points. For the best variety selected from among the plants exhibited in Class B—for the best dark variety, £1; for the second best variety, 10s.; for the best light variety, £1; for the second best variety, 10s.

FRUIT GARDEN.

DIFFERENT TREATMENT GRAPES NEED.

THERE are few edible fruits in which the different varieties require so much difference in the shape of warmth and other matters to bring them to perfection as Grapes. It is needless to say that such kinds as Miller's Burgundy, Black July, Royal Muscadine, Black Hamburgh, and other hardy kinds that come early to maturity require treatment very different from what is needed to bring out the true character of the Muscats, so long in cultivation, and some of the black and also white sorts that in times more or less recent have made their appearance. The first three named are now rarely met with under glass, yet it is a question in the case of many who try Grape growing in houses, often without fire-heat and with little cultural knowledge, if the results would not be better by growing some of these all but forgotten early ripening sorts than confining the cultivation to others that when skilfully managed, are no doubt preferable, but which, without the requisite treatment, are often a failure. Grape growers know from experience that with regular attention to shutting up the house early in the afternoon whilst the sun is on it, so as to secure a high temperature for some time, good Black Hamburgh Grapes can be grown without fire heat; but on such short as well as sunless summers as the last was nothing less than unremitting attention to the closing would secure ripe fruit, and, for another year, the equally important condition of fully ripened wood.

What I have, however, more particularly now to urge is that, even with the admitted difference in the requirements of the different kinds of Grapes, it often happens that a useful variety gets condemned when it is the treatment which is at fault. When Madresfield Court first came out most growers got it, but the greater number discarded it on account of its disposition to crack unless its roots were drier during the time it this way suffers than the majority of kinds require. Yet so good, as well as good looking, is this Grape, that it has been again reinstated in most gardens, the little precaution needed to prevent the berries splitting being well repaid by having it in right order. Lady Downes got similarly out of favour through the liability its berries have to scald, which unless means are taken by an extra amount of air being given during the critical period occurs to an extent to which other varieties are not subject. What it required was soon found out, and the necessity of using fire heat, which many growers keep up continuously, along with air always on during the scalding time, does not entail so much extra labour as to prevent a large number of growers from putting their main dependence on this variety for a late supply. Gros Colmar is another case in point. When first this sort came sufficiently under notice to admit of an opinion being given about it, there was all but a general cry of condemnation against it, and no wonder, for, managed as it mostly was, and with many still is, it has little to recommend it beyond size of berry. Yet all that was said against it had no effect in preventing it when grown as it requires, holding by a long way the first place with the public who buy late Grapes; for when grown with sufficient heat to bring it thoroughly up to the mark it is as much improved in quality as it is in appearance.

This, by the way, holds good with that very old, but best of all Grapes—according to most people's verdict—the Muscat of Alexandria, which, when grown with the full amount of warmth which it requires, is as gold to dross in comparison with what it is when short of fire heat.

Any allusion to the particular requirements of individual varieties of Grapes would be incomplete without mention of the Duke of Buccleuch, which, as an early white sort, when well managed, has no equal for appearance and quality combined, and there is abundant proof that it can be produced free from spot or cracking simply by attention to its peculiar requirements. It is scarcely needful to say that the varieties just named are far from being all the Grapes that require something or other different in their treatment from that of the Black Hamburgh and kindred sorts; conformity to the requirements that answer for these often appears to be the grounds on which some rest their verdict for or against a Grape; but the all-alike-treatment test proves too little to be accepted by everyone.

Of the number of new sorts that have been raised in this country, and of others new and old of Continental origin that have been brought into cultivation in comparatively recent times, the majority have not enough good properties to admit of their taking the place of the older well-proved kinds. But the varieties I have named have sufficient merit to repay the trouble of deviating from the ordinary track in their management.

T. B.

RIPENING OF LATE PEARS

LATE Pears seem very erratic in their time of ripening, and some much more so than others. Our fruits of Easter Beurré have behaved very strangely, being in and over by Christmas, but they have not been of the high quality we have them sometimes; they became spotted and were a little dry and mealy in flesh. The fruits referred to were gathered from pyramids growing on the Quince stock in rather light soil resting on a gravelly bottom, where most sorts, when mulched with long manure, generally do well. The best Pear this season with us has been Glou Morceau, and the finest fruits of this were from an old tree that covers a very large space on a wall having a south-east aspect, a good situation for a Glou Morceau or any other sort of late Pear, as all require a warm, sunny position, and the fruit are never melting and rich unless the trees are so favoured. We have a striking instance of this fact here. A Ne Plus Meuris on a west-south-west wall has some of its branches along and over the top, and from these branches the Pears are not only always larger, but better coloured, and greatly superior to those from the other part of the tree. This is the case with most others gathered from trees in the same border and trained in the same way, and I know a garden in which many of the Pears are planted on the north side of the wall and run up with clean stems till they get to the top, over which they are led and trained above the heads of Peaches on the south side. This, I think, would be a good plan to follow in growing late sorts of Pears. The roots would then be in cool moist soil, and the fruit fully exposed to solar heat, which is so necessary to ripen and finish it up. The Pear we set most store by is Bergamot Esperen, the fruit of which, after anything like a fair summer, is generally very buttery and melting, rich and juicy, as is also that of Josephine de Malines, but the juice of this often has an astringency which is objectionable. Although we sometimes have Josephine de Malines and Bergamot Esperen through March and April, they are both over now, and Beurré Rance is shrivelling, which the fruit of this Pear frequently does unless the autumn is warm and sunny.

S. D.

American Apples.—It has been asserted that American Apples and French Pears are in every way as good as ours. This I deny, but I admit that the Newtown Pippin is a first class

Apple. With the exception of this, however, I am confident that our Apples are, I should say, 50 per cent. better than those grown in America. I have had some experience in growing Apples in Tasmania. They cultivate principally French Crabs, Stone Pippins, Pearmain, &c. These are equal to any grown here, and so are their Cherries, Mulberries, and I might say Walnuts. But in my opinion with proper cultivation, shelter, &c., English Apples will always be preferred to any grown in America.—C. LONG, *Vineyard Villas, Richmond.*

FREEING ORCHARDS FROM LICHEN.

AN effectual plan of freeing orchards trees from Lichen is to burn sulphur under them; the fumes will kill all vegetable growth and also insects, and cause the bark to become bright looking and polished. The way to use the sulphur is to have some old cracked garden flower pots or anything of that kind that will hold fire, which should be made with charcoal, so as to keep burning steadily; on this throw a handful of sulphur every few minutes, and keep the pots moved from tree to tree, placing them on the side from which the draught sets in that the smoke may be carried right through the tops. The best time to apply the sulphur is during a still day when the air is heavy. Of course it will not do to burn sulphur after the buds are in a forward state, as then it would injure them; but so long as they remain closed in their scaly coverings they are safe, and the sulphur fumes will not do the least harm. We have been using them against our walls and not only have they cleaned the trees, but the bricks are completely freed from all moss, and have quite a new look. Pears and Plums that had scale on them throw it off, and since we have fumigated Peaches and Cherries outside, we have little or no trouble with either aphid or spider, and the saving in insecticides, time, and labour is something considerable. Sulphur may be got in any quantity at 3d. per pound, and a man or boy with several pots to attend to can soon get over a number of trees. I have no doubt that the asphyxiators, advertised so extensively some time ago for driving rats, &c., out of their holes, would answer for smoking trees, as the fumes of the sulphur could with one of them be more concentrated and driven wherever required. I am going to use a common fumigator with bellows for our standard Rose stems, as they are mossy, and a puff or two from it will at once put them right. Lime is also a good thing for eradicating Lichens and Moss from trees, but to be thoroughly effectual, it must be got quite fresh, and then slaked in a tub with water, when it may be syringed on, if made to the consistency of thin paint, in which state it will adhere tightly and cover the branches. Besides being so highly beneficial to trees and bushes by destroying the Moss, lime keeps off sparrows and bullfinches from the buds, which they cannot eat when so coated, but which they often when not protected peck out and leave the trees bare. This is almost sure to be the case near towns or farmhouses, where sparrows abound, and I have in such places seen bushes of Gooseberries and Currants quite spoiled.—J. SHEPPARD.

— Being short of labour, your correspondent should make an effort to prevent the growth of Lichen on his orchard trees instead of year after year being pestered with attempts at destroying it. So far as my observation goes, it is solely occasioned by poverty or badly drained soil, often by the conjunction of the two; hence the remedy is obvious, and, at all events, draining ought to be done; and if further cultivation, such as the digging in of and mulching with farmyard or rotted stable manure be impracticable, an occasional dressing of soot, applied early in the year, that it may get washed into the ground, should be given, and in most cases this treatment will prove an effective deterrent to the growth of this parasite, and, as a consequence, prove beneficial to the trees in regard to their fruiting properties. A quick way of destroying the Lichen now on the trees is to get some freshly slacked lime, and mix

it up in a large tub as for whitewashing. To a bushel of lime add half a bushel of soot, thoroughly mixing them together by adding water in such quantity as is needed to make it into a liquid that can be strained through a fine sieve, in order that it can be applied with a syringe, or, better still, a garden engine, over the trees. Dry weather should be chosen for its application, and of course after all pruning that is intended to be done is completed; no fear need then be entertained of the mixture injuring the buds.—W. W. H.

Freeing orchards from Lichen.—This is not at all a difficult matter, as I have proved. The remedy is fresh slaked lime dusted while it is hot over the branches. My first attempt was in a rough and ready fashion. Having a large orchard to deal with, a waggon-load of lime was distributed in three separate heaps about the orchard, and as soon as it was slaked a man with a wheel-barrow full of it stood underneath the trees and threw the lime with a scoop up amongst the branches. This killed the Lichen on all the branches which it touched, but the lime was not sufficiently distributed upon the upper sides of the branches to make a satisfactory clearance. Next year, therefore, I obtained another supply of lime, and by having one man under the tree to hand up the lime and another high amongst the branches to distribute it, every branch in the orchard was effectually cleared of Lichen. If your correspondent wishes to try this plan no time should be lost, as the trees should be operated upon before the buds begin to expand, and dry, still weather should be selected in order to make the remedy a complete success. I may add that the effects of the lime dusting will not be visible for several weeks, and to be efficacious the lime must be hot and strong. The parasite in the first instance will become brown, and then it will fall off and be tossed about the orchard by the wind.—J. C. C.

—“Constant Reader” may clear Lichens from fruit trees by applying hot lime in a powdered state. It is best to apply it when the trees are in a moist condition. The lime freely applied will eventually benefit the trees, besides killing the Lichen. I have also applied nitrate of soda in a liquid state for the same purpose, and with satisfactory results. Lichen, if not too great in quantity, does not appear to injure trees to the extent generally supposed. In the west of England fine crops of Apples may be seen on trees furnished with a fleecy coat of Lichen.—CHAS. McDONALD, *Stokesley*.

—Has your correspondent ever tried quicklime as fresh and hot as it can be had for freeing orchards from Lichen? It should be applied in winter while the trees are wet from rains or otherwise. I have also seen strong brine applied with equally good results, but only on a very small scale, and how it might answer on large trees in orchards I cannot say, but I should consider it rather hazardous for the grass beneath if used in any considerable quantity. The lime does no harm otherwise.—R. STEVENS.

Duke of Buccleuch Grape.—As a grower and exhibitor of this Grape my attention has been called to an advertisement which appeared in THE GARDEN on January 13, but after reading it over three times I confess that its meaning is beyond my comprehension. May I be permitted to ask where it is stated that the Duke “is grown by hundreds of gardeners to the weight of 4 lbs. and 5 lbs.” (presumably per bunch), “and can be kept fresh and plump for more than six months after it is ripe?” If the advertisement in question is a genuine invitation to growers to produce extraordinarily large bunches, why the condition, “perfectly ripe for a month previous to the show?” Surely it is enough if large bunches are perfectly ripe, sound, and in good condition upon the show day. What am I to understand by “being shown at London, Edinburgh?” &c. If an exhibitor show, say in June, at York, “two single bunches,” and they weigh over 4½ lbs. each bunch, and comply with all the requirements of the donors, will

he be there and then awarded the prize? or must he wait until the September shows are over before he can know his fate? How are Grapes shown in June to be compared with those shown in September? I venture to say that before the advertisers can make their proffered special prize practicable, they must throw a little more light upon the subject than is contained in the advertisement.—J. MCINDOE, *Hutton Hall, Guisborough*.

A land of Peaches.—In the neighbourhood of Sydney such fruits as the Peach, Nectarine, Apricot, Plum, Fig, Grape, Cherry, and Orange are as plentiful as Blackberries. The orangeries and orchards of New South Wales are among its sights; and in the neighbourhood of Sydney and round Port Jackson there are beautiful groves of Orange trees, which extend in some places down to the water's edge. Individual settlers have groves which yield as many as thirty thousand dozen Oranges per annum. One may there literally “sit under his own Vine and Fig tree.” If a Peach stone is thrown down in almost any part of Australia where there is a little moisture, a tree will spring up, which in a few years will yield handsomely. A well-known botanist used formerly to carry with him, during extensive travels, a small bag of Peach stones to plant in suitable places, and many a wandering settler has blessed him since. Figs were formerly often fed on Peaches, as was done in California, a country much resembling Southern Australia; it is only of late years they have been utilised in both places by drying or otherwise preserving. A basket load may be obtained in the Sydney markets during the season for a few pence. The summer heat of Sydney is about that of Naples, while its winter corresponds with that of Sicily.—*The Sea*.

QUESTIONS

Ants are very numerous in one of my houses. They swarm more particularly on some large Camellias, and persevere most astonishingly in carrying soil up the stems of the plants. Will any of your readers kindly tell me how to destroy them?—S. O.

Franciscas for cut flowers.—Will some of your readers kindly tell me whether Franciscas are good for cut flowers? If so, which is the best, and whether they fetch a good price in Covent Garden market?—W. G. B.

Picotees for exhibition.—I am desirous of growing Picotees out-of-doors in pots. Will some one kindly answer me the following questions in reference thereto? Do they require much water, and how am I to tell when they need it? Is it better to grow them wholly in the shade, or shade the flower? and if the latter, when should the shading commence? Can I defer the blooming time and how? I have an impression they bloom sooner in pots than in the open. Is this so?—B. H. L.

Ribbon borders.—We have in the gardens here (Belfast) a border on each side of a centre walk, 300 feet long by 7 feet wide, which we propose bedding in the ribbon style this year. This walk leads from the conservatory to a range of houses 300 feet or 400 feet long, in front of which is the flower ground; the ribbon, therefore, needs to be a very effective one. What, may I ask some of the readers of THE GARDEN, would, under the circumstances, contrast best?—S. W. J.

Grubs on fruit trees.—We have been very much troubled for two or three years past with grubs on our Pear, Apple, and Cherry trees. As soon as the buds begin to expand and the leaves to develop we find one and sometimes two or three grubs in each leaf, which they roll up with a kind of web; from the leaves they go into the blossom, which they completely destroy. No insecticide seems to kill them, the great difficulty being to get at them, being rolled up in the leaves. There are two kinds, one a small brown grub like the Rose grub, the other a pale green, about half an inch long when fully developed. Can any one tell me how to get rid of them?—C.

* * * Our readers will greatly oblige by replying, so far as their knowledge and observation permit, to these questions. The title of each query answered should be prefixed to each answer, and replies will be printed in the department of the paper under which the subject falls. The questions that arise and must be solved are so many in these days, that it is only by a general interchange of ideas and experiences among practical men that we can hope to answer them satisfactorily.

PLANTS IN FLOWER.

TWIN-FLOWERED CYPRIPIEDUM HARRISIANUM.—A flower-spike of this handsome Lady's Slipper is sent by Dr. Paterson, a curiosity we have not before observed, though of frequent occurrence in *C. insigne*. Dr. Paterson possesses a fine form of this Orchid, for each of the flowers measure 6 inches across, and are of a good dark colour.

THE HOOP-PETTICOAT DAFFODIL (*Narcissus Bulbocodium*) is grown successfully in pots at Kew for the adornment of the conservatory (No. 4). For this purpose the bulbs are procured in autumn, and treated in the way Dutch bulbs are, the result being fine potfuls with healthy tufts of foliage and large rich yellow blossoms, so distinct from the ordinary run of spring decorative plants.

COTYLEDON FULGENS is the showiest plant now in the Cactus house at Kew. It is similar, if not identical, with the now tolerably well-known *Echeveria retusa*, but the colour of the blossoms is a much brighter orange-yellow than usual and they are more numerous produced. It is a useful plant for cultivating for winter and spring bloom, and it is of the simplest culture in a warm, dry house. A native of Mexico.

TWO NEW SPECIES OF CORYDALIS are sent by the New Plant and Bulb Company, Colchester. They are *C. Ledebourii* and *C. Sewerzowii*. Both are dwarf in growth, with divided and glaucous leaves. The first has pinkish flowers arranged on a closely set spike, while those of *C. Sewerzowii* are an inch long and a kind of bronzy yellow. Both are interesting new hardy plants introduced to cultivation, we believe, by Dr. Regel, of St. Petersburg.

DEDALACANTHUS MACROPHYLLUS is the name of a rather showy plant flowering in one of the stoves at Kew. It is a low-growing plant, inclined to be bushy. Each branch is terminated by a wide-spreading cluster of flowers, which in shape somewhat resemble some species of *Salvia*, though the plant belongs to the *Acanthus* family. The colour of the flowers is a pale mauve, the lower lobe of the corolla being a deep purple. As a free-flowering stove plant for winter it is worth attention, but we doubt if it is obtainable in nurseries.

A BORNEAN RHODODENDRON, recently introduced by Mr. Bull, is one of the finest things in flower in his nursery at Chelsea. It has large deep glossy green leaves nearly a foot long, crowded in clusters at the upper parts of the branches. The trusses, numbering from eight to a dozen blooms, terminate the branches, and are encircled by foliage. The blossoms are nearly three inches across, bell shaped, and of a rich orange yellow. It is in the way of *R. Brookeanum*, but if it be identical with that species it must be a wonderfully fine form of it. It is one of the handsomest tender *Rhododendrons* we have seen, and when Mr. Bull can distribute it, it will be sure to be welcomed.

NOTES FROM CORNWALL.—I send you a few flowers from out of doors. Daffodils are getting quite plentiful with us. A large *Pyrus japonica* here against a wall is quite a mass of scarlet. Some of our Carnations have been throwing up spikes of bloom all the winter, but they have not opened well, having suffered more from damp than cold; a few of the buds seem inclined to open. One plant has over fifty buds on it. The *Primrose* sent seems a good variety; it throws up several blooms on a strong foot-stalk at least 8 inches high; the spike sent has sixteen expanded blooms and buds on it. [A fine variety.] I also send *Amaryllis aulica*, which I find a most useful one for forcing. We had a very severe gale from the S.W. on Monday morning; it commenced soon after midnight and lasted till 10 a.m., when it moderated considerably. Two tall trees (an Elm and an Ash) were snapped off some distance from the ground, and some evergreen Oaks were overturned.—JOHN C. TALLACK, *Prideaux Place, Padstow*.

NOTES.

Now when the wind is howling in the chimneys, and rain-drops patter and splash drearily on the window pane, it is pleasant to think of sunny lands where there is heat and sunshine, and where Palm trees wave beside the glistening sea. "And what do you think excited my ecstasy? It was a fine young grove of Cocoa-nut Palms, seen for the first time waving in a strong breeze. You have no idea from seeing them in hothouses what Palm trees are under the open sky. They are as different as an eagle on its eyrie from the same bird bedraggled in a dirty cage. The plummy leaves shaking to and fro, and rustling in the wind, are noble as well as unutterably beautiful. Truly the Palms are princes of the vegetable world. It never struck me until I heard the sound through their leaves how beneficent it was of Providence to place such huge fan and feathery leaves in the hot climates where they catch the slightest air and play, fan-like, backwards and forwards on their long leaf-stalks, cooling all around them and comforting the air with their aspen music." Such a warm and genial picture is very pleasant, and suggestive in this time of Snowdrops and "Lenten Lilies."

TILLANDSIA IONANTHA.—From Glasnevin Mr. Moore has posted me a very pretty little Bromeliad—one of the most dainty I have ever seen. It is named *Tillandsia ionantha*, and came from Makoy, of Liege, who makes quite a special culture of these South American epiphytes. The curved awl-shaped leaves form a little tuft 2 inches or 3 inches high, and from its crown spring two or three flowers, apparently tubular and of a glossy amethyst purple colour, their smooth brilliancy of tint suggesting that of a bit of stained glass. The lower part of the leaves behind are powdered with silvery scales and shine like burnished metal. The sketch shows the natural size of the plant and its flowers. No Orchid could well be prettier than this and some other *Tillandsias*, and some time these

its smooth and thornless stems! I once heard an old Lancashire fruit grower say that he would give a hundred pounds for a plant of the old Warrington Gooseberry with spineless branches! So, too, I can well imagine people anxiously asking Mr. William Paul for beautiful Roses without the dreaded thorns, which, although crooked enough, seem instinctively to pierce the tenderest part of the hand, intent on "gathering Roses while it may."

ENGLISH PLANT NAMES.—"Marsh Marigold" (see p. 100) may rest assured that although the few may object, the many will be grateful for any pretty and characteristic English names he may devise for beautiful plants. Mr. Barr tells us that the beautiful leaved *Funkias* sell far more readily under the pretty name of "Plantain Lilies" than ever they did under their Latin one. So, too, of *Myrsiphyllum asparagoides*, the "Boston Smilax" of American gardens, which has in some places acquired quite a new popularity under the far prettier and more suggestive (because more truthful) name of "Wreath Lily." Again, take for example, *Parochætus communis*, a lovely Himalayan mountain weed, the beauty of which is as effectually concealed under its Latin name as a bit of blue Gentian is when under an avalanche. Once, however, let anyone see it and hear it spoken of as "blue-flowered Shamrock," and its beauty is photographed on the mind for ever just as Burns photographed the Daisy as "wee crimson tip'd flower," and as Chaucer had long before done as "Day's Eye," or "Eye of Day." "Oh!" say the learned ones, "Latin is a cosmopolitan language, a lingua franca which is understood by savans all the world over, so Latin must ever be employed." All this we hereby do "graunt and firme letton" to the botanist for all time; all we say is that every plant worthy of a Latin name is worthy of an English name in addition to that. It is not as if we wished the botanist to give up his Latin in exchange for English—we freely grant him his rights, but object to his, or anyone, trying to suppress English names. The gardener has as good a right to give English names, or, on just occasion, any other names, as the botanist has. We have as great a respect for precedence of nomenclature as anyone, and shall not give new names to the Violet, or Primrose, or Ivy, or Holly, or Oak, all English names, as lifeless and unchangeable, and as definite as any language can ever be. Travellers tell us that there is scarcely an animal or a bird alive in any country that is not as definitely known (by the natives of the country in which it lives) by a name as characteristic as any Latin nomenclature can possibly be. Is bread of "Triticum" more nutritious than that of "Wheat"?

A NOBLE ORCHID.—A Dublin friend tells me of a fine *Odontoglossum Alexandrie* which is now flowering in a lady's conservatory in Fitzwilliam Place. Last year the plant bore two spikes from one fine plump bulb, the number of blooms on each spike being, as my correspondent believes, thirteen and ten or eleven respectively. Last year the one leading growth "broke double," and this season each bulb bears one stout spike on one of which is thirteen, and on the other nine blossoms. The actual number of blossoms on a spike, however, is of minor consequence, what is far more remarkable being the size and fulness of the delicately-tinted flowers themselves. The broad petals are most exquisitely fringed of a warm white, due to the most subtle flushing of carnation, the sepals being delicately suffused with rosy lilac. The spotting is confined to the lip, which has a solitary blotch of reddish-brown just below the characteristic yellow disc. Just now when importations contain such a large proportion of weedy pallid varieties, the sight of such an exquisitely beautiful kind is all the more refreshing. This variety is from an early importation and was purchased for its present owner by the late Dr. Moore. Seeing the prices now being paid at Stevens' for good forms of this Orchid, one would think it would be a profitable employment for a collector abroad to select the best varieties and mark them ere be consigned them to Europe. Only the other day we heard of half a

plant in flower fetching £30 or £40, and yet imported plants may be had for as many pence. I know a little of the difficulties and dangers under which collectors must ever labour, but I also know the advantages they often have of liberal European assistance, and native labour not over expensive, and in their own interest I ask of them as a favour that they will select and mark exceptional variations, seeing that most men who buy are liberal enough when they can conscientiously write "value received."

STENOGASTRA CONCINNA is a little stove plant now but rarely seen, and yet but few plants are prettier than it is when well cultivated. The

Stenogastria concinna

plant is of tufted habit, barely 2 inches high—a fine specimen would go into a fusée box—and the delicate *Gloxiria*-like flowers are of a soft lilac colour shading into white, the throat of its tiny blossoms being spotted or dotted in a really exquisite manner. It is a choice little gem for associating with the rarer kinds of *Goodyeras* and *Anætochili*, or for pan culture beneath a glass shade or bell-glass, provided air is freely admitted.

SOPHRONITIS GRANDIFLORA.—Once when I was staying with Orchid-loving friends they were in ecstasies because one of their correspondents in India, or Malaya, or somewhere else, had told them of a "bright scarlet species of *Moth Orchid*, or *Phalænopsis*," and they were very anxious for him to send home plants of the new beauty. Alas, for those brilliant hopes which flit past us like gaudy butterflies, something happened, and the plants never came. I shall not moralise on the fallacy of "great expectations;" my readers may moralise for themselves, and I—I have grown so fond of the large-flowered scarlet *Sophronitis* that I do not care whether the scarlet *Phalænopsis* is or is not torn from its native lair. As a contrast to white *Lycastes* and *Cælogynes*, *Sophronitis* is most lovely.

SPRING-TIME.—What hope and promise there is in early spring days when the Grass is chequered with warm sunshine, and the Daisies open their eyes and Crocuses their cups of gold, and the Snowdrops become taller, Daffodils also make sudden growth, and the golden stars of the lesser *Celandine* sparkle in little nebulae on the thin turf beneath the dark Olive, green boled Elms. Blackbird and thrush, like rival prima donnas, sing their newest and sweetest songs, as if doing their best for pride of place in our hearts. Even the noisy rooks suddenly remember that it is nest-building time. Two are there now on a topmost branch nodding to each other most approvingly as they examine their last year's nest. They remind me of the picture of King René and his wife, so intent are they on their housebuilding. Then rosy buds of Almond trees are ready for bursting, and the golden winter Jasmine is supplanted by *Pyrus japonica*, which seems to set the old grey walls afire, so brilliant are its scarlet blossoms.

HARDY SHRUBS NOW IN BLOOM.—Odd coral buds glint here and there among the tender leaflets of *Pyrus japonica*; the soft green bells of

Tillandsia ionantha.

graceful little dwellers on trec-tops will have their day. I do not remember if this plant has ever been figured in colour, a honour which it richly deserves.

"A ROSE WITHOUT A THORN."—What a favourite that lovely, rich Charles Lefebvre Rose (GARDEN, plate 374) must be with many, seeing that it has such vivid crimson flowers on

Clematis cirrhosa sway to and fro in the sunshine; their as yet unopened buds remind one in colour and size of Hazel nuts when fully grown, but unripened. *Daphne Mezereum* is a mass of sweet purple blossoms, and the Japan Jasmine is yet in full glory, and yet the pride of place must be given to one of the hardiest and best of all spring blooming shrubs—*Rhododendron præcox*. A specimen now in full bloom and bud in a sheltered (not shady) corner reminds one of a "specimen" Azalea at a May flower show. Its blossoms are of a lively lilac-purple tint, the buds being deeper red and the leafage dark and fresh, and as glossy as if grown in a hot house. It is perfectly bardy, and once well planted is totally careless, oblivious even of the existence of a gardener. Perhaps this is the reason one so rarely finds the plant either in public or private gardens. In most nurseries it is extinct—"not in stock" is perhaps the right way of expressing the fact. It is a hybrid, I am told, between an Azalea and a *Rhododendron*, but I want to hear where it may be purchased.

HAPPY MARRIAGES.—So one of my friends calls the blending of two sweet-smelling flowers or leaves together, and sends me examples. A bunch of Violets and sprays of golden-leaved Thyme is exquisite in colour, and in fragrance also. Then Rosemary sprigs and winter Heliotrope is another very successful mixture, colour also low and harmonious, and a right royal marriage is that of the Amazon Queen Eucharis with *Narcissus* (*N. Tazetta* var.). Then Veitch's Jasmine (*J. gracillimum*) and Violets again are so distinct as to be positively a new sensation altogether in the way of perfumes. The wonder is, seeing how we fight for delicately blended colours, that we have been so long content with either crude perfumes (*i.e.*, one flower only), or failing that have rushed to the Charybdis of a copious mixture, or what a cynical friend calls "family jam." I am more particularly anxious that lady readers of *THE GARDEN* should tell us of all the "happy marriages" they know of in the way of flower odours. I forgot to say that Tea Rose buds, Niphetos, or Safrano will do, and Paper-white *Narcissus* is a—well, try it for yourself.

SNOWDROPS.—These are now at their best with us—not in fullest blossom, but at their freshest and fairest, with all the promise of budding beauty, which I hold more precious in a way than that fulness "of maturity so suggestive of decay." *G. Elwesi* and *G. Imperati* are alike giants of their race; the latter is here the largest, unless Melville's large variety, which seems to be a little later, eventually surpasses it in size, as it certainly did last year. *G. nivalis*, single and double, are abundant in borders and on the green turf, and where dead leaves have blown and clustered around them I note the flowers are the larger and cleaner for such accidental shelter. *G. Redoutei* produces plenty of its snowflake-like leaves, but "nothing but leaves" is a poor text from which to preach. *G. plicatus* is much finer in leafage and blossom than *G. nivalis*, but not so floriferous. *G. Elwesi* is of all most distinct by reason of the large additional basal blotch on the three inner petals. One or two late flowering varieties are barely out of the ground yet. *G. Imperati* in the bud state is most lovely. If it were an Orchid, everybody would . . . but it is not.

HELLEBORUS NIGER ANGUSTIFOLIUS.—Since I rashly penned my note on this plant several people write to say that *H. altifolius* "sometimes comes pure white," and they gratuitously jump to the conclusion that it is my plant. I know *H. altifolius* well—as the wisest of my correspondents infers; it is quite distinct and "sacred to the memory of the late Miss Hope, of Wardie," but mine is a large—the largest and best—form of *H. niger*, the individual blooms being "large and white as those of a Eucharis," with no red speckling or rosy flushing on any part of the entire plant, simply pale green stalks and pure white sepals. Then someone says that *H. altifolius* (*H. niger maximus* of gardens) as figured in *THE GARDEN* is wrong in colour. This is scarcely true. The flowers are past their best, too old for figuring, in

fact; but the colour of the plant is most faithful, just as its flowers fade away. This plant and *H. niger* (type) have always scapes speckled with red. My plant is never so speckled, nor do its blossoms die off rosy, as do those of *H. altifolius*. I hope someone will recognise my portrait and say a word in defence of such a "swan-like beauty."

VIOLET-SCENTED ODONTOGLOSSUM.—A little plant of *Odontoglossum Warneri* now in bloom is deliciously perfumed like Violets. Has this plant or its first cousin, *O. Rossi majus*, ever been suspected of robbing or of mimicking the spring Violet's fragrance before? Time of day, 10.30 a.m., in bright sunshine. Of course it is now well known that the odour of some Orchids changes at different periods during the daytime. Some even—the *Angræcums* to wit—are most potent in perfume after dusk. Someone once told me *A. virens*, the small blossomed dwarf form of *A. eburneum*, Lindley (= *A. superbum*, Dupetit Thouars), had the fragrance of Christmas plum pudding, and I know for a fact that *Odontoglossum gloriosum* (odoratum var.) has the fragrance of Hawthorn or May. I wish Orchid-growing amateurs would look into this question of fragrance and tell us their experience. It is comparatively an unworked mine, and the results would at least be highly interesting, and might some day be of practical value as well. For the present can anyone corroborate my experience of *O. Warneri* being Violet-scented? **VERONICA.**

Gladiolus planting in January.—Visiting one of the best and most expensively maintained gardens in this vicinity the third week in January, I was rather surprised to find the experienced gardener planting fifty Gladioli corms obtained some days previously. I gently remonstrated as to the early period. He replied, "I find our corms begin to move naturally if the atmosphere is mild and moist invariably in January. If we do not take advantage of this, a check is experienced that I consider affects the subsequent growth." I may just state that the proprietor has been twenty years a most successful grower of Gladioli, and only patronises the best of the gardener's hybrids added every year to his stock. Now, I do not commence to plant myself until February, but I would like to ask if any of your readers have tried planting in January, and with what result. I know Mr. Douglas in certain cases recommends leaving them outdoors during the winter.—**W. J. M.**

THE CHRYSANTHEMUM AND ITS CULTURE.

Diseases and insects.—The Chrysanthemum, being hardy and robust in constitution, is singularly free from diseases. When they are housed or sheltered under canvas in October, however, mildew sometimes makes its appearance. Its origin is by some attributed to very cold nights succeeding sunny days, *i.e.*, to great extremes of temperature. Overcrowding the plants and insufficient ventilation is another fertile cause of mildew. The best of all preventives is to stage the plants thinly, allowing each ample space; give abundance of air and keep a morsel of fire burning, especially on cold, wet nights. It must, however, never be forgotten that it is shelter, not heat, that this flower requires. A fire-heated house is best for preserving the dry atmosphere best suited to the preservation of the blooms. Should mildew actually appear, dusting the affected plants with flowers of sulphur is the best antidote.

Professor Westwood, writing on the insects which infest Chrysanthemums in the *Gardeners' Chronicle* (1881, p. 537), says: "I regret to find that a very large proportion of my Chrysanthemum plants (on which I have for some months past been bestowing a large share of attention) have come blind, the tops of many of the shoots having shown a strong and vigorous foliage—too vigorous, in fact, for the development of flower-buds, whilst many have produced imperfect one-sided buds, instead of the fine round ones which should produce the perfect flowers. How far

the peculiar weather of the last six months has caused such effects I cannot determine, but I do know that, notwithstanding all my care, insects have abounded on my plants, and I have no doubt that in many instances it is to their agency that my failures are to be attributed. Throughout the early summer months I found the perfect cuckoo-spit insect or frog-hopper very commonly on the young plants, it having been developed earlier in the year from the patches of froth, vulgarly called cuckoo-spit, to be found on many plants, in the midst of which the immature frog-hopper is to be found. The perfect insect is extremely active, springing off the plant on the slightest motion, so that it is very difficult to be captured. Taking its place on the tenderest part of the plant, it inserts its delicate sucker into the young shoots and arrests their growth.

"Later in the summer the earwigs make their appearance, feeding by night on the tender foliage, and concealing themselves on the return of daylight within the buds, their heads being invariably turned towards the innermost part of the buds, and their tails towards the extremity of the curled-up leaves. This affords an easy mode of catching and destroying them. On taking hold of the folded leaf and the tail of the insect between the forefinger and thumb of the right, the alarmed insect immediately raises its head, which may be seized by the nails of the thumb and forefinger of the left hand, and the insect decapitated. I observed the curious fact that it is almost always the case that the depredators are females (easily distinguished by the much smaller size of the forceps at the extremity of the body); with these females were sometimes associated the immature earwigs, and I have taken as many as seven of these insects in the head of a single shoot, their presence being indicated by the minute black granules of their excrement on the surface of the leaves."

The writer of this article has published the description and figure of a species of field or plant bug (*Phytocoris campestris*) which constantly causes much mischief in the autumn to the Chrysanthemum buds by inserting the extremity of its delicate rostrum (including four very fine bristles) into the buds, and thereby injuring such of the petals as are in part attacked by preventing them from expanding properly and preventing the so much desired regularity in the bloom."

This species has been unusually abundant on my plants this year, and with it have been associated several other kinds of plant bugs having precisely similar habits, and being equally injurious to the plants. One of these, nearly as large as the preceding, is of a delicate pale green colour, which causes it to be observed on the plant with difficulty. This species was named *Cimex nassatus* by Fabricius. Another species, of smaller size, is the *Cimex* (*Anthocoris*) *memorum* of Linnaeus, about one-and-three-quarters line long, of a black colour and shining, the wing covers of pale whitish yellow spotted with black or pitchy colour; the apical membrane yellowish white, with the middle and end brownish black, and the legs yellow. It is common on trees and bushes from June to October, and hibernates among dry leaves. A greater amount of mischief is committed, however, by a much smaller insect, the *Cimex minutus* of Linnaeus, belonging to the genus *Anthocoris* and subgenus *Triphleps*. This little insect insinuates itself quite into the centre of the bud, its minute size rendering it difficult to be perceived, although the black colour of its body and the black triangular patch in the middle of its wing-covers render it quite conspicuous when exposed, or when the bud is gently opened. In its preparatory state it is also equally injurious, and is easily distinguished by a large white patch at the extremity of its rudimentary wing-covers. The same insect occurs in North America, where, from its habits, it has been named *Anthocoris insidiatus*.

Besides the foregoing insects I have noticed several others on the buds of my Chrysanthemum plants, although of comparative rarity. The common 7-spotted ladybird is one of these, but as this insect is known to be insectivorous, feeding both in the larva and perfect state on plant lice,

it may possibly have taken its place on the plant in hopes of finding its usual prey (which has, however, not made its appearance this year on my plants); in the absence of this, I suppose, it would attack the plant bugs above described. The common long-legged harvest spider (*Phalangium* sp.) has also often been found on the heads of my plants, most probably having got there in search of insects on which it feeds. The caterpillar of the dot moth (*Noctua persicariæ*) also has been occasionally met with, and must be looked after sharply, as its delicate green colour with the dark lines on its back render it difficult to be easily detected from its similarity to the folded young leaves of the bud.

Compost and manures.—The best compost for the *Chrysanthemum* is one mainly composed of sound red loam, and the more vegetable fibre it contains the better. My own practice is to buy a few cartloads of this during November. It is dug from a mountain side where the grass and other herbage is short and fine, being eaten off closely by sheep. Almost any kind of plant will grow in it, and it is of that texture which holds much water and yet is never "soapy," but friable even after it has been squeezed in the hand. Sand in any pure form I do not use in the culture of the *Chrysanthemum* (except for rooting cuttings in), but instead I add a cartload of old lime-mortar to, say, five loads of the loam. A barrow-load of pure soot is added to the heap as it is turned over for the first time in December. If possible let this operation be done during dry, frosty weather. The soot is useful in making the soil unpalatable to worms, and as it consists mainly of charcoal or carbon in a fine state, and holds also some ammonia, it is manurial also. Some growers advise adding a fourth or more of well rotted manure to the loam, but I am convinced that the finest and most floriferous growths are those made in good loam, lime rubbish, and soot as above described. The right time to apply the manure is after the flower-buds are formed in August and September, about which time the soil becomes partially exhausted and quite filled with roots. It is quite possible and easy to grow large plants with enormous sappy leaves by adding manure largely to the compost at the final shift into blooming pots (say in May or June), but it does not follow that plants so luxuriantly grown, and so healthy in July, give the finest flowers in November. It must never be forgotten that size of leaf and apparent vigour of plant is no guide to good bloom, no matter whether the desired results are quality or quantity. I rely on a sound, sweet compost, careful and regular watering, and from the first week after the cuttings are rooted I freely expose the plants to sun and air, except during sharp frost. What is requisite is not growth only, but sound, firm wood, or growth well matured. Once every week during summer the plants receive a dose of soot water. I am now firmly convinced that many growers fail in using a compost containing too much manure during the early stages of the plant's existence, and by relying on a basis of sound loam we have the plant more entirely under control, as manurial stimulants can most easily be given in the liquid state when it is deemed desirable, or when it is most useful to assist forward and aid the development of the flower buds. Now, here is a piece of advice given to me some time ago by Mr. N. Davis, of Camberwell: "Never give liquid manure to the plants while forming their buds, or else blindness will be the result." This advice more especially applies to plants from which "perfect" or "prize" blooms are expected, for we know that really creditable decorative bushes, well laden with third-rate flowers, may be grown by giving manure water freely as soon as the blooming pots become filled with roots, say in June or July. Indeed for specimen plants or large bushes it is almost a necessity, and Messrs. S. Dixon, in their notes on *Chrysanthemum* culture, say, in speaking of large trained specimens, "As soon as the roots reach the sides of the (blooming) pots we commence giving liquid manure." I am particular in clearing up this point of when and how and to what plants to apply

manure water, as there has been much misunderstanding on the point, as there has also been on the delicate question of how and when to stop and disbud, which is fully alluded to and explained in another place.

The addition of much manure to the compost causes unstopped plants to grow too quickly, and so their growth is not sufficiently matured. On the other hand, specimen plants or decorative bushes are stopped frequently up to the second week in July in the south of England, or to the last week in June in the north of England, Scotland, and in Ireland. All this stopping and training of the shoots naturally checks the growth, and so a richer compost may in their case be used with more safety than for unstopped plants with only one to three stems from which large blooms are to be obtained.

Watering.—No plant requires more constant attention as to watering than does the *Chrysanthemum*. This is especially the case during July and August, when the pots become filled with roots, and an additional strain has to be borne, as the plants are at that season about making up that portion of their growth upon which the flower-buds appear. Rain or soft river water is best if it is readily obtainable, but if pump or spring water must be used, expose it for at least some hours in tubs or other open vessels, so that it becomes warmed and aerated. My own practice is to water twice a day after the plants are placed in their blooming pots, say in May or June. Dribbling a little water on the surface will not do; nothing but a thorough soaking serves such a gross feeding plant. Syringing the foliage every evening an hour or two before sunset is of great advantage in keeping the foliage clean and bright and free from green-fly and other insects. When manure water is applied it is essential that the soil be thoroughly moist beforehand. If the earth is in any way dry always give a soaking of pure water before the manure water be applied. It then finds its way downwards, regularly becoming equally diffused throughout the ball of earth within the pot, and every rootlet is fed, and none are injured, as might otherwise be the case if watered with crude manure water when the earth is in a dry state. Soot water is a great aid to culture in many ways, and should be carefully prepared, so that no soot floats on the surface. Syringing with a clear solution of soot makes the leaves of a beautiful dark and glossy green tint, and is an excellent preventive of green fly. We water the whole collection every morning about eight o'clock, paying great attention to the thorough soaking of every plant; and to do this effectively when a plant has been allowed to become dry, three or four waterings are necessary. As the plants increase in size and the ball becomes filled with roots it becomes necessary to watch the edges and sides of the ball narrowly, otherwise most of the water which should diffuse itself gradually and thoroughly throughout the ball of earth merely trickles down the inside of the pots, leaving the ball as dry as tinder, although apparently a thorough good watering had been given. We watch our plants very narrowly, and every week devote some time to ramming down the edges of the ball tightly with a blunt lath. A little labour and attention in this way is abundantly repaid. In very hot dry weather a mulching of rotten hotbed manure may be given, and this is especially valuable if the earth has been in any degree washed away in the operation of watering. Even a handful or two of short lawn grass from the mowing machine will economise labour and water also if it be sprinkled on the surface of the soil in which the plants are grown—I mean early in the season, before the soil is in any way exhausted by the ramifying rootlets; after that takes place mulching with rotten manure is most valuable.

Stopping and disbudding.—Both these operations are of great importance in the growth and training of large specimens for show. Stopping the points of the main shoots must be carefully attended to. First, say in December or January, the rooted sucker or cutting has its

point carefully pinched out, and this causes branches to appear from the axils of the three or four leaves below the part pinched off. Pinching or stopping must be done at the exact moment when side branches are desired, as only the bud at the very end or top of the shoots must be removed. To allow a shoot to grow 3 inches or 4 inches longer than is requisite, and then to stop it back into the partly hardened wood, is fatal in all ways. Here are Messrs. Dixon's rules on stopping, which may well be reproduced in this place. "For specimen plants or decorative bushes stop until the second week in July, that is, in the south of England, in Ireland or the north of England the last week in June is quite late enough to stop; after that time is fatal to good flowers. Again, never stop and shift on the plants into fresh pots at the same time. Ten days or a fortnight should always be allowed between these operations. The repotting or shift then strengthens the laterals. For exhibition specimens," say Messrs. Dixon, "these rules should never be departed from." After the first stopping one to three shoots only should be allowed to grow on. Pick out all other growths with a knife. Unless the cuttings were carefully disbudded or cleaned ere they were inserted in the cutting pot basal growths or suckers are apt to annoy one. Pick all these carefully away as soon as seen. Tall plants for large blooms are rarely stopped more than twice; they naturally stop themselves twice, indeed—in May and in July. To allow them to do this, however, is a sheer loss of time, and the better plan is to pick out the May and July flower-buds as soon as they appear, leaving only one shoot to lead up from immediately below the point on the shoot whence the flower-bud has been removed. It will thus be seen that stopping and disbudding are very nearly related in the middle stage of *Chrysanthemum* culture.

Disbudding proper, however, is taking out all side growths below the flower-bud, which is retained as the most likely to produce a fine bloom. Every axillary growth or flower-bud which appears below the flower-bud must be picked out, care being taken that the leaves are uninjured in the operation. August is indeed a busy month to the grower of *Chrysanthemums*, as it is but rarely that the careful work of disbudding can be left to ordinary assistants. So far as decorative bushes are concerned, where quantity and fair, rather than superlative, quality of the blooms is desired, disbudding may be reduced to a minimum. A due thinning out of the weak shoots, or rather the prevention of their appearance, removal of sucker growths, and ample feeding and judicious stopping, will produce fine plants, each shoot being either a wreath of flowers, or bearing a truss of four or five blooms at the top. Writing in a contemporary, August 20, 1880, Mr. Hinds says:—

"*Chrysanthemum* growers in all parts of the country will now be on the *qui vive* for the buds which will produce their fine show flowers early next November. Outside a very narrow circle the method of growing large flowers is indeed a mystery. Different kinds of compounds are recommended for potting, the size of pot in which they should be grown is diligently inquired after, when to pinch, how to pinch, and how many shoots should be grown to a plant, are all questions that crop up periodically among the uninitiated. There are many who think they have only to 'order the good kinds' to insure success. But what a fallacy! The good or evil will be accomplished during the present month. Those who grow flowers for size usually grow from three to nine shoots upon a plant. I have seen good-sized bushes bearing fine flowers under a skilful system of cultivation and disbudding. Many of the early flowering kinds are now showing bud—of course in an embryo state; still it is there. Young shoots will be observed at the base of the bud, which, if allowed to grow, will render the bud useless. But first of all examine the form of the bud and the vigour of the plant. If the bud is cone-shaped, and the plant does not appear to be over-vigorous, remove the embryo shoots at the base of the bud at once. Of course some know-

ledge of the kinds, as to whether they are early or late varieties, is indispensable. In a doubtful case it is prudent to leave the bud and one shoot, so that in the event of the bud turning out to be imperfect or too early for the kind, there is a chance left of obtaining a later flower from another bud. The removal of lateral growths, skilful disbudding, and feeding the plants occasionally with weak soot water will contribute much towards a display of fine flowers next autumn."

Staking and training.—Staking is necessary for at least two reasons—to prevent breakage by winds, and to enable specimen plants to be trained conveniently. Plants grown for large flowers seldom require more than a single stake to secure them, but it should be sufficiently stout to obtain a firm hold of the earth in the pots. Dwarf specimens may be trained on sticks laid flat-wise over the top of the pot and secured with copper wire to a wire ring fixed below the rim. These and a few short bamboo stakes inserted at various angles in the soil will be sufficient to secure the shoots wherever desired. Soft raffia or worsted may be used for tying purposes. Specimens for conservatory decoration are easily secured to slender stakes inserted soon after the plants are shifted into their blooming pots. Six stakes inserted around the sides of the pot, and three in the centre will, as a rule, be ample, and once in position, the main shoots can be secured as growth is made. When tall plants are grown for cut blooms, a few stout stakes 6 feet high may be driven into the ground, and three or four lines of tarred twine or wire carried along from one to the other, to which the tall shoots may be secured as growth progresses.

Bamboo stakes are preferable to deal sticks being far more durable. As a substitute for either, rods of Hazel, Ash, Poplar, or Willow may be employed. In the case of Willows they should be cut after the leaves fall in autumn, and well dried by being tied in small straight bundles and laid upon a smoke flue or on the top of a boiler. So treated they dry firm and straight, and cause no annoyance by rooting into the soil, as is invariably the case when they are used green.

Raising new Chrysanthemums.—Mr. A. Forsyth writes as follows in the *Gardener's Magazine*, April 20, 1872*: "New varieties of Chrysanthemums are raised by two methods, in one of which Nature takes the lead, and in the other the initiating agent is man. I shall endeavour to describe both methods, so far as I understand them, after many years' experience and observation, during which it has been my good fortune to submit for public approval a few new Chrysanthemums that have acquired celebrity and well rewarded me for my pains.

"In its native country the Chrysanthemum sheds its seeds naturally, and new varieties spring up, as they do amongst all self-sown plants. In this country its never does so, and yet Nature kindly takes care that our collections shall be enlarged, for every now and then a sport occurs, and by this means a novelty is secured. It appears that lilac flowers are the most sportive, and that they frequently change to yellow; that is to say, a plant which should produce lilac flowers will some day, to our delight, present one or two yellow flowers in the midst of those of the proper colour. It appears that nearly all the colours are capable of sporting into white; but it would be difficult to establish any rules, for if we may make a fair generalisation from all we know, it may be pretty safely said that any colour is capable of sporting to any other colour; that is, within the range of colours proper to Chrysanthemums.

"All the four varieties of Cedo Nulli have sprung from one; the form is the same in all, but the several colours are yellow, lilac, brown, and white. Bronze Jardin des Plantes came from the good old yellow variety; the Queen of England

has sported into six different colours, with some slight change of form too, the Golden Queen being the least perfect amongst them. My Golden Tribly was a sport from the old White Tribly.

"It is not worth while to occupy much space with examples, and I shall not say a word on the philosophy of the change, preferring to confess that, while I am familiar with the facts, I am unfamiliar with their physiological import. The question for the practical man is, having obtained a sport, how to keep it? In order to answer the question satisfactorily, I must be particular in what I say. In the case of a sport really worth keeping, the first business is to notice how many terminal shoots produce it, for sometimes the new flowers come in a bunch, though more frequently they appear singly. Mark the branches and cut the flowers, and take off a few fair-sized cuttings from the wood that produced the new flowers, and strike them in a gentle heat with care. Having done this, cut the plant down, leaving uncut the stems on which the new flowers were produced, to obtain from them a good stock of side shoots during the winter for cutting from in February and March. By this course of procedure you will secure a good stock of plants on which, perhaps, in the following season the new flowers will appear, but on which the old flowers may appear instead, and you may just discover that, so far as raising a new variety, all your labour has been in vain: 'Nothing venture, nothing have.' It may happen that the new flowers appear on a sucker from the root, in which case your chance of success is greater than when they appear on the ripe wood; but it is a lottery, and those who enter to win must take their chance of losing. A neighbour of mine had a fine sport of Queen of Anemones a few years ago, and exhibited it at the Stoke Newington Exhibition. He raised a good stock from the wood that produced the sport, but he never saw the sport again, the plants producing flowers of the old sort as if nothing had happened to them.

"It would be unjust to the public for any trader to send out a new variety resulting from a sport without first submitting it to a sufficient proof. The instance just cited will show that in this business we must not count our chickens before they are hatched. It is advisable to grow cuttings of sports in such a way as to ensure the full development of all the flower-buds they form, so as to work them right out, and prove them sound to the core—that is, if they are so. Now, to do this, it is advisable to grow them in a poor soil without stopping, and to train them only so much as will suffice to keep them tidy, and to take care to give them no more pot room than is needful for fair growth, but at the same time taking care not to starve them out of constitution.

"Now, we must consider the method which depends on our own initiation, and in which, while we must, of course, wait upon Nature, she will do but little unless we lead the way. The most distinct varieties are raised from seed, and to obtain seed is a most difficult matter. It may be obtained from China and Japan, but is not a regular article of commerce, and it has been grown in quantity in Italy for the French and English raisers, Mr. Salter having been dependent chiefly on Italian seed for the many new varieties it was his good fortune to send into the market. The amateur who may be ambitious of growing his own seed will be disposed to ask for advice on the subject, and happily on that subject I can say something practical. There is but one way to secure seed in this country, and that is, to manage the plants so that they will flower in the spring.

"It will occasionally happen that, amongst a lot of plants that have flowered in the usual way and have been cut down and stored in a pit, flowers will appear in the month of March on buds that were dormant in the previous autumn, and that escaped the knife through being on short shoots amongst the suckers. I remember that, in a report in the *Floral World* some years ago, it was stated that a very fair specimen of lilac Cedo Nulli was shown in the school-rooms at Brixton Hill in the month of March, on the occasion of Mr. Hibberd giving a lecture there on the cultivation of the Rose. Now, here we have the whole sub-

stratum of the art of raising seed in this country, and will suggest to the ambitious a simple mode of procedure which is likely to result in a very fair production of seed, and, having done so, I will improve upon it and increase its value.

"We will begin with a lot of plants that have been grown to decorate the conservatory. We will allow them to flower, and so far pay no attention to seed-growing whatever. But the instant they begin to look shabby, we are to resort to measures to encourage seed-production. There must be provided an airy greenhouse or a very light shed, or some such place safe from frost and sufficiently lighted to keep the plants in health all the winter. A dry sunny greenhouse is the proper place for them. They are not to be cut down. No; the faded flowers are all to be clipped off close under the base of each by a pair of scissors or finger and thumb—the "cold steel" to be preferred. Now pack them pretty close, keep them rather dry, and let them have plenty of light and air, and exercise patience. In the course of February and March a lot of flowers will open from buds that were dormant when the proper bloom took place. If you do not get seed from these with the spring sunshine at your command, you will never get seed at all, I fancy, and might as well give up the enterprise as an impossibility.

"Now, we are to improve upon this practice, and the improvement consists in striking cuttings in June, and putting them into $4\frac{1}{2}$ -inch pots as soon as rooted, and shifting them to 6-inch pots about the middle of August. They will probably flower very well in November and December under glass, but they will carry a lot of dormant buds with them into the spring season, and should produce seed in plenty.

"But how about hybridising? you will ask. Permit me, in all sincerity and politeness, to say that hybridising the Chrysanthemum is fudge! Take your seed as you can get it, and with it take your chance of the crossing Nature has accomplished for your benefit; but do not suppose that anyone less gifted than a magician can manipulate the flowers of the Chrysanthemum with the certainty that we operate on the flowers of Geraniums and Fuchsias. Depend upon it, in the improvement effected by English raisers in the Chrysanthemum there has been very little crossing done by means of a camel's-hair pencil; but no doubt cross-breeders in the insect world have laboured for our benefit. At all events, if we compare the best Chrysanthemum of forty years ago with the best of to-day, the contrast is wonderful, and therefore we may reasonably hope for still further improvements as the reward of our labour.

"The treatment of seedling plants differs from the treatment of cuttings only to this extent, that we want to make sure of their flowering, and care very little indeed about the shape of the plants. Sow the seed as soon as ripe. Pot the plants singly in $2\frac{1}{2}$ -inch pots as soon as large enough, and shift on as needful until they are in $4\frac{1}{2}$ -inch or 6-inch pots, according to their habit and vigour, and in these comparatively small pots let them flower for the first time. You will, if you are wise, or unless you are wondrously lucky, destroy more than 99 out of every hundred of the stock as soon as the flowers appear. Mr. Salter used to say that for every new Chrysanthemum that he named and sold he destroyed at least 2000. The amateur will feel this to be discouraging, but the truth must be told, and, after all, a fine thing may turn up amongst a score or fifty seedlings—who knows? More than once in the history of floriculture an amateur has sowed one seed and obtained from it a new variety that has made his name famous."

Chrysanthemum sports.—When Mr. Salter wrote his work on the Chrysanthemum he frankly confessed that the causes of the appearance of sports was unintelligible to him. Darwin's works had not then appeared, and botany had not emerged from dusky chaos into the comparatively clear atmosphere of cosmos, as some of us are flattered to think is now the case. Graft hybridism had scarcely been recognised as a fact, and the realities of heredity and reversion were certainly

* Mr. Shirley Hibberd, in sending me this article, at much personal self-sacrifice, says, "You will be glad to hear that the writer of this article, Mr. Forsyth, is doing well in New Zealand, and still sticks to the Chrysanthemum." I am glad to hear this, and so will be all true lovers of the Chrysanthemum.

not seen in visions, even if dreamed of in dreams. Now, however, we know that culture and cross-fertilisation for ages will destroy the fixity of any plant. Again, after a plant has had its fixity broken, or after its characteristics become driven from their permanent or fixed condition—their “angle of repose,” so to speak—we begin to obtain a multitude of widely varying individuals when we raise plants from seed. In the case of the Chrysanthemum this is especially so; in a lot of seedlings no two are exactly alike. Every new generation is like a turn of the kaleidoscope; the elements the same, their arrangement different. Protean variability is an almost constant result of long-continued cultivation on the one hand and cross-fertilisation on the other. Every plant, every individual, having life has two distinct sets of characteristics: firstly, those which are evident and which can be seen; and, secondly, those which are invisible, or latent, but which may at any time, break out or become visible under the influence of certain conditions. The visible characters in one generation may become absorbed or invisible, or partially so in the next. So also the characters of a former generation may again crop out, just as when we have it said of a child that he resembles his grandfather or some bygone ancestor of his line. This occurs in plants in two ways, either wholly from seed direct, or by a partial change in an individual when one bud develops a branch differing from its fellows and which is popularly called a “sport.” Such sports are mainly originated and their production facilitated by culture, aided either by cross-fertilisation or by what is often pretty much the same thing, cross-grafting. Now, if it be true that cross-fertilisation is the cause of variability, one would logically infer that the reverse of variability or fixity of characters would result from self-fertilisation, and this much is practically true, for we know that Stocks, Asters, Zinnias, Primulas, and many other flowers can be bred to come true to colour, habit, size, &c., with certainty by ensuring self-fertilisation for several successive generations.

Here is the golden rule for all hybridisers: To obtain variety, cross-fertilise; and if a good variety, strain, or race be thus obtained, self-fertilise its best and most robust members in order to “fix” the race, and enable it to be obtained true from seed. This rule holds good with all garden or florists’ flowers, and the finest of results may be gained by practising it with skill and careful labour.

Mrs. Marigold was a remarkable sport, “a complete tasselled Japanese variety with pale pink or flesh-coloured florets,” from Miss Mary Morgan. At Mr. Turner’s, Slough, in 1880, a most remarkable sport appeared on a plant of Mrs. Dixon, half the bloom being of that variety and the other half white, exactly like Mrs. Rundle. The florets on the Mrs. Rundle half of the bloom were much broader than those on the Mrs. Dixon, or yellow side of flower.

F. W. B.

Kleinia repens.—I do not say that there is any great difficulty in increasing the stock of this plant, but as I have used it largely for several years past I have naturally endeavoured to find out the easiest way of obtaining the best plants for carpet bedding; neat, compact plants are what is wanted, and it so happens that the old plants when taken up in autumn are rather lanky and naked. These I tried to utilise again another year, but they were so deformed and ugly that a straight line could not be made with them. My practice now is to take off the tops of all the strongest plants in autumn and make them into cuttings; the latter are dibbled into shallow boxes filled with sandy soil. The boxes are then placed on a back shelf in the stove and carefully watered. We have to-day (Feb. 10) examined the cuttings and find them to be well rooted, stout, sturdy material. We have, therefore, removed them to a cool Peach house, where they will remain until the beginning of May, when they will be taken out-of-doors to harden preparatory to being used in the flower beds. We have adopted this practice now for these last two years, and although we

keep some of the old plants we much prefer those raised from cuttings, as they are short and sturdy, with thick, fleshy leaves, and we can make lines or figures of them as true as may be desired. The beautiful tinge of blue which pervades a mass of this plant renders it different from all other succulents.—J. C. C.

KITCHEN GARDEN.

RADISHES AND THEIR CULTURE.

AMONGST the many subjects which we cultivate for salad none are more valued or acceptable than tender, sweet, well-grown Radishes, and an all-the-year-round supply of them may be produced with more ease and less attention than are necessary for many crops. Variety in the way of sorts has much to do with a constant supply, some kinds being most suitable for spring, others for summer, and others again for winter. It would be no heavy or unattainable undertaking to send Radishes to the table every day in the year from three sorts, but as seed is cheap and variety interesting, a few more will be alluded to in the following remarks. Early in spring long growing

Early long frame Radish.

Radishes become ready for use sooner than Turnip-rooted ones, but for summer and winter the latter are preferred. The Early Long Frame Radish is an excellent one for a first crop, and no doubt many of the readers of THE GARDEN will have proved this in the case of Wood’s Early, one of the best frame Radishes in cultivation. The French breakfast kind is olive-shaped, and a variety of great merit; in fact, the best spring and summer Radish which we possess, and should be grown by everybody. The red and white Turnip kinds are useful, and some of the newer varieties, which are of many forms and colours, are interesting additions which may probably in time become standard varieties. The Long White Naples is hardy, but in flavour it is not so good as some others. The black Spanish is, as its name indicates, black in colour externally, but pure white within, and very sharp and hot in flavour. This is so much the case, that few would grow it a second time. I would, in short, avoid it altogether and grow the China Rose for winter use. This variety is undoubtedly the best of all winter Radishes; it bulbs freely late in the autumn, is of a beautiful rose colour, will withstand the most severe weather,

and will remain in good condition from November until March or April. To secure a constant supply of spring and summer Radishes seed must be sown frequently, but not so in winter, as one good patch of this will meet all requirements. The Californian Mammoth now being introduced for winter use is too large and coarse to be generally acceptable.

Cultivation.—There is no advantage in securing great quantities of large-sized roots. A small and constant supply of crisp, delicately flavoured bulbs should be the only aim. The earliest will be had from a hotbed or from under some glass protection. It is seldom we grow a special frameful of Radishes, but secure all we want from frames planted with other crops. In January and February we are frequently making up beds of manure and leaves for forcing Potatoes, Carrots, &c., and amongst these are sown a few Radishes. When the Potatoes, for example, are planted in rows 15 inches apart, a row of Radishes may be sown between, and they will be ready for use and cleared off before the Potato crop in any way interferes with them. In Carrot frames the same thing may be done, and sometimes a Radish seed is dropped in here and there amongst the Carrots, as they will push up and be cleared off before the Carrots require much top room. Thus, young spring Radishes are obtained without any special outlay or extra attention; many, however, who try to grow early Radishes in this way make mistakes. One of these is sowing the seed too thickly. Under such circumstances when the plants come up they are a mat at top and bottom, and when this is the case useful roots are never formed. Thinning out some of the plants as soon as they can be handled is one way of avoiding this, but it is a wasteful way; the better plan is always to sow thinly. One seed every 6 inches or so will give a much finer crop and better results altogether than close sowing. Many doubtless wonder why their Radishes do not all bulb, but allowing them to grow too close together is as a rule the cause of this. Many are most particular, too, in getting their seeds in and the crop brought to maturity, but after the usable part of it has been gathered neglect follows, and where Radishes have been raised in a Potato or Carrot frame it is no uncommon thing to see worthless Radish tops overshadowing everything by the time the other crops should have been at their best. Cultivators should always be particular in clearing out all the Radishes as soon as they become too old for use, and any which do not bulb early may be thrown away altogether. In making up a

Special bed for early Radishes, a very shallow bed of fermenting material is sufficient; about 1 foot in depth is enough, and 6 inches of soil should be put on the top of this. They bulb fastest at this time of the year in a moderately rich sandy mixture. The seed should be sown broadcast, very thin, and it should not be covered more than half an inch deep. The earliest seed may be sown in frames in January and February, but in the latter month and throughout March seed may also be sown along the base of a south wall or in any sheltered sunny spot. Here the rule as to thin sowing should also be observed; in fact, this must be kept in mind throughout. When the little plants appear at first in the colder months of spring a slight protection will favour their free growth. A few branches or some similar covering is all that is needed. From April onwards throughout the summer select spots need not be chosen for Radishes, as they will do almost anywhere, their only requirements being a firm, rich, cool soil. Without this, especially in summer, the roots will become hot and stringy before they are well developed, and the period of their usefulness will be very short. In general culture some may prefer having the seed in rows; others may sow broadcast, and good Radishes may be had in both ways. At no time should the seed be put more than half an inch below the surface, and the soil should always be trodden firmly over it, as this induces the plants to bulb quicker and better than when in loose material. Dates of sowing and quantities to put in at each time cannot be given

to suit all; on the contrary, every cultivator must be guided by his own requirements in this respect. We are never without Radishes; our rule is to sow a small quantity of seed every three weeks from the middle of January until the beginning of September, when we stop all sowings and dealings with the summer varieties, and devote one good large piece of ground to the China Rose for winter. This sowing is made on a south border which may have been previously cleared of Potatoes or some other crop. The seed is put in in rows 15 inches apart, in order that plenty of air and light may be admitted to them in winter, and if the young plants come up too close they are thinned out to 6 inches apart. Under this treatment a uniform crop of useful bulbs is the result. We generally gather some of these by the end of October, when they are no larger than filberts, but at present they are as large as pigeon's eggs, very crisp and well flavoured.

Margam Park, South Wales.

TOO LARGE VEGETABLES.

"A BEGINNER'S" query as to the time for sowing certain kinds of vegetables will doubtless be answered by some of our vegetable exhibitors; but of much greater importance than the limited nature of such an enquiry is the wider one of the purpose and value of vegetable exhibitions. A very natural reply to this suggestion is that competitions in vegetables, as in other products, are promoted to encourage the highest forms of cultivation and the growth of the best and most desirable varieties. No doubt the better cultivation is encouraged because good samples of the commonest kinds of vegetables cannot be got without careful culture, and so far it may be universally accepted that in that respect some good is done by means of competitive exhibitions. But the point as to whether the best and most desirable varieties are encouraged at shows is a different matter, and one very much open to question. Thus Peas are always a strong feature in a collection of vegetables, but are the kinds most favoured by the judges as a rule the best for table use? Is size in both pod and pea desirable? is the latter acceptable on the dining table? are these features usually associated with the best quality and flavour? and lastly, are they usually allied to heavy cropping qualities? Now, it would be pedantic to pronounce distinctly in favour of any one kind of Pea, or to denounce any other variety. To do so would be to evoke a host of protests even from those who are not afraid of protesting too much. What is far better is to put the matter clearly to both judges and exhibitors, whether in pandering to a task for showiness and size they are not proceeding in false lines; are not, in fact, favouring the growth of things that would be rejected if sent to an employer's table. Nay, I may go even farther and ask whether it is not the rule to grow some kinds of Peas for exhibition only, well knowing that varieties of superior flavour and fitness must be grown in bulk for table consumption. Broad Beans, again, on show tables are largely open to animadversion. Do not the great mass of cultivators prefer early Longpods, Broad Windsors, and Johnson's Wonderful for general culture? and yet the best sample of any of these prolific and useful varieties would not stand a moment's chance against the long huge pods of the Aguadule. The most delicious of all Cauliflowers are what we find in the shape of firm white heads of about 6 inches in diameter, taking half a dozen to make an effective dish, yet these are seldom seen in a collection if huge heads of from 9 inches to 10 inches across can be had. The exhibitor in this, as in many other cases, puts up the large heads against his own judgment, but he understands full well the prevailing favour shown by judges towards size, and therefore the big ones have the best of it. There is little to find fault with in either Potatoes, Carrots, and Onions, although sometimes favour is shown towards large and as a rule bad-keeping bulbs instead of medium-sized solid ones that would keep just as solid for the next six

months. Since growers have begun to show handsome medium-sized samples of Woodstock Kidney and similar high-class sorts of Potatoes in preference to the larger but undesirable American kinds, collections have so far improved. Early Nantes and medium-sized intermediate Carrots for summer and autumn exhibitions leave nothing to be desired. The Brussels Sprouts, one of the most acceptable of autumn vegetables, we find an undesirable tendency now to go in for size. No doubt growers have for many years been selecting for stocks that would produce large stems and large sprouts, and now we have in certain popular kinds sorts that are extravagantly big, and in their produce depart altogether from the accepted ideal of a market sample of Brussels Sprouts. It is a fact that market growers would not if they could care to grow a stock of Brussels Sprouts the stems of which were covered with heads as large as hen's eggs. Such huge sprouts are obtained at the cost of flavour and of that delicate piquancy which always characterises a well-cooked sample of genuine Brussels Sprouts. Parsnips are too often shown both too large and too long. The very deep rooting Parsnip usually carries through its entire length a centre core that is both hard and flavourless. The sweetest and most pleasant eating portion of the root invariably is its broad upper portion, which, without being unduly large should be clean, sweet, and succulent. Good fleshy roots some 12 inches to 14 inches in length are better than long tapering roots of 20 inches or more. Leeks are also sometimes too large. They may show high cultivation, but relatively be not half so useful as a handsome bunch of Turnips, a vegetable often shown too large, as also are Beet in some instances. Still with these latter, with Marrows, Tomatoes, and Celery, fewer mistakes of judgment are made than occur in the case with some of the vegetables previously named. Few exhibition products should be more easily judged than vegetables, but as a rule the judgments are oftener than in the case of other products productive of dissatisfaction.

A. D.

VEGETABLES FOR EXHIBITION.

"BEGINNER" (p. 126) asks when Peas, Broad Beans, French Beans, Cos and Cabbage Lettuces, Autumn Giant Cauliflower, and early Cabbages should be sown to come in for exhibition about the end of August; and the question is an important one, especially to those who do not keep up a constant succession of such things. Years ago I had some difficulty as regards this matter, but it was soon overcome, as I kept a book in which was noted down the date when everything was sown throughout the year; an empty line was left under each entry, and this was filled up with the date when the crop reached maturity. From this I could always learn the time when our crops would be ready from date of sowing, and I found the plan to be of the greatest advantage in many ways. From repeated observations noted down at the time one can tell almost to a day when any crop will be ready, and I always work accordingly when shows or any special object is in view. In some seasons the time when crops are fit for use may vary a little, but never more than a few days or a week at most, and allowance can easily be made for this. Some districts, too, are earlier than others, and this may have to be taken into consideration as well as the character of the soil. In light, well-drained material many crops mature earlier than in cold, wet soil, but to meet and deal with these variations I would advise all interested in the subject to begin using their note-book at once, and follow the plan just indicated closely for a season at least. The following dates may, however, safely be taken in the meantime as approximate guides. Peas take from fifteen to sixteen weeks from the date of sowing to be fit for use; Broad Beans, fourteen weeks; French Beans (runners), seventeen weeks; dwarfs, twelve weeks; Lettuces, twelve weeks; giant Cauliflowers, twenty-two and twenty-four weeks; earlier kinds, fifteen and eighteen weeks; Cabbage, sixteen weeks; Beet, eighteen weeks;

Brussels Sprouts, twenty-four weeks; Carrots, sixteen and eighteen weeks; Celery, twenty-two weeks; Cucumbers, eight weeks; Leeks, twenty-four weeks; Onions, twenty-six weeks; Parsnips, twenty-eight weeks; Potatoes, eighteen and twenty weeks; Radishes, six weeks; Salsafy and Scorzonera, twenty-four weeks; Savoy, twenty-seven weeks; Spinach, five weeks; Tomatoes, eighteen weeks; Turnips, eight and ten weeks; and Vegetable Marrows, fourteen weeks. With the exception of Cucumbers, Tomatoes, and Vegetable Marrows, the whole of these dates apply to plants which have been raised exclusively in the open ground, but Celery, Cauliflower, and Leeks may have some slight assistance from being sown near the base of a wall or some such place. "Beginner" will doubtless be able to fix his dates of sowing from the above memoranda. For instance, if I wanted Peas for exhibition by the end of August, I would sow the seed the first or second week in May, and sooner or later according to circumstances.

J. MUIR.

Margam, S. Wales.

FIRM SOIL BEST FOR ROOT CROPS.

BECAUSE Parsnips, Carrots, Beet, Salsafy, and other root crops are supposed to be finest when they run freely and well into the ground, some cultivators think that the soil cannot be too loose and open for their successful culture, but this is contrary to my experience, as I invariably find that the best-shaped, cleanest, and hand-somest roots come out of the firmest soil. True, some roots will run an astonishing distance downwards in a loose soil, but eighty per cent. grown under such conditions will be furnished with an unusual quantity of superfluous fibres, and many of them will be forked and have long thong-like tails. It would, indeed, be a difficult matter to find out of a large number a dozen of the same shape and size, and while many of them will be worthless for the kitchen, very few will be fit for exhibition. It would be otherwise were they grown in the firmest of soil; indeed, if more attention was given to this point superior results would in many cases be secured. In digging or trenching land for these crops, it is of course impossible to make it very firm then; but as soon as the seed has been sown and covered in, firming the ground should be commenced. It should be trodden or rolled over several times, and as soon as the young plants can be seen in the rows the soil should be again firmly trodden down on each side of them, and the same thing should be repeated at thinning time and afterwards if necessary. This will cause the top growths to be very compact, and it has the same effect on the roots, the result being robust, clean, fibreless produce. I am acquainted with an amateur who grows the finest Parsnips I have ever seen, and all his best roots are grown so near the pathways in his garden that the soil which surrounds them almost forms part of the walk, and when the other roots named are treated after the same fashion the result is in every way satisfactory. Our finest Onions and Turnips, too, are produced in the hardest soil, and sound, well-formed bulbs of the highest quality can, I feel assured, only be raised on firm land. Many Onions are inclined to grow with a very long, thick neck, and seldom produce any bulb worth speaking about; this is caused by the soil being loose; thick necks are never found in any great numbers in a piece of Onions grown on firm ground. As soon as Onion seed is sown a heavy roller should be taken several times over the ground and plenty of after-treading will be beneficial. Our biggest and softest Turnips are grown on loose soil, but the best shaped, most solid, and finest flavoured ones come off the firmest ground. In short, wherever high-class roots are desired firm soil must be one of the main points in their culture.

J. MUIR.

Large Leeks.—Some sixteen or seventeen years ago, Mr. Henry, then gardener at Broomhouse, Berwickshire, was considered the best Leek grower in the country, and I believe he is still.

On the 24th November, 1866, six of Henry's hybrid Leeks were lifted, cleaned, weighed, and measured, and the following was the result: Leek No. 1, circumference $12\frac{1}{2}$ inches, weight 5 lbs.; No. 2, circumference $11\frac{1}{2}$ inches, weight 4 lbs. 14 oz.; No. 3, circumference $10\frac{1}{2}$ inches, weight 4 lbs. 12 oz.; No. 4, circumference $9\frac{1}{2}$ inches, weight 4 lbs. 10 oz.; No. 5, circumference $8\frac{1}{2}$ inches, weight 4 lbs. $8\frac{1}{2}$ oz.; No. 6, circumference 8 inches, weight 4 lbs. $7\frac{1}{2}$ oz.; total weight of six Leeks, 28 lbs. 4 oz. Two of the leaves when stretched out measured 11 feet in length, and varied in breadth from 8 inches to 14 inches.—JOHN DOWNIE.

Woodlice in Mushroom-houses (p. 126).

—In order to clear a house of these I know of no better plan than introducing a few toads into the place. These despised, but useful creatures have frequently surprised me by the rapidity with which they pick up the woodlice. They seem to prefer to fix themselves facing the wall, or any part forming the boundary of the bed, and watch for their prey. Whether this is from a dislike to pick them up from the surface of the bed, or guided by instinct, that their victims are sure to come that way in their ramble after food, I am not prepared to decide. I have seen them place their fore feet on the wall and extend themselves after their prey, which they secured when it has been 6 inches up the wall. The toad does not act cowardly; he never attacks his victim when in a state of quietude, preferring to assail him when on the move. Where beds have to be covered with short hay or similar materials, toads labour under a disadvantage. Space should be left on the outside, free from litter, so that they may have a passage round. Every time the material is moved for gathering the crop, commence slowly at one end; the woodlice will, as a rule, rush to the unremoved hay, and in this way they may be allured into one corner or end, where they invariably find a hiding place between the bed and wall. Have a can of boiling water, and pour down, and nothing more will be seen of them. It will be as well to take the hay outside and shake it.—W. P. R.

TREES AND SHRUBS.

THE RED-WOOD AND ITS MANAGEMENT.

THE Sequoia sempervirens or Red-wood is indigenous to the north-west coast of America, and was introduced into this country about the year 1843, yet proprietors have never planted it to the extent which its merits as regards ornament and utility deserve. This may arise in a great measure from the difficulty of procuring seedling plants of it at a cheap rate. It is generally propagated in this country by means of cuttings made of the side branches, and as these are naturally flat they require a great deal of pinching and pruning to induce them to form a conical tree shape; such trees likewise have a great tendency to produce a plurality of leaders, which must be pinched or cut off, always leaving that which is best and most central for the permanent leader. When this tree is cut over by the surface of the ground the root retains its vitality, and produces a succession of young shoots around the margin of the stump, and as these assume an upright pyramidal shape they make superior young trees, and seldom produce rival leaders. I have raised a good many fine young trees from these shoots, and have found them to be in every way as good as seedlings. This conifer bears almost any amount of

Pruning. Several trees I planted about twenty years ago were stem-pruned by gradually cutting off the branches close to the stem for a distance of some 5 feet from the ground; others were allowed to grow in their own way, with the exception of pinching or cutting back several of the branches near the top where the leaders had been lost by frost, so that a new leader had to be supplied by tying up one of the side branches. The bark of the stem of this tree constitutes one of its peculiarities, being a thick spongy substance,

and as soft and pliable as a piece of chamois leather. This, when the tree is stem-pruned, is exposed to view and shown off to good advantage. Of course pruning is in a great measure a matter of taste; however, we may say this much, that when this tree is stem-pruned and the straggling side branches pinched or cut back in order to balance the top, the result is finer and more tree-like specimens than such as have not been pruned, the latter having merely the appearance of large bushes. Trees of this conifer are well adapted for planting among deciduous trees in places where it is desirable to get up cover and procure shelter, and in such cases they should be allowed to grow in their own way, with the exception of cutting off or repressing any rival leaders at the top. In exterior appearance this Sequoia has a great resemblance to the common Yew (*Taxus baccata*). It is, however, quite a distinct species, and produces its seed in the form of a small cone, whereas that of the Yew is contained in a berry. When the timber is cut up for use it is found to be not so elastic as that of Yew, yet it is of good quality, and although the concentric rings of the trunk are of a large size, owing to the rapidity of growth, yet the wood is firmly packed and capable of taking on a fine polish. This tree is not in the least degree fastidious

As regards soil; it is equally at home on deep peat, bog, strong clay, and inorganic fragments of rock mixed with but a small portion of soil. When planted in deep Irish peat bog of a reddish colour and light in texture, I have found it a capital plan to mix a little soil or clay with the bog at the time of planting. This gives weight and firmness to the bog, and gives the trees a satisfactory start. Of course in such cases it is necessary to have the ground thoroughly drained, but when once the trees are well established it is astonishing how they perform that operation for themselves by pumping up the superfluous moisture and rendering the ground firm and the surface drains in their immediate vicinity quite dry. In its native habitats this Sequoia is said to attain a height of some 270 feet, and a girth of stem of from 20 feet to 40 feet, and although I do not expect it to attain such dimensions in this country, yet from what I have seen, I consider it worthy of being planted to a greater extent than it has hitherto been

J. B. WEBSTER.

Birds and Wellingtonias.—Like Mr. Ellacombe, we have been puzzled to account for the seeming aversion which birds have to the Wellingtonia. We have, however, put it down to one or perhaps both of the following, rather unlikely causes, viz., the disagreeable odour given out by the Wellingtonia, and to the outer portions of the branches being thickly beset with stiff sharp spines, which, as in the Araucaria, prevent birds from alighting with impunity; the latter reason would, however, not hold good with regard to the branches close at the stem, as there they are perfectly smooth. Nearly a dozen large specimens of Wellingtonia were examined to-day, and in no case was a nest observed or the least trace of birds having roosted in them at night, although the trees, owing to the sheltered positions that they occupy, would have afforded an excellent lodging. As birds frequent those trees where insects are abundant, can it be that the strong unpleasant odour given out by the Wellingtonia causes a total absence of these? Perhaps some of your readers will record their opinions respecting this curious fact.—A. D. WEBSTER, *Penrhyn, North Wales*.

—I had not remarked the circumstance of the non-building of birds in Wellingtonias before the appearance of Mr. Ellacombe's note, but like him I have never observed a bird's nest in them. May it not arise from the fact of the branches growing in such a strictly horizontal fashion, that though thick and bushy the birds find it difficult to fix nests in them?—W. W. H.

—There is not the slightest ground for supposing that birds will build less in the Wellingtonia than in other trees, whether conifers or other

sorts. We have a Wellingtonia here—by no means a large specimen—which a chaffinch has chosen for a nesting place for the last three seasons, and not from any want of suitable positions, as the place is well wooded on all sides, with trees of all sorts and sizes. One thing worth mentioning, however, is that last season I observed on nearly every coniferous tree standing detached that a chaffinch had taken possession of it. Can this bird have any special liking for conifers in preference to hard-wooded deciduous trees, on which they are mostly seen, and which would be naturally considered the most suitable, their nests being commonly built of the Lichens which grow on them?—R. STEVENS, *Paston, Northumberland*.

Mistletoe Oaks.—In THE GARDEN (p. 131) "Veronica" enumerates twelve Mistletoe Oaks as occurring in England and Wales, and wishes some one to extend the list. In the *Leisure Hour* for 1873 is given the following list of Mistletoe Oaks in England:—

1. Oak at Eastnor, Hereford (discovered in 1851).
2. " at Ledstone, Delamere (discovered in 1851).
3. " at Badhams Court, Sunbury Park, near Chepstow.
4. " at Burningsford Farm, Dunsford, Surrey.
5. " at Hackwood Park, Basingstoke, Hants.
6. " not far from Plymouth (by the side of the South Devon Railway).
7. " at Frampton Severn, Gloucestershire.
8. " at Haven, in the ancient forest of Deerford, Hereford.
9. " overhanging a double cromlech at Plas Newydd, Anglesey.
10. " at Bredwardine, Herefordshire (discovered in 1871), and grows upon it in fifteen different places.
11. " at Hendre, Llangattoch, Lingoed, Monmouth.
12. " at Knightrick Church, Worcestershire.
13. " in Lord Londes' park, Lees Court, Kent.
14. " at Lindridge, Worcestershire.
15. " two miles from Cheltenham.

The Mistletoe has also been found on the following trees: Whitethorn, Apple, Willow, Maple, Poplar, Lime, Service, and, according to a correspondent of THE GARDEN, abundantly on the Scotch Fir between Munich and Innsbruck, in the Bavarian Tyrol. The seed is triangular in shape, and at two of the angles puts forth shoots resembling the horns of a snail. Occasionally both horns take root and form two distinct plants, supposed by some to be male and female. Perhaps some of your correspondents could tell us if such is the case. In the *Journal of Forestry* for February, Mr. Middleton, of Clarendon Park, Salisbury, Wilts, says Mistletoe can be seen on several old Oak trees in the park there.—A. D. WEBSTER, *Penrhyn, N. Wales*.

HAVERLAND HALL, NORFOLK.

HAVERLAND, so far as relates to the present mansion and gardens, is a comparatively modern place. A picturesque lake and grand old woods were accompaniments of the old mansion, which occupied a different site. Round the present hall and gardens are thriving plantations of Oak, Larch, and Silver Fir, with an undergrowth of Hazel. It would be difficult to find woods better managed than those are at Haverland—often a weak point in estate management. The hall, a large, square, Grecian structure, built of Bath stone, with a lofty observatory or tower at the north-east angle, stands on an eminence surrounded on the eastern and southern sides by terraced gardens, from which extensive views of park, lake, and woods can be obtained. The terraces are traversed by broad, dry, gravel paths—excellent promenades in winter. A short distance east of the mansion is

The conservatory, a large handsome structure of stone and glass, corresponding in design with that of the mansion. The house, which has a ridge and furrow roof, is 60 feet long and 40 feet wide. It contains many handsome specimens of Camellias, Palms, and Ferns. Among plants in bloom I noticed a very large specimen of *Sparmannia africana* and a fine old plant of *Brugmansia sanguinea* was flowering freely in one of the borders. The interior of the house is so arranged as to divide the space into four beds

with a handsome vase in the centre, and a border for creepers runs all round the walls. Indeed, these creepers, consisting of Passion-flowers and *Taesonias*, &c., festooning from point to point in the most graceful manner, form one of the chief features of this house. Tea-scented Roses are trained up some of the pillars, on which they flower continuously; one especially called *Moiret*, Mr. Hopkins, the gardener, speaks of as being superior to all others in winter. In summer it is deeply tinged with pink, but in winter the flowers are white, and for a Tea Rose very full of petals. It is an old Rose, for I have known it twenty-five years. Another plant that grows here in the wildest luxuriance is the *Habrothamnus fasciculatus*. *Cassia corymbosa* is also planted out against one of the façades of the building, and flowers finely in its proper season. *Abutilons* consisting of many shades of colour are a special feature planted in the border; they are 10 feet or more high, and blossom freely, one called *Buttercup* being a bright golden yellow, and a good companion for the white *Boule de Neige*. What a striking background plant for a conservatory the variegated Reed Grass (*Arundo Donax variegata*) is! as one enters at the front door its tall, erect variegated growths stand out prominently against the creeper-covered wall, producing a grand effect. Some of the growths made last season are 15 feet high. Connected with the conservatory is a

Creeper-covered wall, on which are *Jasminum nudiflorum*, climbing Roses, the *Pyracantha*, and the *Virginian Creeper*. These plants have grown rapidly, and, the wall being wired, have fastened themselves to it by creeping under the wires. With such a support there is no need for much tying or pruning. Fancy a wall 20 feet high having the appearance of a bank covered with creeping growth falling about gracefully, and now ablaze with the golden blossoms of *Jasmine*. In the autumn the crimson foliage of the *Virginian Creeper* is very striking, and by and by the climbing Roses will be to the fore. But it is in the happy management of the plants (their natural growth) on which their effectiveness depends. If they had been pruned and tied closely in, according to orthodox fashion, they would have been far less effective. The view from the conservatory terrace over the foreground of shrubbery and park and lake, with the wood covering more than 300 acres in the background, is one not easily forgotten—the silver-barked Birch and the dark foliage of the Scotch Fir blending with the stubborn, stately English Oak; beneath all, too, looking ruddy and warm in the winter sunshine, is a groundwork of Bracken. It is, however, in spring in the nightingale season when this wood is so charming—when the Lily of the Valley pushes up its white fairy bells through the *débris* of the Bracken. The walk between the conservatory and museum is a most interesting one. It is about 500 feet long, bordered by turf and cut off from the grounds by shrubs, which form an effective background to a number of statues. The museum, a handsome stone building, forms a proper termination to this walk. At the back of it is a natural fernery in which Ivy and creepers are effectively prominent; a winding path amid Yew hedges leads to a summer house quaintly ornamented with Moss and Larch cones. About the grounds are many handsome specimens of trees and shrubs, including Cedars and other conifers. A Rose garden has also been made, but Roses do not grow well, the soil being unsuitable. Being a winter residence, there is not much bedding out in the ordinary sense of the word, evergreens being used largely for winter decoration. There is, however, in front of the conservatory a terraced flower garden of pretty design and planted so as to look gay in the autumn, and at the same time retain some of its beauty in winter. Mr. Hopkins uses annuals largely, which, when sown late, flower nearly up to Christmas in this sheltered garden in the dry climate of Norfolk. Hardy flowers that bloom late are also grown.

The kitchen garden and forcing department are placed at a convenient distance from

the mansion. A few years ago this garden was noted for its interesting collection of Pear trees both on walls and espaliers, but the roots have now gone down to the sand which forms the subsoil. Moss forms on the bark, and the trees are less fruitful. From the majority of gardens made now and during the last thirty years fluted walls and concreted borders have been discarded, but I am convinced that in our climate the principle is sound. The kitchen gardens within and without the walls consist altogether of about three acres, and the land is light, but fertile, and easily worked. The forcing houses include two span-roofed plant houses for producing plants for the conservatory, a plant stove, in which are many plants of *Eucharis* just now in flower, with the usual assortment of fine foliage and flowering plants and some handsome Ferns. On the roof is a fine plant of *Passiflora princeps* finely in bloom. There are two vineries, one entirely filled by an old black *Hamburg*; the other is planted with late Grapes, of which some *Muscats* and *Barbarossa* of good quality are still uncut. As regards the Black *Hamburg*, it was originally one of a number, but being more vigorous than the others, it was allowed to gradually extend itself until it filled the house with the happiest result. Another house, formerly a vinery, is now planted with *Apricots*. There is also a *Cucumber house*, a house for *Strawberries*, and a small lean-to full of *Figs* in pots. As regards these latter, the trees are very large and old, but very fruitful. Mr. Hopkins says he finds it an advantage to delay the pruning till the fruits are all started and swelling. When the foliage is formed there is no bleeding, and the crop can be placed regularly all over the tree. The *Brown Turkey* is the principal variety grown. There are numerous pits for forcing purposes, the whole of the houses and pits in the forcing department being heated by a tubular boiler. Inside one of the houses is a very fine plant of the purple *Guaia* trained over the roof. It bears very heavy crops of fruit annually. In a house adjoining is a very

Effective Fern wall, constructed by building a series of arched caverns of brickwork against the face of the wall. The brick arches are lined with clinkers bedded in cement. The arches towards the top of the wall are smaller than those at the bottom. In these caverns soil is placed and Ferns planted, the effect being all that could be desired. The double Violet *Marie Louise* is a great favourite here, and is largely grown for autumn and winter picking. E. HOBDAV.

SHOW AURICULAS.

I HAVE to thank Mr. Horner for kindly explaining the absence of cultural detail from the two interesting articles to which I lately alluded. With respect to the variety, Colonel Champneys, "Delta" is so far right that I might have taken another example of a grey edge that was both first rate in quality and inexpensive. The "Colonel" crossed my mind as an attractive variety of strong growth, well adapted for a beginner. It certainly does not fulfil all the strict requirements of the florist, but it must be admitted to be a very beautiful and distinct flower. The specimens of it which I have seen shown were not cup-shaped, and though "Delta" may think it is "never staged unless people are very hard up on a prize stand," it was exhibited at the last show at South Kensington in a prize six by one of the large trade growers who was scarcely likely to be "very hard up" for a flower. It is a very strong grower, and from that cause is apt to have too much colour. To meet this tendency Mr. Turner recommends it to be a little starved, treatment under which it is capable of more refinement than "Delta" would appear to have seen it develop. Similarly I have observed Earl Grosvenor and Ne Plus Ultra (Smith) described, the one as "pleasing in colour, but quite second rate," the other as "large and decidedly coarse." I have never seen either of these in bloom, but I take it such old sorts would not have stood their ground so long, nor appear in the selections of good judges like Mr. Douglas without

distinctive excellence of some kind to recommend them. It is doubtless with *Auriculas*, as with most other flowers, certain sorts not of the very highest types nevertheless possess such distinct characteristics and beauty that we have to "be to their faults a little blind." We cannot afford to be without them. M. R.

GARDEN FLORA.

PLATE CCCLXXVI.

SHRUBBY ST. JOHN'S WORTS.

(With a figure of *Hypericum triflorum*,* *Blume*.)

THE shrubby *Hypericums* form a very interesting study, and are not so generally found in even the best of private gardens as they deserve. They are singularly diverse in geographical diffusion, extending from Europe, through North America, to China and Japan, thence along the Himalayas into Nepal, and finally, so far as size and beauty of individual flowers is concerned, their beauty culminates in this singularly interesting *H. triflorum* of *Blume*, which came originally from the mountains of Java. *H. triflorum* is a plant with a history. About three years ago I was invited to visit the gardens of Mr. Phineas Riall, of old Conna Hill, near Bray, in the county of Wicklow, which somebody once called the Devonshire of Ireland, and among the many interesting shrubs luxuriating on that sunny hillside, overlooking the glistening sea, I saw this three-flowered St. John's Wort for the first time. At first sight I thought the plant looked as if it might be a hybrid between *H. Hookerianum* (*H. oblongifolium*, Hort.) and our old friend *H. calycinum*. So sure was I of this at the time that I mentioned it to friends, none of whom had ever seen or heard of such a plant. My erroneous guessing at truth, however, had its own reward, for Mr. Smith, of Newry, at once set to work hybridising the shrubby St. John's Worts of all kinds freely, and he has now a fine and promising lot of seedlings under his care. Mr. Riall obtained his plants of this rare species from Pennick's nursery at Delgany, and Messrs. Pennick informed me that they believe it came to them from that old home of "good things," the Comely Bank Nursery at Edinburgh. That the plant was grown at Edinburgh I do not doubt, since Mr. Lindsay (in a letter sent through Mr. P. Neill Fraser) tells me that the late Miss Hope had a plant near her door which, although called *H. oblongifolium*, was in reality much larger in blossom. Then, again, our next Irish authority on hardy shrubs, Mr. John Adair, tells me this large-flowered *Hypericum* was one of the things he specially noticed in a corner of Mr. Anderson-Henry's garden in Edinburgh, now many years ago, so that I am quite satisfied that the plant was at one time grown in the gardens around our "modern Athens." Our authority for the name is Mr. Hemsley, who writes as follows from the Royal Herbarium at Kew, under date July 26, 1882: "The *Hypericum* sent by Mr. Riall is a variety of *H. Hookerianum*, a species figured in the Bot. Mag., t. 4949, under the erroneous name of *H. oblongifolium*. It is exactly the *H. triflorum* of *Blume*, from the

* Drawn by Mr. F. W. Burbidge from fresh specimens sent by Mr. P. Riall, from his gardens at old Conna Hill, near Bray, County Wicklow.

Growers or introducers of new plants will oblige us much by early intimation of the flowering of new or rare species, with a view to their representation in our "Garden Flora," the aim of which is the illustration in colour, and in all cases where possible life size, of distinct plants of high value for our gardens.

mountains of Java. The full synonymy of the species, which has a wide range in India, is

Nepaulese Tutsan (Hypericum nepalense). Natural size.

given in Hooker's 'Flora of British India,' i., p. 254." This information is very interesting. Fancy a plant (no matter whether species or variety) from the mountains of Java, from the Tropics near the line, and yet hardy in the county of Wicklow! After that one need not be surprised that some tropical mountain Orchids do not mind a short brush with Jack Frost now and then. Messrs. Cunningham, Fraser, & Co., now the proprietors of Comely Bank Nurseries, believe that they have our plant even yet in cultivation in their nursery under the name of *Hypericum oblongifolium*, and certainly a small plant they were good enough to send me, through a generous friend, does look very much like *H. triflorum*.

Botanically speaking I have no doubt that Mr. Hemsley is right in regarding it as a Javan form of *H. Hookerianum*; indeed, Mr. Gumbleton, to whom I gave one of two plants which Mr. Riall very generously had given to me, wrote me later on that that was also his view of the matter; but as cultivated plants side by side there are great differences in habit and mode of flowering apart altogether from the much larger blossoms which *H. triflorum* produces. Quite a small plant in a pot in a cold greenhouse here has just produced a rich golden flower $2\frac{1}{2}$ inches in diameter, the buds and the backs of the petals being singularly glossy and wax-like. The habit of the growth is lax, producing shoots from 18 inches to nearly a yard in length. These growths are so long, that the weight of the flowers is almost too much for them, as they arch gracefully near the ground, these shoots being bright red or crimson, the leaves on some of these growths being arranged in a decussate manner, while on others they are two-ranked. When compared with *H. Hookerianum*, the latter is far more stiff or virgate and woody in growth, and the ends of its short, stiff young shoots are generally three-branched and nine-flowered, each little branchlet producing three flower buds. Our

woodcut illustrations show the flowers of *H. Hookerianum*, natural size, and also those of *H. uralum* (= *H. nepalense*), a nearly allied, although much smaller flowered species. The only other species intimately belonging to this group is *H. patulum* (also known as *H. pseudo-patulum*—Hort.—and *H. Gumbletoni*—Lavallée). For a good figure of this last-named plant see THE GARDEN, Vol. XII., p. 280). Although *H. triflorum* has proved perfectly hardy in Wicklow for many years, yet it is safest to treat it rather as a half-hardy shrub, in the way of the shrubby Veronicas, or by keeping a plant or two in pots in a cool house for the winter. Messrs. Pennick tell me that recent winters have been too much for it, and they have now lost it altogether, so that to Mr. Riall belongs the credit of having preserved it from a total exodus from our gardens hereabouts. I think I am right, however, in saying that it has proved hardy with Mr. W. E. Gumbleton at Cork. A glance at our plate will show what a noble shrub this is when well grown in the open air—the flowers from which our drawing was made having been received from Mr. Riall in June and July last. It is worthy of remark that when cut, after the petals unfold, all the *Hypericums* are possessed of blossoms the most fugitive, but if they be cut in the bud stage every flower will open fresh and fair in water indoors.

The propagation of the plant is easily effected by making cuttings of the half-ripened wood, or from seeds sown soon after they are ripe. By Mr. Riall's generosity I have been enabled to send a plant to Kew, and also to distribute both cuttings and seeds, so that the plant now promises to take a fresh lease of its life with us. On referring to Mr. T. Smith, of Newry, to whom I

pricking them off to-day. With respect to cuttings, it would, of course, strike as easily and in the same way as *oblongifolium*, *patulum*, &c.; but I keep plants growing in a little heat, and keep taking off bits as soon as they are an inch long; it does not, however, grow very fast at this season, but I see is putting on a little animation now. We strike them in the same house they grow in, half fill a 4-inch pot with sand, stick in the cutting, and put a bit of glass on the top. Almost anything will grow thus." Among other shrubby species of *Hypericum* well worth culture forget not *H. chinense* (*H. monogynum*), a very effective, cool greenhouse evergreen shrub nearly always in flower. *H. balearicum* is a gem with its little crisp-edged leaves and bright golden flowers, the size of a florin, and also merits cool house culture, as does also *H. ægyptiacum*, *H. empetrifolium*, and even the dwarf and scandent *H. Coris*. One of the prettiest of all hardy kinds is *H. repens* (*H. reptans*, Hort.), which droops gracefully over rockery stones and flowers profusely, the blossoms being golden and as big as a shilling, and nicely contrasted with its crimson stems and small foliage. *H. olympicum* and *H. Kalmianum* (*H. prolificum*) are both good free blooming hardy border species, and for carpeting rough stony ground or under trees one may do worse than remember "the Rose of Sharon," *H. calycinum*. F. W. B.

SEASONABLE WORK.

BEGONIAS FOR FLORAL DECORATION.

THE shrubby types of flowering Begonias are always useful when employed in association with other flowers in a cut state, or a few distinct kinds look exceedingly well on sideboards grouped

Glossy-flowered Tutsan (Hypericum Hookerianum)

had sent seeds, he makes this instructive reply: "I sowed *H. triflorum* and have a big batch just showing the first pair of rough leaves; we are by themselves along with their own foliage. Of kinds to be had in flower now may be named *B. manicata*, one of the prettiest that can be had for

trumpet vases to give a finish and relief to larger varieties of flowers. This sort will also last a long time in flower in the conservatory if the plants have not been brought on in too much heat and moisture; when allowed to expand their spikes in a light, airy house they last much longer. *B. nitida odorata* is also now opening its most forward flowers. This sort is not grown nearly so much as it ought to be, seeing that it produces a continuous crop of flowers for several months in succession. It is, in short, one of the most useful, as well as one of the most elegant, white kinds grown. A little later on this kind will be used here in the conservatory, in which we find it most valuable. It has also, as its name indicates, the advantage of emitting a slight perfume. In a cut state, well developed spikes look well on a fringe of Maiden-hair Fern in a good sized vase, with the addition of other flowers over and above them. *B. semperflorens* is another good winter-flowering kind which is always useful. *B. Saundersi* is likewise a valuable kind; flowering shoots of this variety cut with a good length of stem can be worked effectively into many kinds of arrangements. The tall and straggling growing *B. fuchsoides* is very effective in a cut state. *B. ascotensis* also yields useful spikes. The foliage of some larger growing kind will be valuable to use along with the three last named varieties; we find that of *B. metallica* useful in many ways. The new variety shown of late under the name of *C. socotrana* promises to be an invaluable addition to the winter flowering section of these popular plants. All the kinds just named will be found now to be of service in a cut state. Others there are that will do a good turn during the summer in conjunction with the tuberous-rooted varieties, and other sorts are valuable late in autumn, especially *B. insignis*. In gathering flowers of *Begonias* cut them in each case with as long a stem as can well be had, and also give them as much water as can be safely used. This will help to keep them fresh somewhat longer than would otherwise be the case.

FLOWER GARDEN.

Summer bedding arrangements.—The plants necessary for this purpose may now be propagated. Happily, the increased and still growing interest now taken in hardy flowers does not render such matters so imperative as was the case a few years ago, simply because fewer tender plants are required, and these will gradually grow fewer still, as it is seen that equally pleasing, if less showy, arrangements can be made by means of hardy plants. We, however, by no means predict the entire abandonment of tender summer bedders, but only such a reduction in their numbers that space for wintering and spring propagation shall not interfere with other and more important duties. At this stage of the matter we have already, indeed, arrived, for in computing the numbers and kinds of plants needed, tender second-rate sorts are rejected whenever it is possible to do so without destroying the harmony of the general arrangement. Another way of reducing the number of tender plants is to plant them thinly in a given arrangement, and then clothe the ground beneath with a suitable hardy carpeting plant. One of the most admired beds here last season was one very thinly planted with variegated *Pelargonium* May Queen, the undergrowth being *Herniaria glabra*, bright green, which set off to the best advantage the white foliage and rosy pink blossoms of the *Pelargonium*—altogether an infinitely better arrangement than if there had been 200 *Pelargoniums* in a mass, instead of which there were not more than a score. We mention this arrangement as it shows what may be done in the direction of subduing the never-ending monotony of masses of colour so prevalent in some gardens. The sorts and numbers of plants required being decided, the next matter must be their

planted in their allotted spaces, *Antennarias*, *Cerastiums*, *Sedums*, dwarf *Veronicas*, *Ajugas*, *Herniarias*, and all plants of the same thicket-like character of growth must be fresh planted every season, for if left a second year, their dense growth engenders mildew and decay, and the whole groundwork becomes patchy and sickly, faults which it retains throughout the season. The half-hardy and tender section of plants also used for groundwork may, with a moderate amount of warmth, be increased almost as expeditiously as the foregoing. Golden Feather *Pyrethrum* may be grown from seed sown in pans, and pricked off in cold frames as soon as the plants can be handled. *Mesembryanthemum cordifolium* variegatum may be increased in the same way, and also by cuttings, which strike freely in pans or boxes set on bricks over hot-water pipes, where a temperature of about 60° is maintained. *Gnaphalium laetum* may be raised from cuttings struck in warmth and then transplanted into pots; *Alternantheras* by means of cuttings struck on hotbeds of leaves and litter, on which frames are placed containing about 4 inches of light soil (peat and loam) made firm. Cuttings inserted about 2 inches apart quickly root, and there they may remain till needed for planting in the beds, air of course being given to induce a sturdy growth whenever the weather admits of it. These plants are so rapidly increased, that it is not necessary to put in cuttings till March has become well advanced; but the stock plants should now be given abundant heat that cuttings may be forthcoming when wanted. *Iresines* and *Coleus* strike anywhere if afforded warmth; the only remark to make about them is that they should be used as sparingly as possible. *Lobelias* should be raised from cuttings only; seedlings are usually so disappointing, being both irregular in growth and weedy as to variety, that one wonders they are ever used at all. We strike them in a brisk heat, and transplant to frames as soon as they are well rooted; pots or boxes are never used. The herbaceous section of *Lobelias* are most satisfactory when increased by division, though they come fairly well from seed. *Ageratums*, *Fuchsias*, *Gazanias*, *Lantanas*, *Königia variegata*, *Petunias*, and *Verbenas* quickly make root in a bottom-heat of 70°, and will afterwards thrive vigorously in an intermediate temperature. They should all be allowed plenty of space; a well-developed bushy plant is equal to half-a-dozen lanky ones. *Calceolarias* in cold frames should be thinned out by transplanting them to other frames, or in the south of the kingdom they will now do at the foot of south walls if protected in frosty weather. *Violas* and *Pansies* should be treated similarly, or, if needs be, strong plants of these may now be planted permanently.

INDOOR PLANTS.

Hard-wooded Heaths.—Of all greenhouse plants in cultivation, Heaths have the greatest dislike to fire-heat if used for any length of time, or in quantity more than sufficient to keep out frost; and in severe winters, when there is a long continuance of hard weather, great care should be taken that the temperature is never allowed to get too high, or the plants are sure to start into growth, which should never be excited except by the natural return of sun heat. On this account, if, as we generally experience after an unusually mild winter, such as the present, we have a continuance of sharp nights late in spring, no more fire-heat must be used than will render the house safe from frost. It is no use attempting to cultivate Heaths except they are well and regularly attended to. Their greatest enemy is mildew, from the attacks of which they are never safe. It is usually more troublesome in damp, mild winters, when the atmosphere of the houses, as a matter of course, is more humid than when there is a necessity for more use of fire-heat. The plants should be looked over closely every week, and the moment the least trace of the parasite is apparent such as are affected ought to be dusted with sulphur. The importance of prompt attention in this matter cannot be too much urged upon new hands in the cultivation of these and all other hard-wooded plants that are in any way sub-

ject to mildew, for it speedily destroys the vitality of the leaves so much as to cause them to fall off in a few weeks, leaving the shoots bare, unsightly, and impossible to reclothe with foliage. All the Heath family, but more particularly the hard-wooded kinds, are proverbially impatient of any extreme in moisture, either too much or too little. In winter it is necessary to keep the soil comparatively dry.

Epacris.—The early flowering kinds should immediately they have done blooming be cut well back, reducing the last summer's growth to one-third its length. This is the more necessary with the erect habited sorts, otherwise they get into such a weak, straggling condition as to occupy twice the room they should, and be equally objectionable in appearance. Although requiring to be treated similarly to Heaths in the matter of being drier at the roots now than in the growing season, they will bear keeping warmer in the winter; and if after the shoots have been cut in they are put for a few weeks in a night temperature of from 40° to 45° with plenty of light and some air when the weather is fit in the daytime, they will be benefited by it. Treated in this way they will make growth earlier so as to admit of their being exposed to the open air sooner in the summer, with a disposition to bloom correspondingly earlier in the ensuing autumn. The bushy growing varieties, such as *E. miniata*, *E. Eclipse*, and *E. grandiflora*, are best adapted for late flowering; and where there is means for keeping them back by the use of a cool north house, a succession in flower may be kept up until midsummer. Their long sprays of bloom, which stand well in water, are most useful for cutting.

Azaleas and Camellias.—Where there is the convenience of a house with a northern aspect, so as to be little under the influence of the sun, it gives advantages in keeping up a display of flowers in conservatories and for other purposes late in the spring, such as is not possible where all the stock has to be treated in houses that are exposed to the full force of the sun. The latter soon after this time begins to have power enough for some hours in the day to run up the temperature to an extent that moves the plants rapidly, even if all the air is given that they will bear; for it may not be out of place to note that even when there is no growth in motion, it is not well to subject plants to a full current of air through this and the next two months. If a selection of early and late blooming kinds of Camellias are grown, and they are treated in a manner to have their growth matured at different times, there is no difficulty in having them in flower from the beginning of September up to the end of May; but as a natural consequence flowers that come in as late as the latter time do not last near so long as those produced in the winter. There is little doubt that the growth and flowering of Camellias is less interfered with when the potting is done about the time the season's growth is completed and the bloom-buds just beginning to form, as when it is carried out then the unavoidable breakage of the roots, which are very brittle, has less adverse influence on them than at any other season. But where there are plants that have been kept so long in small pots that their strength is thereby interfered with, it may be advisable to pot them before the growth begins. Where this is the case, the work should be done before the shoot-buds show signs of swelling, otherwise the season's growth is sure to be affected, even if no more disturbance of the roots takes place than is necessary to remove the drainage. On this account it will be advisable not to wait until the blooming is over, for the loss of a few flowers now will in most cases be a less evil than failure of the crop of bloom another season.

Cyclamens.—The flowers of these are well adapted for cutting, being both pretty and lasting well, but if too many are used in this way the plants suffer. If the flowers are severed from them in the usual manner by cuttings, the stumps of their succulent stalks remaining generally decay down to the base and rot the young blooms that

are springing up later; consequently it is in some respects better in gathering the flowers to pull the stalks out entirely, but if this is carried too far, so as to remove nearly all the flowers as they arrive at maturity, it seriously injures the bulbs; therefore, where the intention is to keep the bulbs or, more correctly speaking, corms, there should only be a moderate quantity gathered. It is well to raise some from seed each year, as though not capable of producing so many blooms the first year as larger plants will, the first season of their flowering is often the most satisfactory. See that the young stock raised from seed last summer are well attended to. If they have been wintered in pans they should have been accommodated with a temperature of about 50° in the night, and stood close to the glass, or the leaves are apt to become drawn and weakly. If treated in the matter of warmth as ordinary greenhouse plants, they make little progress during the winter, and take two years to bring them up to a size that renders them of much use for blooming. The temperature of an intermediate house appears to suit them best until they have attained a strong flowering state. Keep a close look-out for aphides, which conceal themselves on the undersides of the leaves of these plants much more effectually than on most things.

Pelargoniums.—Any plants of the large flowering varieties that bloomed late, and were not cut down until after the usual time, and are not yet put into their blooming pots, should be moved into them at once. If at the same time the points of the shoots are pinched out the flowering will be thereby retarded, so that they will come in after the earliest are over, at which time they will be found useful. Examples of these and many other plants that are kept for late blooming soon acquire a habit of thus coming in late, consequent upon the treatment they receive, and may be had in after the bulk of the stock is over with little trouble in retarding.

PROPAGATING.

Tuberous Begonias, where the stock is to be increased, should now be potted in a good light soil, say equal parts of loam and leaf-mould, and plunged in a bottom-heat of from 60° to 70°, when they will at once start into growth, and when of sufficient length the young shoots may be taken as cuttings. In doing this it is not necessary to sever them at the joint; they should be cut immediately above one, thus leaving a base from which other shoots will push, and as there is sufficient length of stem from one joint to the other, it will not be necessary to remove any leaves for the purpose of insertion. Put the cuttings singly into 2½-inch pots if large, and three or four around a 4-inch pot if smaller, using the soil just recommended, except that it must be sifted and a fair proportion of sand mixed with it. Cuttings thus treated and kept moderately close will soon root, but from their succulent nature they are liable to damp if kept too moist. This is the course pursued in the case of individual varieties, but it is not so much practised as formerly, owing to the fact that seeds saved from good flowers are readily obtainable, and if sown now produce good flowering plants the first season. Being very minute, they require care in sowing, and more especially in watering. Whether sown in pots or pans, both should be quite clean and well drained; then fill to within quarter of an inch of the top with light, open soil, consisting of three parts leaf-mould, one of loam, and a liberal admixture of sand, the whole being sifted through a sieve with quarter-inch meshes and pressed down moderately firm. An even surface being now obtained, give the pots a good watering through a fine rose sufficient to saturate the whole, and then while still wet sprinkle the seeds thinly over the surface, to which from its moist condition they will at once adhere. No covering is necessary, but place a pane of glass over the pot, when the seeds will readily germinate; then the glass must be removed. Thus treated, they come up more satisfactorily than when covered with soil.

Fuchsias as annuals.—A good deal of attention has been directed lately towards treating Fuchsias as annuals, *i.e.*, raising them from seeds in the spring and flowering them during the ensuing summer. Last year we obtained a fine lot of flowering plants in this way. For this purpose the seeds should be sown at once, placed in gentle heat, and as soon as the young plants are large enough they should be pricked off, for they are very liable to damp off just at the surface of the soil.

Deutzias and Azaleas.—Where Deutzias are forced there will be a fine crop of young shoots, which, if taken off, strike within a fortnight, and if then potted in small pots will make good little plants by April, when they may be planted out. The plants must not be removed into a cooler place before the cuttings are taken, or the check they then receive will very much retard the rooting process. Young growths of Azaleas made in heat in this way strike readily if put in pots of sandy peat and kept close till rooted, but in their case a sharp look-out must be kept for their great enemy, thrips, which in the close atmosphere of the propagating house increase rapidly.

Soft-wooded plants.—The propagation of the various soft-wooded subjects that have been taken into heat to hasten their growth must now be pushed on as rapidly as possible, but in taking the cuttings always leave one joint of the young growth, as it pushes forth other shoots much more readily than the old wood. Where Bouvardias are propagated from the roots the present is a good time to do so, but the best plan is after the plants have done flowering to give them a rest by keeping them somewhat dry, and in as cool a temperature as possible consistent with health; then about the middle of January introduce them into heat, and as they then start at once into growth take off the young shoots and treat them as one would Fuchsias and similar plants, when they will strike readily.

ORCHIDS.

East India house.—During the last ten days the weather has been unfavourable for Orchids. Nevertheless we have some good spikes of *Cattleya Leopoldi* in this house—a showy species much superior to *C. guttata*, and owing to its distinct character well worth growing. Plants of *C. gigas*, placed in a cooler house to rest, should be moved into the cool end of this house, and placed near the glass as soon as they have started into growth. This fine *Cattleya* does not flower freely unless it has a good period of rest. *Oncidium Lanceanum* is a very beautiful species, and when its cultural requirements are understood, not difficult to manage. We grow it in a teak basket suspended near the roof in winter, but in summer the sunlight is too much for it in that position. It is now starting into growth, and must not suffer from lack of moisture. *O. phymatophilum*, a difficult species to flower, taken out of the pot, placed in a teak basket, and suspended near the roof, is now throwing up a spike with the young growth. The character of these two, as well as that of some other allied species, is to throw out a mass of young roots all at once, and if these get injured in any way, the health of the plants suffers permanently. The roots may get dried up by being exposed to an over-dry atmosphere and a high temperature, or they may also suffer from the potting material being packed too closely round them. We have not found woodlice to injure such roots, but a large slug will entirely destroy the produce of a pseudo-bulb in one night, and the plants must be carefully watched in case this should happen. *Oncidium ampliatum* has thrown up spikes a few inches in length, and these are specially attractive to slugs. We have to closely watch these spikes in their earliest stages at night, or we would never see the flowers of this species at all. Keep the night temperature about 65°, but it may fall a few degrees on cold nights.

Cattleya house.—The first blooms of *Coelogyne cristata* are now opening, and also those on spikes of *Odontoglossum pulchellum*. These

two Orchids will continue to supply choice cut flowers for these next two months, or longer if there is a sufficient number of plants. The commonest form of *C. cristata* is perhaps the best, although the variety with a pale yellow or lemon blotch on the lip should be grown to prolong the bloom. There is also the pure white variety, likewise a very desirable form. These now require considerable supplies of water, otherwise the bulbs have a tendency to shrivel. One plant turned out the other day, and divided into three, is now flowering as freely, and looks as well as the others. We also potted *C. barbata*; this species requires considerable supplies of water, and not too much pot room. *C. cristata* would probably in some cases be improved if it received more water than it does during the growing season. The best bulbs we ever saw were produced in a *Cattleya* house temperature, and all through the growing season they were kept quite wet, the *Sphagnum* in which they were growing being beautifully green and growing up amongst the bulbs. *Odontoglossum Phalaenopsis* is now making fine, strong growths, and flower-spikes are also showing themselves. Our whole stock of this species has been turned out of the pots; nearly the whole of the old potting material has been removed, and the plants repotted. *O. vexillarium* and *O. Roezli* have also been looked over; in some cases the plants have been repotted, but in others they have merely been surface-dressed. When a portion only of the plants are repotted, a label showing the date of potting should be attached to each, as a guide for future treatment. As all these *Odontoglossums* are so liable to the attacks of thrips, they should be dipped once in about every four weeks in a mixture of soft soapy water to which some tobacco water had been added. About an hour after dipping, the leaves should be rubbed over with a soft sponge dipped in clean water. *Cymbidium eburneum* now so cheap that it should be in every collection, is showing well for flower. Our plan is to repot such plants of it as do not show at this season, as on examining the roots it will be found that they are just starting to grow. Use a compost consisting of about two-thirds good turfy loam to one of turfy peat. Plants showing for flower must have a good supply of water.

Cool houses.—If the repotting of all that require that attention has not been done, let no further delay occur in the matter. Many do not repot until later than this, but the roots of all those potted here during the last few weeks are starting into growth. We used to pot a large proportion of our Orchids in the summer months after the May and June exhibitions were over, but we believe it to be better to do so at this season. We have tried some plants of *Masdevallia tovarensis* in the *Cattleya* house and a portion in the cool house, and so far there does not seem to be any difference between them; but the temperature in the cool house is not allowed to fall so low as it has hitherto done. We have had it as low as 35° on several occasions, but when it can be kept at 45° or 50° without much extra trouble, it may be better to keep it, especially at this time of the year, up to the highest figure. Many species of *Odontoglossum* do not open kindly in the lower temperature, and owing to condensation of moisture on the flowers they are soon rendered unsightly. Amongst *Masdevallias* there are some that certainly succeed best during winter in an intermediate house, and of these *M. Wagneriana* is one. It makes a pretty little tuft, and should be grown in small pans suspended near the glass in a shady part of the house. The new, or at least rare, *M. rosea* is said to like the coolest part of the cool house, and as it is now probably in the hands of several cultivators, we may hope to see it in flower during the current season. The pretty, sweet-scented *Oncidium cheiphorum*, although it does well in the cool house for the greater part of the year, is now starting into growth, and should be repotted. We found on potting ours that the small fibrous roots were in very active growth. *Epidendrum vitellinum* and the *majus* variety were in the cool house until the middle of January; they were then taken out, and some of them were

divided and repotted in much smaller pots, and placed in the intermediate house. If it is intended to exhibit the large flowering variety at the early summer shows, it will not be in flower unless it is placed in a much warmer house.

THE FRUIT GARDEN.

Strawberries in pots.—Until we have a change to brighter weather great patience must be practised in the management of plants now coming forward, otherwise the tedious labour of this past year will end in failure. If they occupy shelves near the glass keep the latter clean, and avoid overcrowding during their progress to the flowering stage. When in flower give more air, or remove them to a light, airy house where they can be regularly attended to with water and sufficient atmospheric moisture to prevent the blossoms from suffering under bright sunshine. Give gentle fire heat to admit of a free circulation of air by night and day, thin out weak flowers, and fertilise with a camel's-hair pencil when the pollen becomes light and plentiful. Strawberries under artificial treatment being so impatient of a high temperature until after the fruit is set, a minimum of 45°, with a rise of 10° by day, will be quite sufficient, but when fairly set and removed to a Pine stove to swell off, there will be little danger of overdoing them with heat, moisture, and stimulating food. They must not, however, be allowed to remain in this position if flavour is to be the test of skill in forcing. When fully swelled and partially coloured they should be removed to a warm, airy house, where exposure to light and the gradual withholding of water from the roots will greatly improve the quality of the fruit. As days increase in length and brightness, successional crops may be brought on faster by closing for a few hours, with sun heat, and moisture from the syringe, but air must be again admitted at night, when the temperature may range from 45° to 50° when external conditions are favourable. Where light, shallow pits are at command it is a good plan to use them as feeders to the forcing pit by placing 1 foot or 2 feet of fermenting leaves over the bottom and keeping them filled up with plants from the general stock. The leaves should be made very firm to preserve the warmth, and lightly covered with coal ashes to keep back worms and to raise the crowns to within a few inches of the glass.

Cucumbers.—It is difficult to conceive or wish for a finer winter for Cucumbers than this has been, and if the rains would cease, and bright sunny days set in, good fruit through the months of February and March should be plentiful. Growers who work on for this time of scarcity, by maintaining low, steady heat consistent with safety, and crop lightly, will now have clean, healthy plants capable of giving an abundance of fine fruit, but unless they are to give away early in the spring to make room for Melons, overcropping must be avoided, as checks of all kinds, particularly from overloading, make many Cucumber houses barren at a time when good fruit is in daily demand. As the days increase in length a little more heat may be given them if it can be secured from solar influence, but no great change need be made through the night, as hard firing brings many ills. To avoid these, dry covering of some kind should be placed over the lights every night, and the bottom-heat from fermenting material should not be allowed to fall below 80° at the base of the pots. Another important operation is frequent dressing, to prevent the foliage and Vines from becoming bleached and drawn by crowding, and so leave them an easy prey to the first enemy, be it insect or mildew, which may attack them. Keep the evaporating pans now regularly filled with stimulating liquid, top-dress the roots with fresh compost, and bathe the foliage and stems with warm soft water whenever the house can be run up to 80° or more with sun heat. Young plants in small pots intended for training over a trellis in the Cucumber house may be shifted on from time to time if the bed is not ready, but one shift from the seed pot to the hill is always best, and it is

better to throw plants away and fall back upon later sowings than to trust to them when they become potbound and often infested with spider before the points reach the trellis. When young plants intended for pits and frames have made two rough leaves, pinch out the points and keep them close to the glass until the hills are ready for them. If the manure has been well worked and placed in the pits, make it very firm and level on the surface; lay sods of turf, Grass side downwards, across the centre to prevent the roots from striking into the manure, and upon these form a long narrow ridge or small cones of light rich soil. Introduce a bottom-heat thermometer, and when a steady heat of 80° to 85° has been secured, cover the remainder of the bed with sods and plant out in the usual way.

Hardy fruit.—With the exception of one night's rain, the weather of the past month has been all that could be desired for pulling up arrears of planting or other work where the disturbance of the roots of fruit trees comes within the range of the operation. The same favourable conditions having also helped forward pruning, training, and winter-dressing, thrifty hands should now be turned to the preparation of protecting materials of some kind, as we can hardly expect a mild winter like the past to pass away without a few sharp spring frosts, and it not unfrequently happens that one particularly treacherous forepart of the night suddenly changes to a sharp frost the following morning and settles the cream of the fruit crop for the season. With this dearly-bought experience in view, all dwellers in low, damp situations will do well to be ever on the watch, and prepared to cover up on the instant, if they do not make a point of seeing everything safe before they retire for the night. So much having been written upon the protection of the blossoms of fruit trees, it may be well to guard young beginners against the abuse of materials placed within their reach, as excessive covering very often forces a weak, premature growth which is killed, whilst its judicious application retards, exposes, and protects in time of need. For walls the first requirement is a broad coping of glass, if possible 2 feet wide and portable, as everything should be cleared away when danger of spring frosts is over. In front of the trees several thicknesses of fishing-net may be suspended permanently. Canvas, frigi-domo, or an excellent and less expensive material called grey baize, sent out by Messrs. Veitch, of Chelsea, may be used as curtains or blinds, but they must be drawn up or aside every day, otherwise the danger to which I have alluded will soon be present in the form of weak, blanched flowers, which cannot be expected to set and swell into luscious fruit. Apricots this year well furnished with flower-buds will be the first to require attention. These may be coped and poled, but the nets must not be suspended until the blossoms begin to open. Next will come the early Peaches; but as these are still drawn away from the walls, and nailing in will be deferred until a late period, arrangements must be made for rapid dispatch when the proper time does arrive. Work in orchards referred to in my last paper may still be carried on as opportunity serves, and stocks may be partially cut back preliminary to grafting in the spring. A mild season being favourable to early enlargement of fruit buds, small birds are generally troublesome; hence the importance of dusting with soot and lime when wet, or syringing with the same in solution after the trees are pruned. As many kinds of Strawberry are already throwing up their crowns, any deferred cleaning and top-dressing must be proportionately early, otherwise the flowers will suffer. Many people have an idea that spit manure is the best top-dressing for Strawberries, but in old gardens already too full of animal and vegetable matter a good dressing of soot, followed by 2 inches of fresh loam, will produce better crops of finer flavoured fruit. If not already done, autumn-bearing Raspberries must now be cut over quite close to the ground. Belle de Fontenay is a fine, large-fruited kind and well worthy of general cultivation.

MARKET FRUIT GARDENS.

The season being favourable, the pruning of bush fruits is well advanced; as a rule such fruits as Gooseberries and Currants (Red and Black) are cut in severely, even more so than in private gardens, for in the case of Gooseberries, except when the fruit is gathered green, it pays better to have a fair crop of large fruit than a heavier crop of small, under-sized berries, and in order to have size, only the strongest young wood is left. Red Currants, too, are spurred in very closely; after pruning the cuttings are all raked up to the end of the rows and thrown into heaps to burn. A good coating of manure is then forked in lightly round the roots and the soil between the rows is dug up as roughly as possible. As it gets trodden down hard during the gathering season, it is much benefited by exposure, and when forked or prong-hoed down in spring to get out coarse rooted weeds, such as Docks, Dandelions, Couch Grass, or Bindweed, a fine crumbling surface is the result. Cultivating ground in this condition is not only more cheaply performed, but a good layer of finely powdered soil is looked upon as the best antidote against drought, and if the drying winds of spring penetrate to the surface roots the crop is proportionally reduced in size.

Raspberries are being extensively planted, in some cases as intermediate crops between dwarf Apple or Plum trees, but more generally by themselves. They are planted in rows about 4 feet apart, and in patches of three or four young canes, 2 feet asunder in the row. Small canes with good roots are preferred to even good canes with few roots, as the first year's crop is of little value. After planting the canes are cut down about half their length, and the first and second year an intermediate crop is planted between the rows. They are never staked or supported in any way, but the canes are cut down to between 2 feet and 3 feet from the ground. They are, therefore, stiff enough to stand alone. Some sorts make stronger canes than others, notably Prince of Wales, a very fine Raspberry, but some others, such as Fastolf and Carter's Prolific, are largely grown for market. After the second year's growth they are at their best, and with rich dressings of manure, so as to get large fruits, constitute one of the most profitable crops grown. When gathered, they are put into tubs and consigned at once to the jam manufactories, as being very perishable they quickly deteriorate if left on hand any length of time. At present, however, the supply is not equal to the demand. Although the Raspberry delights in a rich, rather moist soil, it is grown to great perfection in soils by no means naturally rich.

Fruit trees intended for grafting should now be beheaded just above where it is intended to re-graft. If left until late in the season a good deal of the strength of the tree is wasted. Shoots about the size of a man's wrist are the best for grafting on. All those done last season should now have their stems cleared of lateral spray left on at the time for promoting root action, and the leading shoots from the graft should be topped about one-third of their length and otherwise treated as young trees forming a head. A supply of grafts should be at once secured and laid in by the heels in trenches in a cool, shaded position; do not tie them in bundles, as the centre ones are liable to get dry and shrivelled, but lay in each variety separately with its name or number at the end of the row. The best shoots for grafts are those of medium strength; they are generally better ripened than the largest ones, and weakly shoots have not stamina enough to form a healthy shoot. Old established trees where Moss grown should now be dusted with freshly slaked lime worked well in among the twigs, as, in addition to its beneficial effect in cleaning the wood, it forms a valuable manure when washed off into the soil. See that all freshly planted trees are securely staked and the stems protected from chafing or being barked by sheep or game. A coating of Birch or a surrounding of rabbit-proof netting makes a good protection, and some case the stems

in rags or sacking, and smear them with tar or other noxious compounds.

Apples of home growth are now realising fair prices; good dessert kinds, such as Cockle Pippins, Reinettes, and Golden Pippins, are worth from 5s. to 8s. per sieve; kitchen kinds fetch from 4s. to 6s., and with such a crop as that of last year home growers can successfully cope with foreign competition, at least in the way of Apples, for some time to come.

KITCHEN GARDEN.

JUST now is a very good time to plant Shallots, than which few crops pay better or command a readier sale. The land which we use for this crop is not rich, but should be well worked and made as fine as a heap of sifted ashes. We draw the drills for them about 1½ inches deep, fill them up to the level of the ground with burnt refuse, and in this we plant the bulbs 1 foot apart. Shallots often become mildewed, occasioned by being too deeply embedded in the soil; hence the reason of planting so shallow, that all the bulbs may be above the soil when matured. A most useful spring crop may be had by planting small Onions just now, to pull and use in a green state. These Onions planted on the edges of borders look trim and smart. Small sowings of Celery may now be made in boxes for very early use, but the main crop we never sow until the second week in March. Of early Cauliflower (Dean's Snowball is the best here), a boxful should be sown at once. The same may be said of Lettuces of the true Cos variety, which stands at the head of its class. We are busy planting Potatoes in frames, sowing Radishes, early Carrots; and here we must remark if clean grown Carrots are wished for, mix plenty of sand in the compost in which they are grown, and you will not be disappointed. Cover up more Seakale and Rhubarb, and keep up a good supply of Asparagus and French Beans. Our young plants of Tomatoes are now in single pots (3-inch ones). We intend planting a house with them next week. The winter plants are now done; therefore directly we can get the house thoroughly cleaned we shall plant the spring batch. Our winter Cucumbers are still bearing, and doing us good service. Our young plants for pits are now potted, and will be ready quite as soon as they are wanted. As to salads, the large variety of Chicory called Witloof is just now most useful. We place a dozen roots in a large flower-pot, and blanch them in the Mushroom house. Keep up successful sowings of Mustard and Cress, and when well up remove them into cool houses.

FLOWER GARDEN.

HERBACEOUS PHLOXES.

THERE is now an immense variety of Phloxes, and when an admirer of these most useful hardy flowers lights upon a catalogue containing a list of very nearly one hundred varieties, he is naturally enough somewhat at a loss what to select; and it is not always wise to leave the selection to dealers, for they make up a select collection according to the varieties they have in stock and what they can best supply. When looking over a fine and select collection at Messrs. Sutton & Sons, Portland Road Nurseries, at Reading, last August, I jotted down the names of the following varieties as being especially fine and well deserving of being included in a select collection: Coccinea, rich crimson-scarlet, very effective; Resplendens, bright rosy scarlet, very fine; Boule de Feu, bright fine red, striking in colour; Madame Guldenschuch, rosy violet, with a scarlet and purple centre, very fine; Roi de Saumon, rich rosy salmon, very effective; Souvenir de Berryer, deep lilac mottled with white, distinct and pleasing; Czarina, one of the very best white varieties, extra fine; Madame Manuel, very pretty; Richard Wallace, rosy scarlet, extra fine form; Monsieur Marin Saison, red, suffused with orange, crimson centre, very striking; Madame Mouisset, bright rose, suffused with carmine, crimson centre;

La Candeur, white, fine form; and Dr. Masters, rosy salmon, very fine.

These were growing in well cultivated soil in the open ground, and had thrown up strong growths, so that each plant produced a few spikes of very fine flowers. It is in this way a bed should be grown, but I would suggest that young plants be raised from cuttings about once in three years, so that at intervals of that time beds may be renewed. And as improvements are made in old varieties, these last should be rejected and the new forms substituted for them.

Fine young plants can be formed by making cuttings of the young growths thrown up in autumn, or by taking out fresh-rooted shoots at that season of the year. These should be potted singly and grown on in a cold frame, and they come in very useful to make a fresh plantation in April or May.

New varieties are largely produced annually. In Scotland, as well as on the Continent, the raisers are always busy, and perhaps there is some reason to think they are multiplied a little too fast. We can scarcely advise cultivators to trouble much about raising seedlings, but there is always a peculiar pleasure in doing so, though the results may not be such as might be desired. Some care is required in raising seedlings, and a cold treatment is the best. Self-sown seed will lie in the soil all the autumn and winter and grow up into plants in spring.

In some parts of the country herbaceous Phloxes are grown for exhibition. It is the practice to show finely-branched spikes in collections of six, nine, or twelve, and when the varieties are good and the spikes fully developed, a very effective feature is secured. As a matter of course, the spikes should always be shown in vessels containing water to keep them fresh and the flowers fully expanded. But it is only at exhibitions held at the middle or end of August and early in September that these Phloxes can be produced in fine character. Sometimes specimens are grown in pots for exhibition purposes, but never in a satisfactory manner. The difficulty appears to be to get dwarf plants with a balance of good foliage and flowers; but Phloxes are so pretty and inviting when well shown in water it is enough that they be exhibited in that form.

R. D.

SOIL FOR ANEMONES.

"A. D." states (p. 57) that Anemones do better with him on strong soil than on that of a light character, but it must not be accepted as a fact that they always do best in a soil of a very retentive nature. Probably "A. D.'s" Anemones that do so well on strong clay soil are growing on a south border where they get abundance of sun (a situation these sun-loving flowers so thoroughly appreciate), while those growing in light soil are not, perhaps, so happily situated. I grow them in quantity and can fully testify as to the usefulness of the blooms in a cut state. From a medium-sized bed on a warm south border without any protection (in the way of frames, &c.) I have cut a goodly number dating from the third week in December, while at the present time there are scores of buds in all stages of growth. I may state, too, that clumps of them growing in various parts of the garden, and in the same light calcareous soil are scarcely throwing up a flower bud yet. While thus resembling "A. D.'s" plants as regards their blooming propensities, they differ from his inasmuch as they grow on very light soil indeed, but they nevertheless yield an abundance of large, gorgeous blooms for at least six months of the year. The flowers, too, are very hardy, bearing several degrees of frost unharmed. It is surprising how fresh they appear after all the wet, damp, and slight frosts we have had if perchance a fugitive sunbeam lingers behind a few minutes. The unopened buds have a very useful property of unfolding their brilliant petals on being transferred to the drawing-room or anywhere else where there is a little warmth. Position is a great desideratum as regards their culture. I have some growing in a damp, rather shady nook, and the re-

sult is that they dwindle and languishingly send up one or two buds to apologise for the others that do not appear, or it may be to remonstrate with me for not placing them in a more suitable position. For early blooming the combs require to be thoroughly matured; consequently a dry, warm, south border is indispensable. I have had the combs dried in the sun to such an extent that one would never believe there was any vitality in them; still, after being placed in a moist, shady situation and kept moderately damp, they plumped up and sprouted almost immediately, bloomed, and did well afterwards. Of course I do not recommend this drying process—what I mean is that they will bear a great deal of it with impunity.

Thickthorn.

H. DOBBIE.

AURICULA NOTES BY THE WAY.

I DO not feel sure that the unshaded alpine had, at the northern meeting of January 31, or has, in the opinion of the northern florist body, quite the status that Mr. Brockbank would accord to it, by virtue of subscriptions having been accepted for its exhibition at the next Northern National Show. A set of prizes was guaranteed by Mr. Brockbank, and his kind intent to add to the extent of the show was liberally received. But when he interprets this to be the formal and first acknowledgment of the unshaded alpine in the north as a legitimate florist flower, I doubt whether so grave an import was generally understood or attached to his proposition. For my own part I took the question to be simply—May there be exhibition space and a class list for these flowers if prize money is forthcoming? And the meeting said—Yes. But the rank of a florist flower is high, and should not be purchasable. If conferred formally the degree should be granted by the fullest senate available, solemnly convened for that definite purpose. Many northern florists, however, were absent even at our large meeting; and among those present I think would be some who could only say that the unshaded alpine is a weaker type of the flower. Indeed, technically and correlatively, it is as bad as the shaded self would be. The weakest colour point in the self is any degree of shadiness, and in the alpine any lack of it. While the true self is a flower of a dense uniform body colour, and heavily mealied eye, the best alpine is a heavily shaded flower with perfectly unmealied and golden eye.

Shaded alpines with pale, but unmealied eye are recognised, but they are a weaker type. The unshaded alpine is the flower with what has so far been considered its most distinctive property left out. I would not say we are never to find and adopt a new thing or style of beauty, but not for the mere sake of novelty and abundance, and not to the hurt of what is higher, rarer, and more difficult to attain and of gentler worth.

We have allowed a touch of floral comedy and grotesqueness to find an expression by the admission of fancy or nondescript Auriculas, Polyanthus, Carnations, and Picotees at our classical national shows, and I begin to fear whereunto this spirit of good humour and frolic may lead us. Old hands may understand it and be amused and not lose their balance, but young ones and the public may get confused and misled, and not see our real object as plainly as we do.

Who shall say that in the Auricula some one may not next be offering to find the prizes if we will admit a class for shaded self? Have they not beauty also? and is there not a host of them, or soon could be? Then may arise young champions for other mixtures, whose origin is simply out of the obscurity of present rejections from the seed bed, and which may be had in any quantity and variety out of the most carelessly saved seed. I should not like to see this lawlessness let loose upon any of our florist flowers of the old standing. We have no flower more beautiful and well defined than the classic-edged Auricula; none so grave and reverend and refined; perhaps none to be so easily overlaid and lost sight of in a mass of raw, irregular, and loose additions. Who would set their pearls in brick-

bats? Moreover, we have gems yet to seek for, and perfections yet to work out in old lines. We have not yet the golden centre in alpinas of the lilac shades, or golden tubes to our blues in the selfs, or edged flowers of perfect quality with other ground colours than black.

AURICULA VINCTA!

Rule XI. could have borne the interpretation that was put upon it, viz., that a shady exhibitor could have shown a plant he had neither grown nor had in his garden because he could say he had bought it, and left it his property 100 miles away, and now had fetched it to the show. But the old honest interpretation was that for two months before exhibition the plant must have been under the hand of the exhibitor, so that his skill or otherwise should have had time to tell decidedly upon the condition and chances of the plant. It is well to make honourable showing an assurance to all. This safety is priceless. But those who henceforth may think the owner of any powerful seedling is rather close-handed for not letting a circle of friends have a plant to win with may be relieved to know that it is not now the raiser's fault. The word property, as applied to the possession of an Auricula, is to signify that the plant cannot compete unless the exhibitor has the fullest control over it by absolute gift from the donor, therein including, of course, the power to part or have it parted with.

Now it is not hard to find a trusty friend, and plants of outright gift will no doubt appear at the shows; but in the chances and changes of life it would become a great effort on a large scale to keep a dispersed and distant eye on a number of private seedling treasures that from time to time might drop from the hand that held them. This will have to account for the still more lengthened time that may now elapse before any desirable seedling is shown, save by the raiser himself and perhaps an intimate friend. For I take it that no one can afford to let an undistributed seedling very far out of his own hands when he knows he cannot recal it or have any hold upon its dispersion.

Plants lent may, I suppose, be recalled; but though the friend may have grown them the year round and round again, he cannot win with them, for they are not legally his property, and they are not, in the eye of this new law, his growth. He has not grown what he has grown, and seedlings thus disqualified from competition I would rather see shown with their full and lawful franchise, although the raiser be obliged to keep them to himself to secure it.

I willingly voted for a more forceful form for Rule XI., but think that if anyone has certainly had the whole growth of a plant in his own hands, it might, without his necessarily having absolute power over its destiny, be considered for exhibition purposes his property. F. D. HORNER.

Kirkby Malzeard, Ripon.

THE GLADIOLUS FAILURE.

IN the various letters which have appeared on this subject recently many causes have been suggested for the failure of Gladioli, which seems to have been so general during the last few years, but the change of climate which appears to have now become the rule over most parts of England is surely enough to account for a great deal if not all of these losses. Though I have never grown Gladioli in more than a small way, and never went in for show varieties, I always used to have a nice lot till the year 1879, when I lost almost all of them, including Kelway's named varieties and many sent me by Herr Max Leichtlin, which were the produce of crosses between the florist's Gladiolus and some of the true species, such as insignis, Saundersi, purpureo-auratus. When one remembers what is the natural climate of the plant, and what our summers have been for some years, and especially since 1878, it is not surprising that Gladioli die, but rather wonderful that any are left. I find that even the species planted out in frames and not disturbed by taking up have very much deteriorated and diminished

in number, but those which I have grown from seed in a cold greenhouse have been as good as usual, and the seedling bulbs when planted out were even last season very fair. What is wanted, I think, is a strong infusion of the blood of very hardy interesting sorts such as Saundersi, even if something is lost in the form of the flower. Named sorts seem to me a delusion which is not worth keeping up, and I should like to know how many of the varieties which have received first-class certificates in the last ten years can now be found equal to the standard of first-class seedling varieties. It seems to me that the practice of giving certificates to individual varieties of Gladioli, Cyclamens, Gloxinias, Primulas, and other plants which are most readily and successfully propagated from seed is a mistake. Let a certificate be given to the strain or the exhibits of any particular grower when the general standard of his plants is good enough to deserve it, but to keep up 1000 or more named varieties of any plant seems to be an obsolete and useless practice. H. J. ELWES.

NARCISSUS MONOPHYLLUS.

I DO not think Mr. P. Barr or anyone else has any secret about the cultivation of this charming plant, as I have found it more easy to bloom than many other bulbous plants. I may say, however, that I do not think it can be flowered well except in a pot kept in the greenhouse. Mr. Hammond, of St. Alban's Court, Kent, showed a 5-inch pot of it four or five years ago at South Kensington, which had, if I remember right, about sixty flowers out at once, and was good enough to give me bulbs and to tell me how he managed them. Since then I have never failed to have plenty of flowers from Christmas till about the middle of February, and have found the bulbs increase fast. Pot them twenty or thirty in the same pot, well drained, and keep the pot on a hot dry shelf in the greenhouse from about May till October without a drop of water till the leaves show; then water moderately as long as the leaves are green, say, till about April, when gradually dry them off. Do not disturb the bulbs unless they are too crowded, say once in three or four years. I should be glad to know from those who have grown them if the Snowdrops, of which great quantities have been lately imported and sold as Galanthus Elwesi, are equal to the plate of this plant in Bot. Mag., vol. ci., t. 6166, which is a true likeness of it as I first had it. My original plants have diminished in numbers and become smaller in size, I think, and do not seem so hardy or so early as they were. I do not know the origin of the lately imported bulbs, but if anyone visits Smyrna they will find the fine form of the plant in the mountains about two hours' walk south of Manisa, a town on the Cassabar railway, in ravines on the north side of the mountain at about 3000 feet. If anyone can send me bulbs of this form I shall be glad to give anything in my garden in exchange for it. H. J. ELWES.

I do not for a moment dispute that Narcissus (Corbularia) monophyllus may not be grown out-of-doors in certain parts of the United Kingdom. Mr. Ewbank tells us that he can grow it at Ryde. I believe it would do very well in the Scilly Isles, on the west coast of Scotland and the adjacent islands, and perhaps in some parts of Cornwall and Ireland, but that it will ever become a generally established plant in this country I cannot believe. Mr. Barr, Mr. Elwes, Mr. Ewbank, and a few others grow it with considerable success in pits or frames under glass, but in 99 cases out of 100 it simply defies cultivation altogether, and I believe it to be sheer folly to attempt to grow it. There is something in soil, atmosphere, and climate which renders its cultivation impracticable. The same remarks apply to another lovely little Algerian Narcissus, N. elegans (oxypetalus), and the S. European N. serotinus. I can do nothing with the pretty and delicate little N. pallidulus, so common on the mountains round the Escorial. I brought a number of bulbs home from thence between three and four years ago, but I fear they are all dead. I also distributed a considerable

number among various friends. I should like to know whether anyone has succeeded in establishing it. My late friend, Mr. Nelson, of Aldborough, who could grow almost anything, told me he could do nothing with it either in the open border or under glass. Its close ally, N. triandrus, grew like a weed with him. All the Corbularias are capricious, and utterly refuse to grow in many places. I grow all the known species except C. monophylla under glass in a pit, but can do nothing with them in the open border. One of your correspondents, writing from Kent, says he grows C. Bulbocodium luxuriantly in his sandy, peaty soil. I am not the least surprised at this, because it is almost invariably in soil of this kind that all the Corbularias grow wild. The only Corbularia with light coloured flowers which grows in the neighbourhood of Bayonne is the large sulphur-coloured Hoop Petticoat Narcissus, C. citrina. Talking of bulbs which baffle cultivation, I would ask if anyone has succeeded in thoroughly establishing those two lovely Californian Fritillarias, recurva and pudica, or any species of Calochortus? A few years since bulbs of Narcissus Broussonetti and canariensis were imported, the latter by Messrs. Krelage. Has anyone established them?—H. HARPER CREWE, Drayton-Beauchamp Rectory, Tring.

Several paragraphs have appeared in THE GARDEN lately touching the blooming of Narcissus monophyllus. You allude (p. 130) to my successful treatment of it a few years ago. Alas, my hand has forgot its cunning! I have a stray bloom occasionally, but never again five blooming bulbs in a 5-inch pot, which so attracted the attention of a great horticulturist when he saw it standing in Mr. Barr's window, that (as I understood) he took off his hat to it. What I wish to know is whether these successful growers can bloom the same bulbs year after year. That is the point. My friend, Mr. Ewbank, has much in his favour; but, if I remember aright, he told me, three or four years ago he could not manage it. Has he found out the secret? I remember telling Mr. Barr that when I had made it grow I could make it bloom, but I have been mistaken. There are other bulbs from the same quarter (Algiers) which are equally stubborn, for though I have bloomed both Narcissus elegans and N. serotinus, the identical bulbs will then remain two or three years in the ground and not attempt to move, yet keeping perfectly sound. Can anyone tell me where to get a bulb or two of Narcissus viridis? Dr. Durando, of Algiers, says it is only a variety of N. serotinus, but Mr. Burbidge, in his monograph, seems to imply otherwise. Will some correspondent kindly give me the treatment of Saundersonia aurantiaca?—A. RAWSON.

“Veronica” is right in having questioned the correctness of my statement, that the White Hoop Petticoat is found near Bayonne. A friend who lives at Bayonne has asked local botanists, and they send me word that it is not found there. Not having access to a copy of Gerarde's “Herbal” (a book written half a century before Parkinson's “Paradise,” not after, as “Veronica,” by a slip of the pen seems to say), I cannot tell whether the explanation of the name Cantabricus as given to the White Hoop Petticoat because cultivated at Cambridge is Gerarde's or “Veronica's.” Cantabricus, however, ought to mean Biscayan. Cantabri is the ancient Latin name of the Basques, and Cantabricus sinus the classical name of the Bay of Biscay. In modern dog Latin Cantabridgia has been adopted as the conventional rendering of Cambridge, from which an adjective Cantabridgiensis, corrupted in vernacular English into Cantab, has been formed, but this must not be confused with the genuine classical adjective Cantabricus, a name more likely to have been given to the plant in question from an erroneous opinion of its habitat, and which may account for Mrs. London's statement (see page 130).—C. WOLLEY DOD. [Narcissus monophyllus is now in flower at Kew, both in pots in a cool house and under a handlight in the open. In the latter case the handlight is kept closed throughout the year, and the plants under it seem to be thriving admirably.]

BOOKS.

LES PLANTES POTAGERES.*

THE object of this work, as explained in the introduction, is "to invite the attention of the greatest possible number of readers to the vast variety of plants known and used as vegetables, and to the advantages of making a good selection from amongst them; to note briefly their various adaptabilities and the principal properties of each; and, especially, to point out the characteristics by means of which different varieties may be distinguished from one another."

A careful examination has assured us that the volume is in every respect worthy of the distinguished establishment from which it emanates, and that it is a work of the highest importance to all who take an interest in the subject. Its programme has been fully and faithfully carried out, and in this respect leaves nothing to be desired. An introduction of some ten pages (in which the aim and scope of the work are explained at length, together with some interesting and valuable remarks on the subject of "varieties produced by cross-fertilisation") is followed by an alphabetical enumeration of no fewer than 137 species of plants used as vegetables. These and all their best known varieties, amounting to many hundreds, are described under the natural family and botanical name of each, followed by the corresponding name in English, German, Flemish, Dutch, Danish, Italian, Spanish, and Portuguese. Then come particulars as to the native place, whether the plant is annual, biennial, or perennial, and such other distinguishing points as may require notice. The mode of culture and uses are briefly indicated, and the description of almost every species and variety is accompanied by an exquisite wood engraving which accurately represents the plant to which it refers, and in such difficult subjects as the varieties of Cabbages and Lettuces reproduces in a marvellous manner the characteristic features of each. There are in all 624 of these illustrations. Not the least valuable part of the work is a carefully prepared table of the average duration of vitality in the seeds of the various plants enumerated. The same may be said of the very comprehensive index of 81 pages, which, notwithstanding the alphabetical arrangement of the species, the vast number of varieties described and figured has rendered necessary. The volume is well printed on good paper, and contains 650 pages, exclusive of the introduction. As an example of the manner in which the plan of the work has been carried out, we subjoin a translation of two or three of the shorter descriptions:—

Cardoon.

CYNARA CARDUNCULUS (L.).

Natural Family, Compositæ.

Foreign names: *French*, Cardon; *German*, Cardy, Card; *Flemish*, Kardoën, Cardonzen; *Danish*, Kardon; *Spanish* and *Portuguese*, Cardo.

Native of South Europe. Perennial. Notwithstanding the different botanical names which have been given to them, the Artichoke and the Cardoon appear to belong to the same species, cultivation having in the case of the latter developed the leaf-stalks, and in the former the receptacles of the flowers. The Cardoon is a larger plant than the Artichoke, and of a more vigorous growth, but the botanical characteristics and general aspect of both present the greatest analogy. In the Cardoon, the stem, which attains the height of from $\frac{1}{3}$ feet to 6 feet, is enamelled and of a whitish hue. The leaves are very large, pinnatifid, of a slightly greyish green on the upper surface, and almost white underneath, armed, in several varieties, at the angle of each division with very finely pointed yellow or brown spines from one-fifth of an inch to three-fifths of an inch long. The very fleshy leaf-stalks are the edible part of the plant. The flowers, which have usually pointed scales, re-

semble those of the Artichoke in miniature. The seed is thick, oblong, slightly flattened and angular, gray, striped or streaked with deep brown. A gramme (15 grains) contains twenty-five seeds,

Prickly Solid Cardoon.

and the weight of a litre (nearly a quart) is 630 grammes. Its germinating power continues for seven years.

CULTURE.—Unlike the Artichoke, which is almost always multiplied by means of offsets, the Cardoon is always raised from seed, which is usually sown in May, in holes filled with compost, and at a distance of about a yard every way from each other. It might be sown earlier in pans on a hotbed, but this practice presents few advantages, as the Cardoon has ample time to develop itself during the summer and autumn, and is not a vegetable that is sought after before its natural season. The ground must be kept very clean, and the plants should be copiously watered through the summer. As they will not have grown large enough to touch each other before September, the ground between the rows may be utilised in the meantime by sowing some other crop there.

Before Cardoons are used, the leaf-stalks are blanched by tying them all together and wrapping them round with straw, which is also tied with cord, bast, &c. The plants are then earthed up and left so for about three weeks, when the leaf-stalks will be in proper condition to be used. If left longer they will be in danger of rotting.

The Cardoon does not bear frost; therefore before winter the plants should be taken up and placed in a winter vegetable house.

USES.—Chiefly as a winter vegetable use is made of the blanched stalks of the inner leaves, and also the main root, which is thick, fleshy, tender, and of an agreeable flavour.

Echalotte.

ALLIUM ASCALONICUM (L.).

Fam., Liliacæ.

Synonyms: Chalotte; Ail stérile.

Foreign names: *English*, Shallot; *German*, Schalotte; *Flemish* and *Dutch*, Sjalot; *Danish*, Skalotteløg; *Spanish*, Chalote, Escaluña; *Portuguese*, Echalota.

Native country, Palestine. Perennial. Although botanically very nearly allied to the Onion, the Shallot differs from it completely in a horticultural point of view by its mode of growth. It seldom yields seed, but produces leaves in abundance, and the bulbs, when planted in spring, rapidly develop a great number of cloves or bulblets,

which remain attached to a common base, and in a few months become as strong as the parent bulb. It has been under cultivation from a very remote period, and there are several very distinct varieties now in existence.

CULTURE.—The Shallot is planted immediately after winter is over in good, rich, well-manured ground. Well-rotted farmyard manure suits it much better than that which is fresh and contains straw. It is still better, when possible, to plant in ground that was well manured in the previous year. The bulbs should be placed at no great depth in the soil and about 4 inches apart (if the common kind is planted). They may be put either in beds or rows. As soon as the leaves begin to wither (about July) the plants are pulled up and left to dry for a few days; then they are divided and the bulbs are stored in a dry place. Those plants which are to furnish bulbs for the next season's planting may be left in the ground for some little time longer.

USES.—The bulbs which will keep all the year round are used for seasoning. The leaves, cut when green, are also used for the same purpose. After this follow descriptions and illustrations of varieties.

Purslane.

PORTULACA OLERACEA (L.).

Nat. Family, Portulacææ.

Foreign names: *French*, Pourpier; *German*, Portutak, Kreusel; *Flemish* and *Dutch*, Postelein, Postelijn, Porcelain; *Danish*, Portutak; *Italian*, Porcellana; *Spanish*, Verdolaga; *Portuguese*, Bel-droega.

Native country, India. Annual. The Purslane, which is undoubtedly of Indian origin, has become naturalised with us to the extent of becoming a weed. It has a thick, fleshy stem, sprawling on the ground when the plant is isolated, but simple and erect when grown thickly, with thick, shortly spoon-shaped leaves, in the axils of which are produced very small yellow flowers, succeeded by roundish, slightly compressed seed vessels filled with small, black, shining seeds. There are about 2500 seeds in a gramme, and the litre contains on an average 610 grammes. Their germinating power continues for at least seven years.

CULTURE.—Purslane is sown in drills or broadcast in light soil from May to August. The stems and leaves may be gathered about two months after sowing, and the same plants may be cut two

Golden Purslane.

or three times in succession, provided they are well watered.

* "Les plantes potagères: Description et culture de principales légumes des climats tempérés," par Vilnorcia-Andrieux et Cie, marchands grainiers, Quai de la Mégisserie, 4, à Paris. 1883.

Purslane is often sown under frames or on a hot-bed in order to obtain a supply during winter or spring. The seed is sown from December to March on hotbeds, as the plant requires a pretty high temperature to enable it to grow vigorously. It may be cut eight or ten weeks after sowing.

USES.—The leaves are eaten boiled, and are also used raw in salads.

White Dutch or Case-knife Kidney Bean.

Foreign names: *French*, Haricot Sabre à Rames, Haricot Sabre à grande cosse; *German*, Weisse-Schwert-Bohne, Schlacht-Schwert-Bohne.

A very vigorous growing variety, attaining a height of 9 feet or more; stems green and thick; leaves very large, of a deep green, crimped; flowers large, white, passing into Nankeen yellow, and forming long bunches. Pods straight, sometimes undulating on the sides, 10 inches to 12 inches long, and containing eight or nine Beans each, numerous, produced in succession for a long time, especially when the first are gathered green. Beans white, shining, kidney-shaped, very like those of the Haricot de Soissons, but more regular in shape and one-third less in size, seldom exceeding three-fifths of an inch in length. The litre weighs 715 grammes, and 100 grammes contain 245 Beans. They ripen very slowly. The young pods may be used as green Haricots. The Bean, when used fresh from the pod, is one of the best; it is also very good when dried. This is certainly one of the best varieties. The only objection to it is that it requires very long stakes when growing. The Germans cultivate a great number of sub-varieties of it, characterised chiefly by having broader and straighter pods, but, notwithstanding numerous trials, we have never found

White Dutch, or Case-knife Kidney Bean.

any to surpass or even to equal the variety here described. It is the most tender and also the most productive.

Dwarf yellow Canadian Kidney Bean.

Foreign names: *French*, Haricot Jaune du Canada; *German*, Canada Zucker-Bohne.

A very good variety, hardy and productive, but somewhat late, and well adapted for market-garden culture in the open ground. Stems rather vigorous, branching, 16 inches to 20 inches high, thickly covered with medium-sized flat leaves of a clear green colour. Flowers lilac, pods very numerous, green at first, changing to yellow, containing usually five ovoid Beans a little smaller than those of the Haricot de Prague, and of a deep yellow colour passing into brown about the hilum. The litre weighs 815 grammes, and 100 grammes contain about 260 Beans.

The dried Beans are much esteemed. The pods to be tender should be gathered before they are fully grown.

Closely resembling the yellow China Kidney Bean, this variety is distinguished from it by the deeper colour of the Beans, and by its leaves being larger, less crowded together, moderately crimped, and of a deeper green colour.

Spinach.

SPINACIA OLERACEA (L.).

Nat. Family, Chenopodiaceae.

Foreign names: *French*, Epinard; *German*, Spinat; *Flemish and Dutch*, Spinazie; *Danish*, Spinat; *Italian*, Spinaccio; *Spanish*, Espinaca; *Portuguese*, Espinafre.

A plant of rapid growth, with leaves which, in the wild state, are arrow-shaped and pointed, but are much larger and rounder when cultivated, when they are also remarkable for the thickness of their parenchyma, and are almost entirely deprived of their flavour, while preserving their green colour to a marked degree after cooking. The leaves form a rosette, in the centre of which appears, sooner or later, according to the variety, the flower-stem, which in some plants bears only male, and in others only female flowers, the plant being dioecious. The seeds are very variable, those of some varieties being furnished with three very sharp points, while those of other varieties are rounded in shape and without points.

CULTURE.—Spinach is best sown in drills 10 inches or 12 inches apart. In order to have a constant supply, successional sowings should be made every fortnight, or at least every month, especially during spring and summer, when it runs freely to seed. Copious and frequent waterings are neces-

Monster Spinach of Viroflay.—This variety, which is of recent introduction, resembles the Flanders Spinach in the shape of its leaves

Dwarf Yellow Canadian Kidney Bean.

and its manner of growth, but its dimensions are much greater, for it is not unusual to see plants of it which are 2 feet and more in diameter, with leaves measuring 10 inches in length and 8 inches wide at the base. Like all varieties which exhibit extraordinary vigour of growth, this requires an abundant supply of nutriment, and is especially suitable for gardens that are well manured and well kept. W. M.

INDOOR GARDEN.

STEAM HEATING.

IN "Notes from America" a writer says: "Steam heating will give more satisfaction uniformly than hot water or any other form of heating. The price for steam heating is about one-third less than hot water, and it gives us good or better satisfaction"—statements which surely require some explanation. Steam heating was for a time, I believe, considered to be an advance upon the old smoke flue, but it was soon found to be hardly even that, and to say now that it is an improvement upon hot-water heating, and one-third less expensive, is misleading. On the contrary, I am inclined to think it more expensive than hot water, and altogether an unsatisfactory method of heating horticultural or other structures. Few of

Monster Spinach of Viroflay.

sary to ensure an abundant and good crop. The Parisian market gardeners have for a long time given the preference to the pointed-seeded varieties for spring sowing, reserving the round-seeded kinds for the end of summer and for autumn. We have at present some round-seeded varieties which are quite as hardy and as slow to run to seed as any of the pointed-seeded kinds.

USES.—The leaves are eaten boiled.

the readers of THE GARDEN have had experience in this matter, or I doubt not they would readily confirm this statement. I am old enough to remember the time when nearly all the plant houses in the Royal Botanic Gardens, Edinburgh, were heated by steam, and the office of stoker there at that time was a long way from being a sinecure, particularly during severe weather. Steam, of course, is not generated till water boils,

and to keep the pot constantly boiling requires unremitting attention, more particularly when, as in this case, the pot was about the size of a small sitting room, and consumed more than a ton of coals in twenty-four hours, not to mention the constant attention required in turning off and on the steam in the various structures, so as to regulate the various temperatures required. Indeed, I think anyone who may have had experience in the warming of plant houses or structures of any kind by steam will hesitate before recommending that system in preference to hot water. P. G.

LACHENALIA STOLONIFERA.

"B." asks (p. 142) "Does any reader of THE GARDEN know anything of *Lachenalia stolonifera*?" I have grown it for many years and, like him, have never been able to bloom it. I have also distributed it to several persons (I think Messrs. Henderson had it from me) who, as far as I can ascertain, have been equally unsuccessful with it. I had another variety, quite as stubborn, called *nitida*, which I believe to be only the same as *stolonifera*. The tubers are quite unlike those of any other *Lachenalia* with which I am acquainted. Another, called *contaminata*, has beaten me, but it is growing very strongly, and I am not without hopes of seeing a bloom twelve months hence. Is there no one, like Mr. Baker, who will take up and investigate the genus? Loudon enumerates upwards of forty species and varieties, but one of the best, *aurea*, is not in his list, though I think it must have been introduced before the publication of the *Hortus Britannicus*. I have raised many hybrids which, owing to a change of residence, were placed in the charge of the late Mr. Nelson. Early in last year he sent me a few blooms, but though he thought highly of one or two of them, they have hardly equalled his own seedlings. At present my hybrids are in the kind charge of Dr. Foster, who also has sent me blooms this winter, but they all run upon the lines of quadricolor. I have bloomed the following successfully, viz., *aurea*, *fragrans*, *luteola*, *pendula*, *pustulata*, *quadricolor*, *reflexa*, *tricolor*, *versicolor*, *violacea*, *viridis*. If *reflexa* was a species, and not a mere variety (Loudon does not give it), I think it quite equals *aurea* in beauty. I regret to say I have lost it, and the others are mostly dispersed. *L. unifolia* is, I believe very fine, and I hope to flower it next year. Can anyone tell me of a variety I have called *gigantea*? Will "B." kindly say what species he has, and which he has been able to bloom? A. RAWSON.

Widdermere.

STANDARD FUCHSIAS.

IN the revival of what may be termed the natural in gardens, the tall single-stem, and other more or less artificial styles of training, as applied to flowering plants, appear to be gradually falling into disuse. Most notably, perhaps, is this so in the case of the Rose. Plants, however, naturally of a pendulous character are never, I think, in elegant grown in the tree or standard form, and amongst such may be classed the *Fuchsia*. Fragrant-flowered subjects, too, such as *Mignonne*, *Heiotrope*, *Cytisus*, &c., are, when plants are arranged in pots on the floor level of high conservatories, far more enjoyable, as well as more lasting, when grown in this manner. Doubtless the maximum amount of utility and beauty of which the *Fuchsia* is susceptible may be best obtained by planting it out, and training it in single rods along the bars or rafters of plant houses, spur-pruning close in annually, vine fashion, while as a pot plant the most beautiful form it can be made to assume is certainly the not-too-formal pyramid. Still, standards have their uses, and well grown with handsome heads on stems varying in height they are especially suitable for the embellishment of lofty conservatories. These structures are often a source of much vexation when attached to large mansions, inasmuch as there must nearly always be a dark side. In their erection architectural harmony is of course, and properly so, the first consideration, but the

result is a house ill-adapted for the healthy growth of anything except Ferns, Palms, or Camellias. Place well-grown plants of any of the usual decorative subjects in it, and they quickly deteriorate. Perhaps the most satisfactory method of dealing with such houses is to employ for the shaded part plants of a dwarf evergreen character, chiefly Ferns, that will maintain a permanent undergrowth, as it were, so as to hide the pots, and among which flowering plants can be grouped or interspersed at all seasons. Here standard *Fuchsias* might be introduced with the best effect, their graceful drooping heads of bloom, rising above the surrounding foliage, at once attracting attention. As regards culture, if kept growing during the summer in a genial temperature, and shifted into larger pots as required, all the stronger growing sorts may be in two seasons made into handsome specimens. In the formation of standards it is only necessary to allow the leading shoot to grow without stopping until the desired height for the stem is reached, pinching off all the side growths as they appear, and leaving five or six at the top to form the nucleus of the future head. The shoots thus left must also be pinched above each pair of leaves until a sufficient number has been obtained to form a symmetrical head. The same plants may be grown many years in succession by cutting the old wood well back, and shaking out and repotting in the same sized pot each spring. Old dwarf plants also having straight stems may be easily in one season converted into very good standards by trimming up the stems; when they break, train up the strongest upright shoot, and remove all others. It is important that the supporting stake be strong and sound at the bottom, as should that give way, the weight of the falling head will instantly snap the stem. A. MOORE.

Cranmore.

Combretum purpureum.—Although this has never been a popular plant, it used to be grown in some gardens both as a climber planted out and in pots. It is very suitable for covering a small space under the roof of a stove, where its large, leathery leaves, of a bright shining green, set off to advantage its large panicles of deep crimson flowers. The latter, if not brilliant, are at least quite distinct from those of any other plant with which it may be associated, and I remember the time when they used to be worn in the hair, and for other choice purposes of decoration where light and elegant hits of colouring were required. Grown as a specimen in a 12-inch or 15-inch pot, it produces a fine effect, its leafage being abundant and not difficult to maintain in a healthy condition. It is not an easy plant to propagate, but cuttings made of the half-ripened summer shoots will emit roots in eight or ten weeks if subjected to a regular bottom heat and otherwise skilfully managed; the most suitable compost for it consists of three parts peat and one part fibrous loam, with plenty of sand mixed with it. When grown in pots it is important to thoroughly drain them and to pot rather firmly. Like most other hard-wooded plants, it should have a season of rest and a reduction in the way of water applied to the roots, the best time to rest it being from November to the end of January. It is not a very suitable plant for a wire frame; on the contrary, it shows itself off to the best advantage when not too stiffly trained on a few sticks.—J. C. C.

SHORT NOTES.—INDOOR GARDEN.

Cyclamens (*H. J. Elsley*).—Fine blooms of what is known as the *giganteum* strain. The light-coloured sorts are the best.

Bulbs (*J. A.*).—Gloxinias and Cyclamens ought certainly not to be exhibited as bulbous plants. Strictly, their roots are not bulbs, but corms or thickened stem bases.

Chinese Primulas (*J. Dawe*).—The blossoms you send represent very fine varieties, particularly the deep crimson, white, and pink. If as free as regards flower and as sturdy in growth as you state they are well worth perpetuating.

ORCHIDS.

Cattleya Trianae alba.—Mr. M-Leod writes to say that in Mr. Smith's Orchid collection at Brentham Park, Stirling, there is a specimen of this lovely variety with fourteen blossoms expanded—a truly beautiful sight. A flower sent shows that Mr. Smith possesses the true kind, not one of the numerous spurious imitations that pass under the name of the white *C. Trianae*.

Phalænopsis grandiflora aurea is a strikingly handsome and distinct variety of one of the finest of all *Phalænopsis*s. The flowers are larger than ordinary, the petals broader and more rounded, while its particular feature is the large blotch of rich yellow on both of the side wings of the labellum, and which replaces the pinkish tinge usually seen there. This scarce Orchid was the chief attraction of the *Phalænopsis* house at Messrs. Veitch's nursery, Chelsea, a few days ago.

White Dendrobium heterocarpum.—From Mr. Vanner's collection, Camden Wood, Chislehurst, comes a flower of this rarity among *Dendrobes*. It is quite distinct from the type, inasmuch as the sepals and petals are pure white, but the labellum is greenish yellow. This is another and valuable addition to the white-flowered varieties of *Dendrobium*. Mr. Vanner states that it was bought from Messrs. Low, Clapton, who have never seen another white flowered form among all the thousands of this *Dendrobe* they have imported.

Odontoglossum crispum.—There seems to be no end of the varieties of this Orchid, and some of exceptional beauty continually crop up. A variety received from the New Plant and Bulb Company, Colchester, is a very charming one of the stamp that wins so many admirers. It is remarkable for the heavy, irregular blotches of chestnut brown on the white ground of the petals, sepals, and labellum. Mr. Horsman informs us that it was selected from a large importation the company received some time since, and it is expected that all will turn out as fine as the variety sent.

Phalænopsis tetraspis.—Though this comparatively new species cannot compare in beauty with others of the same genus now in flower, it is nevertheless a pretty Orchid. It belongs to the *Luddemanniana* section, and possesses the free flowering character of that species. The flowers, about 2 inches across, have wax-white sepals and petals, a horizontally poised lip crested with a tuft of white down. It has a peculiar odour, not so pleasant as that possessed by many others. It seems to be grown well by Mr. Vanner, who sends us flowers.

Cattleya Trianae.—A flower of a glorious variety of *Trianae* *Cattleya* reaches us from Mr. Vanner's rich Orchid collection at Camden Wood, Chislehurst. It is the nearest approach to the superb and rare *Russelliana* variety that we have seen. The two petals are each over 2½ inches across, and, like the narrower sepals, are suffused with a delicate shade of lilac; the labellum constitutes its chief beauty. The lower half is of a glowing purple-magenta, beyond which is a bright blotch of yellow, while the throat is almost white. This is another instance of the extremely beautiful varieties that repeatedly crop up, and those who can obtain such from among imported plants are fortunate.

Orchids in flower at the Pine-apple Nursery, Maida Vale, include *Lælia harpophylla* and its near, but less showy congener, *L. cinnabarina*, besides numerous forms of the pretty *L. albida* and *L. pumila*. Among *Oncidiums* are *O. Rogersi*, a fine variety of *O. varicosum*, *O. pubes*, and the neat little *O. cheiroporum*, which is nearly always in flower. Of *Dendrobes* there is a large number in bloom, and among them the handsome *D. lituiflorum*, *primulinum*, and *Wardianum* in variety. *Cattleya Trianae* may be seen in its numerous forms, likewise many kinds of *Odontoglossum*, particularly *O. Rossi majus* and the rarely seen *O. constrictum*. *Trichopilia fragrans*,

with its long drooping spikes of large pure white blossoms, quite scents the whole house with its delicious perfume, which is something like vanilla, and another strongly perfumed kind is *Saccolabium giganteum*, also fine here. *Cypripediums* include among others the scarce *C. conchiferum*, one of the *Selenipedum* section, with long twisted attenuated sepaline appendages. The list of botanical curiosities includes *Epidendrum verrucosum*, a very sweet scented species, and *E. purum*, graceful in growth and in bloom.

Odontoglossum Oerstedii.—A specimen of this pretty little species from Mr. Vanner shows well what a gem it is. The flower is not much bigger than a single bloom of *O. pulchellum* majus, to which it bears a resemblance at first sight. They are borne singly on slender stalks some 3 inches long, springing from the base of the tiny bulbs. The flower is nearly an inch across, and the sepals and petals are white, but the broad labellum is whiter, and as a set off the crest surmounting the lip is spotted with orange-yellow. There is a good deal of this *Odontoglossum* in cultivation, but nobody seems to be very successful with it, for one seldom sees more than three or four flowers open at a time even on big masses. Being a native of Costa Rica, it probably requires more heat than the majority of *Odontoglossums* grown in a cool house.

Angracum sesquipedale.—I send you a spike of this Orchid with five fully expanded flowers. The plant from which the specimen sent was cut bore three flower-spikes, two of which had five fully expanded blooms; the other spike had four blooms, one of which was injured when in a small state; consequently it has only three perfect blooms—in all thirteen blooms on the three spikes. Some of the blooms on the spike sent have been fully open for about three weeks.—**DAVID KEMP, Dunlop Gardens, Ayrshire.** [The spike Mr. Kemp sent was a grand one and represented the largest flowered form of this remarkable Madagascar Orchid, having unusually broad sepals and long spurs. It would be instructive to learn the details of our correspondent's line of treatment with respect to this plant.]

A new *Spathoglottis* named *pacifica* is now in flower in Mr. Bull's nursery, Chelsea, having been introduced from the South Sea Islands. It is a pretty plant of elegant growth, having the habit of *Betia hyacinthina*. The globular bulbs produce long plicate leaves contemporary with the flowers. The blossoms are borne on the upper part of a spike about 2 feet high, about a dozen on a spike. They are about the size of *Calanthe masuca*. The oval petals and sepals are white washed with lilac; the labellum, which is in form like that of its congener, *S. Lobbi*, is also white, blotched with yellow and reddish brown. The flowers have a delicate perfume. It is quite a distinct plant and one that specialists will welcome. It appears to be terrestrial in habit.

The Gunnersbury Phalænopsids.—The fine collection of *Phalænopsis Schilleriana* is again the chief attraction of Baroness Rothschild's garden at Gunnersbury House, Acton. Nowhere in the neighbourhood of London can this lovely Orchid be seen in such perfection as here, a condition which has taken years of skilful culture to attain. The plants, about a score in number, are all finely developed specimens with leaves a foot or more in length and spotless. Each of the plants is carrying one or more flower-spikes, some of which are widely branched, and carry some three or four dozen flowers. It is a beautiful sight to see these plants in hanging baskets in one line, throwing out their elegant long spikes crowded with flowers like beautiful butterflies. The effect is enhanced by the delightful carpet of foliage on the shelf beneath them and the other fine-leaved plants in the house. We have watched the progress of these plants for some eight or nine years, and each year they improve in size and gain in strength, quite contrary to what one usually sees in Orchid collections. They are grown in a warm, moist

house with East Indian Orchids, and are hung in a row close under the roof along the front of the house, and immediately above the rows of hot-water pipes, though a shelf intervenes. All are grown in baskets, and the way the roots protrude and fasten themselves on the surface of the wood, and insinuate themselves into every crevice, is a good sign that the plants are thoroughly at home. Mr. Roberts drew our attention to a singular monstrosity in this Orchid. It was the fusion of two flowers laterally, but so complete was the cohesion that they appeared to be one. There were two lips and ten segments, all symmetrically arranged.

Calanthe Stevensiana is the name given to a new Orchid recently introduced by M. Regnier from Cochín China. It is apparently intermediate between *C. vestita* and *C. Turneri*. The bulbs are flask-shaped and necked as in *C. Veitchii*, and produce from their bases flower-stems from 1½ feet to 2 feet high. The flowers, about 1½ inches across, have white sepals and petals, a trilobed lip of a pale lilac, deepened towards the centre. It is a companion plant to *C. Regnieri*, and with it was exhibited at South Kensington on Tuesday last. *C. Stevensiana* was named in compliment to Mr. Stevens, the well-known plant auctioneer.

Dendrobium crassinode album may be seen in bloom in the Royal Exotic Nursery, Chelsea. It in no way differs from the original except that the petals have lost the characteristic blotch of purple at the tips, but the large spot of yellow on the labellum still remains.

Among flowering Orchids at Mr. Bull's which make a long list are the following uncommon kinds: *Odontoglossum Coradinei*, *O. Wilckeanum pallens*, *O. Halli leucoglossum*, *O. blandum*, *O. anceps*, *Pleurothallis scaphylla*, a very singular species with long attenuated sepals. *Masdevallia Shuttleworthii*, and a splendid variety of *M. ignea*, the finest we have yet seen in point of size and colour of flower. *Phalænopsis Stuartiana*, *Aerides Leeanaum*, *Laelia anceps Hillii*, *L. alba* in various forms, and numerous varieties of *Cattleya Trianae*, including a pretty one called *nivea*, which is almost as pure as *alba*. *Angracum sesquipedale*, represented by flowering plants only about 6 inches high, is remarkably fine, as is also a large gathering of *Odontoglossum Rossi majus* in numerous varieties. Among less attractive species are *D. Ruckerianum*, and *D. brisbanense*, and *D. amulum*, the last a very sweet-scented plant.

Varieties of Cattleya Trianae.—Some flowers of this beautiful Orchid sent us by Mr. Fowler, Ash Grove, Pontypool, show well its variations. One is similar if not identical with that form known as *Backhousiana*, for it has broad lilac-tinted petals heavily blotched with rich carmine, which renders them very beautiful. The labellum, too, of this variety is very splendidly marked, being an intense velvety magenta. Another form seems to be the same as that called *Warszewiczii* delicata, the sepals and petals and lip being suffused with a delicate lilac-purple. A third variety is deeper than the last in colour and much larger, and altogether an exceptionally handsome flower; while a fourth is remarkable for the splendid colour of the lowermost part of the labellum in contrast with the delicate soft hue of the sepals and petals. All these varieties, Mr. Fowler informs us, have cropped up from an imported batch of plants.

Flowers of Dendrobiums from Mr. Peacock's extensive Orchid collection at Sudbury House, Hammersmith, include the following beautiful kinds—*D. crassinode Barberianum*, remarkable for the colour which tips the sepals, petals, and lip, being several shades deeper than that of the ordinary form, hence much more attractive; *D. Ainsworthii*, the lovely hybrid between *D. heterocarpum* and *D. nobile*, flowers of which were also sent. Of the well-known *D. nobile* there is sent one of the richest varieties we have yet seen, the colour being a deep purple, and extending all over the sepals and petals, while the blotch on the labellum is almost black. When this favourite Dendrobe is seen in such a fine

variety as this it is scarcely equalled by any other cultivated Dendrobe. Among other blooms sent are *Odontoglossum hebraicum*, the beautiful kind figured in *THE GARDEN*, Vol. XXI., p. 386, and *O. crispum flaveolum*, distinguished by the soft primrose-yellow that suffuses the whole flower, rendering it very charming.—W. G.

SOCIETIES.

ROYAL HORTICULTURAL. FEBRUARY 13.

THERE was a goodly number of exhibits on this occasion, and the council room presented quite a gay appearance, groups of *Cyclamens*, *Cinerarias*, *Primulas*, *Amaryllises*, and greenhouse *Rhododendrons* being abundant.

First-class certificates were awarded to

CALANTHE REGNIERI, a new species recently introduced from Cochín China. It has the habit of growth of *C. vestita*, but it has necked bulbs, and the flowers are quite different in shape from those of that species. They are about 2 inches across, borne in a rather crowded spike on the upper part of stems from 1½ feet to 2 feet high. The reflexed sepals and petals are white with a medial line of carmine-rose. The lip, which projects horizontally, is tri-lobed, of a deep rose stained with a richer and deeper colour in the centre. From Messrs. Veitch.

ODONTOGLOSSUM SCOTTI, an extremely handsome variety of *O. crispum* and one of the finest forms yet exhibited. The flowers measure 3½ in., the petals are much jagged at the margins, and these with the sepals are of a soft creamy yellow marked with irregular blotches of chestnut brown. The lip is intermediate between that of *O. crispum* and *O. Halli*, being surmounted with a prominent crest. Shown by Mr. G. F. Wilson, Heatherbank, Weybridge, with whom the variety originated among imported plants.

AMARYLLIS ACHILLES, a grand variety, having flowers fully 8½ inches in diameter. The three outer sepals are each 2½ inches across, and their colour is a glowing deep scarlet, shaded with lighter and deeper tints. Though so large, the flower is not of such a handsome and refined form as that of the following:—

AMARYLLIS ACIS.—The flowers of this variety measure 6 inches at their widest diameter, and the petals being very broad, and all, except the lowermost, of equal size, make quite an ideal flower. The colour is a deep scarlet inclined to crimson, and conspicuously tipped with greenish white. This partakes of the *Leopoldi* type in a marked degree, and is as fine a variety of this section we have seen. Both from Messrs. Veitch.

ODONTOGLOSSUM CRISPUM AUREUM MAGNIFICUM.—A splendid variety, apparently midway between *O. crispum* and *O. Andersonianum*. The spikes are stout and erect, slightly branched at the base. The flowers are 3 inches across, the sepals and petals are white, edged with lemon-yellow, and blotched with cinnamon-red; the lip is also of the same colour. Each of the three spikes bore thirteen flowers, and, being closely set on the stem, produced a fine effect. Shown by Mr. C. Dorman, Laurie Park, Sydenham.

PHALÆNOPSIS LEUCORRHODA ALBA, a variety differing in no way from the original except that the flowers are pure white with copious spotting on the side wings of the lip and the lowermost sepals. It may be best described as having the foliage of *P. Schilleriana* and the flowers of *P. amabilis*. Messrs. Low, Clapton.

RHODODENDRON PRINCESS CHRISTIAN.—A greenhouse variety of the Javanese section. Its truss contains about a dozen blossoms, each over 2 inches across, with broad overlapping petals, and of a charming rosy pink colour, the most delicate tint we have yet seen among these varieties. A seedling raised and exhibited by Messrs. Veitch.

RHODODENDRON BARONESS SCHREDER.—Also one of the Javanese section, with flowers 2½ inches

across, of a uniform warm orange tint, harmonising pleasingly with the red stamens and glossy green foliage. Shown by the raisers, Messrs. Veitch.

CINERARIA VICTORY, a variety with flowers fully 2½ inches in diameter, having broad overlapping florets of a deep velvety magenta. The plants shown by Messrs. Cannell, Swanley, bore huge broad heads of bloom slightly overtopping the masses of healthy green foliage. It is undoubtedly one of the finest varieties yet raised.

A group of seedling Amaryllises and Rhododendrons was shown by Messrs. Veitch, besides a fine group of Persian Cyclamen, numbering some eighty plants. Among the Amaryllises the following were remarkably fine: Pallas, very large, deep crimson, flaked with white; Fulgens, vivid scarlet, large flower, finely formed; Themis, with funnel-shaped flowers of a deep crimson; Argus, rather small flowers, but of fine form and of a glowing scarlet; Hera, large and of an intensely deep crimson; Ajax, with large flowers, poised, almost erect, deep blood-red, flaked with white; Leander, flowers large and showy, bright crimson; Lavinia, funnel-shaped flowers, scarlet, striped with white; and Orsino, flowers small, profusely spotted with crimson. A large silver medal was awarded for this group.

A similar award was voted to Mr. B. S. Williams for a large collection of his improved strain of Cyclamen persicum; also for Primulas rubro-violacea, Chiswick Red, Alba magnifica, and rubra, all superb varieties of the Chinese Primula. Mr. Williams also showed a plant with three flowers of *Cattleya labiata* Percivaliana, which, however, represented the variety in a poor form.

A silver medal was awarded to Messrs. Cannell, Swanley, for large groups of double Primulas and Cinerarias. Among the former those named *Atro rosea pleno*, purple-rose; *Earl of Beaconsfield*, deep rose-pink; *Alba plena* and *Alba plena fimbriata*, both pure white, were all extremely fine, and represented by large well-grown specimens profusely flowered. Cut blooms of such beautiful varieties as *Marchioness of Exeter*, *Annie Hillier*, *Emperor*, *Princess of Wales*, *King of Purples*, showed admirably how well double Primulas are grown at Swanley. The bulk of the group of Cinerarias was composed of the fine new variety called *Victory*, which was certificated, and one called *Marched Past*, a splendid sort with flowers 2½ inches across, of a rich velvety maroon with white central ring.

Messrs. Carter received a vote of thanks for a fine group of Primulas, which included most of the fine sorts enumerated at the last meeting. Among new forms the most remarkable were *Holborn White*, a superb variety, with flowers 2½ inches across, and not with Fern-like foliage, as in *White Queen*. *Holborn Ruby*, *Holborn Pearl*, and *Holborn Crimson* were among other other splendid sorts; likewise *Holborn Blue*, a decided bluer form of *Holborn Gem*, and bids fair to develop eventually in the much-to-be-desired true blue Primula. A charming panful of *Scilla sibirica* and the peculiar golden foliage of *Primula Gold Leaf* increased the effect of this group.

Orchids were numerous shown. A fine imported mass of *Cattleya Trianae* bearing several flowers was shown by Mr. Philbrick's gardener (Mr. Heims) from Oldfield, Bickley, as well as cut blooms of the same *Cattleya*, and a fine spotted variety of *Odontoglossum crispum*. Mr. Vanner, Camden Wood, Chislehurst, sent a plant of *Dendrobium heterocarpum album*, alluded to elsewhere. Messrs. J. Peed, Roupell Park Nurseries, exhibited a plant of *D. Wardianum grandiflorum* having flowers over 4 inches across. A cultural commendation was voted to Mr. P. Crowley, Waddon House, Croydon, for a plant of *Cœlogyne cristata* fully a yard through and a mass of white flowers. Messrs. Hugh Low & Co., Clapton, sent a fine panful of the pretty little *Angræcum citratum*, with long elegant racemes of white flowers; also a plant of *Calanthe Cecilia*, from the Malay Archipelago, has broad foliage like *C. veratrifolia*, and small mauve tinted flowers with a long projecting spur. Mr. James, Castle Nursery, Norwood, showed a

plant of *Cattleya Trianae* called *grandis*. It is remarkable for the intensely rich colour of the labellum. Besides the plant certificated, Mr. G. F. Wilson showed a variety of *Odontoglossum crispum*, having large flowers with broad petals delicately suffused with purple. The spike bore fifteen flowers, an evidence of good culture. Lieut.-Col. Berkeley exhibited a flowering specimen of the new *Phalaenopsis speciosa*. It is a pretty plant and may be best described as a high coloured variety of *P. Luddemanniana*.

A cultural commendation was accorded to Mr. Lyon, gardener to Sir E. H. Scott, Bart., Sundridge Park, Bromley, for four large and very fine basketfuls of forced plants, consisting of Hyacinths, double Tulips, Lilac, Jonquil Narcissus, and *Staphylea colchica*, the pretty shrub alluded to last week. These contributed in no small degree to the attractiveness of the meeting.

Hybrid Azaleas were shown by Mr. Todman, Bushey Down, Tooting Common. That named *Miss Nellie Connell* is a very free flowering sort, with rosy magenta flowers of medium size. Mrs. John Connell is a good free flowering white, and Duke of Albany is in the way of the old *A. obtusa*, but with larger flowers.

Mr. R. Dean, Ealing, showed a panful of the white-flowered *Myosotis dissitiflora*, which will be a valuable addition to spring flowering plants. It differs in no way from the original, except in the colour, which is pure white. Among Primroses shown by Mr. Dean were two called *Jeannette* and *Jeannot*, the former with flowers 1½ inches across, of a purple-plum colour, barred with white, the latter a deep crimson, also barred with white. Cut blooms of *Abutilons*, shown by the raiser, Mr. George, Putney Heath, included some very fine varieties with quite new colours. A large group of double Primulas from the Society's gardens at Chiswick showed well how finely these plants are grown there.

Fruit.—The most important exhibit was that from Messrs. Rivers, Sawbridgeworth, which comprised about a hundred dishes of Apples in an excellent state of preservation, and representing most of the leading sorts, such as *Rymer*, *Stirling Castle*, *Mère de Menage*, *Braddick's Nonpareil*, *Lord Burghley*, *Betty Geeson*, *Tower of Glamis*, *Manks Codlin*, *Annie Elizabeth*, *Nelson Codlin*, and *King of the Pippins*. The same firm also showed a collection of Oranges, which, with the Apples, was awarded a bronze medal. Mr. Ford, Leonardslee, Horsham, sent fruits of *Pear Josephine de Malines*, and gathered from an east wall, and now in use. The same exhibitor also showed fruits of the *Seckle* and *Passe Colmar* *Pear*, both in good condition. Mr. Horley, Tooting, Dunstable, sent two seedling Apples, as did also Mr. Chester, Conington Castle, all of which were passed over by the committee. A second class certificate was awarded to Mr. Mann, Dunton Hall, Grantham, for *Apple Grantonian*, a large handsome culinary sort of good flavour.

Committees.—The members present were: **Floral**—Mr. G. F. Wilson (chairman), Rev. G. Henslow, Messrs. H. Bennett, J. M'Intosh, J. Laing, W. Bealby, J. Fraser, H. Ballantine, G. Duffield, J. Dominy, H. Ebbage, J. Wills, J. James, S. Hibberd, H. Cannell, H. Turner. **Fruit**—Mr. John Lee (chairman), Messrs. P. Crowley, F. Rutland, S. Lyon, J. Willard, W. Denning, J. E. Lane, G. Bunyard, C. Silverlock, A. W. Sutton, R. D. Blackmore, G. Goldsmith, H. J. Veitch, T. Laxton, and Sir C. W. Strickland.

Scientific committee.—Sir J. D. Hooker in the chair.

Melon grown under electric light.—It appears that the specimen sent to the last meeting was done so inadvertently, as no scientific data had been taken. Dr. Siemens, however, informed the scientific committee that he hopes to test the growth of Melons on a future occasion.

Self-registering thermometers.—Mr. Glaisher remarked on the necessity of observers stating whether minimum temperatures are taken on the soil at an elevation above it, and also whether they have been properly compared with a stan-

dard. With reference to the Hon. and Rev. Boscawen's observations, he remarked that his thermometer registered 10° less than that at Truro. This is probably due to the fact that the position is in a valley. Mr. Boscawen believes that the *Lapageria* mentioned at the last meeting was subjected to only 5° of frost, but that the *Camellias* endured from 16° to 18° of frost, which slightly injured them.

Graft of *Helianthus tuberosus* on *H. annuus*.—Dr. Masters exhibited a specimen from Mr. Laxton with which the attempt had been made, but the graft showed only a slight adhesion and had perished afterwards.

Hypertrophy in Nut and Cabbage.—The Rev. G. Henslow exhibited a sucker from a Nut bush with a mass of buds arising from one spot; also a Cabbage leaf with innumerable small foliaceous excrescences from the midrib.

Orobanche (sp.) on Beans.—A specimen was sent from Marsala, Sicily, where it appears to be very destructive.

Anniversary meeting: Annual Report.—The judgment of the Court of Appeal, which was communicated to the Fellows in a special circular, has necessitated arrangements for the present year which have compelled the Council to modify to some extent the privileges of the Fellows. The Council trust that the Fellows will consider the advantages which have been secured for them in respect of the Great International Fisheries Exhibition a fair compensation for privileges surrendered. The Council hope to be able to arrange for an evening fête, and possibly for other additions to the programme which has been circulated among the Fellows, and which they have endeavoured to make, from a horticultural point of view, worthy of the Society. The Great Show was marred by the absence of exhibits which the Council believe would have been shown but for its length (three days). The Council have in consequence determined to limit the Great Show this year to two days. The useful work of the Society at Chiswick has been continued with regularity, and the Council hope that it will prove of permanent benefit to horticulture. The Chiswick Gardens have been maintained in a high state of efficiency. A greater number of Fellows than formerly have visited them and have appeared to take great interest in the work of the Society.

The fruit committee have had under examination very large collections of Peas and Potatoes, and the season proving favourable, the trials were highly satisfactory. Shallots, Lettuces, and Tomatoes were likewise tested, but owing to the cold, it will be necessary to try them again during the present year. Five of the society's certificates were awarded to new Peas on account of their improved qualities, and three certificates to new varieties of Potatoes. Facilities were afforded to the committee of the International Potato Society for growing and comparatively testing all the new varieties of Potatoes submitted to them. The floral committee trials of the past season included *Achimenes*, *Tydeas*, other gesneraceous plants, *Begonias*, *Lantanas*, *Pelargoniums*, *Verbenas*, *Ceanothuses*, single and *Pompone Dahlias*, and many other miscellaneous plants. The Tea Roses planted two years ago have made satisfactory progress. The rockery and the collection of alpine and hardy herbaceous plants continue to interest visitors. The applications by Fellows for plants of this description are steadily increasing. The collection of Raspberries formed last season is very complete, and promises well. A new collection of all the known varieties of *Rhubarb* has also been formed, which will this season be examined and reported on. The collection of Figs planted out in the old orchard house as an experiment a few years ago did not prove a success. It is therefore intended to resume their cultivation in pots. It is proposed to plant in the old orchard house a selection of the newer American Grapes and other varieties likely to succeed without fire heat. The crops of out-door fruit, although below the average generally, were interesting and instructive, a small quarter of young Apple trees

on the French Paradise stock being laden with fine fruit. Strawberries were abundant and very fine, the Strawberry fête held in the garden being a complete success. The crop of Grapes in the conservatory was up to the average, and that in the other houses unusually good.

The chairman (Lord Aberdare), in moving the adoption of the report, said that the expenses of the lawsuit had been somewhat mitigated by an increase of £500 in miscellaneous receipts, but the society was still left £379 to the bad. The number of Fellows paying four guineas had fallen from 449 to 427, while that of Fellows paying two guineas had increased from 956 to 970. By the result of the suit the Royal Commissioners for the Exhibition of 1851 became entitled to the possession of the grounds, which they had let for the year to the commissioners of the International Fisheries Exhibition. He wished to say in the most emphatic manner that the commissioners of the International Fisheries Exhibition had shown the utmost courtesy, consideration, and liberality in their dealings with the Society. The Society would still have the enjoyment of those parts of the premises which were required for its shows and fortnightly meetings, and would be relieved of the cost of doorkeepers, but would take three-fourths of the receipts on the occasion of its own displays, although some of those who entered might be attracted by the Fisheries Exhibition. The Fellows would be admitted on every day, and the chief loss of the Society would be from the daily admissions, a source of revenue which had been unusually great last year (amounting to £444), owing to the fine weather on the bank holidays. While the Fisheries Commissioners had granted personal privileges to Fellows of the Society, the Society had been unable to secure for its ticket-holders the same rights which, while it was itself in legal possession of the buildings and gardens, it extended to them. Fellows would be admitted to the opening ceremony of the exhibition on payment of 5s., the charge to the general public being one guinea, which admitted also for the season. Mr. H. Guedalla seconded the adoption of the report, and invited the chairman to make certain further explanations. In response, Lord Aberdare said that by the arrangements to which he had referred the Society would retain their standing at Kensington this year; and, as to the future, committees had been named by the Royal Commissioners of the exhibition of 1851 and also by their own body to negotiate. It was not, however, likely that the deliberations would be pushed on very fast during the tenure of the Fisheries Exhibition. It had been said that they had maintained the litigation with the commissioners with too much pertinacity, but the fact that in the first Court in which the suit was tried the decision was given in favour of the Society showed that there was at least a substantial question to decide, and they had felt it their duty to the debenture holders to try the case, although at considerable cost, as the Fellows might see by the item "Law charges, £911 0s. 4d." in the current account. In fact, a distinguished authority, who was conversant with the case, had said to him, "What you did, you were bound to do." The financial position of the Society was not due to any of the present council. It was due to the unfortunate disputes at the time of the International Exhibition, which had cost the Society the loss of Fellows representing £4000. They had done their best for the debenture holders, who, apart from what he might call their compassionate claim, were only entitled, as against the Society, to interest after the expenses of maintenance of the Society's property had been paid. In some years the interest had been paid prior to such charges, and the Society had gone into debt for the purpose. He was glad to say that new Fellows continued to join in considerable numbers, and he looked forward with hope to the future.

The report was unanimously adopted, and the retiring officers were re-elected, vacancies in the council being filled by the election of Sir C. Strickland, Sir P. Cunliffe Owen, and Colonel Beadome.

MEALY BUG ON VINES.

THERE is perhaps no insect which infests plants that is more dreaded by cultivators than mealy bug, its eradication when once it gets established being exceedingly difficult. Fumigation with tobacco, so fatal to aphides, has no effect upon this pest, and its woolly covering protects it from liquid applications unless applied with such force as to drive it from its stronghold—no easy matter. The rapidity, too, with which it spreads over a collection of plants is truly wonderful. Grape Vines are not particularly liable to the attacks of this insect unless plants infested with it are brought in contact with them, and when this is done it is by no means an unusual occurrence for a house of Grapes to be in a very short time rendered worthless. Mealy bug never attacks plants growing in the open air in this country, and it does not often attack plants in the temperature of an ordinary greenhouse. In none of its stages can it resist the action of frost, so that as far as the Grape Vine is concerned, there is no better remedy than exposure to the temperature of an ordinary winter. As an example of this I have a distinct recollection of a large viney, on the back wall of which was trained a fine plant of *Stephanotis floribunda*, which had occupied the same position for many years. It, however, became at last infested with mealy bug, which soon began to show itself upon the Vines, more particularly when the fruit was beginning to colour, and although syringing with the view of keeping it in check was continued much longer than would otherwise have been deemed advisable, it nevertheless ruined a large number of the bunches. The *Stephanotis* therefore was reluctantly sacrificed, and as soon as the Vines were at rest they were carefully dressed with some approved composition, the ingredients forming which I cannot now recollect. The inside of the structure was also thoroughly cleaned and painted, and a perfect cure was for a time supposed to have been effected. In the following season, however, the Vines again gave unmistakable indications of the presence of this unwelcome visitant, and in spite of every effort in the way of sponging and syringing, many of the finest bunches of fruit were again rendered worthless. At the end of the season exposure was tried, and resulted in complete success. The Vines, as soon as the leaves were about to fall, were pruned. The front lights were opened and the rods were drawn out and arranged lengthways under their shelter. A temporary front was formed to the house, excluding of course the Vines, and the house was used for wintering bedding or other plants. Had the winter proved very severe it was intended to have slightly covered the Vines with dry litter. But as no very great depression of temperature occurred, this was not considered necessary. Early in the following month of March the Vines were again taken into the house, and not the slightest indication of the insect was ever perceived upon them afterwards. This shows that in the case of such plants as the Grape Vine, which may, when at rest, be subjected without injury to a very low temperature, mealy bug in any of its stages may be thus got rid of.

P. GRIEVE.

Cheap winter dressing for wall trees.

—What a number of "best" insecticides we gardeners are constantly being solicited to try; it really is becoming puzzling to know which to use to destroy or prevent the attacks of insects and yet leave the buds and leaves uninjured. Soap-suds have both these properties, and why they are not used more largely than they are one cannot understand, unless it be that they are cheap. That is, however, the very reason why we use them, more especially as a winter dressing for wall trees. We apply them with a syringe to trees and walls alike, repeating the dose twice or thrice in the course of the winter, and they are so effective that we are rarely troubled with insect pests. Currant and Gooseberry bushes are treated in like manner, and as a consequence Moss or Lichen on the stems is all but unknown with us. —W. W. H.

Simplex glazing.—"T. C. W." speaks highly of this system, especially with reference to the ease with which the work can be done, even by those who have no experience. This opinion I can fully confirm, and can further add that the appearance is very neat and good; the cost of maintenance and repair is reduced to a minimum, and the whole of the work can easily be done by local workmen or even by amateurs. "T. C. W.," however, brings forward what he believes to be two faults in the system, namely, that the sheet lead is affected by heat so as to curl up, thus allowing the wet to get underneath, causing drip in the house, and permitting the glass to slip, and also that the action of soft water on lead causes an unsightly stain or deposit on the glass. With regard to the first point, it is evident "T. C. W." has not seen the printed instructions to builders, &c., sent out by the manufacturers with each order, and which contain the following: "Before placing the glass into position, the angles which are to receive it must be coated with best white lead paint, mixed very thick, and applied with a small brush. Place the glass in position, turn down the lead flanges, dress down the lead so as to follow the surface and close up against the butt end of the glass. Wipe off the paint squeezed out, and the work is complete." This simple process causes the lead to adhere to the glass, and counteract the bad effects imagined by "T. C. W." Even without the paint, however, drip from the outside is rendered almost an impossibility if the rafters are made with grooves, as shown in the section drawing in your advertising columns. I know many houses built on this system which have stood all the changes of temperature of our English climate for several years, but I never heard of an instance of a pane slipping. As to the second point, whatever the chemical action of soft water on lead may be, I can only say I never noticed any unsightly deposit, and do not see why a greenhouse should suffer in this respect more than a church window, glazed on the old-fashioned lead principle, after being exposed to the weather for a century or so. I may add that I am in no way interested in the manufacture or sale of these houses, and only write in fairness to a system which I consider a decided step in the right direction.—A. L. S.

Primula (Ferneia).—A very beautiful variety as regards colour. It is similar to that called Chiswick Red, considered to be the finest of its colour.

Angræcum sesquipedale.—Among the Orchids now in flower in Lord Crewe's garden, at Crewe Hall, is a specimen of this *Angræcum* bearing eight fully developed flowers.

Hardiness of *Dracaena indivisa*.—A plant of this *Dracaena* has stood out of doors here for two winters unprotected without a leaf being hurt. It is planted in the bole of an old tree root, and its graceful and healthy appearance is admired by everyone who sees it. It does well in a compost consisting of two parts peat, one of loam, and a little sand and manure. The drainage should be good, and if grown indoors it should have a fair amount of pot room.—W. RAMSHAW.

Rose buds by post (p. 126).—Certainly Rose buds will "take" two days and even more after removal from the trees. As many as fifteen shoots, each bearing six buds, may be sent by sample post. They should be packed in humid moss, enveloped in air-proof paper, and finally protected by cardboard. We post buds to most countries of the Continent, and they always take well. Even a journey of a week does not prevent growth. On their arrival the shoots should be inserted in the soil and the buds taken off as wanted.—SOUPELT & NOTTING, Luxembourg.

Names of plants.—*D. P.*—1, *Eucalyptus*, probably *citriodora*; 2, *Schinus Moll.*—*Orchid.*—1, *Dendrobium fimbriatum*; 2, *D. litiflorum*; 3, *D. Ruckerianum*; 4, *D. crassinode* (good variety); 5, *Calanthe Veitchi*.—*A. B. S.*—1, *Maranta zebra*; 2, *M. fasciata*.—*Sub.*—*Polypodium vulgare cambricum*.

"This is an Art

Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

CATTLEYA LABIATA PERCIVALIANA.

IN reference to the above plant, and also in reference to what Mr. Crawshaw wrote in THE GARDEN, January 27, 1883 (p. 94), I have only to say that of all the flowers of *C. Percivaliana* I have yet seen, not one is in any way equal in beauty, or size, or colour to the worst form of *Cattleya Warneri* I ever saw. There are fifty varieties of *C. Mossiæ* superior to it in every way. *C. Percivaliana*, so far as I have seen and heard of it, has precisely the great fault of bad *Warneri* varieties—that is of making two growths in a year, and not seldom it fails to bloom from either of them. Both the red and the green-leaved forms of the true autumn or old *Cattleya labiata* bloom quite freely even from growths so weak that similar growths on *C. Mossiæ* or *C. Trianae* would never be expected to flower by the most sanguine of new beginners in Orchid culture. The one great characteristic of the true old autumn flowering *C. labiata* is that it grows vigorously under fair treatment, and blooms with more certainty than many others, I might say most others, of the *Cattleyas* now in cultivation. Mr. Crawshaw gives a good many measurements of *C. Percivaliana*, and a good deal of description not to the point, and which conveys no idea as to whether *C. Percivaliana* is better or worse than the "dark variety of the old *C. labiata*," of which he tells us he had two flowers in front of him when he wrote. He measures and praised *C. Percivaliana* (see GARDEN, p. 94), but had not the courage to tell us plainly which was the best *Cattleya* of the two, whether the true old *C. labiata* or the new *C. Percivaliana*. I have always doubted if *C. Percivaliana* was worthy of being added to the *C. labiata* section, even of the genus. Now that I have seen flowers I shall speak and write of it as a *C. Mossiæ*, and a very poor, little, crumpled-up, and disappointing *C. Mossiæ* it is! I say this much firmly and decidedly, although, of course, I am open to correction and even conviction; and, further, will publicly and frankly acknowledge that I am wrong if Mr. Sander, or Mr. Percival, or Mr. Crawshaw, or anyone else will convince me by fresh flowers. I distinctly refuse the evidence of a writer who acknowledges he had two flowers of "the true old *C. labiata*" before him and yet refrained from measuring and describing that variety also, as contrasted with *C. Percivaliana*, for the main point between Mr. Crawshaw and myself has ever been not as to sameness, but the main point superiority. As soon as my plants of *C. Percivaliana* came from the auction room, I at once knew they were not of the variety so many had supposed from the description for which Mr. Sander is responsible.

In the *Gardeners' Chronicle* for February 10, 1883, p. 178, Mr. Crawshaw will find an account of *Cattleya Percivaliana* which, I think, will take him some little trouble and time to reconcile with what he wrote in THE GARDEN, 1883, p. 94. The writer is Sir Trevor Lawrence, and this is his opinion of *C. Percivaliana* as therein expressed: "I consider this *Cattleya* to be a small var. of *C. Mossiæ*—possibly autumn flowering, but as to this it is too early to speak. It might fairly have been called *C. Mossiæ Percivaliana*. It is small in all its parts; the segments do not spread well, and the sepals are very poor and narrow. The lip is striped with yellow and brownish purple above, and ends in a patch of rosy purple below, of variable size and brightness. It is small and puckered up like an old woman's cap. On the whole, this *Cattleya* is decidedly inferior horticulturally to an ordinary *C. Mossiæ*. Like other *Cattleyas*, there are no doubt good and inferior varieties—I speak of those which have flowered out of the numerous plants I myself bought."

It is quite time a stern protest be made against auction sale advertisements, which—I do not say are intended and drawn up with any evil intent—are misleading. It is perhaps thought that so soon as a sale of plants is over the advertisements of it are forgotten, but this is not so. I have taken the trouble of saving a few of these specimens of trade literature now and then for the sake of comparing them with the plants sold when they bloom. One may thus compare romance with reality—imagination is tested by bare facts. Such announcements harm all concerned—importer, salesman, and purchaser; indeed, one result is that some amateurs make it a rule only to purchase plants in flower; some never venture near auction sales under any circumstances. I only ask any unbiased Orchid grower to compare Mr. Crawshaw's description of *Cattleya Percivaliana* with that of Sir Trevor Lawrence, to which latter I subscribe in every way.—F. W. BURBIDGE.
