—From Sir W. Marriott's collection, Down House, Blandford, Mr. Denny sends us a flower of this *Cattleya*, by far the finest as regards colour we have seen. The outspread flower measures $4\frac{1}{2}$ inches across the petals, which are just over $1\frac{1}{2}$ inches in width and wavy at the edges, the sepals being three-quarters of an inch broad. Both petals and sepals are of a uniform soft violet-purple, veined with a deeper hue. The labellum is extremely handsome. It measures 1 inch across, and is exquisitely frilled at the margin. The inner half is of a rich orange, blotched and freckled with maroon. The outer half is a velvety maroon, edged with magenta, the frilled margin being a pale rose-pink, a gorgeous combination of colours, of which we have not seen the like in any other *Cattleya* or Orchid whatsoever. Those who possess such a variety as this need not trouble much whether it be a form of *labiata* or of *Mossiæ*, which some assert it to be. It seems to us that there has been a good deal of useless cavilling about this Orchid, simply because it was at the outset stated to be a form of *C. labiata*, but to compare it with the summer-flowering *C. Mossiæ*, whether it be a form of it or not, seems absurd. One might as well compare a spring flowering *Phlox* with an autumn flowering one; both are beautiful, but neither can be had in bloom at one and the same time. That there are inferior forms of this *Cattleya* we well know, and what Orchid is there that is not represented by good and bad varieties? When this *Cattleya* has had a fair chance, that is when it becomes fully established and well grown, even those who have prejudged it will probably have to alter their opinion respecting it.

Lælia superbiens.—A glorious spike of this Guatemalan Orchid reaches us from Dr. Paterson, Fernfield, Bridge of Allan. It measures 7 feet in length, and is terminated by a charming cluster of blossoms fourteen in number. The flowers, which measure 4 inches across, are of a purplish lilac colour; the lip is of a deeper hue, and marked strongly with yellow—another instance of Dr. Paterson's skilful Orchid culture.

Dendrobium lituiflorum, grown on a block with some Sphagnum over the roots, makes growth with us nearly 4 feet long and flowers from nearly every joint the whole length. When making its growth we hang it on the back wall of the stove and supply it rather liberally with water. In very hot, drying weather the plants are frequently dipped in a cistern three times a week. As autumn approaches we reduce the supply considerably, and from November until the end of January no water at all is given. About June, as soon as the new growth is well started, I always cut away the shoots that flowered a few months previously. As I am not an authority on Orchid culture, I do not know whether this practice is a good one or not, but I am satisfied with my practice, because the results obtained are quite equal to those in which annual pruning is not practised. I adopt the same rule of cutting out the exhausted flowering shoots on the other *Dendrobiums* which we grow, and which include *D. nobile* and *D.*

Pierardi, and I am quite sure the plants are benefited by it.—J. C. C.

Angræcum citratum.—Among the smaller kinds of epiphytal Orchids this little Madagascar rarity is, indeed, a gem. According to the *Irish Farmer's Gazette*, two plants of it are at present in flower in the College Botanic Gardens, Dublin. The little plant is of a very dwarf habit; the gracefully curving flower-scape is from 12 inches to 15 inches long, and for the greater portion of its length is furnished with a symmetrically arranged double row of pure white flowers, each with a proportionally long spur, the double row of spurs below corresponding with those of the flowers above, and enhancing the beauty of the flower-scape. The plant is a native of Madagascar, from whence, we believe, it was introduced by Messrs. Veitch and Son. It is as yet rare, but no choice collection of these plants should be without it. Mr. Burbidge's plants are growing and flowering in extremely small, shallow pans suspended from the roof.

Dendrobium Wallichianum.—There are several varieties of the beautiful old *Dendrobium nobile* more or less distinct from the type, such as *D. pendulum*, *elegans*, *intermedium*; but *D. Wallichianum*, one of the finest and one of the best specimens of it we have seen, is in Mr. Soper's garden, at 283, Clapham Road. This plant has a score or so of bulbs, and each of the old ones is completely wreathed with blossoms. These are larger in every part than those of the type, and, moreover, possess a firmer texture. The colour of the sepals and petals is half a waxy white and half a bright violet-purple white; the labellum is creamy white, with a large velvety maroon, in fact, almost black, blotch. The growth is stouter and taller than ordinary, and the plant is altogether distinct. Mr. Soper flowers this and other Orchids in a small stove in company with a miscellaneous assortment of flowering and fine foliaged stove plants—a sufficient proof that successful results may be obtained in Orchid culture even though a separate house is not set apart for them exclusively.

Lælia harpophylla.—This is one of the most distinct and also one of the most beautiful Orchids in season, the colour, a glowing orange-red, being so attractive and so different from that of the ordinary run of Orchid flowers. Lord Crewe sends us from his garden at Crewe Hall a very fine example of it. From one sheath no fewer than seven finely developed flowers are produced, which make a beautiful cluster. We have never before seen so many flowers borne on one spike, and it shows what good cultivation may do. Probably Lord Crewe's gardener (Mr. Whitaker) could instruct us as to its treatment, for it unfortunately falls in the category of miffy Orchids. But perhaps it is because its requirements are imperfectly understood. Anyone who aims at possessing a representative collection of Orchids must have this one, as it is the best of its colour, much superior to the older and better known *L. cinnabarina*, the flowers being nearly twice the size in well developed specimens, and the colour much richer. As regards colour, however, it varies considerably; in some it is a pale, washy orange; in others, as in that before us, it is a rich orange-red, and some are even more brilliant. The deepest tinted form we have seen was one singled out the other day from a batch in Messrs. Shuttleworth and Carder's nursery, Clapham. The flowers were not very large, but the colour was equal to that of *Epidendrum vitellinum majus*, and the frilled white lip was a fine set-off for the glowing orange-red tint. It is a native of Brazil, and therefore succeeds best in an intermediate house, that is, in a temperature ranging between that of the East Indian and the cool houses.

Odontoglossum Ruckerianum will doubtless for some years to come rank among the choicest and rarest of cool house Orchids, as it is so seldom imported, and its propagation is necessarily slow. To those who know it not it may be described as being identical in habit of growth, size, and form of flowers with the better known, but still choice, *O. Andersonianum*. The flowers

are produced in tall and often widely-branching spikes thickly set with flowers, which are about 3 inches across. The sepals and petals, as well as the labellum, are somewhat narrow and attenuated. All the segments are flushed with a violet-purple hue, particularly on their exterior faces. The sepals are almost spotless, but the two petals are conspicuously spotted with cinnamon-red on a creamy white ground. The labellum is likewise blotched, and has a large blotch of yellow on its base. It is, therefore, a handsome plant, and at once distinguishable from any other kind. These notes were taken from a fine variety now in bloom in Messrs. Shuttleworth & Carder's nursery, Park Road, Clapham. It cropped up from an importation of *O. crispum*; but, singularly enough, from the thousands of this species imported by the firm, a *Ruckerianum* is of rare occurrence. Of the popular *O. crispum* there are some uncommonly fine examples in this nursery worth seeing just now, and we noticed two or three varieties of exceptional beauty. One had its flowers wholly suffused with rosy purple, which gives the spike an attractive and beautiful appearance. Others are remarkable for the perfect form of the flowers or the richness of the markings.

Twin-flowered Cypripediums.—I notice Dr. Paterson has had a twin-flowered *Cypripedium Harrisianum*. We have this winter had a great many varieties come double flowered, and have still some in bloom. The following are the names of what we have had, viz., *Cypripedium Argus*, *C. venustum*, *C. Ashburtoniæ*, *C. villosum*, *C. Boxalli*, *C. insigne*, *C. barbatum*, and *C. pardinum*. I remember a good few years ago, when going through the late Provost Russel's houses at Falkirk, being much struck at the great number of twin-flowered *Cypripediums* which he had, and on remarking this to the gardener, Mr. Sorley, he said, "They always come so here."—W. THOMSON, jun., *Clonfertford*.

Orchids in bloom at Messrs. Shuttleworth and Carder's nursery, Park Road, Clapham, include the following: *Masdevallia militaris* is the brightest of the genus in flower. It is a near neighbour of *M. ignea*, but differs by the brilliancy of its colour, which is a glowing scarlet inclined to crimson. It seems to be quite as free a bloomer as *M. ignea*, and habitually flowers in winter and early spring. It is a valuable species, particularly for cutting from, as the flowers last so long in perfection. That little gem *M. Shuttleworthi*, originally discovered by a member of this firm, may be seen in great perfection. Some of the plants are carrying no fewer than a dozen blossoms, some of which measure as much as 4 inches across. The flowers are triangular in outline and with concave sepals beautifully grained with violet-purple on a yellow ground. The three long, attenuated tails give the plant a grotesque appearance. All the plants of this Orchid are grown in suspended pans, close under the roof, in a cool *Odontoglossum* house; under this treatment they thrive admirably. A very singular Orchid is *Gongora portentosa*. It produces from the base of the bulb a long pendulous spike of very curiously shaped blossoms, with widely diverging segments mottled with cinnamon-red on a creamy yellow ground. It is a rare species; at least we seldom meet with it. Among other noteworthy kinds in bloom are *Masdevallia Chimæra* and a similar, but quite distinct form which will probably prove quite new; *Odontoglossum Uro-Skinneri*, a handsome, but somewhat neglected species; *Cypripedium Spicerianum*, a fine form; and a handsome unnamed *Oncidium* in the way of *O. serratum* are all in bloom. We were interested in a very fine form of *Cælogyne cristata* called the Chatsworth variety. Its flowers are fully a third larger than those of the ordinary type.

Cattleyas should be repotted (if they require it) just when about to emit new roots. This is the usual advice. Will one of your readers who knows say if this may be done while they are furnished with flower-sheaths, or must I wait until the plants have flowered? In some recently repotted the sheath has turned brown and withered. May root water be used to destroy worms in the case of *Odontoglossums*, &c., which it is not desired to repot at present?—W. B.

PLANTS IN FLOWER.

LATE CHRYSANTHEMUMS.—A correspondent sends flowers of *Chrysanthemum Elaine* and *M. Lemoine*, the latter a Japanese variety with straggly heads of bronzy red florets. *Elaine* is inclined to be pink, but still very pretty, and it is remarkable that it is one of the earliest as well as one of the latest sorts we have. A note should be made of both of these sorts for late flowering.

MONOCHÆTUM ENSIFERUM is a bright-flowered plant that deserves the attention of cultivators. It always flowers at the beginning of the year when most wanted, and it is of easy culture in an ordinary greenhouse. It is of dwarf shrubby growth, and produces an abundance of reddish purple blossoms between 1 inch and 2 inches across. Another similar and quite as desirable species is *M. sericeum*, differing from the preceding by its leaves being covered with a silky down. Both are grown largely in the Royal Exotic Nursery, Chelsea, where they are now in full bloom.

SINGLE CRIMSON ROSE.—Mr. George Paul sends us from his nursery, Cheshunt, a bloom of what he calls Paul's Single Crimson Rose. The flower is between 4 inches and 5 inches across, deliciously perfumed, single, showing no tendency to double. The petals are over 2 inches across, and of the richest satiny crimson-magenta hue imaginable. Such a splendid colour as this makes it highly attractive, and the golden tuft of stamens and broad healthy green foliage is a fine set-off to it. Those who have a predilection for single flowers would like such a one as this, and it is the more welcome at this season, though of course it has been forced into bloom. One great drawback to single flowers is that they do not last long when cut.

FICARIA GRANDIFLORA.—One of the brightest plants in bloom in Messrs. Barr & Sons' trial grounds at Tooting is this, a near relative of the lesser *Celandine* (*F. ranunculoides*), but altogether a larger and finer plant, being fully twice the size in every part. The flowers are nearly 2 inches across, and the petals are of the brightest yellow and very glossy; the flowers, borne singly on stalks some 6 inches high or more, just overtop the dense tuft of foliage. In this nursery there is a bed of it some few yards square, and the whole is a dense mass of flowers and foliage. Though so plentiful here it is not so in gardens generally; indeed, we very seldom see it. It has but few equals as a hardy yellow flower, coming in before the earliest Daffodils, or, indeed, any other hardy yellow flower. It is of the simplest culture in ordinary garden soil, and though it is said to be a native of Southern Europe and Northern Africa, it is perfectly hardy. It is grateful for a little shelter, and its golden blossoms seem to shine out brighter in a subdued light.

THE SNOWDROP season is now at its height. A few days ago we had an opportunity to make notes of almost every cultivated species and variety at present in gardens in Messrs. Barr & Son's trial ground at Tooting, where they are grown largely. The finest of all is *Galanthus Imperati*, which has flowers fully $1\frac{1}{2}$ inches long, with broad milk-white segments. Next in size is *G. Elwesii*, the new species introduced a few years ago from Smyrna. It may be at once recognised by the two distinct blotches of green on the lobes of the inner segments of the flower, and a large blotch of pea-green above them, separated by a band of white. The Crimean Snowdrop (*G. plicatus*) comes next in size. From all other Snowdrops it differs by the edges of its leaves being folded back. A major form of *G. nivalis*, the common Snowdrop, has flowers of about the same dimensions, but the outer segments are much narrower. The Dunrobin seedling Snowdrop is a large form of *G. nivalis*, quite distinct from any other form, the flowers being more globular, the outer segments broader and whiter than ordinary, and the green of the inner segments deeper. It is also a good deal earlier than the other forms of *G. nivalis*. A minor form of the latter, with narrow leaves and small flowers, together with the common double kind, are also in the collection, and to complete the list is *G. Redoutei*, or more

correctly, *G. latifolius*, which is the most distinct of all the Snowdrops, though some consider it but a form of *G. nivalis*. The flowers are almost identical with those of the common Snowdrop, but the leaves, instead of being glaucous, are quite green and fully twice the breadth.

LACHENALIA REFLEXA.—In the Heath house at Kew this plant is flowering for the first time in this country. It is an interesting species from the fact of its being placed by Mr. Baker in a sub-genus by itself. The leaves are borne in pairs on each bulb, are dark green, channelled, and recurved. Towards the tip the tissue seems to thicken, the extreme tip being almost horny, and turning inwards so as to form a sort of cup. The length of the leaves is from 6 inches to 8 inches, and the width 1 inch. The scape is some 4 inches in length, green, with a slight tinge of brown. The flowers are 1 inch long, bright yellow, tipped with green, while the unequal length of the segments suggests Mr. Baker's sub-genus *Orchiops*, though I observe he has omitted to mention this character as belonging to *L. reflexa*. This arrangement consists in one of the outer segments being longer than the other two, and having at the tip a green cup or sack. The inner segments, on the contrary, are 2 inches longer than the other, and the tips of these two are enclosed in the sack of the long sepal. This species is not a very ornamental one.—W. WATSON, *Kew*.

THE EARLY SAXIFRAGES are beginning to make themselves conspicuous. Already the neat little white-flowered *S. Burseriana* is in full blossom, and in the Exotic Nursery, Tooting, we noticed a few days since that *S. oppositifolia* and its varieties are fast expanding their bloom. The type seems to be the earliest, followed by a rich deep-coloured form called splendens, and succeeded by the Pyrenean variety (*pyrenaica*) and its high-coloured forms, such as *maxima rubra*. We observe that Mr. Parker grows *S. oppositifolia* and its allies in the open border simply planted as other hardy perennials, and without a vestige of rock or stone around the plants. Care is taken at the outset to put out strong plants in good soil and to keep them from being over-run by any other plant. Treated thus, it is grown with perfect success, and no doubt two-thirds of alpine plants may be grown in the same way; but pot culture, as regards specimen plants, is Mr. Parker's favourite plan, and he certainly possesses some remarkable plants grown in this way. He uses pots varying in size from 4 inches to 8 inches in diameter, and the plants of the encrusted-leaved section form dense healthy cushions, which during spring are studded with blossoms.

IRIS RETICULATA is decidedly the gem of the open border just now. No other flower that we know of can rival it in beauty—not even an Orchid, whether we look to its graceful habit and beauty of form or splendid colouring. The deep rich purple of both the petals and sepals, relieved by the bright golden crest on the falls, is quite unlike what is seen in any other flower, and the fact of its being as hardy as the hardiest of border plants makes it the more valuable. About a fortnight ago Mr. Barr sent us his first blooms of the early variety of *I. Krelagei*, and now we see in his trial grounds at Tooting that the type is in full beauty. It is pretty generally known that there are two forms of this Iris, the earlier *Krelagei* being at once distinguished by the flowers being of a more violet hue and shorter in the tube; in fact, scarcely exceeding the spathe. It is not generally understood, however, that it differs considerably in the important point of scent. *Krelagei* is quite inodorous, while the type, with the deepest coloured blossoms produced later, possesses a delightful perfume akin to that of Violet blossoms. Now that this lovely hardy bulbous plant can be obtained at a moderate price, everybody should possess it who cares to have bright early flowers. The finest bed of the true *I. reticulata* we have yet seen is now in perfection in Mr. Parker's nursery, Tooting, the flowers being unusually large and highly coloured—the result of allowing the bulbs to remain undisturbed for some years.

HERRENHAUSEN BOTANIC GARDEN.

SITUATED about a mile and a half from the town of Hanover are the famous royal gardens over which the Wendlands have so long and so successfully presided. In the town itself there is much to interest the visitor; its magnificent railway station, beautiful buildings and monuments, and what may not be without interest, the fact that both town and province of Hanover was once a British possession. Between the town and the Herrenhausen Gardens is a very fine avenue of Lime trees, or rather three avenues running parallel with each other, occupying the place where the fortifications of the town used to stand. On the left of these avenues is what is called the George Park, which, like many of the German public parks, is little more than a forest pierced here and there by a few paths. The village of Herrenhausen is quiet and secluded, something like what Kew possibly was before the inroads made of late by bricks and mortar. Here also, as at Kew, royalty spent its summer season, the handsome castle and its surroundings, which include the Botanic Garden, rendering the village of Herrenhausen exactly the sort of place in which one would expect to find a royal residence.

The Botanic Garden is laid out in a style that looks like a mixture of French and English, the formal style of the former being associated with the more natural expression of our own gardens. There are here many fine specimens of choice trees and shrubs to be seen out-of-doors, among them being trees of *Nyssa aquatica* and *N. triflora*, *Quercus imbricaria*, and many large and fine *Acers*. A poor specimen of *Wellingtonia* was pointed out as being perhaps the finest in the province of Hanover. *Hollies*, many of our *Coniferae*, and evergreen shrubs and trees are unable to stand the severe winters experienced here, so that during that season outdoor vegetation is very bare. A fine collection of *Hellebores* along with some of the finest and hardiest among the many beautiful species of herbaceous plants are admirably well managed at Herrenhausen. A fine *jet d'eau*, 3 feet in circumference, from which the water rises to a height of 80 feet, is one of the features of the outdoor garden. London, I observe, speaks of this and two avenues of Lime trees as being the two principal attractions of the place at the time when he wrote his "Encyclopædia of Gardening." Things must have improved here wonderfully since then, for, apart from the well-known collection of Palms at Herrenhausen, the orangery, with its fine specimens of old-fashioned greenhouse and hard-wooded plants, its gigantic Orange trees, the Heaths, of which Mr. Wendland possesses perhaps the finest collection grown, Ferns, Orchids, and such like,

constitute for the plant lover attraction sufficient to make a visit enjoyable, while to the ordinary sightseer there is the Garden Theatre so beautifully decorated inside, once the scene of royal festivities, but now used as a wintering house for large tub plants. The mausoleum, too, which, from its beautiful interior and the figures in it done by Ranche, is a feature of special interest. It stands in a quiet part of the garden, tastefully surrounded

the requirements of the plants it was intended for. The only plants in pots are those on the side shelves—Palms, Cycads, Pandanads, Dracenas, Ferns, Erythrinas, Strelitzias, and similar material, being all planted out in beds on a level with the paths. Amongst these is an undergrowth of smaller plants, such as Begonias, Aroids, Eranthemums, and such like, growing as freely and looking as happy, aye, happier than such plants look

in pots near the glass, and these are 70 feet from it. The secret of all this is the mode of watering. Two galleries run round the inside of the house, one above the other, and from this there can be sent down, by means of an excellent arrangement, a good force of tepid water, a warm shower, in fact, over the whole of the plants, and this is done at least twice a day in summer and on all fine days in winter. Steam, too, is used for moistening the atmosphere, and Mr. Wendland believes that many of his finest Palms owe their luxuriance to the good effects of steaming. The Palms, as I have said, constitute the principal feature here. To this Order Mr. Wendland has paid devoted attention for many years, and he has now the finest collection of them in the world. The rarest and miffiest are at home under his care, and many are the specimens pointed to with pride by their grower as unique in Europe. To notice the whole of these would occupy more space than could be spared, so I must be content with a passing notice of some of the most attractive. *Pholidocarpus Ihur* is represented by a fine specimen, its beautifully striped rachis and large broad spines being singularly beautiful. *Licuala paludosa*, a yellow petioled species, is a magnificent Palm, as is also *Raphia Hookeri*, of which there is a very fine specimen and the only one known. It is an *Attalea*-like plant with the edges of the petiole bases split up into strips about half an inch wide and 3 feet long. These hang about the base of the plant in abundance, and as they are shining black they contrast well

Interior of the Palm house at Herrenhausen, showing a specimen of *Stevensonia grandifolia*.

by trees and shrubs. Turning our steps towards

The Palm house, we behold a tall, massive angular structure of not very great architectural beauty, yet doubtless the sort of house preferred by the director for his pets, the Palms. The severity of the Hanoverian winters necessitated double walls of glass. Its height is about 70 feet, and it covers an area about as large as that covered by the temperate house at Kew. On entering this house one is at once struck by the luxuriance and health of the collection of ordinary plants, while gigantic and graceful Palms tower up towards the top as happy looking as if they were in their native habitats. Mr. Wendland is not only a botanist, but an excellent cultivator, and doubtless fashioned his house to suit

with the green of the foliage. *Gronophyllum microcarpum*, a Pinanga-like Palm, with black petioles, *Socratea exorrhiza*, *Archontophoenix Veitchi*, *Veitchia Johannis*, *Wallichia disticha*, and many others equally rare and beautiful are represented here by fine specimens. The broad-leaved Palm, shown in the accompanying view of a portion of this house, is a very fine specimen of *Stevensonia grandifolia*—the thief Palm, as it is called, from the fact of its having disappeared from the Kew collection directly after its introduction, and shortly afterwards revealing itself in a Continental establishment. Owing to this the name *Phœnicophorium*, which means stolen Palm, was first given to this Palm, but Sir William Hooker, not desiring to have anything of so disagreeable

a nature as this theft commemorated in such a way, altered the name to *Stevensonia*. Mr. Wendland uses abundance of cow manure for his Palms both to heal the sick and feed the strong. To both he applies the same material, and I saw an instance of the action of cow manure on sick plants in the case of a Tree Fern (*Hemitelia integrifolia*), a species not often met with, and, as Mr. Wendland said, difficult to grow. At first it appeared impossible to get this plant to recover, yet on applying a plaster of fresh cow manure over the whole of the stem, the plant quickly revived, and when I saw it roots were growing through and running down the manure as thick as Orchid roots, and the head was quite bushy with healthy fronds. For Orchids, Ferns, Palms, and almost all other plants, Mr. Wendland uses large quantities of this manure. The collection of Cycads at Herrenhausen are, of course, very fine, almost equal to those at Kew, and in *Zamia* even richer. A fine specimen of *Renanthera Lowi* was bearing three spikes of its large and handsome flowers, one spike having thirty-eight and the two others thirty flowers. This plant flowers every year and generally bears four spikes.

Orchids are well grown at Herrenhausen. The treatment in favour here is one of plenty of heat, light, and moisture during summer and cool rest in winter. Mr. Wendland looks after the health of his plants, but the arrangement of them is not by any means of so much importance with him as it is in some botanic gardens where the plants must stand with their kind whether they are happy or not. In the Victoria house, the ferneries, the Palm house, anywhere where a plant is likely to do best, there it is placed. Some of the best coloured *Gymnogrammas* I have seen were on a shelf above the second gallery near the top of the Palm house. They were doing well there, and the director knew that although they would make a fine display among his other Ferns, it would not last long. And so it is with Orchids. *Schomburgkias* are hung up in the Victoria house along with *Dendrobiums* and other heat-loving Orchids, where they make good growth in the summer time, after which a cool temperature is found to be best for them. *Arpophyllums*, *Cypripedium Stonei*, *caudatum*, *Pearcei*, and *Lindeni* were the healthiest of plants in a cool greenhouse. The pretty little *C. Fairrieanum* was flowering nicely in the same house. *Paphinias*, *Catasetums*, *Stanhopeas*, *Acinetas*, and many others were in a remarkably fine condition grown in a cool house near the glass. Of Ferns Mr. Wendland has many fine specimens, some of them rare, while of the usual miscellaneous stove and greenhouse plants there is a rich and well managed collection. Heaths are well represented, and are grown out of pots planted in beds out-of-doors in summer and taken up and potted for winter. In this way many kinds are kept in health that when in pots have been found difficult to manage. Adjoining the Botanic Garden is a large piece of ground devoted to the

Propagation and rearing of fruit and forest trees. This also is under Mr. Wendland's management, and the well-stocked beds of young healthy trees showed that he is as much at home in the nursery as in the botanic garden proper. Herrenhausen Botanic Garden is perhaps one of the two finest botanic gardens in Germany, and, so far as one can judge, for skilful management and good cultivation it stands second to none in Europe. W. K.

Forcing Almond blossom.—Our attention was directed the other day by Mr. Soper, Clapham Road, to the plan which he practises in order to get Almond blossoms for room decoration long before the flowers expand naturally. He cuts off twigs—last year's shoots—a foot or so in length just as the flower-buds begin to show colour, and places them in water in a warm, moist greenhouse, where, in the course of a few days, each shoot is wreathed with beautiful open blossoms of a delicate pink colour. These twigs, placed in a vase by themselves, have a charming effect and last

a long time before fading. No doubt the same could be done in the case of other spring-flowering trees and shrubs.

THE CHRYSANTHEMUM AND ITS CULTURE.

Chrysanthemums as cut flowers.—"While cutting some Chrysanthemum blooms recently," says a correspondent of the *Journal of Horticulture*, "the thought occurred to me that a note on the varieties which are yielding flowers at this season might be useful. The following gave their first flowers—that is, from the end of the leading shoots—Princess Teck and Mr. Gladstone, both incurved; *Fleur de Marie*, Miss Margaret, and Empress, Anemone-flowered; Cry Kang, Purple Prince, Japanese, and Julie Lagravère, reflexed. The following yielded a second crop of flowers from side shoots, viz., Lady Slade, Venus, Mrs. Shipman, and General Bainbridge, large-flowered; Criterion, Tokio, Peter the Great, Elaine, Marie Lemoine, Fair Maid of Guernsey, and Bouquet Fait, Japanese; and *Beauté du Nord*, reflexed; George Sand, Marginatum, and Princess Louise, Anemone-flowered; *Baronne du Prailly*, Red Dragon, and some of Cry Kang, Japanese, have yet unopened. Of Pompones, Golden Cedo Nulli, Antonius, President, Perle, Madame Montels, and Mustapha afforded flowers for cutting. Four hundred fresh flowers have been gathered this week, 1200 from Christmas week, and we have still many hundreds to gather as required."

"The Chrysanthemum has occupied a very prominent place for several years in the houses here, both as a decorative plant and as a producer of flowers for cutting, nor has it ever been known to fail to respond to our simple treatment. Though I should not recommend so many varieties as we have here to gardeners whose sole aim is to procure flowers for cutting, as I have been placed in this position, that variety and large blooms up to the florist standard were as much requisite as the flowers themselves for furnishing purposes. However, were cut flowers alone a requisite and plenty of them, the varieties I should select would be these—viz., Mrs. George Rundle, Mr. George Glenny, Elaine, *Beauté du Nord*, Julie Lagravère, Peter the Great, James Salter, and probably Miss Margaret for very late blooms. If purple flowers were in request I would add Prince of Wales and Purple Prince.

"With the exception of the cluster of buds at the ends of the main shoots of some of the varieties, I would allow the plants to bear as many flowers as they could. Rich feeding would bring the flowers to a good size. If small flowers are not objected to, some of the Anemone Pompones might be grown; these are very pretty. Golden Cedo Nulli in its way is quite as beautiful as Mr. G. Glenny. Madame Montels is a lovely flower, and Antonius is also worth growing for cut flowers.

"The cuttings may be struck at any time up to May, but December is the time to insert them if the largest possible quantity of flowers is wanted. I employ very little heat, use short healthy cuttings, and when rooted grow the plants in a cool and airy position. I cannot obtain too strong soil for them, nor press it too firmly into the pots, nor injure the plants in any way with liquid manure, when once the roots have a firm hold in the soil."

Select Chrysanthemums.—A good selection of decorative varieties is a great want on the part of amateur growers. Mr. Samuel Barlow writing in the *Gardener's Magazine* says, "For the guidance of others I add a list of the plants I have selected and am growing for the coming season's bloom. I have discarded many well-known varieties for their habit of growth, mainly because they are too weak to support the blooms in an erect position; such are Prince of Wales, Dr. Brock, Beverley, and others. The selection is based on twenty years' experience in growing the Chrysanthemum, carefully noting them each season. The number of plants of each variety indicates

the relative positions which they hold in my estimation. The list is fairly representative, and includes all classes and colours, except the very early bloomers:—

Incurved varieties.	
10 Mrs. George Rundle	4 Lady Talfourd
6 George Glenny	4 Jardin des Plantes
6 Mrs. Dixon	3 Princess Teck
6 Pink Venus	3 Hero of Stoke Newington
6 Blonde Beauty	2 Lady Slade
6 Barbara	2 Beethoven
6 Empress of India	2 Lady Harding
4 Antonelli	2 Prince Alfred
4 Nil Desperandum	2 Little Pet
4 White Eve	2 Queen of England
4 Golden Empress of India	2 Golden Queen of England
Recurved varieties.	
6 Sœur Melanie	2 President or Dr. Murray
4 Progne	2 Ariadne
4 Julie Lagravère	2 Jewess
2 Dr. Sharpe	
Japanese varieties.	
10 James Salter	2 Fair Maid of Guernsey
6 Elaine	2 Ethel
2 Peter the Great	
Pompones.	
6 Mrs. Dix	3 Golden Ste. Thais
6 Argentine	3 Aurora Borealis
4 Model of Perfection	3 Snowdrop
4 Saint Michael	3 Miss Wheeler
3 Mdlle. Marthe	2 White Cedo Nulli
3 Golden Mdlle. Marthe	2 Golden Cedo Nulli
3 Bob	2 Lilac Cedo Nulli
3 Sainte Thais	
Large Anemone-flowered.	
2 Glück	2 Miss Margaret
4 Fleur de Marie	
Anemone-flowered Pompones.	
4 Madame Montels	3 Antonius
4 Jean Hachette	3 Mr. Astle
4 Dick Turpin	2 Marie Stuart

Chrysanthemums for market.—The Chrysanthemum is peculiarly suited for what is called "market work," that is, for culture as a decorative plant to bloom in small pots or for the supply of cut flowers during November, December, and the beginning of January, at a time when they are a particularly scarce commodity, and so all the more certain of sale at a remunerative price. By growing the dwarf early-flowering kinds a supply may be kept up for three months, or even longer; and as almost the entire growth of such plants may be made in the open air, few plants yield a better profit on the outlay for cultural appliances.

"Were Chrysanthemums grown only for the production of exhibition specimen plants and show blooms," says a writer to the *Gardener's Chronicle*, "it is very obvious that the culture of this fine race of autumn flowers would be very restricted. The autumn exhibitions, at which the Chrysanthemum is the chief feature, are, as compared with summer shows, comparatively few, the greater portion relatively being found only in the neighbourhood of the metropolis and in large towns. Still farther, these particular exhibitions extend over a very limited period of time, at the most perhaps a couple of weeks, and just at the present moment we are in the midst of the season. A week ago it began, in another week it will end, and the growers of show Chrysanthemums will retire again for another year into seclusion, till the short, but active time of the show period brings them into public notice again. But only the few grow our queen of autumn flowers for exhibition, and the many cultivate her for various decorative purposes. Visits just now to nurseries and to many private gardens, not omitting the famous gardens of the Templars and our public parks, show how the Chrysanthemum displays varied and beautiful decorative qualities—nay, in almost every garden, be it ever so small, we see the favoured autumn flower doing its best to lend beauty when most other flowers have for the season passed away.

"But it is in the market growing establishments, literally huge manufactories of flowers, that we see the Chrysanthemum in bulk. Here it is grown by tens of thousands, and too often under conditions such as would stagger the humdrum cultivator who has ample glass room at his disposal, and knows nothing of those emergencies which are as familiar to the trade as shifts and privations are to the hungry. We looked in the other day at the Royal Nursery, Feltham, where Mr. Roberts has truly enormous numbers of plants

growing under every possible and almost impossible condition. Every inch of space is utilised, whether it be on stage or beneath stage, by the side of walks narrowed now almost to obliteration, and in any and every position there are found Chrysanthemums, both in and out of pots, giving up their beautiful flowers in vast quantities to satisfy the demands of the great flower-loving British public. Of course, we look in vain here for show flowers. One or two growers have devoted houses to their production; not for exhibition, but growing them as show flowers are grown, for sale in the market. That it is not a very remunerative aspect of Chrysanthemum culture is evident from the fact that few care to embark in their production; but, without doubt, in favourable seasons plants grown naturally to produce naturally developed flowers do pay very well, because the Chrysanthemum is singularly amenable to rough and ready treatment when that most critical period of its culture, the blooming period, arrives.

"But the market grower has the advantage of being able to extend the blooming season far beyond the capacities of the show cultivators. The new late summer or true autumn-blooming race of Chrysanthemums open the season in the month of August, and bring it on to the end of October. Then the older strain of what may properly be termed winter blooming kinds begin their season of flower, which is by them carried right on to the end of the year; so that we have a period of five months, the last months of the year, over which Chrysanthemums florally reign more or less supreme. Owing, no doubt, to those market traditions which always favour decided colours in flowers (whether the public is or is not consulted in this matter we know not), we find in this huge collection of Chrysanthemums that whites, yellows, and crimsons predominate. Thus the season opens with early struck plants of the soft white and compact habited *nanum* and the clear yellow *Hendersoni*; whilst a handsome addition is being made in *Madame Destrange*, a near likeness of the most popular *Elaine*; but it is dwarf and early, and under glass very pure and beautiful. Then come the wonderfully floriferous *Aigle d'Or*, so productive of clear yellow trusses of bloom; a huge patch of this pushed on early in the open ground is there cleared without the necessity of taking any under glass. *Elaine* is, of course, most abundant. It is seen not only in pot plants trained low to make pretty little specimens, but in thousands of big ones lifted from the open ground and blocked into every available space, and then overflowing into sheds and between the houses, so that all possible shelter may be utilised. It is found that *Elaine* is in November hardier than in the month of October, when the buds are small and the wood young and sappy. Even 10° of frost has not done so much harm in the open to the buds at this time of the year as 4° would do a month earlier. *Elaine* is now the white market flower *par excellence* in the esteem of the grower. It is very free, robust, does well, the flowers are of good size, exceedingly pure, and generally elegantly formed, presenting, indeed, a very marked contrast to the formal rotund blooms of *Mrs. George Rundle*, a variety that, once so favoured, has now been relegated to the background, and which has sinned beyond pardon in giving origin to yellow and sulphur coloured duplicates, which with their white mamma are yet unpleasantly prominent at exhibitions.

"Perhaps next to *Elaine* in popularity comes the pretty, though very full flowered, *Mlle. Marthe*, because its trusses are so neat and even, and when well developed the flowers are so pure. It is a capital pot variety, as the large number found in the regulation 4½-inch pots show. Of the Anemone-flowered section (for these have their admirers) one of the most pleasing of whites is *Lady Margaret*, the finest blooms of which will come of great size; and where that is the case they are sold individually, whilst in all other cases the blooms are sold in big bunches at prices varying from 9s. to 12s. per dozen. Of all white kinds grown for market, or, indeed, for any purpose,

probably none excel in elegance and rare beauty the pretty feather-edged *Marabout*. This is a true reflexed or tasselled flower, of the finest form, rather small than otherwise, and becoming pure white as it ages, though in its developing stage tinted with pink. *Marabout* is not a free kind, and its habit is not of the best; but its striking and lovely flowers compensate for other defects. Of yellow later kinds the most favoured ones are *Jardin des Plantes*, rich, free, and robust; *Chevalier Damage*, bright golden yellow; *Peter the Great*, pale straw yellow; and *Mrs. Dixon*, though the latter is mostly grown in pots. *Golden Cedo Nulli* is also largely grown for the same purpose, as, indeed, is its older white form, because so dwarf and free.

"The bronze section, a hue of colour so abundant in the Chrysanthemum, is not largely in request. A few sell well at times, and the most favoured kinds are *Barbara* and *Antonelli*. Then of crimson hues none excel *Julie Lagravère*, which is seen everywhere, and is so striking in its rich crimson colouring. Cut in large quantities for bunching, it then becomes wondrously effective, whilst in the gaslight its brilliant hue is intensified. *Dr. Sharp*, too, is a very useful and striking kind, though not nearly so free. Of all the intermediate hues, few are more pleasing than is the rosy lilac *Adèle Presette*, a variety that has a neat dwarf habit, and produces compact trusses of flowers, admirably suited for bunching. Of course, late kinds make just now little display. The very latest is the pure white *Fleur de Marie*; for though so dwarf and full of growth, the flower buds are but just forming, and may be expected to expand about Christmas. Another good late sort is *Princess Teck*, so well known as a Christmas decorative kind. It is in the production of late or true winter bloomers to which raisers should direct their attention. Kinds that will help to extend the blooming period through the gloomy month of January will, indeed, prove invaluable, not only to the general grower, but specially to the producer for market."

Chrysanthemum Calendar.

January.—Prepare a compost of sound red turfy loam, well rotten manure, and sand. Where good suckers are short, stout basal shoots can be obtained, with a few rootlets attached; pot them off singly, picking out all eyes below the soil.

The following directions by Mr. Douglas are quoted from the *Gardeners' Chronicle*: "Still continue to take off cuttings if the required number was not put in in December. Some varieties are shy in producing suckers, and it is necessary to wait until March sometimes before they are ready. Slugs are troublesome, and eat over a considerable number, but we must search for them at night with a good lamp. Place the pots containing the cuttings over a gentle hotbed. As soon as they are rooted the young plants may be removed to a frame or cool greenhouse, where air can be admitted more freely than it can be to a frame where cuttings have not formed roots. Some cuttings are so stubborn that it may be necessary to renew the heat for them." Root suckers make the best cuttings. Stem cuttings rush into bud and flower early, and rarely yield good flowers. One good cutting in the centre of a 2½-inch pot is a good way of rooting them. "Mildew is a very troublesome parasite; it would, perhaps, be difficult to get a large collection into the blooming state without it. Continue to dust the leaves with flowers of sulphur, and keep it off as much as possible. The only work that can be done now is to attend to the plants with water, and to remove decaying flowers before they injure the others. Some time during this month the cuttings must be put in. I prefer to put one in a small 3-inch pot, using light sandy loam. If very large specimen *Pompones* are desired it is quite necessary to put in the cuttings very early in December. The best way to get large specimens of the large-flowered section is to select old plants that have been grown to produce exhibition blooms. Those that have formed from three to six growths 2 inches or 3 inches up the stem are the best. The plants should be taken up, and

have nearly all the soil shaken from the roots, and be potted in 6-inch or 7-inch pots. Place them in cold frames, or on a shelf in the greenhouse. *Pompones* seldom do well treated in that way, but it is best to propagate them from cuttings. Some varieties, including *Mrs. Rundle*, and its forms of the large-flowered section, can be grown into good specimen plants from cuttings put in early." Late sorts will remain in flower until near the end of this month. Give ample ventilation and a little fire-heat in wet or cold weather. Cut over the old flower-stems of plants which have ceased blooming, and store the plants in cold frames, plunging the pots as a security against frost.

February.—Chrysanthemum seeds may now be sown in pots, pans, or boxes on a slight bottom heat, taking care that so soon as the young seedlings appear they are placed quite close up to the light. Still continue propagation by suckers or cuttings, which will quickly emit roots on a genial hotbed, give air on fine days to prevent damping. Cuttings or suckers already rooted may be potted off and stored in a cold pit or frame; protect with mats in frosty weather; give air freely if mild. If green-fly appears dust with snuff or tobacco powder. A solution of tobacco and soft-soap in warm (80°) water will kill green-fly. Plants still in flower should have a little fire heat and ample ventilation. Prepare compost, pots, &c., for forwarding on cuttings next month.

March.—Pot on all early rooted cuttings as they require it. Many fail through allowing the cuttings to become root-bound in the small cutting pots. This is fatal to good blooms. Keep the frames close for a couple of days after potting, and shade if the sun is powerful, after which give air whenever possible. Cuttings may still be inserted in heat. Early sown seedlings may now be selected from the seed pans, each being carefully potted off into a 2½-inch pot in a light compost of leaf-mould, loam, and sand. Place near the light, but shade from hot sunshine, and keep close for a day or two until they establish themselves. Small seedlings may be pricked out in rows in pans or boxes. Seeds may still be sown as before directed. Towards the end of the month the cuttings potted some two weeks ago may be stopped.

April.—Cuttings may still be inserted for late blooming and for ordinary decorative uses. Cuttings potted off last month should have air on all favourable occasions. Syringe morning and evening, and leave air on the frames all night in fine weather. Attend to stopping or pinching and training of "specimen" plants as occasion demands. Harden off plants ready for placing outside next month. Syringing once a week with clear soot water will prevent the appearance of green-fly and add colour to the leaves. Pot on all strong early rooted cuttings as they require it, and also early seedlings, so as to get them strong and hardy for placing outside next month. Pricked out or potted seedlings may now be brought into cold frames or pits. Remove decayed leaves, stop as may be essential about once every fourteen days, but never immediately before or after repotting. Prepare beds and borders and positions out of doors where pot plants are to be placed.

May.—Little or no artificial protection will now be necessary for Chrysanthemums until the plants are sheltered or finally housed in the middle of October. Cuttings rooted now in a cold frame make nice dwarf specimens for small pots in the greenhouse or window for November flowering. Place all plants out-of-doors in mild weather. Stop and thin out the shoots, leaving only one to three on a plant where large blooms are desired. Train specimens and secure or stake the tallest growths to prevent wind breakages. Watering and syringing must now be performed with punctual regularity. Pot on such plants as require it. Prick off or pot later seedlings. Make open-air plantations and plant the strongest seedlings out at the foot of walls or fences, where they are to remain for blooming. Seedlings should be allowed

to grow away with one shoot only, and may be planted 9 inches or 12 inches apart. Prepare compost heaps for final shifts, and also 8-inch and 12-inch pots; procure crocks or oyster shells for drainage, and mix manure water in tubs or tanks. Provide stakes and trellis for tall plants. Destroy green fly, caterpillars, earwigs, and "cuckoo spit." Insects will now begin their ravages; syringe with clear soot water as a preventive. Dust with snuff or tobacco powder, or syringe with tobacco water and soft soap mixture. Earwigs will soon appear and may be entrapped in hollow stalks or in little rolls of brown paper into which they like to creep for shelter.

June.—As the pots become filled with roots liberal supplies of water will be requisite. Syringe morning and evening, and keep insect pests at bay as already recommended. All stopping should now be performed for the last time. If aphid is an annoyance, dust the tips of the growths with tobacco powder, snuff, or immerse them in a decoction of soft soap and tobacco. Tie down shoots of plants intended for trained specimens. The most vigorous and forward plants may now be potted for the last time into 8-inch or 10-inch pots. One plant in each pot will give far finer flowers than where root-crowding is induced by placing two or three plants in a pot. Place the plants out in a sunny, airy position and water freely. If the pots are plunged in coal ashes to economise labour in watering, turn them frequently so as to prevent the plants from rooting through the bottoms of the pots.

July.—Watering will now be the chief factor in Chrysanthemum culture. As the pots become filled with roots weak manure water must be given every alternate watering. See that tall-growing shoots for the production of large blooms are properly supported, or a gust of wind may destroy one's hopes for a season. Where there are three main shoots to each plant they should be secured by a triangular bast tie; mutual support is thus obtained and breakage prevented. See that the earth is pressed down firmly around the edges of the pots in dry, hot weather. The July bud will now appear at the points of the strongest and earliest shoots, and must be at once carefully removed. From below two or three shoots will appear, and the terminal buds of these shoots produce fine shapely flowers. If green-fly appears dip the tips of the shoots in a solution of soft soap and tobacco, an effectual remedy.

August.—A mulching of well rotted sheep manure may be given to the tops of the pots during hot weather, and more liberal supplies of liquid manure will also be needful. Never forget that the Chrysanthemum is of all other plants a gourmand. Syringe frequently and watch for greenfly. Earwigs and caterpillars will also now be plentiful. Destroy as before advised. Growth will now be in full swing. Cleanliness and watering are the main items of culture. About the end of August, or beginning of September, the flower buds begin to show at the ends of the strong young shoots. Beneath each terminal bloom bud will be noticed three or four prominent growths breaking from the axils of the leaves immediately beneath the flower bud. These axillary or side shoots if allowed to remain would draw considerable nutriment away from the flower buds; hence they must be removed while in the bud stage by picking them carefully away with the point of a knife. After removal of these the bloom buds swell rapidly, and must be assisted by liberal and repeated applications of liquid manure.

September.—Syringe and water freely; disbudding will likewise require attention. Specimen plants will also require tying out with a view to their future effect. High winds must be provided against by careful tying to stakes or wire trellises. Liquid manure of a substantial kind will now be required. First water with clean water, then give a strong dose of manure water, thus enabling it to permeate the entire body of soil in the pot. "Disbudding" and "setting" the buds as directed last month will still be necessary as the plants vary in forwardness. Specimen plants now re-

quire great and continual care in watering and staking. Mildew must be banished by dusting with sulphur. Specimen plants may now be staked, regulating each shoot in its final position. Disbud as already directed in case of large flowered kinds.

October.—Tying specimen plants and watering are the main operations. Disbudding must also now be continued and insect pests watched carefully, or they will mar the symmetry of some of the finest buds. Secure weakly shoots from rude winds. Feed the plants liberally until the colour shows in the buds. Neglect in timely watering and mildew are a fertile cause of annoyance now among specimen plants. Early flowering kinds must be taken under shelter before the end of this month. Wet and frost are alike fatal to blooms showing colour. The insertion of cuttings for next year's plants will now be commenced by taking off all short, basal shoots of rare kinds. Prepare for housing general collection.

November.—Water as before, withhold liquid manure as the flowers expand. Carefully remove the plants indoors early this month if not already done. Frosts of some severity may now be expected. Give ample room to each plant and admit air freely. If mildew appears, apply sulphur dusted from a coarse canvas bag. A little fire heat should be applied on cold or wet nights. Early kinds will now be in full beauty. This great fog month is made genial and sunny by the smiles of our "winter queen." Remove all suckers as they appear, retaining rare kinds for next season's growth.

December.—At the latter end of last and beginning of the present month Chrysanthemum-tide is at its height, and the careful grower is rewarded for his year's labour, that is if he has made it a labour of love. Fire heat should be applied during cold, wet weather, and air freely admitted on all fine days. Any suckers which appear now on good or rare kinds should be removed and potted. Many kinds and some of the finest do not sucker well or even afford good cuttings in the spring. Mind that the plants do not suffer for want of water. Give late blooming kinds a little weak liquid manure and the lightest position possible. Remove dead flowers and leaves as they appear. F. W. B.

GARDEN DESTROYERS.

HORNETS AND WASPS.

(VESPA CRABRO AND V. VULGARIS)

THERE are few insects which are better known or more cordially disliked than the common wasp. The hornet is by no means as common, and is fortunately comparatively a rarity, as its large size and powerful sting make it indeed a formidable insect to meddle with. Both, however, have many good qualities. They are remarkable for their boldness and pertinacity. If driven away, they will return again and again, and are by no means the useless insects they are generally supposed to be. They are often of considerable service in destroying grubs, caterpillars, and flies. They also kill daddy-longlegs, spiders, and bees, though killing the latter cannot in any way be considered a service. It is said that in some parts of America the farmers hang hornet's nests in their sitting rooms to get rid of the flies. One would imagine that this remedy would be worse than the disease. Unfortunately these insects do not confine themselves to animal food, but attack ripe fruit of all kinds. Some persons imagine that they do not touch fruit unless it has already been injured by some other insect or means, but this I cannot think is the case, as the jaws of a hornet or wasp are quite strong enough to cut through the skins of such fruits as they feed upon. Wasps are very hard-working insects. One which was watched by Sir John Lubbock made 116 journeys in one day from its nest to some honey in Sir John's study. It was at work when he entered the room at 4 a.m., and did not cease working until 7.47 p.m. Each visit was duly noted, and during the whole

time, except after the two first visits, it was not away from the room for more than 10 minutes minutes together. One hardly knows which to admire most, the industry of the wasp or the observer. Hornets are said to work even harder than wasps, as they will at times work all night, particularly if it be moonlight. Many persons imagine that insects can communicate freely with others of their own kind, but it seems almost certain that wasps cannot. Sir John Lubbock several times marked wasps and watched them, noting the number of journeys they made, and in very few instances did other wasps come to the honey, which undoubtedly they would have done had they known of its existence, and those who did would have communicated their knowledge to the others if they could, as it would have been for the benefit of the nest generally.

The sting of a wasp is a very complicated apparatus, and consists of several parts, as shown in fig. 3. The actual sting (A) is smooth, somewhat curved, and of a horny substance; it is channelled beneath, in which groove lie two hair-like organs, that can be protruded beyond the point of the sting, called spicules; one of these (C) is shown withdrawn from its proper position. These hairs are barbed at their points (fig. 4), and are the chief factors in making the wound; they are separated at their bases, and are brought round the swollen termination of the sting, where they are attached to the muscles which move them. The poison bag (D) is connected with the sting by a fine tube, and is composed of muscles, which can evidently contract with great force. When not in use the sting is moved forward and protected by the two sheaths (E). When the wasp uses the sting it is thrown quickly backwards, the two barbed hairs are rapidly worked in and out with a saw-like motion, the poison is ejected at the same time, and enters the wound as it is made. When stung the best thing to do is to suck the place well or to make it bleed, and then rub in hartshorn or ammonia in some form, sweet oil, washing soda, or the juice of an Onion; if the sting is very painful, keep as quiet and cool as possible; anything which tends to make the blood circulate freely should be avoided. It is useless trying to kill wasps on a small scale if a nest is near at hand; when we consider that a nest, when in full working order, probably contains from 20,000 to 30,000 inhabitants, what difference shall we make if we kill a few hundreds? Later, however, in the autumn queen wasps may be found about houses and out-buildings, searching for sheltered places to winter in, or early in the spring, having just left their winter quarters; these should always be destroyed, as each queen will make a separate nest. Windows in lofts or lumber-rooms to which wasps have access (and they will creep in anywhere) are capital places for finding them in the spring. The wasps, having found snug quarters, remain torpid until aroused by the warmth of the first mild sunny weather; they then naturally fly towards the light, and may be found vainly trying to get out through the windows. Probably one of the chief reasons that wasps are so much less plentiful in some years than in others is that the queens are killed soon after leaving their winter shelter; tempted out by a warm day or two, they fall victims to a sudden change of weather against which they have no protection, unable to regain their winter shelter and not having commenced a nest. Insects when hibernating seem able to stand a great amount of cold, but when in full animation cold seems to paralyse them. As soon as the nests are found, by far the best means of

Killing wasps is to destroy the nests at night when all the inmates are at home. Various methods have been devised for effecting this; among the best are the following: Rags dipped in coal tar, pushed into the entrance of the nest, and then lighted; cotton wool dipped and well saturated in a solution of cyanide of potassium (use just enough boiling water to dissolve the cyanide) and thrust with a stick into the hole, will kill the wasps, or 2 ounces of cyanide of potassium dissolved in one pint of water, poured

into the nest. This drug is a very violent poison and should be handled with great care. A lighted squib, composed of about equal parts of brimstone, gunpowder, charcoal, and saltpetre in a stout brown paper case, pushed into the entrance of the nest; rags dipped in melted brimstone, or flowers of sulphur thickly sprinkled on cotton wool, lighted, and kept burning if necessary by means of bellows so that the fumes must enter the nest, or hot gas tar poured into the nest. A turf should be placed over the mouth of the nest as soon as possible afterwards to prevent the fumes from escaping, whatever plan may have been tried, and the nest should be dug up the next morning to ensure the entire destruction of its inhabitants. Wide-mouthed bottles filled with beer and sugar,

contains as many as 16,000 cells, and as each cell is supposed to be used three times in the course of the season, it has been calculated that a large nest before the close of their year will contain some 30,000 individuals at least. It must always be remembered that wasps do not store up honey or pollen, as bees do, so that their cells are only used for rearing their grubs in. The cells in the lower tiers are larger than those in the others, and in these are reared the males and females. As the mouth of the cells is downwards, the egg is attached to the top of the cell by a glutinous secretion. The young grubs are also kept in the cells in the same manner, but when they are more mature the size of the front segments of the body prevents them from falling out. The grubs are hatched about a week after the eggs are laid. At first they are fed with the sweet juices of fruit or honey, but afterwards animal food is also given them. Those who have had an opportunity of watching them describe the grubs as opening their jaws to be fed just as a young bird does its beak. The grubs are full grown in about a fortnight, after which they become chrysalides. From these, in the course of a week or ten days, the perfect wasps appear, who within a few hours begin to assist their mother in enlarging the nest, adding fresh combs, and feeding the grubs. The early wasps are all neuters, or rather imperfectly developed females. The males and females do not appear until September. They take part in the work of the nest like the neuters; the males, however, do not build or feed the grubs, but act as scavengers at the end of the season. There may be 200 or 300 females in the nest, who do not in any way interfere with one another as queen bees do. Before the cold weather sets in the females are impregnated by the males, who die soon afterwards. About this time the neuters, who seem to know that the grubs still in the cell cannot live long enough to become wasps, drag them out and destroy them. The females then disperse in search of winter quarters, and the neuters gradually get fewer and fewer. Hornets in their economy much resemble wasps, but they usually select hollow trees or the eaves of bothouses, barns, &c., to build their nests in. There are two species of wasps which are equally common in this country, *Vespa vulgaris* and *Vespa germanica*. They resemble one another so closely that it is by no means easy to distinguish them apart; besides these two species there are four others which are not so common.

Vespa vulgaris (fig. 2) may be described as follows: The females measure from five-eighths of an inch to six-eighths of an inch in length, and nearly 1½ inches across the wings; the neuters are half an inch or rather more in length, and a large male is about the same size as a small female. The colouration in all is the same. The head is black, with two yellow spots on the face—one between the antennae, which are black, and one behind and in front of each eye. The thorax is black and hairy, with a yellow line on either side, and two pairs of yellow spots near the base. The body is yellow, each joint having a black band in front, which is widest in the middle, where it is produced into an angle; it then narrows very rapidly to the sides. Behind this band on either side is a round black spot. Wasps have four wings, the lower pair being furnished with fine hooks, with which they can be attached to the upper ones. The upper wings, unlike those of bees and most insects, are capable of being folded longitudinally, and the wings are generally so folded when they are not in use. The legs are of moderate length. The thighs are black, except at their tips, which with the rest of the legs are yellow. The grubs when fully grown are nearly three-quarters of an inch in length, and are fat and fleshy with their joints very distinctly visible. They have no legs, their heads are small, and are furnished with a pair of jaws. The chrysalides much resemble the perfect insects in form with their limbs closely folded to them. The hornet (*Vespa crabro*—fig. 1) is much larger than the wasps, and may at once be distinguished from them by their general reddish brown colour, having no black or pale yellow markings. The females are from 1 inch to

1½ inches in length and measure nearly 2 inches across the wings, and the neuters five-eighths of an inch to seven-eighths of an inch in length. The general colour of the insect is reddish yellow with darker markings. The eyes are nearly black, and the antennae reddish brown. The thorax is of the same colour, with a darker triangular patch on either side. The first joint of the body has a dark reddish brown band behind the middle, and the second has a curved irregular band of the same colour. This band is almost wanting in the third joint, only a small triangular spot being visible, on either side of which is a small round spot. The fourth and fifth joints have a dark spot on either side. The legs are reddish brown, and the wings yellowish with brown veins. G. S. S.

Hydrangea Insects.—My Hydrangeas in the conservatory have had their leaves mutilated of late by semi-circles being bitten out of their edges. No enemy is visible during the day, but last night the enclosed beetles were found eating the leaves. Kindly say what these beetles are, and how best to get rid of them.—R. MILNE-REDHEAD. (The insects attacking your Hydrangeas are the clay-coloured Vine beetle (*Otiorynchus picipes*). They feed at night, and will generally fall to the ground if the house be entered after dark with a bright light. If they do not, a sharp tap or two on the stem of the plant will bring them down. Place the pots on a white cloth before dark; this will enable you to see the fallen insects better. The grubs of these beetles are very destructive to the roots of plants. They are particularly fond of Primulas and Cyclamens.—G. S. S.]

INDOOR GARDEN.

CANNELL'S SYSTEM OF TOP-HEATING.

IN referring to this system (p. 146), "A. D." seems to be under the impression that the great success achieved by Messrs. Cannell at Swanley in the cultivation of winter flowering Pelargoniums is chiefly due to their adoption of this system. Least there should be any misapprehension in the matter, allow me to quote a paragraph from "A. D.'s" remarks: "Some day, perhaps, Vine growers, and especially those who want to ripen early Muscats, may give a trial to this plan of top-heating: in fact, two or three 2-inch pipes running along at regular intervals, just beneath the rods, might be productive of marked success in securing not only a free set, but rapid development of the berries as well as rich colouring." After reading this paragraph, there can, I think, be no doubt as to the implied position of the top-heat pipes in the Swanley houses. Perhaps Mr. Cannell will be so good as to inform your readers interested in the question in what number of his new houses appropriated to Pelargoniums he has introduced this system. He would also confer upon us an additional favour by stating the extra per-centage of dryness he obtains in the air in those houses where it is in excess of that in houses where no root pipes are present, and where the pipes run along the sides in the usual way, assuming, of course, that the same amount of heat be maintained in each case, that the heat radiating surface from pipes be nearly equal, and that the two houses or sets of houses be as nearly alike in pitch, situation, and other respects as practicable, so as to render the comparison an equitable one.

It may be thought that I am somewhat sceptical about the existence to any extent of these roof pipes in the Swanley houses, and also of their being the great cause of the undoubted success to which the Messrs. Cannell are so justly entitled. To this I unhesitatingly plead guilty. My impression is that the worthy veteran at the head of this establishment is too able and experienced a general to point to this particular manoeuvre as the chief one amongst the numerous tactics he has resorted to in securing the palm of victory in the cultivation of Pelargoniums. No doubt Mr. Cannell has experimented with, and to some extent advocated, this somewhat novel method of arranging pipes, but I scarcely think he is sufficiently impressed with its few supposed merits to recommend it very strongly, even for the purpose

Fig. 1, the hornet (*Vespa crabro*); 2, the wasp (*Vespa vulgaris*); 3, sting of wasp (magnified); 4, barbed point of one of the spicules.

or treacle and water, hung on trees or walls which have ripe fruit on them will catch a great many and attract them from the fruit. A female wasp which has survived the winter and the perils of early spring begins looking about for a suitable place in which to make her nest. She usually chooses a convenient hole in a bank, and at once commences a few combs under an umbrella-like covering, entirely unassisted. The nest, both covering and combs, is constructed of a grey paper-like material, formed of fine fibres of wood, which she gnaws from palings, gateposts, or any woodwork which may be most convenient. These fibres are mixed with an adhesive secretion from her mouth. The nest is begun from the top and built downwards. The first cells are not finished at once, but as soon as they are large enough an egg is laid in each, and they are enlarged from time to time. By this means the young wasps are reared some days earlier than they would have been otherwise, and are thus able all the sooner to assist in the construction of the nest.

The combs, unlike those of the honey bee, which are vertical, are horizontal, and the mouths of the cells are downwards; the nest when finished is oval, and measures 16 inches or 18 inches from top to bottom, and 12 inches or 13 inches in width, and contains from twelve to fifteen tiers of combs, which are placed about half an inch apart, and are attached to one another by small columns. The outside of the nest is a casing of several thin papery layers, with spaces between them, which keeps the combs dry and prevents any intruders from getting into the nest except through the entrance. A large nest sometimes

of growing winter flowering Pelargoniums, to say nothing of early Muscats, and even if he did so, I fancy he would so arrange the pipes just under the glass, and not just under the rods of the Vines, as suggested by "A. D." To be placed between two fires is said to be an unenviable position, and to be placed immediately between frost and fire would, I fear, be almost, if not quite, as destructive.

For the purpose of economy, convenience, and good results I imagine Mr. Cannell would prefer to recommend for this purpose a rather sharp pitched roof, and the pipes situated at the lowest convenient level, where the air is said to be the coldest and most dense, and so endeavour to imitate Nature's wise law and example.

W. C. T.

DAMPING OFF IN PITS.

A MILD winter often causes greater destruction amongst half-hardy plants in cold pits or houses than a frosty winter. Frost may be kept out by warm coverings. Straw in any form is an excellent protector when kept dry. Straw mats or hurdles lined with straw, or light wooden frames covered with it, are some of the forms in which it may be cheaply and effectively employed. But damp comes from no one knows exactly where, and is difficult to guard against. It rises up out of the ground; it comes in through the walls and cracks in the glass if there are any. It makes the plants look delightfully, almost preternaturally green at first, then little brown spots appear round the edges of the leaves, old wounds decay and become gangrenous and mildewy, the bottom leaves fall, and when this stage is reached, if something is not done, and that quickly, the whole collection becomes a mass of rotteness. Wood ashes in a dry dusty state are good to drop in among plants suffering from damp in cold pits, so also is dry dusty peat; and if a dry day comes, lift the plants out, pick them carefully over, put an inch of dry ashes in the bottom of the pit, and set the pot on this dry bed. This will do more to banish damp and restore health than anything else that can be done. Ventilation may do much, but in a mild, wet winter something besides careful ventilation is needed to keep plants from damping off which are dug up from the border or even soft cuttings struck in August. Then, again, most people, especially if at all enthusiastic about flowers, are apt to aim at too much. Planting too many cuttings in a pot and placing the pots too close together is one of the causes of damping off; it prevents all circulation of air, and as a consequence in such places the damp settles and works its will.

E. H.

LEAD-BAR GLAZING.

THIS method, to which two of your correspondents have referred, has only recently been made publicly known in the horticultural world, owing, doubtless, to the fact of a lead-bar system having obtained the only award at South Kensington last May. "T. C. W." speaks of the tendency of the lead strips to curl up from exposure to sun heat in summer, and so admit wet and cold air afterwards. This is what takes place, too, with the many zinc bars in use of late years, and is causing patent glazing systems to be looked upon with suspicion, and in many cases to be replaced with the old putty glazing, as the lesser of two evils. In the Simplex this curling up is due to the thinness and softness of the strips, which weakness also causes the glass to be insecure during violent winds, which force the glass upwards from underneath. The remedy, "A. L. S." says, is to bed the glass in thick white lead paint; but if this is necessary, what is the use of the lead strips at all, for a good layer of white lead on an ordinary sashbar with a couple of sprigs in it above the glass and another brush over the top will be as secure glazing as the other without its trouble and expense. The replacing a broken pane bedded in white lead on a lead bar will be as difficult as the hacking out of old putty. The other or prize

medal method of glazing (called the Eclipse) is effected by means of a strong small bar of a patent composition of lead and tin, which is not open to any of the objections named by "T. C. W." It is no heavier than its rival, and does not require the wood bars or rafters underneath (which make the other roofs so heavy), nor does it require any bedding of paint; it can be used with any glass, straight, angular, or curved, and is the nearest approach with which I am acquainted to the old-fashioned church window bars that have lasted for centuries. A roof here glazed with these bars last spring has not shown the slightest sign of curling in heat or bending in storm; in fact, it is impossible to push a piece of note paper anywhere between the dry lead and glass. I am interested in the sale of both these methods, but am old-fashioned enough to prefer good putty glazing for most work. One of the chief objections to these patent systems is that they are generally used with a cheap class of wood framing (in order to reduce the total expense), and therefore cannot possibly last many years exposed to the moisture and heat of a greenhouse. In fact, this failure of the woodwork is a thing to be desired by the so-called builders who supply it, as an evidence of the superiority of their metal bars over the wood they use; but a house built of properly selected wood by a skilled horticultural builder will last longer than any of the metal ones, and in the long run give more satisfaction.

B. W. W.

ADHATODA CYDONIÆFOLIA.

THIS was introduced to this country, from Brazil, by Messrs. Veitch many years ago, and it still retains its position in several choice collections, doubtless because of its exceptional merit among allied plants. It may, according to the treatment it receives, drag out a comparatively useless existence for years, or it may grow into one of the finest ornaments of the warm conservatory. I am not aware that it can be made to flower well or symmetrically in a small state; therefore it would not be suitable for what is termed a "furnishing" plant. To make it appear in its truly handsome character, it is best treated as a pillar plant, or it may be trained as a climber near the glass in the way in which many plants of it are grown around the sides of the Palm house at Kew. The secret of success as regards culture seems to be chiefly in liberal treatment. It must be made to grow freely, and a convenient means of securing strong healthy growth is to plant it out in a prepared border, when success may almost be guaranteed. If grown in pots it must be shifted on from small pots gradually to large ones, in order to avoid the weak growths which are produced by pot-bound plants. With these considerations kept in view, it will not be found a difficult subject to cultivate. It does not really require peat, but so much may be used with good loam as will make an open compost, so that with good drainage there may be no stagnant water, of which during the growing season it should have a good supply. Like the majority of the Acanthaceæ, it strikes freely from cuttings at almost any season of the year, but best in spring. It blooms in October and November. The corolla has a white tube; the upper lip is also white, tipped with purple, and the larger lower lip is deep purple with a white streak down the centre. In habit the plant is somewhat straggling, thus indicating the position we have recommended for it. The stems are obtusely tetraginous, and the leaves softly pubescent. Well grown, this plant, whether in flower or not, will invariably justify its position in the stove or warm conservatory.

R. I. LYNCH.

Botanic Gardens, Cambridge.

Hybrid Heaths.—Does not the success which has attended the crossing of some of our hardy Rhododendrons with the Indian kinds suggest the possibility of good results being obtained from carefully hybridising our hardy Heaths with

some of the Cape kinds? We have almost thousands of hybrids in the latter class, but so far as I know little or nothing has been done with a view to raising plants which shall possess the rich beauty of the Cape species and the hardiness of our own mountaineers. This work, if undertaken in an intelligent and patient way, might be productive of some good results.—B.

Cyperus alternifolius variegatus.—With me the foliage of this lovely variegated plant has been almost white. I would advise all when shifting their Cyperus plants to try the experiment of potting them in nothing but cinder ashes or silver sand; then place them in a brisk stove, and keep them well up to the glass; take care, however, to keep them well watered at the roots, but never syringe them. Thus managed the variegation of this becomes nearly white, and the plant is most lovely when placed amongst Ferns on a dinner-table.—G. H., *High Leigh*.

Combretum purpureum.—"J. C. C." is quite correct in stating that this plant "is not easy to propagate" from cuttings; in fact, so far as my experience goes, it requires "very skilful treatment" indeed to increase it in that way. I do not think it is usual to attempt to propagate it from cuttings, grafting on its own roots being the surest and quickest method; or if there are no roots strong enough, some of any other strong grower would answer. If I find a plant at all difficult to increase by the usual method, I have recourse to this plan of grafting on roots of the same plant, and often succeed. Sometimes it does not answer, and then layering or Moss is tried. Most growers know that *Daphne indica* does well on and always unites with roots of *D. Mezereum*, and many other instances of the usefulness of this plan might be mentioned. I think Mr. Lynch said he struck cuttings of the Combretum, but it seems to me quite an exceptional case.—B.

Steam heating.—The statement that the cost of this is one-third less than that of hot water, an assertion doubted by "P. G.," may be, and doubtless is, quite correct, considering the country in which it is used, as the winters in North America are terribly severe, and to keep up a temperature of only 35° Fahr. in a glass-house where the outer air is 30° below zero (as mentioned in a letter just received from Iowa, where the writer threw a cupful of warm water into the air and saw it fall a lump of ice) is something more than ordinary hot-water pipes are capable of doing; therefore the more intense heat from steam pipes is necessary, and at the same time more economical than from three or four times the quantity of hot-water pipes, especially in a country where the materials cost more than in England—the home of cheap iron and coal. In ordinary circumstances, heating by steam or by the high pressure system of super-heated water is neither cheap nor satisfactory for the purposes of either plant or fruit culture.—B. W. WARHURST.

Saxifraga ligulata.—At Chiswick there are now in flower some handsome specimens of this plant in pots. As an early spring flowering subject for the herbaceous border this Saxifrage is in great favour in most gardens, but I am not aware that its usefulness for indoor work has yet been recognised. *S. pyramidalis* is a beautiful plant whether grown on the rockery or in pots in the greenhouse, and the same may be said of *S. ligulata*, whose large bouquets of bright rose-coloured flowers, brighter and cleaner-looking when flowered under glass than out of doors, are exactly the sort of thing to prove highly serviceable for cut-flower purposes and the decoration of the conservatory. At Chiswick cuttings of this plant are struck in the autumn and kept in pots in a cold frame until the following spring when they are plunged in ashes out of doors and treated liberally as regards water and food. As winter approaches the plants are placed in a frame again, where they are allowed to remain until their flowers begin to open, and then placed in a greenhouse. They remain in flower for some weeks, and when cut and stood in water they keep fresh for some days. I was informed that too much heat

causes the flowers to come washy; therefore it would not be advisable to force them.—B.

Seedling Heaths.—Seedling-raising is not often resorted to for increasing any of the kinds of Heaths, but still this method of propagating them might be useful. The best time for sowing the seed is in spring, though it would germinate freely if sown at any season. The danger of losing the seedlings if weak in the winter months is, however, against sowing Heath seeds, or, in fact, any seeds of plants which in the seedling state are very delicate during the late autumn or early winter. Pots prepared in the same way as for cuttings, but without sand on the top, will answer for Heath seeds. The soil should be well saturated with water and allowed to drain before the seeds are sown. A little dry sand sprinkled over the seeds is sufficient to keep them moist and covered. A square of glass should be placed over the pot, which may then be set on a shelf in a warm greenhouse and shaded from bright sunshine. As the seedlings grow the glass may be removed, and on their becoming large enough to handle they may be pricked off and treated in the same way as cuttings.—B.

Rogiera gratissima and its culture.—How seldom does one meet with a healthy well-grown specimen of this beautiful greenhouse shrub in gardens; and yet, judging by a grand specimen of it grown in one of the plant houses in Messrs. Backhouse's nursery at York, it is not so difficult to cultivate as one would infer judging by its general scarcity. The plant in question is planted out in a brick enclosure about 2 feet square at one end of a span-roofed house, the centre bed of which is occupied with healthy Camellias. The side stages are filled with Heaths and Lapagerias, thus pointing to the fact that a cool, moist greenhouse is the most suitable place for it. The soil in which it is growing is a mixture of equal parts fibry peat and turfy loam, with a liberal admixture of coarse silver sand resting on a well-drained bottom. It is trained up the end and partly over the roof above the pathway, though not tied down stiffly. When I saw it last October I counted fully a hundred trusses of beautiful flesh-coloured blooms on it either fully or partly developed. I had the opportunity of again seeing it a few days ago, and there were quantities of blooms still on it, though many had been cut in the meantime for bouquets and for other purposes of indoor decoration.—H. J. CLAYTON, *Grimston*.

Pleroma elegans.—When skilfully managed but few hard-wooded plants are more beautiful than this Pleroma. Many will remember the time when this was looked upon as a test of the cultivator's skill as a plantsman, because it was not always seen in the best condition. The most successful cultivator of this plant I ever knew was Mr. William Kail when gardener at East Horsley Towers; he used to grow and flower it in the most satisfactory manner. An intermediate temperature is unquestionably best for it, and it must be very carefully shaded from the time when it commences to make its growth until the wood and leaves get somewhat hardened. It also dislikes cold draughts at any time. I have known a fine healthy plant of it to be seriously disfigured by standing for a few days exposed to currents of air from open ventilators. When properly treated it should flower in May and June. As soon as it has done blooming it should be encouraged to make growth in a rather close house, carefully shaded, and where the internal atmosphere is somewhat moist, or red spider and thrips will be very likely to attack it. It will also bear the free use of the syringe while it is making its growth. In regard to moisture at the roots, it requires to be as carefully watered as a choice Heath. The best soil for it is a good fibrous black peat and a fair proportion of silver sand. When larger pots are needed, they should be given directly the plants go out of flower. If large specimens are required, the plants should not be allowed to flower when young, and the points of the shoots should be stopped twice during the summer. A few neat sticks is all that is required

to make a large plant presentable in shape. In growth it is short-jointed, and the habit is branching and somewhat stiff. Cuttings of the half-ripened wood, if put in about the middle of July and placed under a bell-glass and the pot plunged in bottom-heat, will strike in a few weeks.—J. C. C.

Leggott's adjustment for ventilating lights.—This simple and efficient arrangement for ventilating purposes has been patented by Messrs. Leggott, of Bradford. Its appearance will at once commend it to gardeners and hothouse builders. It consists simply of a toothed arm or rack, worm, and rope or chain. It is made of malleable iron or brass, in four or more sizes as required. It can be fixed to lights opening in any position; the lights may be regulated to the greatest nicety by simply pulling the cord, and perhaps the greatest advantage is that they remain perfectly locked

Ventilating apparatus.

whether open or closed. It is a decided improvement on the cranked arm, as the thrust is always straight. They are easy in action, compact in form, neat in appearance, and the cost reasonable.—T. C. W.

Cassia corymbosa.—This hard-wooded greenhouse plant is by no means difficult to cultivate. Indeed, it is a capital exhibition plant for the months of July and August. Owing to its flowers being bright golden yellow, a fairly large plant of it has a striking appearance, and under ordinary management it will last in good health and vigour for many years. It is propagated by means of cuttings made of the half-ripened shoots; if half-a-dozen cuttings are put into a 6-inch pot and plunged in bottom heat in a close frame they will be rooted in about two months. The quickest way of making a large plant is not to pot off the cuttings singly, but in the spring following that in which they were struck they should be shifted into a pot 2 inches larger without disturbing them. A little artificial warmth at this time would help to give them a longer season of growth, but that is not absolutely necessary. A light position on the stage of a greenhouse devoted to similar subjects will suit this Cassia best, but as red spider is rather partial to it, it should be syringed twice a day in hot, dry weather when not in flower. After it has completed the first summer's growth, and before it commences to grow again in the spring the young shoots should be shortened back to within 4 inches of the pot, or at least shortened to such an extent that there will be three buds left. From these buds young shoots will start next year, and in all probability the strongest of them will flower. Every winter the previous summer's growth should be cut back more or less according to the strength and condition of the wood. In February, if necessary, the plants should have a shift into larger pots. The soil to be used should consist of three parts loam and one part leaf soil,

with a good proportion of coarse sand, and I may add that a moderate amount of pot room is necessary, or a weak growth will be the result, and the length of the flower-spike will be in proportion to the strength of the plant.—J. C. C.

Tuberoses.—I would recommend "A. B." (p. 123) to prepare a compost for these as follows, viz., one part peat, one part turfy loam, one part well-decayed cow manure, and one part sand, the whole to be well mixed together and used moderately dry. Having selected and divided the bulbs into threes of uniform size, pot them rather firmly in 7-in. or 8-in. pots, three in each pot, allowing the tops of the bulbs to just show above the soil. When potted plunge them, if required for early blooming, in a bottom-heat of about 75° in a temperate house; keep them shaded from the light and perfectly dry at the root till they exhibit signs of growth, when they should be gradually exposed to light and receive moderate supplies of water. They should be very gradually removed from the plunging material and placed as close to the glass as possible in a pit or house where the temperature ranges between 55° and 75°. As growth proceeds an occasional watering with liquid or artificial manure will be advantageous, especially at the time when the flower-spikes begin to develop themselves. Their greatest enemy is red spider, which should on no account be allowed to injure the foliage. Should a succession of bloom be required a portion of the bulbs may be kept unpotted for another three weeks in a dry atmosphere of medium temperature, after which they should be treated like the others. When, however, they have made a moderate growth they may be placed in a somewhat lower temperature in May or June in a cool pit or frame, so as to prolong their blooming season, and in order to keep them as dry as possible, which is a very essential point in their cultivation. The Italian bulbs have hitherto been the most in demand, but now the American Pearl variety is the favourite.—W. C. T.

—Tuberoses should be put in 6-inch pots in a mixture of equal parts turfy loam, peat, and leaf mould, and placed in a pit. They need very little water at first, but as they begin to grow freely increase the supply and keep them near the glass. When they begin to push up their flower-spikes they will of necessity require to be placed where they will have sufficient space for the proper development of their tall spikes. They will come into bloom from August to October, when they will require a temperature ranging from 60° to 70°, the latter being preferable. If wanted in bloom earlier, the pots should be placed in a warm pit, and on a hotbed the temperature of which should be about 75°, so as to start them into growth more quickly. American Pearl is a dwarf variety with large double flowers and deliciously fragrant.—T.

Hyacinthus candicans forced.—"G.'s" remarks (p. 109) may be advantageously supplemented by a note on the adaptability of this plant for forcing. For this purpose a few bulbs that have not flowered should be taken up early in September, and laid on a shelf in a cool dark place, as it is important that they should have as long a season of rest as it is possible to give them. Bulbs so treated may be potted in the way in which "G." suggests, but it must be done about the middle of December, and they should be at once placed in a temperature ranging from 55° to 60°. Bottom heat is not absolutely necessary, but they will start into growth quicker if supplied with it than they otherwise would do. If treated as here recommended they will be making vigorous leaves by the middle of February, when they require rather careful treatment. They must be in a light position and have a reasonable amount of fresh air given them. Under the best management it will be found, however, that the leaves grow longer than they do in the open air, but that cannot be avoided. Under favourable conditions, viz., slow forcing and as much air as the season of the year will admit, they will be in flower about the beginning of May. In order to secure successional supplies they may be potted at intervals according to the demand. To the bouquet maker this must be a valuable plant, for

when the blossoms are well expanded it is only necessary to nip out the dark anthers to secure perfectly white flowers.—J. C. C.

SOUVENIR DE LA MALMAISON CARNATION.

MR. GROOM, writing about this Carnation to THE GARDEN a week or so ago, says that it will not bear forcing—words of wisdom that anyone wishing to grow this beautiful plant would do well to bear in mind. I know of no plant more impatient of heat and damp. I take my knowledge of the plant from close observation of Mrs. Mark Wood's collection, and I always attributed her success in a great measure to an entire absence of heated houses. To grow this Carnation well the following points must be strictly observed, viz., good and effectual drainage; be careful to exclude worms at all times; stand the plants in the open air fully exposed to the sun from directly after flowering until the commencement of the autumn rains; for soil we have always used a very close sandy loam brought from the neighbouring forest of Hainault. Though fairly easy to grow, some few plants will generally rot off, and though in a large collection, like Mrs. Wood's, of 300 plants, these are not missed; amongst a few plants the loss of two or three good ones makes an ugly gap. M. LOCKWOOD.

Harlow.

FRANCISCEAS.

"W. G. B." enquires if the flowers of these plants are useful for cutting. I have grown most of the kinds, and have used some of them in a cut state, such as *F. Hopeana* and *F. confertiflora*. The latter is much the best species existent when brought out as well as it can be, a condition in which it is rarely met with. To bloom it really up to the mark the plant requires to be treated differently from anything else. The flowers of all the kinds are very soft in texture, and correspondingly easily bruised, and on that account, if required for market, would want exceptional care in packing. Blooms of both the above-named sorts are very effective, especially when young, when the colour is of a deeper shade than that of older flowers. Those of *F. confertiflora* is a lovely shade of deep violet-purple, and wonderfully effective in bouquets when rightly managed; but as usually seen they have a poor, faded appearance. The individual blooms have very short stalks and require to be mounted, otherwise the shoots would have to be cut, which would cause a great waste, as when vigorous they bear from one to three dozen flowers on the extremities of each, and keep on opening in succession for a considerable time. The flowers of *F. Hopeana* are much smaller individually, paler in colour, and not produced near so many on a shoot, but the plant is much more branching in habit, and on that account the shoots along with the flowers could with more advantage be cut. Francisceas have been seen little, if any, in Covent Garden, and it takes some time for any flower new to the buyer, no matter how beautiful it may be, to make its way. In form, size, colour, durability, and general appearance it may differ no further from old-established favourites than might be supposed to afford a pleasing, and yet it will have a very cold reception, and I should have little confidence in the flowers of any of the Francisceas meeting with a demand in the market such as to repay the grower. *F. eximia*, *F. calycina*, *F. Lindenii*, and *F. violacea*, the other species more or less grown, are not so suitable for cutting as the two above named. For decorative purposes, or for exhibition in a group of specimens, *F. confertiflora* has few equals when properly done in the whole range of either stove or greenhouse plants, its charming violet-purple colour affording a contrast to everything else. T. B.

Leschenaultias and their culture.—I remember the time when the *Leschenaultia* was grown so large that one plant would tax the strength of two men to carefully place it on an exhibition stage, and I can unhesitatingly assert

that for rich colour and quiet effectiveness there is not now another plant grown that can surpass it. A plant from 3 feet to 4 feet in diameter and studded thickly with blossoms shines in the distance like a ball of fire; yet, like many other hard-wooded plants, it seems to be dropping out of cultivation. Cuttings of it strike readily in what may be called a dry heat, and, except that at all times watering must be carefully attended to, their management is by no means difficult. When struck the young plants may be placed on the front shelf of a greenhouse stage free from cold currents of air, and where they can be shaded when in flower, which is generally in May and June. A shift once a year into a larger pot early in August will be necessary in order to keep them in health. Thoroughly clean pots are essential, and the drainage must be more carefully attended to than is necessary in the case of stronger rooting plants. The best compost for them is a fibrous peat, to which must be added more than the usual quantity of silver sand.—J. C. C.

Saundersonia aurantiaca.—Mr. A. Rawson asks for information as to the treatment required by this plant. We flower it yearly, and that without any extraordinary care. If Mr. Rawson grows *Gloriosas*, then, with a degree or two less heat than what is necessary for the well-doing of these closely-allied plants, he has the treatment enjoyed by *Saundersonia*. The *Gloriosas*, *Littonia modesta*, and this *Saundersonia* we have just brought out from their winter quarters (under the stage of a warm greenhouse), and shaken them out of the old soil, repotting in a mixture of loam, peat, and manure. Although the two last-mentioned plants require less warmth than the *Gloriosas*, it is a good plan to start all three together in a warm house, as, indeed, it is for most greenhouse bulbous or tuberous-rooted plants that are rested through the winter. If they get a good start, and are carefully hardened off they keep on as the summer advances. We grow our *Saundersonias* in a warm house until about the middle of April or when the shoots are some 2 feet long, after which the cool greenhouse, Heath house, or conservatory is a suitable place for them. Trained up a rafter or a long stake they soon make headway, and by midsummer their yellow cup-shaped flowers are hanging from the axils of the leaves as thick as Solomon's Seal almost. Precisely the same sort of treatment suits the *Littonia*, which is as like *Saundersonia* as—two Peas, I was going to say, but not quite so near as that. Still, leaving out botanical characters, these two plants are very similar, and as they thrive together here and hail from the same habitat (Natal and Kaffraria), they may be recommended as a pair of good plants for the greenhouse. No doubt M. Max Leichtlin grows the *Saundersonia* out-of-doors. I must warn Mr. Rawson against pinching out the ends of the growths to cause them to branch, as these plants—all three genera, in fact—are like *Liliums* in this respect—they do not branch when stopped.—B.

—A lovely plant with golden flowers, which remind one of the pendulous globes of *Urceolina*, and yet how rarely seen. Once only, I saw stems of it 6 feet long laden with blossoms near their apices, in the old lean-to Begonia house at Kew (1867 or 1868), and I have never forgotten it. I have tubers of it here from Mr. Thompson's seeds. *Gloriosa* (Sierra Leone tubers) does well; *Littonia modesta* does moderately well; *Saundersonia* is a failure. And yet my memory of the plant at Kew in days gone by reminds me that there is a way to grow it if we can find it out. It was in a pot at Kew, the stems being trained up the rafters quite near the glass.—F. W. B.

Lachenalias.—There is a slight mistake in the paragraph about these in THE GARDEN (p. 167). In line nine the word "nitida" should be "rubida." There is no *Lachenalia nitida*.—A. RAWSON, *Fallbarrow, Windermerc.*

Peat moss.—Good peat is both dear and difficult to procure here. Would some of the readers of THE GARDEN, therefore, kindly state their experience of peat moss litter, either used fresh or out of the stable as a substitute for it?—W. S. L.

GARDEN FLORA.

PLATE CCCLXXVII. THE GREAT ROSES.

(With a coloured plate of *La France*.)

To all lovers of delicacy rather than glare *La France* has long been one of the most highly prized of Roses. In colour, form, and fragrance it has no equal. The colour seems to play over rather than to be fixed in the bloom; hence the difficulty of describing it and the variety of descriptions given. Almost as well try to arrest a sunbeam as to fix the colours of *La France* by any cut-and-dried description. Pink, pale pink, silvery peach, lilac, rose, silvery rose, rosy lilac—these are but samples of language struggling to do what the coloured plate or the Rose itself can do—exhibit all the exquisite softness of peachy pink and pale lilac shading of the original. But the original itself also varies widely in colour, according to the age of the flower, the season of the year, locality, culture, stock, &c. In regard to age of bloom, the younger the more colour, and *vice versa*, may be pretty well accepted as an axiom. The buds possess a mine of undeveloped pink beauty that dissolves into silvery rose as the petals get more fully developed. This transformation of colour is admirably illustrated by the artist. *La France*, also like not a few objects even more fair, changes colour under undue excitement. Brilliant sunshine, hot, dry air, rough winds, long journeys in close boxes, the stifling atmosphere of exhibition tents, play havoc with its delicate colours, cause them to run or bleach out the major portion of their exquisite pink, leaving in its stead a misty, washy residuum of French white. The earliest and latest flowers are also, as a rule, the best coloured. The necessary data are lacking to enable us to pronounce authoritatively on the influence of locality on colour. But one can hardly note the wide difference in colour that distinguishes the exhibits at our shows without being convinced that some localities pronounce more strongly in favour of certain tints than others. Of course such peculiarities are more strongly marked in the case of such soft coloured Roses as *La France* than in the more lavishly coloured Roses such as *Duke of Edinburgh* and *Charles Lefebvre*.

Culture also exerts a disturbing influence in colours, and in our spasmodic efforts to develop size colour is not infrequently sacrificed. What may with much propriety be called the battle of the stocks, has never, so far as I am aware, been fought on colour lines. But I have sometimes thought that *La France* is, as a rule, more richly coloured on its own roots than worked, and it would be pleasing as well as profitable to have the testimony of rosarians on this point.

Next to the colour, perhaps the form of *La France* is its chief charm. In bud, as the coloured plate shows, it resembles the best *Teas*. As it expands it is, however, more like the most chaste and charming of all the Hybrid Perpetuals. The form bears some resemblance to such popular favourites as *General Jacqueminot*, *Monsieur Noman*, *Marquise de Castellane*, and a few others. Globular with pointed centre is the adopted definition for lack of a better. It is so far unsatisfactory that I should prefer founding a class

Growers or introducers of new plants will oblige us much by early intimation of the flowering of new or rare species, with a view to their representation in our "Garden Flora," the aim of which is the illustration in colour, and in all cases where possible life size, of distinct plants of high value for our gardens.

on the base of *La France*, and would venture to submit to the National Rose Society that it might, with much propriety, eliminate the first of their five types of exhibition Roses, viz., the flat, and substitute *La France* in its stead. The class would include some of the best Teas and a few of the more exquisitely formed Hybrid Perpetual Roses that can hardly be correctly described as merely "glo-bular," cupped, or imbricated. But if our vocabulary of adjectives has been severely taxed to describe the colours or define the form of *La France*, it is a still more hopeless task to give any adequate idea of the surprising delicacy and satisfying fullness of its fragrance. Suppose, for instance, we had a bouquet composed of some of the more fragrant Roses, such as *Pierre Notting*, *Mdme. Victor Verdier*, *Beauty of Waltham*, *Alfred Colomb*, *Camille Bernardin*, *Boule de Neige*, *Devoniensis*, *Mdme. Margottin*, *Maréchal Niel*, with a dash of Sweet Brier, and a suspicion of *Gardenia*, *Jasmine*, *Stephanotis*, and *Mignonette* to boot—*La France*, single and alone, would probably be preferred to the fragrant combination.

La France has not yet attained its majority, nor, it must be added, the popularity it deserves. It was raised in 1867 by M. Guillot, the younger, who has enriched and enlarged the Tea Roses with such welcome additions as *Catherine Mermet*, *Comtesse de Nadaillac*, *Madame Angele Jacquier*, *Madame Camille*, *Madame Margottin*, and others. Singularly enough, however, though *La France* is now sixteen years old, and so fragrant and beautiful, it does not seem to have been fruitful of good seedlings, nor to have exerted its potent influence in modifying the colour, improving the form, or increasing the fragrance of our Roses. A whole family of this class would prove extremely welcome to rosarians. True, the texture is thin, but this but adds the charm of a more exquisite refinement and greater delicacy while it permits a perfect prodigality of petals to be piled up within a reasonable compass, and moulded in perfect form. Hardly any Rose can be more floriferous, nor can better deserve the character of perpetual in the sense of continuity of bloom. Grown on its own roots against a warm wall, it is not only one of the first Roses to open, but the last to close, while it is seldom without a flower or a bud from May to November. It also does well on the Brier or the Manetti, though buds and bark being somewhat thin, *La France* does not take quite so freely as many other varieties. Its growth is often described as vigorous. That depends a good deal on culture, site, and climate. On the average its growth is moderate rather than vigorous. It also grows more freely as a dwarf than as a standard. Worked low on the Manetti, so as to root independently above the bud or graft, seems the best way of growing this fine Rose.

Few Roses yield a better return than any others for high culture and liberal feeding, especially on walls; frequent soakings of sewage, soap-suds, or other manure water not only assist them to climb, but stimulate and support them to a thorough continuous blooming; the more they bloom the less pruning will be needed; only the weaker shoots should be thinned out, and those left moderately cut back. Dwarfs in beds or border may be pegged down to cover the ground, and even root into it where practicable. A great future is probably before *La France* for forming beds and masses in gardens and pleasure grounds. A dry base, a rather warm site, and a soil somewhat lighter than

that used for Hybrid Perpetuals in general, seem to suit *La France* best. This fine Rose is also admirably adapted for pot culture, and in cold localities well merits the protection of glass. Growth indoors but adds to its refined delicacy of tint and gracefulness of form without sensibly lessening the amount or lowering the quality of its inimitable fragrance.

ROSE GARDEN.

PRUNING ROSES.

THIS phrase is a convenient rather than a correct one, for the tendency of modern practice is to prune when required rather than defer it to any particular time; hence every year shows more summer and less winter or spring pruning. And yet it is needful to supplement or complete summer pruning after the plants start into new growth. In many cases, too, the prunings are converted into cuttings or scions, and thus the exigencies of successful propagation introduce another disturbing element into the time and extent of our annual prunings, for if four prunings are to be converted into rooted plants either in the soil or on the stocks of wild or other Roses, it goes almost without saying that they should be removed as soon as may be after the 1st of October. No doubt cuttings will root and scions take for months after that date; but the earlier ones have a coign of vantage wholly impossible to later ones; their sum total of vital force is complete, and they can afford to wait for favouring conditions for its development. Later cuttings are already emptied of some of their growing force, while top growth is prone to impoverish them still further, and thus enfeeble their capacity for forming roots. Hence those who prune for the purpose of propagation prune early, whether best for the well-being of the permanent plants or not. Then, again, the daily increasing demand for two or more crops of blooms in the year, or rather continuous blooming, leads to what many would designate untimely pruning. As flowering shoots fade they are cut back, and thus forced to break nearer home than they otherwise would, and to produce a succession of blooms. For this reason not only are different Rose bushes pruned at different times, but even different shoots on the same plant.

Another disturbing effect on the general pruning consists in the removal of weakly or misplaced shoots at any season. This, and the thinning out of superfluous shoots, and the stopping of those left to more fully fill their base buds, reduces the winter or spring pruning to a minimum. The fact is the practice of summer and autumn prunings has become so general among rosarians as well as pomologists, that less and yet less is being left to be cut away in the winter or spring; and but for the growing excitability of Roses, largely fostered by our modern innovations in culture and pruning, as well as by the infusion of more Tea and Noisette blood into our Roses, probably no spring pruning would be needed. But we have to reckon with this danger and guard against it as best we may. Hence a certain amount of superfluous material is left on our Roses throughout the winter. This acts as the safety-valve to the steam boiler. When the pressure of vital force is prematurely applied the terminal buds burst, and the lower ones remain in a semi-dormant condition. Novices, noticing these growing buds fresh and green to-day, maybe blackened by the frost to-morrow, cry out, "What a prodigal waste of force!" But the prudent rosarian is content to waste the forward samples that he may save the main bulk of buds. Thus pruning, instead of becoming a mere mechanical operation or cutting back to so many buds all round, becomes a rather complicated vital problem of the deepest interest and highest importance. He will solve it best whose practical knowledge of the character and habit of each Rose is most minute and special. So much is this the case, that the time will probably come when almost each Rose will have its special mode and time of pruning.

At present, however, a large amount of generalisation must still be indulged in. Our first caution in reference to general pruning is to prune not at all; cut not a single twig or bough unless it be necessary, and it is by no means always necessary. Probably summer pruning and thinning may have already proved sufficient. And, besides, some sorts of Roses, such, for example, as *Maréchal Niel*, may need no pruning, their shoots breaking full length when left intact, and each break is one or more Rose buds in embryo.

The next point is to cut no more away than is necessary. Contrary to what might have been expected, the stronger the shoot the less should it be shortened back—the weaker the more; for much material and vital force are sacrificed in deference to the phrase, "keeping the Roses at home." Why, the home of the Rose is the largest space it can fill with fragrance and beauty in field or garden. But the phrase means cribbing, cabining, and confining the Rose to the narrowest limits consistent with its health. There is a grain of sense and reason in this phrase, as practical Rose growers will see; but to cut to the best bud is a far safer rule than to cut home. As to the time for the general pruning, much depends on soil, season, and locality. Could we depend on the weather after March, this general pruning might be completed in February; but as our seasons go, perhaps the four weeks included, from the middle of February to the middle of March is the best time for the pruning of Hybrid Perpetuals. Teas in the open may be deferred till three weeks or a month later. Those on walls, however, should be pruned early, and be protected against weather severities should they come. Where abundant space be provided for Teas, the less most of them are pruned the better. To loosen them and let them go free alike from the pruner's knife and the trainer's hard and fast lines would not merely enlarge the area, but enhance the character of their beauty. As for varieties such as *Niphetos*, protect vigorously against severe pruning. The wood buds are mostly developed contiguous to the flower buds. If these are cut off, the lower buds that are mostly rudimentary not seldom refuse to break, and the pruner draws a blank, shoots as well as flowers refusing to follow the sharp, severe cuts of the knife. Fortunately, however, *Niphetos* has few imitators in this respect, and the majority of Teas thrive and flower well under infinitely varied modes of pruning. The novice, however, had better not prune his Roses at all than prune them too often or in excess. More freedom, larger liberties for our Roses will probably be the next great step in advance. Perfection of individual flowers has probably almost reached its limit and had its day, and a day full of rich and glorious beauty it has been. The time for the emancipation of the plants from this unnatural thralldom and the cruel slavery of the pruning knife in excess is at hand, and when that day comes the place and power of the Rose in our gardens and landscapes will be revealed and made fully manifest.

D. T. FISH.

Rose buds by post.—In reply to "R.'s" queries respecting Rose buds travelling by post and keeping fresh two days in a state fit for budding, allow me to say that all depends on the way in which they are packed and sent. To be in good condition they must not be sent as buds, but on the wood, which should be firm and of fair length, to admit of the buds being taken off properly, with half an inch or so of bark above and below the shield. The packing should be done in a little damp moss or wadding, and then the bundle rolled in gutta-percha tissue or placed in a close-fitting tin box so as to prevent any drooping or shrivelling of the bark, which would be fatal to getting the buds off successfully, as the rind could not be slipped from the wood.—S. D.

Rosa berberifolia.—Can anyone tell me where this beautiful species is procurable? It has, I believe, a single yellow flower with a large blotch of crimson in the centre.—K.

SEASONABLE WORK.

FLOWER GARDEN.

Amarantus.—Several varieties of *Amarantus* are extremely effective in the summer flower garden, but on this occasion we shall only allude to two, viz., *A. caudatus* (Love-lies-bleeding) and *A. hypochondriacus* (Prince's Feather). The latter in good soil grows 5 feet high and produces its erect plume-like flowers in great profusion. Given plenty of space for full development, this kind makes a strikingly effective bed; but perhaps the best of all positions for it is as a dot plant in large basket beds. We have also used it alternately with *Humea elegans*, the light feathery flower-stems of which show off to the greatest advantage the more formal and stiff plumes of the *Amarantus*. *A. caudatus*, as its name implies, produces long drooping racemes of flowers frequently 30 inches in length; under good cultivation the plant will grow 4 feet high and erect, but the heavy inflorescence renders it necessary to keep it tied to supports. Treated in this manner it makes an excellent front or outer line to large beds of *Cannas*, and is unequalled for basket-bed planting, near the outer edge of course, in order that the long racemes of flowers may droop over the sides, and when thus used no supports are needed. Seeds sown in warmth any time during March, and the young plants pricked off into small pots two or three together as soon as they can be handled will make large plants by the middle of May, at which time they may safely be transferred to the open ground.

Roses and climbers.—The mild winter puzzles one to know what to do with *Roses*, for the wood is as succulent as it was in September last, and new shoots are, in some cases, several inches long. Such untimely growth must, to say the least, injuriously affect the future well-being of the plants. If pruned now, the buds as soon started might be crippled by sharp frost, and if left to grow as they now are doing, they must of necessity be constitutionally weakened. In such a dilemma it is best of two evils to choose the lesser, and this, we think, would be to prune forthwith, and also closer than usual, i.e., to the lowest prominent buds which, as a matter of course, will be the latest to start, and may consequently escape injury from frost. The mulching should still be left on the beds. Newly planted standard *Roses* should be tied to supports, and also mulched. The weather and state of the wood are this season both in favour of late planting, so that any *Roses* yet to be planted may be expected to do as well as those put in in November. Prune and nail, or tie in climbing *Roses*, *Clematises*, *Wistarias*, *Virginian Creepers*, and all other deciduous climbers. If the principal shoots are well secured to the walls, wires, or trellises at this season, they will give but little trouble all the summer, and may with greater certainty of safety be left to grow somewhat loosely from the wall or trellis, an infinitely better plan than that of keeping the young growths closely tied in. Ivy on buildings should be trimmed up before the plants start into new growth. Such annual trimming is necessary to ensure a bright green surface of foliage in summer, and equally so to prevent vermin effecting a lodgment in the Ivy. Similar remarks are applicable to banks and edgings of Ivy; the latter soon get out of form, and become objectionable unless they are trimmed up twice a year at least.

Fernery and rock garden.—If other work is pretty well advanced attention may now be directed to a general overhaul of the hardy fernery and rock garden—both departments that, because they can be neglected without seriously injurious consequences, are, as it were, too frequently left to take care of themselves. If the Ferns are at all overcrowded a general re-arrangement and extension of the fernery may take place, the present being a very good time for moving the plants; others will be benefited by being given a top-dressing of fresh peat or light loam. Dead fronds, Couch Grass, and other weeds should be forked out, and bare spaces furnished with mossy

Stonecrops, the tufty-growing wood Mosses, and clumps of wild Hyacinths, Scillas, Daffodils, Snowdrops, Wood Anemones, and Primroses. The addition of these hardy wildflowers produces a natural effect which is desirable, and the flowering kinds for the most part bloom at a time when deciduous or herbaceous Ferns are destitute of fronds, an additional reason for using them in such a connection. Much the same attention is required in the rock garden; there should first be a thorough clearing out of weeds, and next every plant should be well firmed in its place, and, if needs be, fresh soil given. Strong growing kinds should be prevented from encroaching on weaker ones by cutting away any portions that are likely to do so, and any spare plants so obtained can be utilised for filling up vacancies, or for furnishing any new addition that may be made to the rockwork.

INDOOR PLANTS.

Utricularia montana.—In every garden where there is the convenience of a warm stove and a disposition to cultivate something beyond the commonest plants this *Utricularia* should have a place. Its handsome and singular flowers, and its Orchid-like habit of growth render it doubly attractive. It is one of the best of small growing basket plants, requiring treatment as to soil, heat, and moisture similar to other West Indian subjects. It thrives well in a rustic wood basket in a mixture of peat, Sphagnum, and potsherds, keeping the collar well up above the surface of the soil. Its white, yellow blotched flowers are produced freely, and are very pretty.

Chrysanthemums.—Where the propagation of these is not done before the close of the year it will be well to at once put in a sufficient stock of cuttings, which will root if kept moderately close under a propagating glass in a little warmth, or even in a greenhouse, only the rooting process will be longer in the latter. Cuttings that were put in before Christmas should, as soon as struck, have enough air to prevent their being at all drawn. With a selection that includes the earliest and latest bloomers, as well as those that come in at the usual season, *Chrysanthemum* flowers may be had from September to the middle of January. In addition to the Japanese varieties, which are greatly liked by those who object to the formality of the show kinds, there are a number of free flowering sorts, of which the dark crimson *Julie Lagravère* and the blush coloured *Hermione* may be named as examples that are much more useful than the largest flowers.

Forced *Roses*.—Where *Roses* have to be forced along with a miscellaneous collection of other plants they cannot be expected to succeed nearly so well as when accommodated by themselves, and where such shifts have to be made there will always be a difficulty in keeping up a continuous supply of flowers through the winter not experienced when they have a house to themselves. The *Rose* under natural conditions requires plenty of air to keep it in health, but when forced the foliage cannot bear the admission of external air to an extent that most other things require without its leaves continually becoming a prey to mould. Where mixed forcing is carried on, and *Roses* form a part, the air given should be confined to admission at the roof ventilators, and only in small quantities, at the same time giving the plants plenty of light. In forcing *Roses*, especially the Tea varieties, the quantity of flowers produced will always be dependent on the strength the plants have in them; consequently from the time of their introduction to heat they should be regularly supplied with manure in some form, giving it either in the shape of liquid or in a solid state applied to the surface to be washed down to the roots in the ordinary process of watering. The Tea varieties are much the most under the influence of such feeding as here described, for so long as there is enough strength in them they at once start into fresh growth after one or two crops of flowers have been produced, which growth will bloom if not too weak. Plants of the Tea kinds that were put in heat in the autumn

and have been at work ever since will now require a rest. Assuming that they are grown in pots, they should be accommodated in a house or pit where they can be kept moderately close and not subjected to cold draughts or frost, for upon their being well treated now in this way depends their yearly gaining strength and ability to give an increased amount of bloom the ensuing winter. They should be kept as free from mildew and insects all through the spring and summer as they have been during the time of forcing. Another lot of plants ought to be put in to take their place, and if strong and in good condition, with fair treatment they will yield a succession of flowers that will keep on until the spring is far advanced. In *Rose* forcing during March and April a good deal of forethought is required in firing. The sun by that time gets powerful, and if the fire is not stopped early in the morning whenever there is a likelihood of bright weather, the temperature runs up so as to necessitate the admission of much more air than the tender foliage will bear; it is better when such occurs to let the heat rise even to 85° or 90° than to let in cold draughts on the plants. The use of thin shading in an emergency of this kind is preferable. Hybrid Perpetuals that have been prepared by a season or more's growth in pots may now be put in heat, and if not hurried will give a much better return than if started earlier. Even plants that were potted up in autumn from the open ground will yield a moderate quantity of flowers; but where no further preparation has been given than this, unless allowed to come on with little, if any, above a greenhouse temperature, the plants will be of little use for pot work, as the bloom they give under their unprepared condition is produced at the expense of the strength that was in them when taken from outdoors. Where *Roses* are wanted all the year round the right course is to get a sufficient quantity of plants strong and well established in pots, when with proper attention they will keep on gaining strength to produce many more and much finer flowers than partially established or non-prepared examples. If any of the plants are affected with worms, a little soot laid on the surface of the pots, where it will be washed down into the soil, will drive them away; their presence in the soil of pot *Roses* has a worse effect than with most things.

Pelargoniums.—Where considerable quantities of cut flowers are regularly required, a sufficient stock of early large-flowering *Pelargoniums* should be grown, selecting such varieties as are cultivated by the market growers which are naturally early and free bloomers, and will bear a good amount of fire heat without running to growth. The flowers of these are mostly of the frilled, or crimped petalled type, and on that account from their less formality are greater favourites for cut purposes than the even-formed florists' varieties. Where well prepared plants are at hand with their pots filled with roots, they will bear a temperature of 50° in the night without becoming drawn, provided they are kept close to the glass in a light house or pit. They may be had now in colour from almost pure white up to dark crimson.

FRUIT.

Pines.—The secret of success in modern Pine culture is rapid growth from the sucker to the fruit; the means to this end is the selection of one strong sucker from each plant after the fruit is cut, or perhaps two where stock is scarce. The best medium for the expeditious rooting of the young plants is the old-fashioned bed of fermenting leaves or tan, which should be well worked and placed in a close, compact pit, and when the heat has settled down to 90°, the suckers may be taken off, trimmed, and potted at once into pots ranging from 5 in. to 8 in. in diameter. From the middle of February to the middle of March is a good time to start with the first batch, and if the compost is rough, warm, and dry, there will be little danger of potting them too firm. Plunge at once into the bed with their leaves well up to the

glass, give them plenty of room, and defer watering until they begin to make roots into the new soil. Let the temperature of the pit range from 55° to 60° at night, with a rise of 10° by day, and damp the walls with a fine syringe after closing on bright afternoons. The stock of winter fruiters having by this time been greatly reduced, those left may be plunged into a sweet, fresh bottom-heat in a smaller compartment, or well-heated pit to finish off. The house they have hitherto occupied will then require a thorough cleansing and scalding preparatory to getting in fresh plunging material for the second batch of summer fruiters; meantime keep the plants steady and on the dry side in a bottom-heat of about 70°. Keep the air about fruiting plants generally moist and range the temperature from 70° at night to 85° or 90° after closing, with solar heat. Plants now throwing up fruit must be closely watched, and if, as is sometimes the case, the bed shows signs of a rapid decline from exhaustion of moisture, water between the pots with tepid water, and turn on more fire-heat to prevent it from descending much below 90°. This, with the aid of generous liquid in the pans and an abundance of solar heat, will help the fruit well out of the hearts of the plants without having recourse to continuous hard firing at a critical period when our uncertain climate does not always favour steady ventilation, and a liberal use of the syringe to counteract its drying influence.

Vines.—Remove all surplus bunches from the early Vines before they come into flower, leaving the most compact and best placed for the crop, and fertilise with Hamburgh pollen when they are dry and the temperature of the house has reached the maximum. All the Muscat-flavoured varieties, with the exception of Madresfield Court, require a little more heat than Hamburghs to set them properly, and on this account they should be grown at the warmest end of the house. But the mixed system is a bad one, and the sooner the large houses in private places give way to compartments for the different kinds of Grapes, the better will our culture be. The thinning of Grapes is a very important operation, and requires great care both in the manipulation and selection of the berries intended to make up the perfect bunch. If insufficiently thinned the berries become wedged and distorted, and seldom keep well even in summer, while, on the other hand, too much thinning results in a large-berried, straggling bunch, which never travels well, and spreads all over the dish as soon as it is cut from the Vine. To avoid these two extremes, so well illustrated in one of the classes at Manchester, a thorough acquaintance with the capabilities of the Vine is the first essential, the rest is a matter of mechanical skill; but in all cases the early and complete thinning of free-setting kinds as soon as they are out of flower should never be neglected. With increasing length of days and a continuance of mild weather, good progress may be made by shutting in plenty of sun heat, but 60° to 65° for Hamburghs, and 65° to 70° for Muscats through the night will be quite sufficient.

Succession houses containing such kinds as Black Morocco, Mrs. Pince, Gros Colmar, and some of the best white varieties, exclusive of Muscats, should be helped forward with fire heat and fermenting material to insure an early break and a long-growing season. If Hamburghs are not grown with them for fertilising purposes, see that a stock of pollen is collected from the early house when in flower. The much neglected Black Morocco, one of our best January Grapes, when left to itself is an invariable failure, but careful fertilisation with Hamburgh pollen for several days in succession secures to us a set equal to the most prolific Hamburgh. Provision should also be made for fertilising the Muscats when in flower, not with their own, but with foreign pollen, which may be kept for several weeks in a dry, warm place after it is collected. An important adjunct in the setting of all shy kinds of Grapes is the maintenance of fresh, active roots in a warm, well-drained internal border, and where these conditions do not exist the vigorous

application of steel forks, new drainage, and fresh compost will be found the best remedy.

Late houses.—The worst managed Vines in many gardens are the late ones. They are expected to accommodate themselves to a house full of bedding plants through the early spring, to break into growth, and set with a minimum of fire heat, to ripen their fruit and wood by September, and support a full crop until Christmas, the usual time for bottling. Another drawback is the inconvenient season for renovating the borders, but this should not stand in the way, as first-rate old Grapes which will keep up to the advent of new ones cannot be expected where the roots are not in the highest condition. Internal borders may be renovated at any time after the Grapes are ripe; the month of February is perhaps the best for lifting and relaying the roots outside, and quality, being of more importance than quantity, the borders should be elevated on good drainage, with a run of 6 feet to 9 feet inside and out. Good sods of turf built up as the border is made make the best retaining walls, as they are dry, warm, and elastic. Rich turfy loam, burnt earth, and about 12 per cent. of crushed bones make an excellent root-producing compost, and frequent mulching with rotten manure will keep them in full activity near the surface.

Melons.—Former directions having been followed, the first batch of plants will now be taking to the compost, in which they have to grow until they have matured a crop of fruit. If in 16-inch pots keep the fermenting leaves in which they are plunged frequently turned and renovated with a little short horse manure to prevent the bottom heat from falling below 85°. Place a stout stick to each plant, and train up to the trellis as growth proceeds. When this stage has been reached remove all side shoots at the first bud from the main stem, and carefully preserve the leaves for the twofold purpose of increasing the vigour of the plants, and the prevention of canker when the time arrives for shutting up with strong heat and an abundance of moisture. To secure an early set of fruit free kinds may be stopped when they have extended from 3 feet to 4 feet over the trellis; they will then throw out a great number of side shoots, bearing female blossoms, which must be fertilised, thinned out, and pinched when a pair of equal size have been decided upon. Although Melons are gross feeders when swelling off a crop of fruit, they require careful watering through the early stages of growth, particularly where the pots are plunged up to the rims in moist leaves, and unless the compost is very poor they never require feeding until after the fruit begins to swell. To keep up a steady supply of fruit a few seeds should be sown singly in small 3-inch pots every fortnight, and all surplus plants should be destroyed before they become pot-bound and infested with red spider.

Cherries.—As a precautionary measure in the management of these and Plums the fumigation of the trees just before the blossoms begin to expand should never be neglected. Some growers syringe with a strong decoction of Quassia, but Tobacco smoke permeates every cranny and makes short work where the liquid might fail. If inside borders were well watered and mulched at the time of starting the roots should be in good growing condition, but with success in all matters of artificial culture depending upon attention to minor details, this important point must not be overlooked. Pay particular attention to ventilation, as Cherries, like all other kinds of stone fruit, cannot be expected to set in a close, humid atmosphere. Syringe regularly until the flowers begin to unfold; give a little air at 50°; gradually increase it through the fore part of the day until a free circulation is secured; close again at the same figure, and allow the temperature to recede to 40° when fire-heat is needed, and 45° with a chink of air when the weather is mild. When the flowers are fully expanded and a sharp slake sets the pollen free, fertilise with a camel's-hair brush about noon on fine days. Discontinue syringing, but damp the floors frequently when there is a circulation of air strong enough to pre-

vent condensation of moisture on the glass and petals of the flowers.

KITCHEN GARDEN.

We have just sown our first spring seeds, including Dean's Snowball Cauliflower, Carter's crimson Incomparable Celery, Paris Cos and Hick's selected Lettuce, and a few Onions, to be pulled green for salads. The best Rhubarb which we get through the year is that grown in early spring by merely laying a little long litter on the crowns. The same may also be said of Seakale, but this should be covered with burnt refuse to exclude light, finishing off with a few half-rotten leaves. This is ready to cut in the end of March, and is truly delicious. Early Radishes we grow in boxes, 6 in. deep. They are placed in gentle heat until well up, when they are thinned out and transferred to cold houses close to the glass. Tarragon, Mint, and small salading we grow in the same manner. Early Potatoes in boxes should now be earthed up to the level of the box, giving no more water than is absolutely necessary. We know nothing so impatient of water as early forced Potatoes. As a matter of fact our early frame Potatoes only receive one watering during the time they are growing, and that is before they are earthed up. By watering at that time and earthing up immediately afterwards the soil about the roots keeps sufficient moisture for their wants. We planted our first house of Tomatoes February 12. The young plants grow much stronger when planted out than in pots; keep the house humid and warm, say from 55° to 60° at night, with a proportionate rise in the daytime, admitting air on all favourable occasions. The general work just now is to keep well ahead with digging. Every vacant inch should be turned up, so that the soil may get well pulverised by frost. All kinds of spring Broccoli will this year be a great success in more ways than one; it will give us an opportunity of selecting for succession the best varieties; here Snow's Broccoli heads the list for early work. We have been cutting a full supply of it since November. It is now (Feb. 12) finished. A variety called Hoskin's Broccoli is likely to prove a capital kind, coming in after Snow's; the heads are not large, but white and solid. Lymington will be the next, followed very closely by Watt's variety. These two last for some time, and are followed by Cattell's Eclipse and Burghley Champion, giving a succession until the second week in June.

Cottagers' shows.—In a valuable article on cottage garden associations, bearing the name of Mr. William Paul, and published in THE GARDEN of December 9, I particularly noticed the following paragraph: "Cottagers' shows of vegetables, &c., are very useful in stimulating the cottagers to exertion, but they should be so managed that no one exhibitor can take all the leading prizes." I have been secretary to a cottagers' society for some time, and in my experience I am bound to say that this very thing does take place in a more or less degree. I have also noticed the same sort of thing in reading reports of annual shows, both horticultural and agricultural, year after year, finding the principal prizes divided amongst four or five exhibitors. How to bring about an alteration so that the prizes could be a little more evenly divided, I am unable to say, but, seeing the fact mentioned, I am induced to ask if there is any remedy. I have known societies disqualify an exhibitor (first prize winner) for two or three years; others have limited the amount of prizes, and the consequence has been that a cottager so situated loses all interest—well, not altogether in the cultivation of his plot—but certainly in the welfare of the society. May I also ask the opinion of the readers of THE GARDEN as to what class labourers should be placed in who have sons living at home (or jointly in the same cottage), and whose daily occupation is in private gardens as labourers, the father being the occupier of the cottage for all intents and purposes, as far as the landlord is concerned.—D. G.

AMERICAN NOTES.

Thawing pumps.—It is not often that the water in pump tubes is frozen on cold nights if care is taken to let the water run down on the approach of evening by raising the handle. Pumps out-of-doors, or those not frequently used, may be secured from freezing by means of a small opening a few feet below the surface of the ground, allowing all the water to run out from the upper portion in the course of a few minutes. This small opening does not interfere with the ordinary use of the pump. But when the water in the pump becomes frozen solid, it is difficult to remove the ice unless right means are adopted. If hot water is poured in it only remains at the top, and scarcely thaws half an inch down. A contrivance which shall drive the current of hot water directly against the ice will melt it rapidly. For this purpose procure a small tube, which may be of lead (or even the hollow stem of a reed), place a small funnel in the upper end, and let the lower rest on the ice. Now pour hot water into the funnel, when its weight will carry it directly through the tube on the ice, which will be quickly melted, the weight of the settling tube keeping it all the time in close contact with the ice. A foot in length will be thus melted in a minute or two, while merely pouring in hot water from a pitcher would not effect as much in an hour.

Sheltered avenues.—Every footpath in the rear of the dwelling which is frequently traversed during the day in winter may be easily made more comfortable by flanking on one or both sides with evergreen trees, feathered with branches to the ground. If these trees are tall or rapid growers they may be easily kept of moderate size by cutting or pinching back, while they may be allowed to form a roof overhead even if standing a few feet from the walk. If planted from 3 feet to 6 feet apart they will soon form a good screen against winds and drifts. Health and comfort are sacrificed when feeble persons are compelled to expose themselves daily for want of this cheap and effectual protection.

Warm cellars.—An awkward and too common way to keep cellars free from freezing is to bank earth against the walls outside before the ground freezes in autumn, or to heap up manure instead of earth if not done till later. Both of these have a repulsive appearance, and are attended with a good deal of labour. A better way is to build the underpinning with double walls, with a space of air, with or without tan bark filled in, if the material of which the wall is built will admit it without losing strength. If the wall is not double, frost may be excluded with a few inches of sawdust kept in place by boards. Where neither of these modes can be adopted, an effectual exclusion of frost has been effected by banking against the underpinning with leaves, which are held in their place and kept from blowing away by forming a thin roof for them of evergreen branches laid in an inverted position to throw the rain downward. The leaves are raked from the lawn where shade trees have dropped them; and the evergreens are obtained by shortening in the trees on the ground which are spreading too wide or running up too high.—*Country Gentlemen.*

Absorption of water by roots.—Professor Goodall, in a recent lecture, says: "Aquatic plants absorb water through the surface of all submerged parts. Plants fixed in the soil absorb water through the superficial tissues of the youngest roots, and chiefly through root-hairs. Leaves of such plants absorb no moisture, even when wet by rain. When a plant is torn roughly from the soil, nearly all these root-hairs (which are delicate, elongated cells, thickly clothing a short portion of the youngest roots just behind the root tip) are left behind, and the power of the plant to absorb water is ended. The idea that the tip or spongy end absorbs water has been exploded by experiments, as also the idea that when these root-hairs, or the portions of the root which bear them, are torn off, water is absorbed by the wounded part. The whole work (except in the

case of coniferous trees, which have no root-hairs, and absorb water by the newer parts of the root, but never by the tip) of forcing water into the plant, against a pressure of three to five atmospheres, is done by these minute and delicate root-hairs.

A new Water Lily.—Mr. E. Sturtevant has raised a new variety of Lily from *Nymphaea devoniensis*, which, though not a species, Dr. Asa Gray thinks may be called *N. Sturtevantii*, provided a cross (x) is placed before the name in writing it. According to the description the flower is paler than the original. *N. devoniensis* was produced from *N. dentata*, which is a white flowering species, *N. devoniensis* being dark red.—*Gardeners' Monthly.*

Wearing natural flowers.—A St. Louis florist says: Probably more ladies would wear natural flowers if they knew how to fix them without danger of staining the dress by moisture. How can it be done? Easily enough where the spray has a background of Fern or Smilax, neither of which is moist. Roses, Carnations, and the Bouvardia, that spiked flower that looks like Jessamine, never stain. Any or all of these placed on Smilax, for instance, and the ends wrapped in tinfoil, could be worn with safety. If the spray should be at all damp, laying it on white unglazed paper will soon absorb the moisture. With a little care of this kind flowers could be worn on any dress.

Native Potatoes have been discovered in Arizona by Prof. Lemmon. They were found in a cleft of one of the highest peaks north of the Apache pass, under a tangle of prickly bushes and Cacti. Eager to know if the *Solanum* found was bulb-bearing, he carefully uprooted the little tuber, which proved to be an undoubted representative of the true Potato family. According to the researches and reasonings of Humboldt, this was the location to look for the home of the species from which our first Potatoes sprang. In May last Prof. Lemmon again set out in search of more specimens, choosing the Huachuca Mountains as his point for exploration. These mountains have two peaks over 10,000 feet high, with sides furrowed into deep canyons, those of the north-east being filled with trees, among which are Maple and Ash. In July last he discovered the Potato plants he was searching for on the southwest side of the range, hidden among the rich bottom soil of a dell in a high valley. A few plants of the white species were found in full bloom, and farther on blue blossoms were found. The white-flowered specimens formed tubers on shorter subterranean stems than the blue ones. The blue-flowered Potato plants sent off their runners from 18 inches to 2 feet. July 12 they were in full bloom. The blossoms were large and the white-flowered were of a creamy white colour, with greenish midribs to its corolla lobes. The subterranean stems were not longer than those of our common Potato. The blossoms of the blue-flowered are smaller, bright purple, with pale white midribs to the corolla, with fifteen to twenty flowers to a head. They are found at an altitude of about 8000 feet in Tanner's canyon, and some of the plants were 2 feet high. Later in the season they produced Potato balls of unusual size, comparatively speaking. These native species of Potatoes, which may have been and very likely are the original native stock from which all our Potatoes now used have sprung, deserve a fair trial and careful propagation to develop them to the size now attained by our best Potatoes. By the 1st of September the blue-flowered plants formed bluish-coloured Potatoes, oblong, about 1½ inches long by half as wide and a third as thick, with from four to ten unmistakable Potatoes on each plant. The white-flowered plants produced white Potatoes, nearly round, from half an inch to 1 inch in diameter. These Potatoes are unquestionably indigenous. Still another variety was found near the summit of a peak 10,000 feet high, under the shade of Fir, Pine, and Poplar trees, growing in soil kept moist during the greater part of the year by melting snows. Its nodding balls of ripened seeds were surrounded by Golden Rods and brilliant

Asters. Their tubers were tinted with purple, and seed-balls were either solitary or in pairs. Prof. Lemmon brought back with him over three quarts of these small Potatoes, comprising the different varieties, beside some seed-balls. A hermit in these mountains, whom Prof. Lemmon interested in his discovery, has recently written him that in digging up the bed of an old pond he has secured a lot of these Potatoes, perfectly white, as large as hen's eggs, which on being cooked tasted well, and have all the appearance of very fine Potatoes. Various cultivators have manifested the utmost interest in Prof. Lemmon's discovery, and are making careful preparations to cultivate the specimens he has forwarded them.—*Pacific Rural Press.*

NOTES.

The Rush Lily.—One of the most dainty and graceful of all early spring blossoms for contrasting with the Snowdrop is *Sisyrinchium grandiflorum*, rich claret-coloured, or white bells trembling in the wind at the apices of slender rush-like stalks. Before the flowers appear the whole plant is distinctly rush-like, indeed quite unlike most other early blooming bulbous plants.

The Killarney Butterwort.—Of all native bog plants this is one of the prettiest and easiest to grow in pans of peat, surfaced with living Sphagnum moss, kept constantly wet by placing the pan in a saucer full of water. Its botanical name is *Pinguicula grandiflora*, and in Norway it is sometimes used in place of rennet in cheese making. Apart from any economic interest, however, it well merits careful culture, and its mode of hibernating in the shape of little buds or green bulblets is of additional interest. In some localities it has been observed to become very scarce

Bulbils of Butterwort.

betimes, more especially after one or two mild winters, and this, as a friend is good enough to tell me, is due to the birds being fond of the green hibernating bulbils. When winters are severe and protracted the snow covers and protects them, but during mild wintry weather the birds make great havoc amongst them.

Prickly Ivy.—I forget just at this moment whether it is Herodotus or Pliny, who, writing of Smilax, says it is like unto Ivy, but has prickles upon its stems and leaves. Of the kinds most commonly seen *S. aspera* is one of the hardiest and best, and seldom fails to establish itself on a warm, dry border, or near a wall or tree stump. It has thong or quill-like roots, and throws up numerous shoots bearing grey blotched leaves of a dark glossy green tint. Its long, leafy stems cling to each other or to any supports near to them by means of numerous tendrils, and when cut are very useful for entwining into wreaths, or the leafy twigs endure fresh in water for many days, and are especially serviceable for associating with cut flowers because of their endurance, as also for their distinctive beauty.

Rare Pitcher plants.—The English home of the *Nepenthes* at Chelsea is always worthy of a visit, but at this season perhaps more especially so, just as the plants are producing their new crop of urns. *N. sanguinea* (red variety) still remains a beautiful rarity, so also the distinct *N. Veitchii*, but I am inclined to think that the new hybrid *N. Mastersiana* will be, when sent out, one of the best, and, moreover, most easily grown of all the Pitcher plants for some time to come. Its parents are *N. sanguinea* and *N. distillatoria*, and to the rare beauty of the one parent seems to have been added the free growth and robust constitution of the other. The extreme length of time during which its pitchers remain fresh and perfect alike in form and colour is worthy of remark; indeed, I am almost afraid to say how long

this is actually the case, but a specimen now before me has on it fresh urns considerably over a year old.

Hellebores are becoming more popular every day, their gracefulness of form and delicacy of colour during the earliest months of the year becoming more and more apparent. *H. colchicus* is a charming kind, its rich claret bells dangling on stout stalks a foot in height. *H. olympicus* and *H. orientalis* are also very attractive. The pink-flowered *Dr. Moore* is, when well established, very showy and distinct, as are also *H. atro-rubens* and *H. purpurascens*, with its mouse-coloured flowers. *H. cyclophyllus*, *H. odoratus*, and the evergreen *H. argutifolius* bear apple-green blossoms in dense clusters, which contrast well with those of the white and purple kinds. The great thing with all *Hellebores* is to plant them well in deep rich soil in sheltered positions and then leave them alone.

Orchis longicalcarata is one of those Algerian Orchids with which M. Durando rewards his patrons, and it well merits the most careful of culture wherever hardy terrestrial Orchids are appreciated. Its leaves are tufted and green, and from the centre of each little group

Orchis longicalcarata.

curves upwards a slender scape bearing from ten to twenty flowers, the sepals, petals, and spur of which are white, lilac, or purple, the lip being of a bright claret-purple tint. The white variety is the prettiest, and it is that shown in the illustration.

No words could well describe the graceful way in which the buds and blossoms are poised and clustered around the stem; there is a sense of animation about them very pleasing to notice, and a subtle fragrance enhances the other charms. Buds and long-tailed flowers alike are suggestive of a shoal of dolphins at play; no other simile seems to give any idea of their airy gracefulness of form, and certainly no epiphytal Orchid could well be more lovely than this Algerian beauty, which blooms thus early in the year.

A good wall shrub.—*Forsythia suspensa* is of all quick growing shrubs one of the best for sunny walls, its warm-tinted twigs and shoots being just now a light, airy mass of dangling yellow bells. A cloud of its gold-flecked branches is peculiarly attractive as seen thrown and tossed up by the wind against a bit of blue sky. The plant grows so freely from cuttings or layers, that one the more wonders why it is so rarely seen at this dull season.

A correspondent of the *Irish Farmers' Gazette*, speaking of the Chilean Pine, *Araucaria imbricata*, says, "The Woodstock *Araucaria* which, next to the Dropmore, is the finest specimen in the kingdom, was in 1881 52 feet in height; diameter of branches, 29 feet; girth of stem at 3 feet up, 7 feet 1 inch. The height of one of the common silver Firs growing in the woods is remarkable in this climate—107 feet high; diameter of branches, 59 feet; girth at 4 feet up, 14 feet 9 inches." These facts speak well as to the climate of Ireland, and more especially as to its being well suited to the growth of Conifers and other forest trees.

Hepaticas and hardy Cyclamens are now lovely in the spring sunshine, single blue and double rose Hepaticas being especially pretty. No hothouse flowers could well be finer in colour or freshness. I saw a lovely bouquet entirely of hardy blossoms the other day made for a lady who especially wished to have one so made, because, as she said, everyone else would be sure to have theirs made up of hothouse rarities. Snowdrops, Violets, Daisy buds and pink Hepatica blossoms, sprays of winter Heath (*Erica carnea*), and snowy white buds of the best Christmas Rose were used with great effect. Some day we must offer prizes for bouquets of hardy flowers at our horticultural exhibitions; it will be a "new departure" and might possibly do much to increase the popularity of hardy flowers and foliage.

Rare Nepenthes. The *Irish Farmers' Gazette* remarks: "That of that latest and most marvelous of the Messrs. Veitch's introductions in the way of Pitcher plants from Kina Balu Mountains, in Borneo, *Nepenthes Rajah*, there is a small specimen at Glasnevin (one of Messrs. Veitch's seedlings) now growing admirably, and giving promise of, at no distant day, showing the remarkable amplitude of its wonderful pitchers. Mr. Moore appears to have hit on the right treatment and right temperature (much cooler than that in which its fellows are grown) for this denizen of the mist zone of Kina Balu." This bears out what Mr. Baines wrote, that so soon as the cultural treatment of the species was adapted to its requirements, there would be no difficulty in securing as large, if not larger, pitchers in our hothouses as those it is known to produce "at home."

Garden catalogues.—Amongst many, two of these just to hand are so distinct and interesting, that all plant lovers should at once get a peep at them if they have not already done so. The one is Mr. W. Thompson's annual list of new and rare seeds; the other is M. Max Leichtlin's list of rare plants, which includes many not elsewhere procurable. Among other rarities in the latter list we especially note *Corbularia citrina*, the large sulphur-coloured Hoop Petticoat Daffodil, two or three rare Snowdrops, also of Torch Lilies, *Tecophylæa cyanocrocus*, a gem some time ago figured in *THE GARDEN*, and good kinds of *Yuccas*

and of *Anemones*. A rare old plant, *Calceolaria Kellyana*, is mentioned, as also the giant umbellifer *Euryangium Sumbul*, and two or three rare *Ferulas*. I wish M. Leichtlin would get up a stock of *Ferula persica*, of which Mr. John Bain had for years a unique specimen in the College Gardens at Dublin. *Narthex asafetida* is another much wanted plant. Botanical gardeners will be delighted to see that *Rheum Ribes*, one of the rarest of all the Rhubarbs, is offered in this list, as also some rare species of wild Roses.

Vanda furva is an old East Indian Orchid now but rarely seen. No doubt it has been banished from many collections because not showy

Vanda furva.

enough for modern taste. Among all cultivated Orchids, however, its colour is unique; but, colour apart, its sweet odour alone ought to secure it a place. Especially is its fragrance perceptible at night when it diffuses a subtle odour of Cowslips. One or two of its glossy brown flowers (behind they are whitish) in a glass of water are a great treat, and endure fresh and sweet a fortnight or even longer. The plant is robust and easily cultivated in any ordinary warm plant house, and is very graceful even when not in blossom.

Of all Pinguiculas, perhaps *P. caudata* (*P. Bakeriana*) is one of the most distinct and peculiar of cultivated kinds. It is quite *Echeveria*-like in habit; in fact, a friend tells me he had some sent to him which arrived in his absence, and his men unpacked and potted them off immediately, and then placed them in the greenhouse, imagining them to be plants of *Echeveria canariensis* in a small state. It grows well in an intermediate temperature on a shelf near the glass. It is said to be easily increased by means of its fleshy leaves inserted as cuttings. If anyone who has succeeded in so increasing the plant should chance to see these notes, I hope they will tell us how best leaf-cuttings may be induced to grow into little plants. Its long spurred, *Masdevallia*-like flowers are so beautiful, that any trouble would be amply repaid by its successful culture. Some day the bog plants and aquatics will become the fashion in our gardens, and then we shall introduce the shrubby *Droseras* from the Cape and the giants of their race from Australia, and the South American Bladderworts, including that lovely *Utricularia Humboldtii* and its allies, of whose beauty all travellers speak highly.

VERONICA.

Boundary fence.—What need is there for "W. J." (p. 72) to bother his head about a fence, unless he needs one for the protection of his own property? If he puts up an iron or wood fence he

may place it on the boundary line; but a hedge must be planted sufficiently far from the boundary to admit of being cut and dressed or otherwise repaired without trespassing upon one's neighbour's land; 3 feet 9 inches is the usual distance in this county (Durham). "W. J.'s" neighbour cannot be compelled to fence in his ground so long as there is nothing objectionable or dangerous on it or about it.—OLD MORTALITY.

FERNS.

THE BEST KINDS.

Asplenium.—This genus, one of the most extensive amongst Ferns, is composed mostly of evergreen species, nearly all of easy culture, and is represented in all parts of the globe by numerous subjects varying from a few inches, as in *A. alternans* or our well-known British *A. Rutamuraria* and *A. Trichomanes*, to several feet in height, as in the equally popular *A. dimorphum* and *A. lucidum*. It is very rich in highly ornamental plants suitable for decoration, and while some are very distinct and really interesting from a botanical as well as from a commercial point of view, the majority of them make grand specimens for exhibition, and those with long, drooping fronds are, on account of their leathery texture, particularly well adapted for growing in hanging baskets. *Aspleniums*, as a rule, are not fastidious in their habits; most of them succeed best in a mixture of fibrous loam, peat, and sand in equal proportions. In potting them great care must be taken that the drainage should be as perfect as possible, as if it is at all defective the plants soon become flabby and begin to show evident symptoms of ill-health. Above all, they dislike being potted hard. Certainly many of them will stand the full rays of the sun under glass, but although I have seen that mode of culture advocated in their favour and have been able to appreciate its results at their full value, I fail to find it beneficial in any way to the plants, which instead of being of a bright shining green colour, as nearly all of them are when enjoying good health, have a yellowish tint, although they are perhaps more hardy than those grown in partial shade. Nearly all the *Aspleniums* are either viviparous, with the upper surface of their fronds studded all over with young plants, or at least proliferous at their apex, producing at the extremity of each of their fronds one or a couple of bulbils, which later on develop into young plants. In either case if there is any desire to increase the stock of any particular proliferous or viviparous species, the parts of the fronds bearing the rudiments of young plants should be fastened down to the soil by means of wooden pegs and kept moderately moist, when they will soon root and make plants partaking of all the characters of the specimens which produced them.

A. alatum.—A very handsome species from Tropical America, producing from a thick, fleshy crown an abundance of fronds of a cheerful, light green colour, which often attain 15 inches to 18 inches in length; they are pinnate, with pinnae deeply serrated on their upper margin, whereas their inferior part is perfectly smooth; the fronds have their stalks winged the whole length, and are proliferous at their extremity; they arch over gracefully and make the plant very valuable for suspending in baskets. Stove.

A. alternans.—This distinct and interesting dwarf-growing species from the Himalayas at first sight resembles very much our British *Ceterach*, of which it possesses all the outside appearance with the exception, however, of the dense scaly covering of the underside, which is quite a peculiar characteristic of the species above named. The fronds are densely produced from a crown, and reach about 6 inches in length; they are pinnate with pinnae roundish and of a very pleasing light green colour. Its best place is in the crevices of rocks in the fernery, but it is essential that it should be situated where no drip or constant moisture is likely to be brought in contact with it; there it will be found to do best if planted on stone with a little peat only. Greenhouse.

A. apicidiens.—A very interesting species from the South Sea Islands, and closely related to *A. schizodon*, also from the same habitat, but from which it is readily distinguished by its sori being much shorter and set at a much more obtuse angle with the mid-rib. It is an evergreen Fern, producing from a thick caudex its smooth pinnate, firm, but scarcely leathery fronds growing to about a foot high, with smooth greyish brown stalks. The pinnae attain 3 inches in length and about 1 inch in width; they are borne on stalks and shortly lobed at the anterior base; their margin is toothed; the teeth near the base shallow, but elongated and more conspicuous near the extremity. It is altogether a most distinct species. Stove.

A. auritum.—This evergreen species from Tropical America and the West Indies produces from a thick decumbent caudex its very graceful fronds 15 inches to 18 inches long and tapering to a point; they are pinnate with the exception of the pinnule at the base, which is divided at the bottom, and is besides strongly auricled. The whole of the plant is of a lively light green, and capable of standing very well in the close atmosphere of a Fern case. Stove.

A. Baptisti.—A species recently introduced from the South Sea Islands, the habitat of so many good Ferns already in cultivation. This is a very distinct-looking Fern, perfectly evergreen, producing from a stout decumbent caudex broadly ovate fronds about 1 foot long, furnished with rather distant pinnae, each of them provided with a distinct stalk a quarter of an inch or rather more in length. The slender stalks of both pinnae and pinnules give a very open appearance to the centre of the fronds, which are also thick and leathery in texture. The basal part of the pinnae is split up into a few distinct narrow-stalked pinnules, bearing on their margins and at distant intervals a few linear-pointed teeth projected forward, which greatly add to the elegance of the plant. Stove.

A. Belangeri.—This handsome and deservedly popular species from Java is also known under the synonym of *A. Veitchianum*, but whichever name might receive the preference, no collection, large or small, should be without it on account of its distinctive characters, its compact and even growth, and the elegance of its general appearance. Its graceful feather-like long fronds are produced in great quantities from an erect and succulent caudex; they grow to about 18 inches or 20 inches long, are bipinnate, the pinnules being narrow and linear, and of a pleasing deep green colour; they are, besides, proliferous on all their length. It is a beautiful evergreen plant, and does not require any special care in its cultivation, but it must be borne in mind that slugs and woodlice, the latter especially have a particular liking for it when within their reach. Stove.

A. bifidum (A. lineatum).—A very pretty evergreen species from the Mauritius, and one of the best adapted for growing in a Fern case, although it will make a very handsome specimen grown either in the fernery, on rockwork, or in a pot. Its fronds, dark green in colour, are produced from a short decumbent rhizome covered all over with dark chaffy scales; they are from 15 inches to 18 inches in height, erect, tripinnate, and lanceolate in form, and the extremity of each pinnule is cleft or bifid. Stove.

A. brachypterum.—This is a very interesting little species from Fernando Po, where it is found at a great elevation. Although of remote introduction, it has not been so widely distributed as it really deserves. Perhaps the fact of its being a native of West Africa has caused it to be kept in a warmer temperature than it requires, and it has been in many instances lost after a short trial. The warmest end of a greenhouse or the coolest end of a stove suits it best. It is a dwarf, bipinnate evergreen Fern, whose finely cut fronds, about a foot long, of a bright green colour, are produced abundantly from an upright short stem; they have also the peculiarity of growing perfectly horizontal, on which account they are very useful for baskets of small dimensions.

A. bulbiferum.—This handsome species from New Zealand, perhaps the best known and most universally grown of all the *Aspleniums*, on account of its robusticity, is of a very rapid growth and easy management. Its handsome, pale green fronds are produced in great numbers from a scaly, fleshy rhizome; they reach from 18 inches to 2 feet in length, are very floriferous, so much so, in fact, that although being naturally of an erect habit, they are made quite pendulous by the great quantity of young plants to be seen upon them at any time of the year. Greenhouse.

PELLEA.

Bouquet Ferns.—What are the best Ferns to plant under a trellis on each side of a conservatory door for bouquets and for wearing in the hair? The house is heated with hot-water pipes.—C. W. [The following will probably answer your purpose, viz. :—]

<i>Adiantum emululum*</i>	<i>Davallia tenuifolia stricta</i>
<i>fulvum*</i>	<i>Microlepia strigosa</i>
<i>formosum</i>	<i>Nephrolepis exaltata</i>
<i>gracilimum*</i>	<i>pectinata*</i>
<i>mundulum*</i>	<i>Onychium japonicum</i>
<i>Asplenium bulbiferum</i>	<i>Polystichum flexum</i>
<i>dimorphum</i>	<i>Pteris cretica</i>
<i>laxum pinnulum*</i>	<i>c. albo-lineata</i>
<i>auritum*</i>	<i>longifolia</i>
<i>Davallia bullata*</i>	<i>scaberula*</i>
<i>canariensis</i>	<i>serrulata</i>
<i>dissecta*</i>	<i>s. cristata major</i>
<i>Mariesi*</i>	<i>straminea</i>

Those marked (*) are plants of comparatively dwarf growth. —S.]

KITCHEN GARDEN.

A SCARCITY OF PARSLEY.

How many gardeners are there who can conscientiously assert that they have never been without a sufficiency of Parsley? I should say very few indeed, and I may also safely remark that any who have experienced the worry attending a scarcity of Parsley will not readily render themselves liable to a similar recurrence. Parsley cooks must have, and we must grow it in sufficient quantity to meet the demand, and, further, instead of haphazard culture, it is imperative that we take such pains with it as it both requires and merits.

Small sowings of seeds made in any out-of-the-way spot may result in a sufficient plant to meet the needs of a small establishment, but if this practice is resorted to, even on a larger scale, where a good sized bunch of Parsley is required daily, failure will sooner or later be the result. The breakdown, as a rule, happens during the winter, spring, or early summer months, and unless extraordinary measures are taken to regain lost ground, the chances are that the scarcity will extend over many months. When scarce, every little bit of growth is closely pinched off, and no headway is made. Such a state of affairs existed here when I took charge of the garden. This was in mid-winter, but as I had previously "bought my learning," I knew what was best to be done under the circumstances. My first proceeding was to prepare heating material, consisting of leaves and stable manure in sufficient quantities to form a hotbed about 3 feet high at the back, and large enough to hold two 3-light frames. These were duly placed in position, and in them, when all danger from over-heating was past, was put a depth of 9 inches of good soil. In one frame Parsley seed was sown in drills about 6 inches apart, and into the other as many Parsley roots as I could buy or beg of the cottagers were thickly dibbled. In a short time the latter became established, and by keeping the frame rather close, we were enabled to maintain a fairly good supply till such times as the seedlings in the other frame were available to pick from. These seedlings were only slightly thinned out when they were in rough leaf, but when slightly hardened off, a considerable number, about the middle of April, were pricked out at the base of the warmest garden walls, and many more on a south border. They succeeded admirably both in the frame and transplanted, and since that time we have invariably sown Parsley

in heat, and pricked out a large breadth. Last summer especially we had good reason to congratulate ourselves upon the success attending this practice, as

Seed sown early in the open ground either failed to germinate, or the plants were cleared off by slugs before they could make any progress. Nor were we at all singular in our experience, as Parsley has been, and will be for some time to come, extremely scarce in this neighbourhood. A dripping season seems altogether unfavourable to Parsley, at any rate on heavy soils. It grows slowly, and will not keep after it is fully grown. In such a season it also appears to be more liable to bolt, but, strange to relate, that transplanted from the frame did not behave badly in this respect; in fact was no worse than the earliest sown in the open ground. We are frequently directed to sow Parsley at intervals from February to the end of May. This may be advisable in some cases, but I have never found it really necessary to sow more than twice, viz., once in the frame, the plants from this sowing being pricked out 6 inches asunder in rows 10 inches apart, and to succeed these a good breadth is sown in the open early in May, the plants resulting eventually receiving the same space as those transplanted. Should there be any gaps in the rows these are made good by dibbling in during showery weather plants obtained by thinning out where crowded. We consider Parsley both requires and deserves good open and well manured ground, this, for convenience, being selected near a pathway. Every plant should have room and time to develop, but the thinning out should be done gradually in case of accidents or rather attacks from insect pests. Any plants that run to seed prematurely are closely pinched back and continue to yield serviceable leaves.

W. J. M.

A LASTING HOTBED.

THE following description of a hotbed refers to the plan which we adopt in order to secure a crop of early Cucumbers, and as it has been in use here for many years I have no hesitation in recommending it. I should, however, state at the outset that it is not adapted for gardens where fermenting materials are limited. We use a three-light frame 12 feet long and 6 feet wide and of the ordinary depth. As a foundation for this frame a pit is dug out 2 feet deep and 2 feet larger in every way than the frame. A drain is connected with the pit to carry away any water that may accumulate there, for it is indispensable that the materials forming the bottom of the hotbed should be kept free from any excess of moisture. Brick piers are provided in the pit to support the frame; for a three-light frame four piers back and front are necessary; the piers are 1 foot square and about 6 inches higher than the surrounding level. A piece of plank projecting 6 inches inside the frame and of the same length as the frame is then placed on each line of piers. On these planks the frame rests, and when put in position there it remains; there is no sinking, nor is it placed, like the ordinary hotbed, high up in the air where the wind has so much power as to considerably reduce the inside temperature when most wanted. When once such a pit is formed and the piers built it will last for many years without requiring any attention; at least, so we find it in actual practice, and as I have had to grow early Cucumbers under all sorts of conditions in pits and in frames, I must say that by this plan not only are earlier crops secured, but the work is accomplished with less trouble and greater certainty.

Preparing the fermenting materials.—We use fresh manure from the stables, prepared in the ordinary way by placing it in a heap and turning it over once a week until it gets thoroughly heated, when it is fit for use. Before the frame is put on the pit is filled up to the top of the piers with the hot manure; the planks are then placed on the piers, as has already been stated, and the frame is put in its place. To support the soil in which the plants are grown, boards must be provided to fit the inside of the frame; these rest

on the projecting sides of the planks. Our boards are 7 inches wide and 2 inches thick, and we find that good Larch boards will last for a period of ten or twelve years. Thus it will be seen that after the fermenting materials sink away from under the boards, which they do long before the season is over, the bed of soil remains intact, and suffers nothing because of the outside linings, which are above the level of the surrounding ground. The construction of the bed may now be said to be complete, and all that is wanted is to keep up a regular temperature inside.

Linings.—Supposing operations for the production of early Cucumbers or Melons are commenced at the beginning of the new year, the heat supplied by the manure in the pit will suffice with just a thin lining outside to keep up the temperature for three or four weeks, but as soon as the heat declines in the frame the linings must be attended to, the thickness applied depending upon the heat required. We make our linings 4 feet wide all round the frame; we do not like thin linings through which every puff of wind can blow. The manure for the linings does not require much preparation. If very long and dry, as brought from the stables, we place it in a heap and turn it over once. We never turn the old linings, but simply add to them as the heat in the frame declines, and by commencing early in January, and by putting out small plants raised from seeds sown and placed in the stove a month before that time, we have in favourable years been able to cut Cucumbers as early as the 8th of March. It is, however, only right to say that we have wooden covers to place on the linings; they are 4 feet wide and made of feather-edged boards nailed to cross-pieces, and there is no doubt that these covers confine the heat and compel it to enter the frame. However, we experience but very little difficulty in keeping up the temperature to 70°, and far less steam is generated in a bed of this description than in a common hotbed. I should hardly like to say how many thousand cuttings are struck in our frames during the first three months of the year, but this I may say, that we find it superior to the propagating pit for succulent cuttings. We find it necessary sometimes during a spell of cold weather in May, when the linings have reached the top of the frame, to remove a portion of the old lining altogether and substitute some well-prepared hot manure. This soon revives the heat, and the bed will then go on through the season without any further attention, i.e., if confined to the growth of Cucumbers.

The depth of soil placed in the frame is about the same as would be placed on a hotbed made in the ordinary way; but as the soil is supported by the boards, it is not difficult to understand that whatever may be planted out in the bed will require more water to keep it in a satisfactory condition as regards moisture than when the soil rests on the fermenting material, as is the case in a common hotbed. At first sight the details just given may appear prohibitive, but, speaking from a lengthened experience of the management of hotbeds generally, I can freely assert that the plan here given will, if carefully worked out over a series of years, bear favourable comparison with any other with which I am acquainted.

J. C. C.

Magnum Bonums and Champions—

I grew several acres of these Potatoes side by side last year, and have had considerable experience of them for several years, and shall ask permission of your versatile correspondent, "Peregrine," to differ with him, especially as to the keeping properties of the Champion variety. He says, "they are really coming in season after this date (p. 147)." This is correct as regards the Magnum Bonum, but from this forward, especially after March, the Champion—the flesh of it when cooked—has a number of black patches like as if bruised, rendering it almost worthless for table use. For ordinary purposes up to that time it is decidedly the best general crop Potato, but I differ from "Peregrine" in saying it "affords good food until new Potatoes are plentiful." I wish for the sake of my countrymen this were true.—W. J. M., *Clonmel*.

FLOWER GARDEN.

PLANTAIN LILIES.

(FUNKIAS.)

FEW hardy perennials are more ornamental and showy than Plantain Lilies, as not only have most of them very beautiful foliage, but they bear a profusion of Lily-like flowers, the spikes of which are exceedingly useful for cutting, as they look well and last long in water. Besides being so fine and effective for borders, many of them make capital pot plants, the best for which purpose are the variegated-leaved sorts, such as *F. ovata aurea variegata*, *F. ovata glaucescens variegata*, *F. ovata undulata aurea*, *F. ovata maculata*, *F. ovata argentea*, and *F. o. elegans*. Any of these, taken up and forced make a splendid show in a greenhouse, as does also *F. Sieboldiana*, which has magnificent leaves that are very striking on account of their colour, which is of a bluish metallic green, with a glaucous hue pervading the surface. Planted out in deep, moist, rich soil in a shady position, this peculiar hue is intensified, and plants of this Funkia form noble objects in the hardy fernery, or near the margins of ponds, in either of which positions they look quite at home by associating well with the various surroundings. The best for growing for the sake of their flowers are *F. subcordata grandiflora*, which blooms in the autumn, *spatulata speciosa*, *Fortunei*, and the different varieties of *ovata*, the latter being very free and affording plenty to cut. The time to propagate and plant Funkias is from now to a month or so onwards, as they are just beginning to grow, and may with safety be taken up and divided to almost any extent. The way to effect the division is to either dig up the plants to be operated on and pull them apart or by the use of a sharp trowel or spade cut clean through the crowns where they stand, securing to each portion a prominent eye with plenty of root. The plants so obtained may then be distributed about in the borders according to their strength, or planted out in rich soil somewhere to grow on for lifting and cultivating in pots. When required for this purpose they should be potted in the autumn or winter and stood in cold frames to come gradually on and fit them for forcing, which needs to be done slowly if the foliage is expected to be of good texture. To get the variegation fine the plants must have plenty of light, which may be afforded by keeping them well up to the glass, and it may be necessary also to keep them freely supplied with water and liquid manure.

S. D.

SHOW AURICULAS—ALPINES.

IN Mr. Horner's interesting notes (p. 163) he omits to say that the unshaded form of the alpine Auricula has a very different "status" at the exhibitions of the southern section of the National Auricula Society from what it has in the north, and consequently our northern florists, who show only the shaded form, very seldom win first-class honours when they come against Mr. Turner and Mr. Douglas, who exhibit both shaded and unshaded. It was to assimilate more nearly the northern practice with that of the southern that I proposed the admission of the unshaded alpine at our northern show. I see no reason why self-alpines should not be produced as successfully as are the selfs of the ordinary show Auricula. It is pointed out by Mr. Douglas, in his "Florist's Flowers" (p. 21) that the alpine Auricula has not been so long nor so patiently cultivated as the other sections, and that it is only within the last ten or fifteen years that the best varieties have been produced. Are we to stand still and say that alpine show Auriculas must for ever be shaded? Rather say, if good selfs are produced, we welcome them also, and will allow them to compete for the prize. For my own part, I value the alpine Auricula even more highly than the other variety, because it is more hardy, and is useful in the open garden ground, without all the care and protection which its greater rival requires. At recent shows several entirely new forms of the shaded alpine have been placed on line, and have won prizes against

the older sorts. They are much taller in the flower-stalk, larger in the flower, and shaded almost to a fault, suggesting the term laced Auricula in describing them. It is believed that this class has been raised from German seed, and there are numbers of them to be picked out of the market florists' seedling beds at Sale and other places near Manchester almost good enough for the exhibition table. These boldly shaded and laced alpine are very useful for gardening purposes.

M. Gusmus, of Villach, has sent me a long and very interesting letter upon Primula hybrids, written from the purely botanical point of view, and with reference to my remarks in THE GARDEN of February 3 (p. 116). He consequently takes a very disparaging view of our pet Auriculas; "They are not Auriculas at all, but are bastards of the Auricula through crossing with *hirsuta*, *villosa*, &c., for one always finds them in the wild state as bastards, unless they are yellow in the flowers." But there are florists as well as botanists and it is amongst the former that we class ourselves. I hope to have some of these original parents of the Auricula in flower this spring, and it will be an interesting subject for enquiry. There can be no doubt, in my opinion, that the alpine Auricula has a different Primula parentage from that of the show Auricula proper, and it is possible enough to perfect it so as to raise new varieties, as has been done with the other. If these prove not only beautiful, but perfectly hardy also, they will be of great value. WM. BROCKBANK.

Brockhurst, Didsbury.

ENOTHERA EXIMIA.

I AM rather doubtful whether the true *E. eximia* is in existence. In 1873 the late Mr. Niven, of Hull, received a plant bearing this name, but he told me it was not true. It was planted in a bed of peaty soil, such as he grew his best Japan Lilies in, and it grew rapidly and flowered well. Its rambling tendency was quite as dangerous as that of another equally beautiful species, viz., *E. speciosa*. Whether the true species is tender or not, Mr. Niven must have known this was, as anticipating severe weather he covered it with peat siftings, principally composed of dead Bracken roots. I remember seeing it grow and thrive well for three successive summers, always appearing, like Coltsfoot, in the most unexpected spots.

A plant of *E. eximia* came to Mr. Whitehead's garden at Southwood Bickley, in the spring of 1878, from Mr. Parker's, Tooting, which proved to be precisely the same kind as that which Mr. Niven had. I have not seen Mr. Parker's catalogue for two or three years, and so cannot say whether he still offers it or not. At Southwood it was planted in the lower parts of the rock garden slope, near the level ground, with a view to wintering it in the same way as at Hull. It grew rampantly during the wet season of 1878, and flowered tolerably well, but its tendency, probably through excessive moisture, was to climb the slope and get into drier, stony soil. In the following autumn I protected it with a mixture of peat and river sand, but the winter being very severe nothing was left of it in the spring of 1879 except pieces which had got into drier soil, and these were so weak that they succumbed to the dry east winds and hot weather which followed in June; since then I have never seen it.

E. eximia (?) flowered in the way of *E. taraxacifolia*, but had entire leaves, and it had not the large cross-angled seed-carpels of the latter, and it rambled underground, like the Coltsfoot, not above. *E. taraxacifolia*, moreover, is little better than an annual, sowing itself freely in some localities. Perhaps Mr. Eyles can give us some description of the variety he had, and where obtained. T. H. D.

New yellow Feverfew.—Looking over the lists of novelties for this year as they come to hand, I have been much struck with this, and would, with your permission, ask further about it. If it can be compared with the hardy perennial double white, and is as useful for garden decora-

tion, but especially for cutting purposes, to my mind it is the best hardy flower introduced for some time. The double white bloomed last year with me continuously, producing perfectly double flowers for eight months out of the twelve, while even now the foliage is handsome. A dwarf yellow with such characteristics would be an acquisition, especially for cutting.—W. J. M., Clonmel.

NIEREMBERGIA RIVULARIS.

THIS is a charming plant, beautiful in all its phases, but particularly so when its cushions of green foliage are studded with open, cup-like

so high amid the dwarf surrounding herbage as to be discerned from a distance. Hence one would infer that it is a moisture-loving subject, which undoubtedly it is, but, strange to say, we have seen it do well in a dry sandy border, such, for instance, as in the herbaceous ground at Kew. The healthiest tufts we have seen were on the margin of a running stream in full exposure, but where the soil was perpetually moist, but not submerged in winter. The soil was a stiff loamy clay. Though such conditions as these cannot always be obtained in a garden, any approximation thereto is better than

Nierembergia rivularis.

flowers nearly 2 inches across. The colour of the blossoms is a creamy white, sometimes faintly tinged with rose, while the centres are invariably of a golden yellow. It flowers during the summer and autumn months, often without intermission, when the plants are perfectly flourishing. It is a trailing plant and forms a dense carpet of foliage in a short time, and when once the roots have got a firm foot-hold it is a difficult matter to eradicate them, for small pieces will vegetate. The majority of cultivators of hardy plant collections have had some experience of it as regards culture. In some gardens it thrives with little or no attention, while on the other hand some try their utmost to coax it to flourish without avail. It abounds naturally by the banks of the River Platte, but only within high tide mark, its flowers rising

placing the plant in an ordinary border to take its chance with the ordinary hardy perennial. Two conditions are necessary—plenty of moisture at the roots and full exposure. It may be easily propagated by division; in spring each portion will root readily in a short time. This little gem was introduced about sixteen years ago by Messrs. Veitch, in whose catalogue of new plants for 1867 it was first announced, with the annexed illustration.

Viola Mrs. Gray.—To those having much summer bedding to do, and who are anxious to economise the labour of getting up sufficient stock, as well as to save space in pits and houses for more valuable plants, I would strongly recommend this Viola. It is a long way the best of all white-flowered, dwarf-growing bedding plants that

have come under my observation. It is dense and spreading in growth and more floriferous than any *Viola* with which I am acquainted, except it be the old cornuta, and it is equally telling in masses or marginal lines, and when mixed alternately with plants of *Ageratum Cupid*—delicate lilac in colour—no more pleasing bit of colouring could possibly be imagined. It flowers, too, continuously from the time when it is planted to the end of November.—W. W. H.

SNOWDROPS IN SOMERSET.

THOUGH common Snowdrops are indigenous, there are, I believe, no counties in which they grow in such quantities as in Somerset and Wilts. Here they are to be seen, at least where protected, as plentiful as Primroses will be shortly, and are certainly more valuable than these in every respect. At the present time immense quantities are being collected and sent to the markets, Covent Garden salesmen receiving by far the greatest quantity. According to our experience the single forms, though much the prettier, are either gradually becoming double or are dying out. In the grounds here we commenced picking Snowdrops on January 14 from plants growing in sheltered spots. About a week later there were abundance in the woods and shrubberies, while yet a week later our lawns and the orchards of other people were literally clothed in white. They appear to spread more rapidly in and near the hedgerows, and all the bulbs are at a great depth below the surface. I find that the strongest bunches are at least 6 inches deep, and, in addition to piercing through this depth, the growth and flowers are unaffected by thick spits of turf that had been disposed over a quantity of them. Our soil is a strong clayey loam with a clay sub-soil, and this also prevails in the neighbourhood. From these facts it will be seen that the Snowdrop succeeds best on heavy soils, and should not be planted near the surface. In our case they do not interfere in any way with the mowing, the foliage, or rather bulbs, ripening early; and nowhere are they so effective as on turf.

For decorative purposes the blooms are invaluable. For instance, we employ several hundred bunches during the season for dinner-table decoration, and, owing to their unusual earliness, they have been available for the country house as well as the town house. We seldom use more than two colours at a time on the dinner table, or when filling vases, and I am of opinion that white flowers alone with Ferns are the most pleasing. We recently employed Snowdrops, Maiden-hair Fern, and Moss on one night, using the same materials with Marie Louise and Czar Violets on another; while on the third night, highly-coloured leaves of *Berberis Aquifolium*, with a spray of *Jasminum nudiflorum* laid on each, are substituted for the Violets. Nearly the whole are disposed on the cloth, as nothing either tall or heavy is admitted. The Moss is first laid round the candlesticks, either in a plain circle or in the form of a geometrical figure, and on this are placed small bunches of Snowdrops, or these in mixture with bunches of Violets, the Fern fronds being freely disposed among them. Sometimes the designs are wholly filled with Snowdrops and other flowers, or, if these are not available in sufficient quantities, miniature Ferns or fine foliaged plants are substituted. In addition to this, the table is also festooned with Moss, Ferns, and Snowdrops, so as not to interfere with the space required for those who are to dine. Sometimes a perfectly straight band of Snowdrops (in bunches) is taken round the table, just outside the dessert dishes. We also fill small glass bowls with Snowdrops, a frond of *Adiantum gracillimum* being disposed slightly above the blooms. These bowls are arranged in the outer line, the scrolls running up to or surrounding them.

Leut falling early this year, dinner parties will be few while Snowdrops are to be had, and it is more especially for wreaths and crosses that they will be found serviceable. It falls to our lot to have some of each to make or fill every week, and

Snowdrops are largely employed for the purpose. For both we usually bunch them, putting about twelve blooms in a bunch. When making a wreath, the groundwork consists of sprays of *Cupressus Lawsoniana*, the outer and inner rings are composed of Snowdrops, some other white flower is taken through the centre, and fronds of Maiden-hair Fern and points of *Panicum variegatum* are intermingled. A serviceable wreath consists of Snowdrops and Christmas Roses, while Snowdrops, and either white Azaleas, Deutzias, or double white Primula, though less durable, are extremely beautiful. A wreath should be full, yet light and elegant, and, to succeed to perfection, each flower or each bunch should be bound on separately. To attempt to bind on whole handfuls at a time will produce a bad result. Crosses, unless in the form of zinc troughs filled with sand or water, are made somewhat similar to the wreaths. The prettiest, yet most durable, arrangement I have attempted consisted of Snowdrops and Christmas Roses, while on the cross was hung a neat wreath formed of the foliage and blooms of Marie Louise Violet. W. I. M.

BEDDING CALCEOLARIAS.

FEW have been more tried than I have been to get Calceolarias to succeed in a satisfactory manner when bedded out in the flower garden in summer. In hot, dry weather such as that which we experienced in the summer of 1870, the plants died off after being planted in a very mysterious manner. Strong, healthy plants, apparently thriving and full of vigour in the morning, would look in the evening as if a blast of scorching wind had passed over the beds and singled out here and there a plant on which to expend its fury. Under such circumstances the only consolation I had was to know that I did not suffer alone, for in gardens widely apart the same thing occurred. I do not, moreover, remember that the reason for their so suddenly dying was ever clearly explained, and I make no attempt to do so. I am glad to say that during these last five years I have been more successful, and as I have altered my way of preparing the plants, that may have something to do with it, as may have also the comparatively cool, damp summers that we have lately had.

Cuttings are put in under handlights and in cold frames in October, and are protected during winter from severe frost. Early in March we prepare a position under the north side of a high wall. We make the ground fairly rich, and are careful to break it up well with a fork, and as our land is heavy we place on the surface 2 inches of sifted material from the potting bench, a mixture which contains all kinds of soil, and in many cases a good deal of sand. It is really a valuable mixture for such a tender-rooting plant as the Calceolaria, which evidently likes it, for our plants commence to make new growth in it soon after they are planted. We plant out about 9 inches apart every way—a distance which gives room for the plants to branch out from the main stem and become bushy. I should have said, however, before that we make a point of taking off the top of every plant a fortnight before they are taken out of the cutting frames, so that by the time they are planted out on the north border side shoots are already bursting out at the axils of the leaves, and if we get a very mild growing time through the month of March we generally top them once more about the middle of April. In order to protect the plants while undergoing preparation before being bedded out we construct a temporary framework and cover it with mats when there is any appearance of frost. This night protection is continued up to about the third week in April, after which no further shelter is needed; but it must be understood that we are in the west of England. Early planting has been frequently recommended as the best means of preventing Calceolarias from dying off; but I doubt its efficiency, and in but few places is it practicable, for spring gardening has become so general that it is quite the end of May and sometimes later before the flower beds are ready to receive their summer occupants. Of this I feel certain

that it is unwise to plant out Calceolarias in very bright weather, the roots being liable to get scalded by the hot dry earth. It will always pay to wait for a dull day on which to plant, a remark which refers more especially to plants prepared as I have advised, by growing them in a north aspect. It is on this particular point that I base my present success. J. C. C.

The blue *Hepatica* here in the cold north-east of England, despite the saline blasts from the German Ocean, is now covered with hundreds of flowers, and near at hand the white kind (*H. triloba alba*) shows a number of its delicate blooms—truly a pretty sight. On a sheltered part of the rockwork, *Saxifraga Burseriana* is also in full bloom. Plants of this putted in autumn and wintered in a frame come into flower at this time, and prove useful companions for Hyacinths, Tulips, and similar spring flowering bulbs.—P. M. M., Hull.

The winter *Heliotrope* (*Petasites fragrans*) is a very desirable plant to grow in quantity in the wild garden where there is not much grass. It is flowering freely with us this mild wet season, and we find it useful for cutting from. Although hardy, it is not a native of this country. Therefore in sharp frosty weather during its flowering period its blossoms rarely escape destruction, except in very sheltered situations indeed. I have seen it do well behind a north wall on a sort of rocky border.—J. G. N., Stamford.

Narcissus viridiflorus (p. 164).—Mr. A. Kingsmill, of Eastcott Cottage, Pinner, is the only one whom I now remember to have collected bulbs of the above in modern times. It is generally considered a true species, but there is (or was) a variety of *N. Jonquilla* at Kew singularly like it, except that it flowers in May instead of October. I once passed the neutral ground where it grows between Gibraltar and Algeiras, but, alas, our boat did not coal there. M. Durando, however, may have bulbs of it to offer.—F. W. B.

Aponogeton distachyon dying off—I can fully confirm what your correspondents say as to the destruction of this plant. But are they sure there is not something else besides either rats or mice at work? In the case of a plant here I feel certain the injury was not done by either of these troublesome little animals. The tank in which our plant was growing is a concrete one, oval in shape, with upright sides, and the water never reaches nearer the ground line than 18 inches, and as this tank is close to one of the most frequented walks in the garden, I think it impossible for either rats or mice to get in and out of it without being seen. The plant disappeared much like that described by "R." (p. 116), viz., the leaves first and then the flowers, but in the case of our plant the root was left. It, however, rotted through being constantly denuded of its leaves. All I ever saw to account for the evil were numerous round-headed little fish, which I am rather inclined to think destroyed the plant, and I think it probable that there might have been something of the kind connected with the destruction of "R.'s" plant also.—H. CARTER, Downhill, Coleraine, Ireland.

Garden Anemones.—The assumption of Mr. Dobbie that my Anemones, which have done so admirably and bloomed so freely all the winter in strong soil, are set on a warm, south border is erroneous, and is characteristic of the opinions which seem to prevail that Anemones are but fair-weather plants, and will only thrive in specially prepared light soils and under specially favourable conditions. It is that error which I am anxious to combat, and, indeed, it is my own experience that plants growing in light soil and in much the warmest position are not nearly so forward as those where the soil has for weeks past been little better than soaked clay. *Anemone fulgens*, usually so early to bloom, has not yet, on a warm south border, opened a single flower, whilst last winter the same roots bloomed continuously from November. During the previous summer we had some real ripening heat, hence the roots were well matured and vigorous. Last summer proved cool,

the autumn being specially so, hence the lack of vigour in the roots this spring. My coronaria Anemones were well baked for a week or two in the summer and got well ripened, then when the early autumn rains came they started into growth and were full of strong leafage in November, and bloom followed in great abundance. Mr. Dobbie holds that the tubers need ample ripening. I think in that point lies one of the great secrets of successful culture. Although the soil here is so wet and stiff in the winter, yet being exposed to the full action of the sun it burns or bakes quickly in the summer, and thus the Anemones get the full benefit of the sun's ripening powers. The production of new or enlarged tubers is going on now, and of course the earlier the better. Then the more thoroughly the soil is baked in the summer the better for the tubers, and the earlier they push growth in the autumn. I am disposed to think the tubers are much better preserved in the soil than if taken out and put into bags elsewhere to dry off.—A. D.

Lobelia cardinalis fulgens.—This is such an extremely pretty and useful plant for the flower garden, when under liberal treatment, that it is quite invaluable, especially for a mixed style of gardening, where, in addition to bedding plants, biennials and perennials are largely employed. From the latter part of July until far into autumn no plant can surpass it in brilliancy; its handsome foliage also is always strikingly effective. We winter our plants in a cold pit, where they remain until early in March; they are then placed in a little warmth, when, as soon as the side shoots have grown 2 inches or 3 inches, they are divided into single plants, and returned to the quarters whence they came until well rooted, when they may be gradually hardened off, and finally planted out from the middle to the end of April. A considerable advantage over ordinary bedding plants is thus gained, the plants being out of hand a month earlier, by which space and labour in watering at a very busy season are saved. If treated as a herbaceous plant, and left in the bed or border from year to year, this Lobelia throws up too many flowering stems, which do not attain the height, vigour, or luxuriance of plants that have been divided and restricted to a single shoot. The beds chosen to receive them are broken up 2 feet deep, and well enriched with good rotten manure. They require plenty of room, and should be planted not less than 16 inches asunder, in order to allow the lateral shoots to fully develop, as it is from these laterals, after the main stem has finished flowering, that a brilliant and continuous display will be obtained. I was much pleased with some beds of this plant which I saw last season at Blickling Hall. They were planted with standard variegated Acers (slightly pruned) in the centre. The Lobelia came next, and the edging was *Tagetes pumila*. The brilliant flowers and dark foliage of the Lobelia, mingling with the green and white of the Acers, was very rich and pleasing. These Lobelias were in the most robust health, from 4 feet to 5 feet in height, and well furnished with lateral shoots one mass of flower.—W. ALLAN.

Hardy Primroses.—Clean and beautiful as Snowdrops look, even after the heavy rains we have had, it is, alas! otherwise with hardy Primroses; although the season of their fullest bloom is so near, they look far less gay than they have done at any time during the whole winter. In fact, they are now almost, under water, so flooded is the ground in all directions. But strong plants full of bloom have wonderfully recuperative qualities, and should a day or two of sunshine and quiet come the myriads of buds nestling down in the robust leafage would send up some pioneers to report on the general outlook, and if but a fortnight of dry, sunny weather came these few would be changed into a multitude. Primroses are so very sweet, that not only do the birds exhibit a greedy taste for the flowers in many gardens, but slugs do so everywhere; and hence many a lovely flower becomes food for these vermin, instead of gladdening the eyes of mortals with its beauty. Some dry weather would rectify this,

and send up blooms faster than slugs could destroy them. But such is the notorious uncertainty of our winter seasons, that early in the year I took the precaution to lift a few roots into a frame, and these, happily protected from the almost unceasing beat of wind-driven rain, are just now most fresh and beautiful. Of course, these spring flowers should not be blooming at such an unreasonable time of the year; but as they are, and there is no help for it, it is better to have some blooming in rich loveliness under glass than to leave all to be slug-eaten and bedraggled with rain, wind, and dirt.—A. D.

FRUIT GARDEN.

OUTDOOR STRAWBERRIES.

It is the practice with many, especially amateurs, to dig amongst their Strawberries at this season, which is a great mistake, as by so doing surface roots are injured and destroyed, and these are the most important and principal feeders. Another thing that is almost equally hurtful to Strawberries is the denuding plants of their old foliage, which is their natural protection, and should not be removed, as it breaks off wind during the cold month of March, and shelters the young leaves, which gradually push up under and through it till they quite hide it from sight. Instead of the trimming and shaving to which they are usually subjected, it will be much better to allow them to remain as they are with their winter dress on, and to add another coat by covering the ground among them with short stable manure. Before this is done, however, the land should be cleaned by hoeing, but only just sufficiently deep to cut up the weeds, which may then be raked off, cleared away, and destroyed. In some gardens where the soil is stiff, wet, and cold, slugs are troublesome, and as their headquarters are generally among the Strawberry beds, it is a good plan, before putting on the manure, to mix some soot and fresh slaked lime with it, which will not only be fatal to the slugs harbouring about the plants, but destroy their eggs at the same time, and thus prevent further breeding. It often happens that old plants of Strawberries grow themselves out of the ground, as it were, and get their crowns much raised, and in cases like this it will do them much good to top-dress the beds with an inch or two of rich mould, and to work the same well up round the collars, when the plants will soon root out from the stems and gain much in strength. Where beds are exhausted and it is desired to make fresh ones this is a good season to do it, but the land where it is intended to plant should be deeply trenched and heavily manured, as success in the growing of Strawberries depends on their getting well down. In trenching, however, the sub-soil should not be brought to the top, but kept below and have the manure mixed in with it there, to which the roots will be attracted, and there find something to feed on during dry weather. Although Strawberries require deep ground to grow in, it cannot well be made too firm, as when loose and hollow the plants run too much to leaf, and do not make the fine crowns and bear with that freedom they do when the land is more solid. This being so, it should be well trodden and made level by raking, when all will be ready for marking the beds out and planting the plants. The distance at which these should stand depends very much on the sorts, as some require more room than others, and nothing is gained with any by crowding, as though they may bear more fruit, it is sure to be of inferior quality, and especially is this so with Queens, which require a deal of sun and light to ripen and colour them well. The best way with this kind is to have the rows a yard apart, as the plants may then go closer in the rows than when they are only the usual distance of 2 feet, and therefore almost as many plants can be put in on the same sized piece of land by having them about 18 inches asunder, a sufficient distance when the rows are at wide intervals apart. By planting in this manner, the strawing down can be done easily, and the picking of the fruit carried

out without danger of treading on and spoiling it, as there is plenty of space left clear for working and walking. If young plants can be obtained, they are the most preferable for planting, but some growers are quite indifferent about them, and dig up and pull the old crowns to pieces, and make fresh beds from them. All that is necessary in doing this is to select the strongest and best pieces, and secure with them as much of the stem part as can be got, when they may at once be dibbled in and buried close up to the leaves, immediately below which they will quickly send out a host of young roots, and during the summer form fresh plants at the sides. S. D.

DIGGING AMONGST RASPBERRIES.

THESE, like Strawberries, are often much weakened and injured by the spade or fork, as being surface rooters, they cannot be dug amongst without the principal feeders being destroyed, and therefore the ground should never be disturbed beyond what is absolutely necessary for keeping weeds down. The way we manage is to give a good dressing of half-rotten manure, which we put on immediately after the canes are thinned out and restaked and tied, and as it lies the greater part of the winter, the juices get washed out and enrich the soil for the plants. During spring and summer the manure is of equal or even greater service by the shade it affords, thus preventing evaporation, which is of great importance to Raspberries, as they require much moisture when swelling and ripening their fruit. A mulching, in a great measure, secures this for them, especially when put on early, as then the rains are kept in the earth instead of being drawn out by the sun and wind in the spring. Many who grow Raspberries are much put to for stakes to support them, and various are the plans adopted to do without them, one of the best being to bring half the canes of one plant over to the other, so that they meet and form an arch by bending and interlacing or tying the tops. This keeps them stiff and erect, and another good way is to strain a strong piece of galvanised wire down the sides of the rows, to which the Raspberries may be made fast by a tie. What I prefer, however, are iron rods, which, though a little dear at first, are the cheapest and best in the end, as they last for an indefinite time. Bars about five-eighths of an inch are quite large and strong enough, and as they are made in 15-foot lengths, they are long enough for three stakes; a ton of metal, costing about £7, will make a great number. All the labour that is required on them is just to cut them and hammer one end to a point when red-hot, and then dip it in tar, which will preserve it from rusting. The other part may either be brushed with tar or painted lead colour, either of which will last on for years. S. D.

Freeing orchard trees from Lichen.—On a foggy morning when every branch is wet have ready some finely sifted, freshly slaked lime, then place a ladder up the centre of the trees infested with Lichen or Moss. With bucket in hand ascend to the top and work downwards, dashing the lime all over the branches and stem. By following this practice I have by an annual dressing completely cleansed an old orchard from this pest.—W. C. T.

Well drained fruit tree borders.—If hardy fruit growing in many parts of the country is to be attended with anything like success, greater expense than has hitherto been incurred will have to be generally gone to in the preparation of the ground. In this northern climate (Durham) it is out of the question under ordinary circumstances to attempt Peach cultivation out of doors; but, even with Peaches, a good deal could be done to ensure success. If, for instance, as much care were exercised in making a border as is the case with them under glass, Peaches might even here be grown on open walls. In the first place, thorough drainage is wanted to warm the gorder, and this should be done by at least one good drain being made down the middle of it.

This drain should be as deep as it is practical to make it—from 6 feet to 8 feet would be none too much. Drains are often rendered almost useless by being too shallow. They then only take off surface water, while the subsoil still lies cold and damp—the greatest enemy to fruit trees. If this drain could be filled up to within 2 feet of the surface with rubble, so much the better. The border should next be thrown out 2 feet deep; and if the soil is unsuitable for the trees, let it be entirely removed. In the bottom place about a foot deep of rubble, which may consist of stone, broken bricks, or some such porous material, and cover this over with rough ashes, to prevent the roots from sinking down to the soil below; next make up the border with suitable soil 2 feet thick at the back and 18 inches at the front, on a border, say, 9 feet wide. For Plums, Pears, Cherries, and Apples, a border made on this principle would also pay the labour and expense bestowed on it. By the trees standing high and dry, the wood would be better ripened, less damage would be done by frost, and a more certain crop would be the result. A great deal can also be done in the training of wall trees to help their fruitfulness; for instance, the branches should not be placed too closely together, nor should they be allowed to be over-crowded with spurs; thus there would not be too much foliage to shade the forming fruit buds from the influence of the sun and air. The main thing, however, is to have the trees dry and warm at the roots; and to ensure this, the border should be well drained and not too deep.—A. M.

Duke of Buccleuch Grape prize.—Mr. McIndoe is informed, in response to his inquiries, that the statements respecting the hundreds who grow this Grape to 4 lbs. and 5 lbs. weight, and other matters, are to be found in *THE GARDEN* of October 28, 1882, and in the *Journal of Horticulture* of December 7, 1882. Mr. McIndoe is himself the author of the other testimonials quoted. He is also referred to the revised advertisement in *THE GARDEN* of January 27 last, which meets his other inquiries. The advertisement has been worded so as to afford the widest opportunities to exhibitors, and the object of the prize is stated. The conditions have been suggested by the various statements of those who have vouched for the weights and keeping qualities of the Grape, like Mr. McIndoe, and who may accept the offer as a challenge on their part, while the prize is open to all who care to try for it, but the subscribers do not intend to enter into any controversy on the subject.

TREES AND SHRUBS.

THE LAWSON CYPRESS.

THIS Cypress (*Cupressus Lawsoniana*) attains in its native habitat in North California a height of about 100 feet. In this country it has proved to be thoroughly hardy, of quick growth, and one of the best trees of late introduction as regards ornament, shelter, and general utility. It is propagated principally from seed, contained in small cones, which ripen on the trees in abundance. As a rule, the cones should be gathered when they begin to open, as if left too long on the tree the seeds are apt to be shed and lost. Sow broadcast in April in nursery beds about 4 feet wide, and as the seeds are small in size I have found a light sandy soil, well worked and thoroughly pulverised, to be most suitable for that purpose. The after-nursery treatment is similar to that usually required by Larch, Scotch Fir, and other hardy conifers. In forming a new plantation in 1870, on the property of the late Sir William Verner, Co. Armagh, Ireland, I planted a mixture of *C. Lawsoniana* along with Larch, Scotch Fir, *Picea nobilis*, and a few others. The plantation contains an area of about thirteen acres, the soil of which consists of three classes: First, poor gravelly soil with a thin coating of moss on the surface; second, stiff argillaceous clay; and third, peat bog. Plants of *C. Lawsoniana* were planted here and there throughout the whole plantation,

with the view of testing their capabilities as forest trees, and for the most part they have proved to be a complete success, the only exception being where they were planted on a few patches of stiff plastic clay, so impervious that rain water laid on the surface. On these patches the Larch also refused to grow, or at least made very little progress. With this exception the trees throughout the rest of the plantation are all that can be desired. The most remarkable feature of this plantation is its scenic effect, which is widely different from anything one is accustomed to see in woodlands generally. Although the seeds were all collected from one parent tree, raised in one seed bed, and planted out at the same time, yet the progeny showed great variety both in appearance and habit, some of them being perfectly conical and with branches gracefully pendent; others more upright, close and stiff, and a shade darker in colour. The site of this plantation is somewhat exposed, being surrounded on the north and west by a Heather-covered peat bog, and on the east by a lake consisting of about ninety-five acres. When planted out in quantity in exposed situations, large plants ought to be avoided, as from the density of their foliage the wind exerts a greater pressure on them than on the Scotch Fir or Larch; the top of the latter being less dense, wind passes freely through the branches, doing little harm, whereas if large plants are used of the Lawson Cypress they are apt to be upset.

As regards hardiness, this tree is all that can be desired. I have seen it growing side by side with the Larch, and while the latter was severely seared by late spring frosts, the former stood unscathed. Sometimes this tree produces a plurality of leaders, a circumstance which must be set right by pinching off all but the most central. I have, however, often cut them clean off with a sharp knife, and as this tree will withstand any ordinary amount of stem and branch pruning with impunity, the operation does no harm.

J. B. WEBSTER.

TREES AND SHRUBS FOR TOWN GARDENS.

IF I say that the common Aucuba is the only evergreen shrub that really thrives in London I shall be told by many that Box and Holly and perhaps a few others do equally well there. Let those who think so go up to town and walk round the parks and squares; they will see what a different appearance all the evergreens, with the one exception of Aucubas, present from those growing in the country; both Box and Holly will be seen to have a thin, starved look, their leaves few and far between. I often wonder why the Chief Commissioner of Works, or whoever the Government official responsible for the public parks is, does not try the same system for planting the parks with evergreens as people who go up to London for the season do in the case of a carriage and horses, viz., "job" them. It would, I should think, be easy to contract with some of our principal nurserymen for Rhododendrons and other handsome evergreens, choosing especially those with compact roots that would not suffer in transplanting, all to be renewed every two or three years, before the London smoke has had time to spoil them. If this plan were adopted one could walk round the parks and look on bright shining clumps instead of the half-dead specimens that are there now. [This has already been tried to some extent in the case of Rhododendrons in Hyde Park.]

"F. W. B." might have added a few good things to his list of deciduous shrubs suitable for town parks. The following occur to me to be hard to beat, and are all easily grown, viz., Lilac (the French varieties), some of which have larger and showier blooms than the common kind; Weigela, Philadelphia, or Mock Orange, commonly called Syringa; there are many beautiful varieties of this Viburnum, Rhus Cotinus.

AN OBSERVER.

Mistletoe on the Peach.—There is at Penshurst Place, Kent, a Walburton Admirable Peach on a south wall with Mistletoe growing on it. Is Mistletoe on the Peach a rare occurrence?—F. B.

Early Rhododendrons.—"Veronica" has been wrongly informed respecting the parentage of Rhododendron *præcox*. It is not a hybrid between an Azalea and a Rhododendron, but was raised by myself from *R. dahuricum* and *R. ciliatum*, the latter being the pollen parent. It is now twenty-three years since it was first sent out, and though it has been widely distributed it is not so well known as it deserves to be. "Veronica" is correct in his description of the plant, and in addition to the good qualities named I may say that it is extremely useful for forcing, as it may be brought into flower early in November by successive years' forcing. There are two other forms of *R. præcox*—*rubrum*, a shade darker in colour, and *superbum*, with larger flowers and somewhat earlier. I have many hundreds now expanding their blooms, and at this season of the year when outdoor flowers are scarce these make a most attractive display in the borders.—ISAAC DAVIES, *Brook Lane Nursery, Ormskirk*. [A drawing of *R. præcox superbum*, sent with this note, shows well what an attractive shrub it is. The flowers are represented as large, produced in massive trusses and of a deep mauve colour.]

QUESTIONS

Drive gates.—Are any drive gates made that will let wind through, and yet be impervious to curious eyes? My present solid 10-foot doors are often damaged by gales. Would something ornamental in the jalousie blind way suit?—W. V. L.

Begonias.—Can any reader of *THE GARDEN* tell me where to procure the following Begonias, viz., *splendida*, *Mayeri*, *nelumbifolia*, *peltifolia*, *Warszewiczii*, and *heracleifolia*? These are magnificent at Kew, but I cannot find them anywhere else.—M. P. F.

Tropeolum speciosum.—Would some reader of *THE GARDEN* give cultural directions for this beautiful *Tropeolum*, and say whether it may be successfully grown in the southern portions of the British Isles? No lover of flowers who has seen it in the north of Scotland can help wishing to bring it further south.—AMATEUR, *Dublin*.

Slugs.—Will any reader of *THE GARDEN* kindly tell me of some means of keeping slugs from eating my plants of different kinds—Lettuces, Peas, Pansies, &c. I have been told to try paraffin oil mixed with water, but I do not know the quantities. Can anything better be suggested? If so, I will feel much obliged by being informed of it.—T. C. B.

Diseased Ixoras.—Can any reader of *THE GARDEN* advise me as to the best plan of getting rid of a disease in *Ixoras*? We have three fine plants which, up to last autumn, were very healthy, but since then they have been affected with brown blotches on the leaves, and I find now that the wood is also beginning to decay in different parts. They appear to be quite healthy at the root.—F. S.

Peach buds dropping.—What is the cause of the wood buds of Peaches dropping? It cannot be put down to want of water, as I had the lights off and they were exposed to all the autumn rains. The other day I examined the border down to the drainage, and I found it to be quite moist. They have made good wood, which is, I think, well ripened, and the bloom buds just opening look well and strong. If any of your correspondents can enlighten me on the matter I shall feel obliged.—SUB.

Brown Mushrooms.—Will some of your readers kindly answer a question or two about Mushrooms. I have been pretty successful in growing them (in a Mushroom house) lately, but they frequently turn brown after watering. This is done about once a week with lukewarm water. The temperature of the Mushroom house is from 55° to 60°. Side by side with the brown failures appear really fine Mushrooms of a good colour. The brown ones wither up and are useless. Can anyone explain the reason of this?—MARK NESFIELD.

Fruit tree grubs.—We have been very much troubled for two or three years past with grubs on our Pear, Apple, and Cherry trees as soon as the buds begin to expand and the leaves to develop. We find one, and sometimes three or four grubs in each leaf, which they roll up with a kind of web, and from the leaves they go into the blossom, which they completely destroy. No insecticide seems to kill them, the great difficulty being to get at them, as they are rolled up in the leaves. There are two kinds—one a small brown grub like the Rose grub, the other a pale green, about half an inch long when fully developed.—W. C.

NOTES OF THE WEEK.

OPEN SPACES ABOUT HACKNEY.—Mr. Runtz, the Hackney member of the Metropolitan Board of Works, has stated that it is the intention of the board to take steps for the immediate improvement of Hackney Downs, London Fields, Clapton Common, Stoke Newington Common, and other open spaces within the Hackney district, by forming paths, planting trees, providing seats, &c., at an aggregate cost of nearly £1500.

INTERNATIONAL POTATO EXHIBITION.—The schedule for the next show to be held in the Crystal Palace on September 13 and 14 has just been issued. It contains 21 classes, similar to those of former years, but with some additions. The arrangements for growing and judging new varieties are, by the aid of the Royal Horticultural Society, to be continued. Intending competitors in the seedling classes should therefore send samples to Chiswick as soon as possible, in accordance with the published regulations.

THE DUKE OF WELLINGTON'S STATUE.—The First Commissioner of Works proposes to appoint a committee to inquire into and report upon the subject of the most eligible site for the statue of the Duke of Wellington, now being removed from the place where it has stood for thirty-seven years at Hyde Park Corner. The following have agreed to form the committee: Viscount Hardinge, Sir Frederick Leighton, Mr. James Fergusson, Mr. Boehm, Mr. Mitford, and the Duke of Wellington. The sites which will be chiefly brought under consideration are—a spot within the new grounds now being laid out near Hyde Park Corner; a position in St. James's Park, opposite the Horse Guards; and one in Hyde Park, opposite the Knightsbridge Barracks.

PRIZES FOR EARLY PEAS.—In order to stimulate the production of new sorts of early Peas of high quality, and also to test the value of Mr. Laxton's latest effort in this direction, Messrs. Hooper & Co., of Covent Garden, offer the following special prizes to be competed for at the Royal Horticultural Society's meeting at South Kensington, on May 22, next, viz.: for two dishes of early Peas, one of them to be Laxton's Earliest of All, 1st prize, £3; 2nd, £1 10s.; 3rd, 15s. Each dish to consist of twenty-five pods, and the trademark of the seed packet of Earliest of All must be placed on the exhibit as a proof of its genuineness. Intending exhibitors will please make a note of this announcement, as it is not inserted in the Society's schedule.

EARLIER OPENING OF KEW GARDENS.—Some time ago attention was directed to the hardship occasioned to many persons by keeping Kew Gardens closed every day till one o'clock. The representations made to Mr. Shaw-Lefevre on this subject have just obtained from him some concession in that respect. The other day when Sir Trevor Lawrence asked for some information on this point, the Chief Commissioner of Works announced that for the future the gardens will be thrown open at midday to visitors instead of at one o'clock. An hour is thus gained, which will prove a considerable boon in early spring and in the latter part of the autumn, periods when there are not many hours of daylight. We trust, however, that the time is not far distant when Kew Gardens, at any rate in summer, will be opened each morning at ten o'clock.

—The following letter from the Treasury to the Office of Works, with reference to the extension of the hours during which Kew Gardens are opened to the public is published in a parliamentary paper:—

Treasury Chambers, January 12, 1883.

Sir,—The Lords Commissioners of Her Majesty's Treasury have considered the proposal made in your report of the 1st instant, that the Royal Gardens at Kew should be opened to the public at noon throughout the year, and as they gather that this extension of the public hours will not interfere with the management of the gardens or with the important work carried on there, they are

pleased to approve of this proposal. My lords are unable to check Sir J. Hooker's estimate of £200 17s. 2d. for this purpose, as transmitted by you. If, however, you are satisfied of its correctness, and that no more economical arrangement will suffice for the purpose, my lords sanction the requisite provision being made in the Royal Parks Estimate for 1883–4, so that the scheme may come into force on the 1st of April next. I am, however, to say that in arriving at this decision they have had regard only to the purposes for which Kew Gardens are maintained at the public expense, and they cannot impress upon you too strongly the importance of bearing in mind that these gardens are a national institution, whether as ornamental garden or scientific station, and not a local park. Your department and the director of the gardens should be on their guard against appearing to make any changes merely to meet the needs of local residents, whose interests may often conflict with those of the public, and who may easily be led to think that they (as opposed to the nation at large) have vested rights, of a general or specific kind, to the enjoyment of the gardens.—I have, &c.,
LEONARD COURTNEY.

The First Commissioner of Works.

Ghent International Exhibition.—The programme has just reached us of the forthcoming international exhibition to be held at Ghent by the Société Royale d'Agriculture et de Botanique. The show will be opened on April 15, and will continue to the 22nd. The schedule comprises 292 classes, and of these 268 are devoted to groups and specimens of plants. The first twelve classes are for new plants in collections of twenty, twelve, and six, and for single specimens. Seventeen classes are devoted exclusively to Orchids, and some are for species of one genus, such as Vanda and Masdevallia. Fine foliaged plants, including Palms and Ferns, occupy nearly a hundred classes, and the rest are devoted to Azaleas, Camellias, Rhododendrons, and ornamental trees and shrubs, such as Conifers and Hollies. Ample provision is made for spring-flowering bulbous plants, which will be just in perfection, and also for Roses, Clematises, and a host of other classes of plants. The prizes in every case consist of medals. Three are given in each class, the highest value of the gold medal being one hundred francs. The other medals are in silver and bronze. Altogether it appears to be a thoroughly representative programme, and in all probability there will be an excellent and extensive show. We notice that the cups offered by Mr. William Bull, and usually competed for in London, will be competed for at this show this year.

Woodlice.—The only way in which we rid Mushroom houses of these pests while the beds are in bearing is to trap them and kill them, which may easily be done by the use of a number of small flower-pots with a piece or two of boiled Potato in each as a bait, and a loose wisp of straw or hay as a shelter to the woodlice when they crawl in to feed. The pots should be lifted and examined every morning and the woodlice emptied out into boiling water, or killed in some other way so as to prevent their escape. Fowls are very fond of them, and if carried to them and thrown down they will soon eat them all up. Woodlice only harbour and breed in dry places, and all parts of the house where these are should have boiling water poured occasionally on them; if it does not reach all it will drive them out and force them into the traps. When the house is again clear, and before any fresh beds are made, it will be advisable to fumigate by burning sulphur, and if the door is kept close shut, the smoke will force its way into all cracks and crevices, and settle accounts with the woodlice, so that the next start may be made with a clean bill of health.—S. D.

—I have always found the following to be effectual in clearing pits, frames, and houses of woodlice: Get a few 6-inch flower-pots and put a piece of Carrot about the size of a Walnut over the hole inside; then fill the pot three parts full with soft, dry hay, pressed in firmly, but not too hard.

Invert the pots on the beds and examine them every morning, and evening too, if very numerous, and shake the woodlice out into boiling water; replace the Carrot and hay as before. Another way is to get a few Turnips, cut them in halves and partly scoop them out and lay them about the beds. A third way is to make a few holes about 4 inches wide and 6 inches deep close to the side of the beds, and fill them with hay. Each morning pour boiling water on the hay, putting fresh hay in each time.—GARDENER.

—Has "C. F." tried pouring boiling water into any cracks or crevices into which they may hide? They very much dislike moisture, so that if the bed could be thoroughly wetted, and then some small garden pots filled with dry Moss laid about, into which they might creep and be dry, would probably in the morning be found to contain a number. A piece of cold boiled Potato placed amongst the Moss forms a good bait. Toads are very useful in destroying woodlice. Searching the house at night with a lantern for a few nights would probably diminish their numbers very much. Fill up all cracks in walls or floors where these creatures can hide.—G. S. S.

Ants.—I have been troubled like "S. O." with ants, and have found this to be a good plan: Fix a piece of string to a clean, fresh bone, and place it near the plants, and when the bone is covered with insects lift it up by the string and quickly immerse in hot water. The same bone may be used several times. Also look out for their nests in the pots, and shake out the ball of the plant over hot water and repot, still persevering with the bone traps.—G. A. F.

OBITUARY.

MR. T. SNELLING, gardener at the Middle Temple, died very suddenly on Tuesday last, the 20th inst. When passing along Fleet Street in the morning of that day he was observed to fall to the ground insensible, and when conveyed to King's College Hospital he was found to be dead. He was 45 years of age, and was appointed gardener at the Middle Temple about four years ago, on the death of Mr. Dale.

Names of fruit (J. L.).—Beurré Rance.

Books (J. Tullett).—Paxton's "Botanical Dictionary" or Johnson's "Gardener's Dictionary" (Bell & Son, Covent Garden).

Principal country seats of Great Britain.—H.—These are illustrated and described from time to time in THE GARDEN. Many years ago McClean, in the Haymarket, published a work on the subject with coloured plates, and possibly it may still be procurable there or from some of the large second-hand booksellers.

New mode of killing thrips and red spider.—Under this heading I see described (p. 148) a method which I have adopted these last six years for exterminating these pests, and with the most satisfactory results; but instead of using clean water of late, I have found it advantageous to mix with it a small quantity of soft soap. I found that a temperature ranging from 118° to 130° effected their destruction and that simply dipping was sufficient to kill both thrips and red spider. By repeating the operation a week hence the plants were seen to be thoroughly cleansed.—J. R.

Names of plants.—H. T. R.—*Eranthemum pulchellum*.—E. Hunter.—1, *Croton Wismanni*; 2, *C. interruptus*; 3, *C. aucubefolius*; 4, *Phyllanthus nivosus*.—M. & Co.—*Cornus Mas*.—E. C. A. "This is an Art

Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

AMARYLLISES AT CHELSEA.

IF the late Dean Herbert, who devoted a lifetime to the study of the Amaryllis family, could have seen in his day such a gathering of hybrid Amaryllises as that which now forms the chief attraction in Messrs. Veitch's nursery at Chelsea he would doubtless have looked upon it with mingled admiration and perplexity. Such an array of mule productions would certainly have somewhat embarrassed him; he could not have classified and described them so methodically as he has done the comparatively few that existed when he compiled his still valuable work on the Amaryllidaceae. At that time what may be termed primary hybrids only had to be dealt with, that is crosses between species and between species and introduced varieties; consequently a pretty correct idea of the origin of each could be obtained. Since then, however, those hybrids, which numbered some three dozen, all furnished with Latin names, have intercrossed amongst themselves and later introduced species, the result being the marvellously increased number of Amaryllises now in existence, and which appear to have reached the acme of perfection. Thirty years ago it was possible to record correctly the parents of each, but now the varieties have become so intermingled that their origin is in a great measure obscured. Among the three dozen hybrids recorded by Dean Herbert there appears to have been a strong family likeness, but this was not the fault of the hybridist, whose materials were then comparatively limited.

In point of numbers, the type species then in cultivation far exceeded those to be found at the present time in gardens; indeed, it is doubtful if some of the species the Dean of Manchester grew in his garden at Spofforth forty years ago could now be found anywhere in Europe. Though there was a larger number of species at that time, there was a similarity among most of them in general appearance, though differing in structural characters; hence no great steps could be made by hybridising. Nearly all these species, which numbered about a dozen and a half, with about as many wild varieties, were worked upon by the hybridists, but they evidently had a preference for a few of them from which they were most likely to make the greatest strides in point of size, shape, and colour. The principal species worked upon then were *A. Reginae*, a plant figured in the *Botanical Magazine* so long ago as 1799. This crossed with *A. vittata*, another old plant figured in the same work in the year 1790, gave *A. Johnsoni*, which seems to have been one of the very first hybrids. This is now in bloom in the Chelsea collection. By crossing *Johnsoni* with *A. aulica*, which has played a most important part in Amaryllis hybridising, gave the beautiful high-coloured *Acramani*, raised by Messrs. Garraway, of Bristol. This, however, is quite distinct from *Acramani pulcherrima*, a variety which has more than any other infused such high colours in Amaryllises. This hybrid was also raised by Messrs. Garraway about 1850. It was a cross between the broad-petalled variety of *A. aulica*, called *platypetala*, and *A. psittacina*, also a species which has been used freely by hybridists, and which has left its impression upon a large number of present hybrids. This *Acramani pulcherrima*, which has large, intensely brilliant crimson flowers, has been a great help to Messrs. Veitch in infusing high colours in their strain. The West Indian *A. equestris* was also used freely for crossing, and its horizontally poised flowers is its distinct character, and one that has its counter-part in some of the finest crosses. Other species which Dean Herbert and others worked on were *A. rutila* and its dozen native varieties; *A. solandiflora* and *A. ambigua*, which I am inclined to think is

identical with what is called in gardens *A. marginata*, one remarkable for large size and high colour, but to be shunned by florists, as it has such ragged-edged petals. *A. reticulata* was also crossed, but as it belongs to a different class, flowering in winter, it does not concern the present subject. Modern hybridisers have, however, succeeded in completely altering the complexion of the race of hybrid Amaryllises through the agency of a few species introduced about a dozen years ago, such as *A. Leopoldi* and *A. pardina*. The advent of these distinct species gave an impetus to Amaryllis hybridisation that has gone on at an astonishing rate for these last ten years. The greatest strides, however, have been made within the last seven years, when the work was taken in hand in earnest by Messrs. Veitch. This firm indisputably holds the foremost rank in Amaryllis raising in this country, and, indeed, in any other, forestalling even their Belgian and Dutch *confrères*, who so long took the lead in this kind of work.

The collection in the Chelsea Nursery at the present time is enormous, as may be inferred from the fact that it consists of no fewer than 1500 flowering bulbs, and there are fully a thousand spikes either in an incipient stage or with expanded blossoms. The main portion of the collection is housed in a spacious span-roofed structure (70 feet by 18 feet) specially constructed for Amaryllis culture. In a bed running down the centre of the house is the bulk of the flowering specimens plunged in old tan about 18 inches in depth. The entire surface of this bed is a thicket of flowering spikes in all stages of development, but the majority bear expanded blossoms. Such an array of Amaryllis flowers is gorgeous in the extreme; and no one can fully realise such a floral display without seeing it, being so different from the stiff formal arrangements with which one usually meets at flower shows, where they are generally placed on a level or on a gradual slope, and invariably with the flowers looking one way. Here the plants are at home and unfold their resplendent blooms undisturbed, and their informal arrangement enhances their effect. Apart from the brilliant display of such rich masses of colour, this vast collection is full of interest to those who look upon it in a scientific aspect. The theory that mule productions are sterile is entirely refuted, for here are examples of crossing of distinct species, the progeny of which is quite as fertile as the originals. Though the effect of repeated crossings tend to obliterate the characters of the original species, each of the crowds of Chelsea hybrids bears a sufficient impress of its parentage to enable one to trace its lineage pretty accurately, so that nearly every variety may be ranged under distinct types or groups, a very convenient way in describing the varieties. The principal groups are the *Leopoldi*, which comprise the great bulk of the Chelsea hybrids, the *Acramani*, the *marginata*, the *aulica*, and the *pardina*, all named after the species or varieties which form as it were the fountain-head. The *Leopoldi* group is a well marked one, and each member of it may be singled out at a glance. The chief distinguishing features in the flower are the three broad outer segments which form an equilateral triangle, and, like the narrower petaline divisions, are of firm texture. It is the great aim to obtain the inner segments as broad as the outer ones, and so have a perfectly symmetrically formed flower so far as the perianth is concerned. Other invariable characters of the *Leopoldi* group are the capitate stigma, that is, one that is not split into three divisions, as in most other kinds; also the white filaments of the stamens. The colouring, too, of the *Leopoldi* section is a good guide. In nearly all the hybrids from this species the floral segments are green at the base, and tipped more or less broadly with creamy white, while intervening is a broad band of intensely rich crimson, though the amount of high colour varies considerably. *A. Leopoldi* has without doubt played the greatest part in the improvement of the Amaryllis, for from it florists have obtained those large, symmetrically formed and massive flowers now plentiful, and by infusing into it the

blood of the high coloured species, the result is obtaining the numerous high coloured forms of this section. When about a dozen years ago Pearce first sent home this handsome species to Messrs. Veitch from Peru, he said it was the finest Amaryllis he had met with in his travels, but I wonder what he would have said to the finest of its progeny.

The *Leopoldi* section is well represented by flowering plants at the present time at Chelsea, the most remarkable of which are John Heal and Shirley Hibberd, both of which it may be said are the ideals of perfect Amaryllises as regards size and form. Both are similar in colour, the segments being broad, the upper one in John Heal being fully $3\frac{1}{2}$ inches and of an intensely deep velvety crimson, broadly tipped with creamy white. The first named is perhaps the finer of the two in point of shape. Normally, *A. Leopoldi* bears but two flowers, but this particular plant of Shirley Hibberd is carrying four massive flowers on a stout stalk about 2 feet high. By far the finest of those flowering for the first time, and indeed of the whole collection, is one named William Goldring. It embodies dwarfness of growth (a desirable point), is extremely floriferous, perfect in form, and brilliant in colour. The bulb bears two flower-spikes, each carrying four blossoms nearly 7 inches across, and with very broad segments, which overlap so as to form a symmetrical bloom. The colour is a vivid scarlet-crimson, which is in strong contrast to the broad band of white which runs half way up each division. The whole plant is but 15 inches high, and is altogether a perfect specimen. Though a descendant of *Leopoldi*, it is some few removes from it, as may be seen by the high colouring of the flowers. Other noteworthy varieties of the *Leopoldi* type are King Arthur, one of last year's seedlings, of fine form, but surpassed in size; Royal Standard, somewhat similar, but of a deeper colour; Mrs. Freeman, a large and tolerably well formed flower, with white segments sparingly barred and spotted with crimson. This is the nearest approach to a white flower in the group. Another almost white-flowered kind is Virgil, which is remarkable on account of each of its divisions being much reflexed, rendering it distinct from all the rest. It is one that ought to develop a new strain. Dido has deep crimson flowers with broad tips of white, and Brightness is another in a similar way. Cambodia is a very brilliant variety, with large flowers, but far removed from the typical *Leopoldi*, so much so that the characteristic white tips to the segments are almost obliterated. These are a few of this section seedlings flowering for the first time, but numerous others are unfolding their blossoms.

The *Acramani* group is an extremely beautiful one, and, moreover, very distinct. It is characterised by intensely rich colour, but the segments of the flower are narrow, inclined to reflex, and somewhat uneven and waved at the margin; the stigma is trifid, and both the style and filaments dark coloured. The fault of the varieties in this section is want of form in the flowers, but that deficiency is certainly compensated by the splendid colour. The varieties bear from two to four flowers on a stem. The finest varieties of this section in flower are Mrs. Baker, Prospero, Richard Wagner, Oriflamme, Prince Leopold, and Gustave Doré, all of which have flowers of an extremely rich crimson, but though all are quite distinct, the fine gradations of hue are quite impossible to describe. Other varieties that fall in this group, though not so near the type as the preceding, are Bucephalus and Achilles, the latter a very large flower, fully 8 inches in diameter, and of a uniform bright crimson. As in the original *Acramani pulcherrima*, there is a tendency in the foliage and flower-stem to assume a purplish glaucous hue, which is a distinctive character.

The *marginata* and *pardina* sections are seemingly later than the preceding, as there are at present but few representatives of them. The finest in the *marginata* group is one called George Taylor, which has flowers 7 inches across and with broad petals of a vivid scarlet, flaked and pencilled with white, and each division is also

striped and margined with white. Another called Baroness Henry Schröder is also a fine one and remarkable for the large size of its blossoms and the breadth of the divisions. The colour is a deep crimson barred with white. The pardina section, characterised by the flower segments being copiously spotted with red on a light ground, is represented by a beautiful variety called Orsino. It is a cross between A. Leopoldi and A. pardina; therefore being a primary hybrid, it is exactly intermediate between the two parents. It gains form and substance from Leopoldi, but yet retains its beautiful spottedness. The aulica section is rather early, and the only variety which represents it is Ajax, which has large massive flowers with broad segments of a deep crimson heavily veined with a darker shade.

The above are some of the most striking varieties now in bloom, but in a few days these will be augmented by thrice the number, and many of the finest of the older seedlings are yet to flower, such as Empress of India (the brilliant variety which won so many admirers last year), Duchess of Connaught (pure white), Henry Little, Miss Alice Gair (very beautiful), Cecilia, Beauty of Cornwall, Storrs' Beauty (one of the finest), The Siren, Mme. Antoinette Stirling, Dr. Masters, and The Giant. These comprise some of the best of the named varieties, but it is expected that these even will be surpassed by the new seedlings which each day unfold their blossoms for the first time.

The thousands of Amaryllises that one sees here have nearly all been raised from seeds, for it is only to propagate particular varieties that recourse is had to propagating by offsets. Most of the flowering bulbs here are three years old from seed, but a good many are four and even five years. It is surprising to see what a large number of bulbs are throwing up two and even three flower-spikes this season—a plain indication of skilful culture. It is also very interesting to observe how some of the bulbs which carried such fine spikes of flowers last year are again developing equally large spikes. Even that grand variety, The Giant, which bore three ponderous spikes last season, and which everybody predicted would draw all the sustenance out of the bulb, is throwing three huge stems, which no doubt will carry as many blooms as last year. Thousands of plants may be seen, from last year's seedlings to those large enough to bloom, and particular care is taken in their culture from their infancy onwards. It is, however, in the matter of hybridising that Messrs. Veitch have obtained the lead of anyone else, and the Amaryllis in their hands has improved in ten years more than in the half-century previous. To Mr. Heal, the foreman in this department, credit is due for the intelligence and skill which he brings to bear on the hybridising and culture of this beautiful family. As an account of the mode of culture was given in these columns about this time last year, it is hardly necessary to revert to it here. W. G.

COTTAGERS' SHOWS.

"D. G.'s" complaint, in a recent issue, as to the prizes at cottagers' and other exhibitions of garden produce falling into the hands of prominent exhibitors year after year is one best corrected by inducing and encouraging more persons to grow and to enter into the competitions. It is very evident that if one or two exhibitors present always such capital samples of garden produce that the judges have no option but to award them the chief prizes, it is but an acknowledgment of the well-understood rule that the best must and ought to win. Still farther, it is well that the exhibition of good samples should be encouraged, because it is only by doing so that any benefit from exhibitions may be looked for. To handicap a good grower is to offer a premium to indifference in culture and quality, and would tend to remove from such good growers all stimulus for increased exertion. But the very success of one or two persons should be the chief means of stimulating others to do better, and it should be the special aim of local committees and officials to work upon that fact, and thus strive to promote

higher culture and more extensive competition. It may be, and often is, the case that the one or two specially successful exhibitors have better facilities than others have. They may have more time for labour, better soil, a greater quantity of manure, or perhaps more practical knowledge, but it is almost impossible, without doing to such well-placed cottagers an injustice, to inflict upon them any special penalties when they wish to exhibit their garden produce. It would not be at all unfair to create distinctive classes, such as six vegetables and four vegetables, or six plants and four plants, giving exhibitors the option of selecting either one only out of the section. That is a common rule in many exhibition schedules, and is enforced not upon cottagers only, but also upon all classes of exhibitors. The object of such an arrangement is, without in any way handicapping the larger or more favourably situated exhibitor, to prevent him from competing with others who work and grow their produce under much less favourable conditions. Experience of shows of all kinds has satisfied me that any one or two specially successful exhibitors seldom run their course of luck beyond two or three years. Then others gradually edge in, for in these matters, as in others, there is always a good fish in the sea as ever came out of it, and presently the former very successful men have to take a back place, and the newer, and perhaps younger, men come to the front. The very peculiar case of cottagers who have sons living at home and helping in the garden with the advantage of experience gained as labourers in gentlemen's gardens is hardly one for which special provision is needed. In the first place, it is gratifying to find that young men are so well conducted and industrious as to be willing to assist in the culture of the cottage garden after having been engaged in gardening all the day; and, in the second place, so long as no undue advantage is taken of their employment in gardens in the daytime it seems impossible without acting unjustly to prevent them giving their fathers assistance; in fact, to discourage their doing so would be disastrous. It is very common for men, whether aged or youthful, to have a special taste for gardening, and, indeed, great love for it as an evening's recreation, even though their daily employment is of a very diverse kind. What these may lack in practical knowledge they often make up for in enthusiasm and energy, so that the assumed advantage possessed by the garden labourer is more imaginary than real. The best plan by which the difficulties suggested by "D. G." may be overcome is to offer liberal prizes in many classes and plenty of them, and to show an active and intelligent interest in the garden work of all cottagers, and specially to help them by advice and by donations of plants and seeds.—A. D.

I am pleased to see this subject discussed, as cottagers' shows and cottage gardening societies well deserve attention. The Margam Cottage Gardening Society has now been in existence five years, and it is annually developing in all its bearings. The first year we did not offer more than £20 in prizes, but now we give double that sum, and the gardens are now very much better managed than they at one time were. Last year £9 was added to the reserve fund, which has been accumulating, and now amounts to £51 10s. In getting up large shows it too often happens that there is no money in hand nor any certainty of securing any. Subscriptions and takings at the gate are depended on, but in such cases a wet day may render the society insolvent. Now did such societies begin like the cottagers' ones and secure the money before they spent it, many failures would be averted. Speculative shows have rarely an honourable or very useful career, and should not be encouraged. On the other hand, those who are satisfied to begin in a small way and work their way upwards deserve the utmost support, and it is this system that should be followed. It is the one which has answered beyond our expectations here. In former years we have given five prizes for the best cottage gardens in the parish. "The first is

£1 10s. and the last 5s. These are competed for early in August, but this season more prizes are offered for the best stocked garden in November, and this will doubtless encourage the growth of winter crops as well as summer ones. Those winning the first prize for good garden management cannot compete again for three years, but we have no such rule with regard to those who win at the exhibition. They may get, say, first prize for a collection of vegetables this season and secure the same again next time if they can. "D. G." (p. 183) asks for a remedy for this, but I can offer him none, nor do I think it would be desirable to do so, as from experience I should say to make an alteration in this matter would be dealing hard with many deserving competitors. We always notice that those who attend best to their gardens invariably receive most prizes. I never knew a cottager who did little or nothing else but grumble at others being before him become a prominent prize-taker, but I have known beginners who "took stock" of the "old hands" one year equal or surpass them the following season; this was simply accomplished through attention and perseverance, a short recipe for great results. We have cases like that mentioned by "D. G." where the garden men live with their fathers who are not so employed, and although we tried to make classes to suit all parties at one time, the whole of the cottagers now compete together, and we consider it right that they should do so. Indeed, it is only some of the "lag-behinds" who would object to this arrangement: the persevering ones say, "All the more credit if we can beat So-and-so with all his advantages," and they often do so.—J. MUIR, *Margam, S. Wales.*

TREES AND SHRUBS.

Wellingtonias and birds' nests.—Although this neighbourhood abounds with songsters of both woods and glens, the Wellingtonia does not appear to be a favourite tree with them for nest building. It is over twenty years since twelve Wellingtonias were planted here; they are now from 30 feet to 40 feet high. During that time a bird's nest has not been found on any of them. The habit of the tree is not adapted for building purposes.—W. D., *Windermere.*

New varieties of Portugal Laurels.—M. Tomasse, of Pau, who has long been engaged in the raising of new hardy fruits, has lately devoted much attention to hardy evergreen and deciduous trees and shrubs, and is stated by M. Michelin, in the Journal of the French Horticultural Society, to have obtained many interesting and valuable varieties from seed. The Portugal Laurel has received special attention, with the result that some varieties have been raised differing considerably from the type, and which are shortly to be put in commerce by M. Baltet, of Troyes. It is to be hoped that M. Tomasse will continue a work so useful as the improvement of our hardy evergreen and other trees and shrubs. Even the common Laurel has much beauty when allowed to develop freely, and new varieties of it and the Portugal kind would assuredly be welcomed.—J. C. B.

SHORT NOTES.—TREES AND SHRUBS.

Chimonanthus fragrans.—This is a real gem in the depth of winter. There used to be two fine specimens of it in the conservatory at Gunton which were annually covered with their deliciously scented blooms. I have a plant of it on the south wall which blooms freely every year, the blooms being of a brighter lemon colour than those at Gunton; some spare Melon lights are placed before it to protect it from wind and rain. The soil is light on a gravelly subsoil.—S. E.

Kerria japonica.—This in some places is sadly neglected. It is a most useful plant for the wild garden. I well remember the grand appearance of some planted in an out-of-the-way yard, a very hot, dry sandy situation against a south wall. They were left to grow as they liked, except that a few of the dead pieces were cut out. They retained their beauty the greater part of the summer. It is a plant that deserves to be planted more extensively than it is.—S. E.

INDOOR GARDEN.

CAPE HEATHS AND THEIR CULTURE.

AMONGST the host of plants amenable to pot culture it is a question if there are any which combine so many desirable properties as the Cape Heaths, furnishing as they do every shade of colour from the purest white to the deepest crimson and several shades of yellow. The flowers, too, are

a speciality. Prominent amongst these were Fairbairn, of Clapham, and Rollisson, of Tooting, to which may be added Mr. Turnbull, of Bothwell Castle, the best of whose hard-wooded summer and autumn-flowering varieties are not surpassed by those of any who have tried their hands in the raising of new sorts. Heaths require peat to grow in, their extremely fine hair-like roots not taking to any other description of soil. The peat must also be good in quality and of dry consist-

putting them singly in small pots well drained, a condition of vital importance in all stages of the existence of Heaths, without which disease, or more frequently actual death, is certain to overtake them. For this first potting the material should consist of finely-sifted peat with a liberal addition of sharp, clean sand, pressing the soil moderately firm in the pots. Care should be taken that the soil is fairly moist, but not too much so, when the plants are put in it, so as to avoid the ne-

Specimen of Erica Cavendishiana. Grown by Mr. Cole, Exeter. (From a photograph).

produced in the greatest possible profusion, and in the case of many kinds they are more than ordinarily enduring. Even when not in bloom the dense healthy foliage, embracing every shade of green, never fails to give to a collection of Heaths a charm such as few families of plants can lay claim to. Nor are there in the whole range of cultivated plants any that have more readily responded to the requirements of the hybridiser, or that have yielded such great variety in form, colour, and general appearance. Heaths, indeed, all but encircle the year with their wax-like flowers. Two or three of the old nursery firms, the names of which were once familiar to the gardening world, made the raising of new varieties

ence, containing a fair amount of vegetable fibre. Nothing of a soft boggy character will answer.

Their propagation is effected by means of cuttings made of the points of the half-matured shoots, such as are obtainable in the case of most kinds in the latter part of the summer. These should be closely inserted in 5-inch or 6-inch pots filled with a mixture of finely sifted peat and sand, the surface being all sand; the cuttings must be kept moist, closely covered with propagating glasses, shaded, and placed in an intermediate house or pit until well rooted, which will be before spring, dispensing with the glasses as soon as sufficient roots exist to support them. By March the young plants should be in a state for potting off,

cessity for giving water as long as possible until the roots have begun to act. Never give water to a Heath immediately after a shift by way of settling the new soil about its roots, in the way sometimes recommended in the case of newly potted plants of various kinds, as such a proceeding is not unlikely to destroy the delicate points which, to some extent, undoubtedly get more or less bruised in the removal, although unapparent to the ordinary observer. The young stock should be set in a light position near the side of the house or pit which they occupy. Avoid putting them on bare, dry shelves, as is sometimes practised, as these help to dry up quickly the small amount of soil which the little pots contain. In place of this

set them on a stage covered with an inch or two of sand or fine ashes, which, being kept slightly moist, will reduce the frequent necessity of giving water, and also prevent their getting too dry. When well established,

Heaths are air-loving subjects, requiring more than most plants, but until the young stock get fairly into growth they must not have too much given them; for this reason they must be kept a little close until they begin to move freely, and as the sun gets powerful it may be necessary to afford them a thin shade for a few weeks. As soon as they commence to grow pinch out the points of the shoots, so as to ensure their branching out low enough, without which it is impossible to have them well furnished at bottom. The size attained during the first summer will depend on the varieties; soft-wooded quick-growing kinds like the winter-flowering *E. hyemalis* and others of that class make much more progress than the hard-wooded kinds, and amongst these even there is a wide difference in the rate of growth. As the season advances give more air, allowing some to remain on in the night in summer; during dry, hot weather the stock should be looked over, as to water, twice a day. Keep them well up to the glass in order to secure stout, well-matured growth, giving plenty of air, but not subjecting them to keen draughts. Through the autumn and winter let them have a light position where they can be kept a few degrees above freezing. During the dormant season let the atmosphere be dry, and now, as at all other times, never give water until the soil is so dry that its longer being withheld would be likely to cause injury. Again, early in spring they must be shifted; 3-inch pots will be the right size; this time break the peat fine by hand in place of sifting it, adding sand as before. The strongest shoots must again have their points pinched out, with a view to still further induce the formation of branches. Treat them as during the last summer in respect to air, water, and general routine, continuing to keep them well up to the glass.

A low light span-roofed pit is well suited to the requirements of Heaths, especially in their early stages, as in such a structure they can easily be kept close to the light, and yet in hot weather the air is not so dry a condition as to have a parching effect on young plants before they get into pots holding a larger body of soil. In summer during very hot weather it will be an advantage to moisten the floor of the pit, which will correct the over-dry state of the air, for although Heaths do not like a damp, stagnant atmosphere in autumn and winter, nor are they improved by the application of water overhead, yet under glass it may be drier than is good for them. Treat through the winter as before, and again give them a shift early in spring. The advantage of potting Heaths, especially whilst small, early enough before the external air has got hot and dry is that there is less likelihood of their suffering through the effects of removal than if the operation is deferred until later on.

Stopping and training.—Again pinch out the points of all the strong shoots, and in addition to this the strongest must be tied out horizontally close down to the rims of the pots. This has a double advantage in throwing the strength into the weaker growth left in an erect position, and of ensuring the dense bushy habit natural to Heaths generally, and which they would assume without assistance if growing in the open air. Use the soil now in a less finely broken condition than previously, and at each subsequent potting, as the plants get larger, it should be used in a still more lumpy state. The additional size of pots given should be regulated by the strength of the plants and the more or less vigorous habit of the variety; soft-wooded, quick growers attain size sufficient to make them attractive much sooner than the hard-wooded sorts, and amongst these there is as much difference in the rate of growth as there is in the ultimate size which they attain. It is well to avoid the extreme of too much pot room or the opposite of too little. At this stage 2-inch additional sized pots for the slow-

growers will be sufficient, whilst the freest will bear a 4-inch shift. This season a few small sticks will be requisite to tie the strongest shoots out so as to train the plants to the desired shape, but now, and in all subsequent stages, do not use more supports than cannot be dispensed with, as the act of thrusting sticks into the soil has the inevitable effect of destroying more or less of the roots, and the use of more than is required directly tends to destroy the appearance which the plants should have either in or out of flower. This season, towards the close of the summer, they will be all the better for having the lights drawn off them in fine weather, by which means their growth will get better matured, a condition still more necessary in after years as the plants acquire more size. The larger they get the more are they liable to be affected with mildew, the worst enemy that attacks Heaths, and one which it is necessary to continually guard against. The best preventive is a good light house to grow them in, keeping them as near the glass as possible, with plenty of air whenever the weather will permit, and full exposure to sun and air through August and September. In place of propagating their own plants the majority of growers will doubtless prefer to buy them of the ordinary trade size, the subsequent treatment of which requires to be in no way different from that here described, simply giving them a shift each spring into pots proportionate in size to their condition and the variety to be dealt with. When the plants have reached half specimen size, if given a good shift when potted, they will not require moving every season, but they should not be allowed to remain more than two years without additional room until they have attained something like full size, after which they may be kept in a sufficiently vigorous condition by the use of manure water during the growing season. In the

Potting of Heaths the mischievous, antiquated practice of loosening the outside of the ball with a pointed stick or similar instrument should never be resorted to. It is useless and highly injurious, as it cannot be done without bruising and breaking quantities of roots, the effect of which is that many plants so treated are some time before they make much progress, and not unusually they die off altogether, though often not so soon after the operation as to lead to the supposition of what is the real cause. As the specimens attain size they are better for being placed out-of-doors for six or eight weeks towards the close of summer, in which case they should always be placed in a position where they will be fully exposed to light and sun and sheltered from rough winds. A bed of coal ashes should be placed under them to keep out worms, which on no account must be allowed to get possession of the soil, or the roots cannot be kept in health. When so turned out the outsides of the pots must always be covered with pieces of mat, canvas, or something of a similar character to ward off the sun, otherwise the young roots which lie thickly against the inner surface are certain to be injured by the drying influences they are thus subjected to. There is one matter connected with the cultivation of Heaths that has hitherto not been sufficiently urged; that is, that immediately they have bloomed the flowers should be removed, and not, as they often are, allowed to remain on the plants until seeds have been formed. Few cultivators, it would appear, have ever observed or noted how differently Heaths that have borne a full crop of bloom start into growth again when the flowers are picked off as soon as they have faded compared with others on which they have been allowed to stay until seeds are formed. The latter process seems to tax their powers even worse than the development of the bloom; consequently immediately the flowers are dead they ought to be removed.

Habit of growth.—The varieties that annually make a considerable length of wood, such, for instance, as some of the tricolors when vigorous, *E. Austiniana*, *E. Irbyana*, *E. cerinthoides coronata*, *E. jasminiflora alba*, and many others of a like habit should at once, after bloom-

ing, have the shoots cut back to about half or one-third the length formed the preceding year; this is necessary to prevent their getting too tall and straggling whilst yet young enough to be useful. If this is not done it necessitates shoot-twisting, so objectionable in appearance when the plants are trained. Kinds that make only short growth each season, like the varieties of *E. aristata*, *E. æmula*, *E. elegans*, *E. retorta major*, *E. Marnockiana*, *E. depressa*, and a host of other slow-growing kinds, require no cutting back, or rather would be injured by it, and immediately the blooming is over they should have the flowers picked off, not giving time for seeds to form. Strong free growers, such as *E. Cavendishiana*, *E. affinis*, *E. vestita*, *E. hyemalis*, *E. Wilmoreaana*, and others of similar habit will bear cutting back freely, in some cases even into the strong wood, and often after this has been done to the extent of reducing the plants to half their size, they make free growth; whereas if the slow growing, very hard-wooded sorts were cut back in this way they would be all but sure to die at once. The most difficult matter in Heath culture is

Watering, that is, knowing into what condition of dryness the soil ought to be allowed to get before water is given. Even in the growing season the slowest growing hard-wooded sorts should never be watered whilst there is much moisture in the soil; otherwise they are not likely to remain long in a healthy condition. The quicker-growing sorts, although impatient of too much moisture, will not bear the soil being allowed to get so dry before water is applied as the hardest-wooded kinds require it to be. A want of studying the requirements of the different sections of this beautiful family of plants has often led to failure, and to it may be attributed their being less generally grown than they deserve to be.

Varieties.—The following selection comprises some of the most desirable kinds: *E. Cavendishiana*, *E. depressa*, *E. metulæflora*, *E. tricolor Barnesi*, *E. t. Holfordi*, *E. t. elegans*, *E. t. coronata*, *E. t. Wilsoni*, *E. t. profusa*, *E. ventricosa coccinea minor*, *E. v. grandiflora*, *E. v. superba*, *E. v. Bothwelliana*, *E. v. magnifica*, *E. Parmentieri rosea*, *E. venosa*, *E. Savillei major*, *E. retorta major*, *E. Shannoni*, *E. S. glabra*, *E. Paxtoni*, *E. obbata*, *E. Marnockiana*, *E. Irbyana*, *E. Austiniana*, *E. McNabiana rosea*, *E. Lindleyana*, *E. insignis*, *E. Farriana*, *E. exquisita*, *E. elegans*, *E. Devoniana*, *E. cerinthoides coronata*, *E. Candolleana*, *E. aristata major*, *E. ampullacea obbata*, *E. æmula*, *E. odora rosea*, *E. hyemalis*, *E. Wilmoreaana*, *E. Sindryana*. The above by no means exhaust the list of good and handsome Heaths, yet they are the cream, and anyone growing them will have a succession of flower nearly all the year round. The accompanying illustration represents a well-grown, well-flowered example of *E. Cavendishiana* (grown by Mr. Cole, The Cottage, Exeter), one of the best decorative Heaths in cultivation. T. B.

Strelitzia Regina.—This interesting Musad is well worthy of more attention than it generally receives, being handsome and having flowers both singular and beautiful. Being a native of the Cape of Good Hope, it readily submits to a comparatively cool temperature during winter, which should, however, be considerably increased as spring approaches, when it will generally bloom throughout the months of April and May, or even later, as the many coloured and peculiarly formed flowers remain long in good condition. It is a plant which is easily grown, and by no means particular as to soil. It is usually increased by division, and this method necessarily renders its increase somewhat slow. But it is quite possible that it might be induced to ripen seeds in this country if the pollen was carefully saved and applied to the stigma after the honey which accumulates in the nectary has been carefully removed; the plant should afterwards be kept in a comparatively high temperature. It appears that it ripens seed freely enough in South Africa, where the Kafirs are said to use it as an article of food. —P. G.

FUCHSIA MRS. MARSHALL.

FUCHSIAS are not so much grown for spring flowering as they should be, but I am sure that anyone seeing the fine healthy little plants in 4½-inch pots which are brought into Covent Garden during the spring months would be ready to acknowledge their value for decorative purposes at that time of year. Some kinds lend themselves better than others to this method of culture, and prominent amongst them is Mrs. Marshall, which evinces such a tendency to flower in early spring, that even in a cool greenhouse it will come into blossom at a time when the generality of Fuchsias are but fairly started into growth. The flowers thus obtained, however, are produced from wood made the preceding autumn, for this Fuchsia, if kept moist at the roots all the winter, holds all the autumn-made foliage, so that the young wood remains green and full of sap, and buds form again soon after the new year. It may, indeed, be regarded as an evergreen winter-flowering variety, only requiring a constant temperature of from 50° to 55° to bloom with freedom at that period of the year. This Fuchsia is much liked by market growers, owing to its floriferous, compact-habited nature and the ease with which it may be brought into flower in winter and spring. The foliage, too, being ample and of a pleasing shade of green, the flowers are shown off to the greatest advantage, and there is but little difficulty in furnishing young specimens with leafage to the rim of the pot—an important consideration in the case of plants of any kind grown for market or, indeed, for decorative purposes generally. For winter blooming cuttings should be struck late in spring, growing the young plants along freely all the summer, but not allowing them to flower, and shifting for the last time in July, so that the pots get full of roots by the late autumn. Plants of this description will bloom well at Christmas in a light, airy intermediate house, and if kept cool all the winter will come into flower nicely in March, April, and May in an ordinary greenhouse temperature. It would be well if raisers of Fuchsias would take in hand varieties such as this, which require but little inducement to flower early in the year. We should then probably secure a race of fine free winter-blooming kinds, the value of which can be scarcely over-estimated.

J. C. B.

THE VARIOUS KINDS OF LACHENALIA.

IN reply to Mr. Rawson (p. 167) I send the following list of Lachenalias cultivated with us and the kinds I have seen in flower. Of known kinds in our collection there are *L. glauca*, *L. orchioides*, *L. pallida* and its variety *sulphurea*, *L. pendula*, *L. pustulata*, *L. tricolor* and its varieties *anrea*, *quadricolor*, and *luteola*, *L. tigrina*, said to be a variety of *L. rubida*, *L. versicolor*, and *L. Nelsoni*. With the exception of *L. pustulata*, the whole of these have flowered with me during the past twelve months, and are all correctly named. With regard to *L. pustulata*, the leaves of which are so curiously puckered, as though they had been frizzled, there can be no doubt of the correctness of its name, and our plant is so strong this year as to encourage hopes of seeing it flower. Turning now to the kinds we possess whose names have not yet been verified, there is *L. stolonifera*, whose name and history seem to be slightly mysterious, and of which no one appears to have seen flowers. Since I last wrote I have sent specimens of this plant to Mr. Baker, who replies, "I have no doubt this is one of the numerous forms of the section *Eulachenalia*, but it is impossible to say which until it flowers." This section is composed of the finest of the genus, viz., *L. tricolor*, *L. pendula*, and *L. rubida*, with their varieties. Curiously enough, I have several pots of what I have always considered the same as *L. stolonifera* named *L. rubida*, and Mr. Baker expresses the same opinion, *L. rubida* being an altogether different plant, having leaves 5 inches to 6 inches long and an inch wide, with purple spots about the base. A third name, *L. unifolia*, is given to this unknown *stolonifera*. Of course, *L. unifolia*, is a perfectly distinct and well

known species. I am anxiously waiting for these three plants to flower. They came from Messrs. Henderson, St. John's Wood, under the above names. Among a collection of bulbs received from Messrs. Johnson & Harman, nurserymen at the Cape, were the following names: *L. erecta*, *purpurea*, *alba*, *Wicki*, *flava*, and *angusta*. The first two turned out to be varieties of *L. pallida*; *angusta* has not started, and the others I know nothing about yet, though after what I have seen in respect to the names from this nursery I do not expect much of them. The variety of *pallida* named *sulphurea* is a very pretty plant; one of the most beautiful of the genus, in fact. I succeeded in getting seed from its flowers fertilised with pollen from a good *quadricolor*, and of course expect something good from it. A very beautiful kind named *L. flava* is figured in Andrews' "Botanical Repository," tab. 456. It is a fleshy, green-leaved plant with a scape almost 1 foot long, bearing flowers almost twice as large as any other kind and of the richest canary-yellow colour, with a slight touch of green on the outer segments. I have looked carefully over Mr. Baker's monograph, but find no reference to the figure or mention of the specific name *flava*. I expected to find it under *L. pallida*.

With regard to the investigation of the genus, I may tell Mr. Rawson that it has already been done in a most complete manner by Mr. Baker, whose monograph of the genus was published along with his comprehensive work on the Natural Order in the "Iñnean Journal." Of course in a work of this kind it is not so accessible to gardeners as one would wish, and the fact of its being in Latin precludes many from using it, as no doubt they otherwise would do. A monograph of the two Orders, *Amarylhidaceae* and *Liliaceae*, which include so many popular garden plants, would, if prepared, as, for instance, Mr. Baker's synopsis of the *Crimms* or that of *Agaves*, prove of great service to gardeners. Mr. Baker has, however, done so much already to reduce many of the frightful mixtures in the nomenclature of cultivated plants to something like a satisfactory and simple arrangement, that we must at least for the present be contented.

B.

GESNERA MACRANTHA.

THIS *Gesnera* is valuable from the fact that it may be had in flower without trouble during the winter months, or, at all events, soon after Christmas, a time at which its bright blossoms are very effective, especially when set off to advantage by the fine foliaged plants which then form the bulk of the occupants of our stoves. It belongs to the tuberous-rooted section, that is, it forms a *Gloxinia*-like tuber, from the centre of which is pushed up one or more strong shoots densely covered with hairs, and which reach a height of about a foot, terminated by a cluster of long, tubular, bright vermilion-coloured flowers, which are also thickly covered with hairs. The leaves, which are large, are oppositely arranged at short distances along the stem, and are pale green in colour. To get the plants in flower at the season just mentioned, the tubers should be potted about the middle of November in a compost consisting of two-thirds turfy loam and one of leaf mould, with a dash of sand. Medium sized tubers, potted singly in 6-inch pots, make pretty little specimens; but some roots require larger spots, and if specimens of considerable size are required several may when potting be grouped together. After this is done place them in an intermediate house, or in the cool end of a stove, and keep them slightly moist till growth commences, when they must be exposed as much as possible to the light. In a growing atmosphere the flowers will soon show themselves, when a little weak manure water may be given. After flowering allow the plants to continue in the same temperature for a time, when they may be removed to cooler quarters and kept during the summer in a cold frame. Treated in this way they die down towards the end of summer, and are then shifted into the greenhouse and kept dry till potted in November; in January

the flowers make a fine display. This *Gesnera* has been long known in gardens, but, considering its winter-blooming qualities, seldom seen. It may be increased either by cuttings of the young shoots or by seeds.

H. P.

LEAF SPOT IN IXORAS.

"F. S." (p. 191) asks what is the best means of getting rid of this disease. The complaint is often seen in different degrees of virulence amongst these plants, some kinds being much more subject to it than others. *I. coccinea*, still far the best of the family, usually suffers the most, so much so that it seems to be affected in the hands of the greater portion of those who now attempt its cultivation, for it is rarely seen at the present day in its best form. The white species (*I. alba*) is also very subject to the complaint. *I. salicifolia* and *I. javanica* (Veitch's form) appear to be much less liable to this leaf affection than the preceding, or than any of the now numerous hybrids. I may say at the outset that plants which are so much affected as to lose the greater part of their leaves will never again become so strong as they should be. When I first began to grow *Ixoras* the plants of *I. coccinea* and of Rollison's form of *I. javanica* each winter used to show more or less of this disease, but not more than made some of the leaves unsightly without to any serious extent reducing the strength of the growth of the plants, yet it did not by any means improve their appearance. At that time I had always plunged the pots in bottom-heat, which naturally induces the production of thin leaves, deficient in substance, unless, as rarely happens, the bed in which the plants are plunged is so arranged as to admit of their heads being within 1 foot or 18 inches of the glass in a good light house, where some at least of the undue exciting influence of the bottom-heat is corrected. Seeing the less susceptibility to the disease in plants not subjected to extra heat to the roots, I gave up its use for these and other things of a like character, after which I had so little of the spot as to make its presence barely detectable. But unless the plants have sufficient warmth in winter, spot is sure to make its appearance, particularly if they have made free growth the preceding summer; if they are in other ways managed as they require, I never saw much harm done by it if the night temperature is not allowed to fall below 66°, which is quite low enough for *Ixoras* that succeed best when kept growing all winter; the little rest they need is best given them in summer, about July or August, by standing them for a month or so in a house with less heat and a less confined atmosphere than the stove. These plants should never be kept dry at the roots, or the atmosphere of the house in which they are grown allowed to get too dry in winter, to which, under the mistaken idea of then resting them, they are often subjected. Where this course is followed not only do the leaves suffer from the disease in question, but there is all but a stagnation of growth, through which they get into a stunted condition, and the spring is far advanced before they begin to move much with a consequent limited production of bloom, for all the kinds, including *I. coccinea*, will produce two full crops of flowers annually if kept growing as they require, and this in addition to the considerable number of trusses the plants bear between the periods of their general blooming.

The great merit of *Ixoras* where cut flowers are regularly wanted is that if well managed and several kinds are grown, there are sure to be some nearly always in bloom. To give an idea of the extent of growth they will make in the winter time I may say that between the beginning of October and the end of March I have often had plants of *I. coccinea* make shoots from the collar just above the soil that have run over 6 feet in length and as many as half-a-dozen of such shoots on a plant at a time. To do this the night temperature must be kept as near 70° as it can be; half a dozen degrees more in the daytime during winter will do. The erroneous idea that all stove plants require to be at rest in the winter and the

consequent low and, to such things as *Ixoras*, stagnating temperature the house is allowed to fall to, results in not more than half the flowers being forthcoming in the course of the year that otherwise would be. But, as I have often pointed out, to keep plants growing thus freely through the dull, short days the house must admit plenty of light, and they must be well managed in other ways; not the least important matter concerning which is to keep their heads close to the roof. Where the conditions are not such as to permit of the most being made of stove plants by this line of treatment it would be much better to grow such things as only require an intermediate heat, of which there are so many fine species now all but neglected on account of there not being warmth enough in a greenhouse for them, and a stove temperature being too hot. T. B.

ABUTILONS IN WINTER.

THERE are now many fine varieties of this useful Malvaceous plant, the greater portion of which flower during winter, thus furnishing cut flowers for indoor purposes, and forming graceful decorative plants for the greenhouse and conservatory. The earliest introduced species were somewhat straggling in habit and shy bloomers, but this cannot be said of a host of hybrid varieties, all of which are everything that can be desired in these respects, being dwarf and compact as well as profuse and continuous flowerers. They are also all plants of easy culture, and will succeed in any compost which may be suitable for the *Pelargonium* or other soft-wooded plants. They are all easily increased by cuttings, which may be inserted either during early autumn or in spring, placing the pots containing them in a close atmosphere on a mild bottom-heat. Possibly the best method of securing suitable plants for blooming in winter is to plant out in suitable soil, in the open air, early in June, well-established, healthy young plants, which will require little attention during the summer months beyond watering during dry weather. Such plants should be carefully taken up and potted early in October, and after being kept somewhat close for a short time, they will continue to bloom throughout the winter if placed in a warm greenhouse or similar structure. Existing varieties of these plants produce flowers of various shades of colour, and as hybrids are in this family easily obtained, each successive season adds to their number. The following are the names of a few which will be found worthy of a place in any collection of winter flowering plants, viz., A. Thompsoni, an old variety, but still worth growing on account of its ornamental foliage and pretty flowers, which are not however, produced in sufficient abundance. The following are of more recent introduction, viz., *Boule de Neige*, a very free flowering variety, compact in habit, and with flowers pure white; *Seraph*, also a very fine white flowered variety; *La Grélot*, pale pink with rich purple veins; and *Lady of the Lake*, also a fine pink flowered sort; *Orange Perfection* has flowers of a deep orange colour, and the blooms of *aurea globosa* are of a rich golden yellow. In addition to these there are also now in the trade many other meritorious varieties of this graceful plant. P. G.

Begonia Froebeli.—I do not think "Beginner" (p. 126) will meet with very great success if he attempts to grow this beautiful *Begonia* in a cold frame. Although it will grow well without artificial heat in summer, it requires a little heat in which to start the tubers. "Beginner" will find it advantageous to convert his cold frame into a hotbed about the 15th of March. This will be found useful for raising many plants from seed both to make his garden gay and also to exhibit at the end of August. The compost should consist of two parts good fibrous loam, one part leaf-mould, and one part well decayed manure, with a good dash of sharp, coarse sand to keep the whole sweet and porous, mixing all well together. This compost should be broken or chopped small, but

not passed through a riddle. The size of pot will depend on the size of the tuber to be placed in it; for a small tuber a 5-inch pot will be large enough to start with, and when it has filled the first pot with roots repot into a 7-inch one. When the flowers begin to show above the foliage, feed once a week with weak manure water and ventilate with care.—H. PARKER.

Top heating.—"Peregrine" is under a misapprehension in assuming that to keep his return pipes, which are fixed close under the roofs of his low houses, in operation it is necessary for Mr. Cannell to place his boilers in the chimneys. At Swanley all the heating is done by patent circulator boilers, fixed in stoke-holes, as is customary, and the smoke is carried from these along a subterranean flue to a big chimney remote from the houses, so that the sooty particles are as far removed from the glass houses as possible. The results, as seen at Swanley, of the system of top-air heating are worth thousands of scientific speculations, which are almost invariably found to be erroneous. Thus it was held to be a profound scientific fact that, given top ventilation, and the heated air within a building would escape through the apertures. Practical experience, a sharp thorn in the side of science, has shown that the cold external air, the heavier body, rushes into these upper apertures, and thus creates miserably cold currents and draughts, thus setting all preconceived notions as to ventilation at defiance. Just so "Peregrine" says "that a buoyant and moving atmosphere in a hothouse is the main point, and we know that by setting a heating apparatus at the bottom of the column of air we set the whole in motion." That is very scientifically put, but the fact is the air in any house, howsoever built, is not a column; it is a shapeless body, the motion of which would be affected only in an infinitesimal degree by a row of hot-water pipes laid on the floor. On the other hand, heat placed on the upper side of the body is likely to prove far more efficacious in creating motion than is an inert body of heat below. In Mr. Cannell's houses there is heat both above and below; hence the good results. As evidence of the benefit of top-heating, where can be seen in the dead of winter such a grand show of *Pelargonium* bloom or more finely grown and bloomed single and double *Primulas* than at Swanley? That they are good all who have seen them will freely admit.—A. D.

FLOWER GARDEN.

TUBEROUS BEGONIAS FOR BEDDING.

THAT these *Begonias* should prove unsatisfactory as bedding plants when selected without due regard to the purpose for which they are required is to me a matter of no surprise, because amongst this important class of plants may be found varieties and forms suitable for almost any purpose if judiciously selected. Many admirably suited for exhibition plants are useless as bedders, and varieties which make admirable bedders would make but indifferent exhibition plants. For all practical purposes the different types may be divided into three, viz., the strong and erect growers as exhibition plants; those with a drooping habit for hanging baskets; and between these two there is an intermediate type suitable for outdoor decoration. It is of this class I wish to speak, but I may state at the outset that in some respects my experience of *Begonias* as bedding plants has been disappointing. I have had my seed from the best sources, and although I have raised a large number of plants, not more than one-third of the number have been adapted for garden decoration; they, in fact, comprised a fair proportion of the three types just enumerated. To speak plainly, only those with an intermediate growth and which produce red or crimson flowers are of any use as bedding plants. This I learned early in the days of *Begonia* culture, and I have not yet seen sufficient reason to alter my opinion. Unless one goes in for saving one's own seed and raising one's own plants it is impossible to form a fair estimate of the value of tuberous *Begonias* as bedders. Plants raised from

ordinary mixed seed as received from seedsmen, although well worth conservatory culture, are useless when planted out in the open ground, and where *Begonias* have failed as bedding plants it is plain that the selection of unsuitable varieties has been the cause. My own practice has been to save my own seed and raise my own plants. I have made it a point to avoid all colours except crimsons and reds, and I have been careful to

Secure my seed from plants of moderate height, and with a neat, compact habit. I have always sown it as soon as ripe, which is generally about the middle of August. Seeds sown at that time will produce bulbs next spring about the size of large Marrow Peas. These are grown the next summer in cold frames, where they produce bulbs large enough to bed out the following year. From this time little management is needed. About the middle of March a two-light frame is placed on a hard bottom in the frame ground, facing south. A depth of about 9 inches of soil is then placed in the frame; in this the bulbs are planted, and I may here state that we take our bulbs from the floor of a house in which only just enough fire heat is used all the winter to keep out frost; to this place they are taken in autumn when they are lifted from the beds, and we take no further notice of them until spring, when we always find them plump and sound. The large bulbs we put 6 inches apart in the frame and the small ones 4 inches. We keep the frame closed and give no water until the young growths are seen peeping through the soil. On cold nights mats are placed on the frame to keep out frost; we find about the second week in April that the young growths begin to come through, and then a little air is given on mild days, and sufficient water is supplied as often as it is required to keep the soil moist. As growth advances more air is given until the season is so far advanced as to allow the lights to be taken off during the daytime. In a general way I may say that we begin to take off the lights about the middle of May. We do this to induce a short, sturdy growth and to get the plants gradually inured to the air. For bedding purposes they do not want any coddling, because they are not more tender than the majority of plants used for summer bedding. Prepared in this way I have no hesitation in saying that we have no other tender plants used for the summer decoration of the flower garden that can equal these *Begonias* for creating a solid mass of flower in so short a time after being planted out. I put out my plants last year on the 1st of June, and in a fortnight after that date they were in full flower, and continued in that state all the summer. It is only right I should say that I have tried plants raised from seed early in the year, and carefully nursed them on until bedding-out time, but, compared with one-year-old plants treated on the cold principle, they are nowhere.

Planting the beds.—This much it may perhaps be necessary to say, that although the *Begonia* does not like fresh, strong manure, its growth is much stronger and more lasting when the soil is fairly deep, somewhat light in texture, and made rather rich by incorporating with it some thoroughly rotten manure, and where practicable it is best to manure the beds in the autumn. When ready for planting we take a fork and lift the plants carefully out of the bed of soil, place them on a hand-barrow, and carry them to where they are wanted; when planting, the crowns should not be placed more than an inch under the surface, and as *Begonias* are fine rooting subjects, the soil about the bulbs should be made rather fine. Avoid too thick planting. When I first began bedding out *Begonias* I made a serious mistake in planting them too thickly; the consequence was there was not room for the development of lateral growth, and the result was the plants did not show their true character. Instead of branching outward they made upward growth, which caused them to reach a height much greater than they would have done had they had more room in which to extend their side growth. To prevent any disappointment in this matter it should be understood that my plants are large, with four and five stems rising from the bulbs.

Amongst the many thousands of bedding plants that we put out every year not one gives so little trouble as these Begonias. They require no stopping; they divest themselves of fading flowers; and any attempt to pinch them or otherwise interfere with their growth will injure them. In an ordinary summer and in a suitable soil they will thrive without the aid of the watering pot. In a word, it is only necessary to plant fair sized well prepared plants as just advised in order to secure the most satisfactory results. J. C. C.

SPRING FLOWERS.

WHAT a lovely thing is *Saxifraga Burseriana* when seen in tufts of from 6 inches to 8 inches across and bearing over fifty flowers! It has been in good form since the middle of January. It blooms better in pots than in borders, especially in wet seasons. It cannot endure the lodgment of wet about the surface. Potted high like Orchids not only suits it, but shows it off to advantage. *S. caesia* and *S. juniperina* are both better for such treatment. Crocuses now render the garden inviting—luteus, biflorus, Sieberi, reticulatus, versicolor, Imperati, and vernus being already in bloom. Hepaticas, too, are beautiful both in open parts and in a little shade. How glorious is *H. angulosa* with flowers 2 inches across! Of this I appear to have two distinct forms. One has persistent foliage; the new leaves are much later than in the others, and much more coloured (purplish green) before they become unfolded. The flowers, however, are the most distinct; the sepals in one are a pale blue, long, narrow, and well apart, much resembling those of the flower of *Anemone stellata*; the other has more cupped flowers of a darker colour, sepals slightly imbricate—in fact, a less and stouter blossom. All the varieties of *H. triloba* are in bloom—red, rose, white, purple, and many shades of blue, including the lovely double form. I never remember to have seen the crowns so thickly and tightly packed with buds; all the sorts promise a long season of bloom; a batch of seedlings are producing some new shades. With me the various Snowdrops are better than usual, though I am not so successful as some with these, excepting the common one. *Anemone ranunculoides*, *Gentiana verna*, double Primroses, *Scilla sibirica*, *Cyclamen Coum*, *Saxifraga oppositifolia*, *S. o. major*, *S. pyrenaica*, *Bulbocodium vernum*, and *B. trigynum*, though small subjects, are all very welcome, and a little perhaps before their usual time. The last named, as figured in THE GARDEN last summer, showed the flowers to be very short in the tube, in fact showing no tube; whereas my specimen shows a tube more than 1 inch long. It is a charming flower, white faintly suffused with lilac, and sweetly scented in the way of new honey. The Hellebores are yet the main attraction in the garden. *H. niger* is nearly over; *H. maximus* has flowers softly tinted, and in one or two instances nearly 5 inches across. What a variety of shades we have in *H. purpurascens*. The flowers of *H. guttatus*, *H. antiquorum*, *H. olympicus*, *H. orientalis*, and *H. abchasicus* are borne aloft and are enjoyable at a distance. Many of the dwarf kinds are equally pleasing when more closely seen. Has anyone observed the perfume of *H. Bocconi*? The commoner Polyanthus have been in flower more or less throughout the winter. Daisies are very forward; the red ones quite a show. The verdant blades of Daffodils are piercing the earth with buds just visible; the high coloured sprouts of the Pæonies, Columbines, Dicentras, and Gentians, and the already well-developed tops of Poppies, Iris, Larkspur, &c., are full of promise of a coming feast of flowers. JOHN WOOD.

Woodrille, Kirkstall.

Calceolaria Kellyana.—The mention of this plant by "Veronica" on page 185 reminds me that it was offered for sale in Mr. Ware's catalogue of the spring, 1881, as a hardy herbaceous Calceolaria. I bought a fine plant which seemed inclined to increase and flourish when planted out, the crowns resembling those of *Mimulus car-*

dinalis; the flowers were few and inconspicuous. I was told by old gardeners who saw it that it was formerly cultivated by the name of *C. plantaginea*. I made several divisions from it, which I tried in different soils and in a frame, but during the winter the whole stock died off, and I observe that it is no longer included in Mr. Ware's catalogue. Perhaps others who bought it may be able to tell us more about it.—C. WOLLEY DOD.

SISYRINCHIUM GRANDIFLORUM.

Who would imagine on seeing this charming, yet fragile, flower in a cut state that it is hardy

Sisyrinchium grandiflorum (natural size).

enough to withstand the cold rains of February or the winds of March. The plant is altogether more slender and graceful than any other open-air plant with which we are acquainted. Its Rush-like foliage, growing erect and tufty, has doubtless suggested its popular name of Rosh Lily, a name which to some is easier remembered and more euphonious than that given it by botanists. When well and fully grown it is from 12 inches to 15 inches high. The flower-stems are intermingled with the foliage and are about the same height. The blossoms are usually borne in

pairs produced on slender stalks drooping out of the membranous sheath called a spathe. One flower usually expands a day or so before the other, and if the stem is cut just as the first flower begins to open the second one will succeed it as if it were still on the plant. Interesting as the plant is in the open border, it seems almost a pity to leave such delicate beauty to the mercy of the weather; and as the flowers last long in perfection when cut it is best to have a few in a vase indoors where their beauty can be thoroughly enjoyed. We have said it is a hardy plant, but the term hardy is subject to conditions, for in some localities, particularly if the soil is surcharged with water in winter, it will succumb to hard frosts. In light soils it is perfectly hardy, but even under such circumstances the plant seems always grateful for a little protective mulching during winter, such as short litter or Bracken. Its normal flowering time is in April and May, but already it is in bloom in some gardens, probably on account of the prevailing mildness. In Messrs. Barr's grounds at Tooting there are some fine beds of it, and each tuft therein is carrying several flower-stems. Their earliness has doubtless been accelerated by the good mulching of litter which has been put on the bed. Though pretty now, the plants will be more beautiful in the course of a few weeks when the days become warmer.

There are two forms of this plant, the one supposed to be the typical distinguished by its very fine vinous-purple blossoms, the other called the alba or white variety, having flowers of spotless white, save the gold-tipped tufts of stamens. It is a hard matter to say which is the more beautiful. Both are charming kinds and worthy of the attention of every flower lover. In both the petals exhibit a transparency seen in few other flowers, and certainly in no other hardy plant. The form and size of the flower are shown in the accompanying woodcut. This is not a new plant, having been introduced so far back as 1826. It is a native of that tract of country in the vicinity of the Columbia River, which was explored by the botanical collector, Douglas, and it was by him it was first sent home.

The culture of this plant is simple. It likes a good friable soil, such as may be found in most kitchen gardens. Some say it likes a shady place, but I have always seen it do best in the open in full exposure, but it is best to shelter it from strong winds in some way, as they tear and knock the plants about so badly. To propagate it the plants should be lifted in autumn, and the tufts pulled carefully into as many pieces as are required, always leaving a sufficiency of roots on each piece to start it into growth. The pieces should be planted immediately in light soil, placing a little sand around the roots in order to induce the formation of new rootlets. Fibrous rooted plants such as this require careful handling when propagated, for the roots soon suffer. Some grow this plant well in pots for greenhouse decoration in spring, and a very pretty plant it is for the purpose. W. G.

HELLEBORUS NIGER MAXIMUS.

Two varieties of Christmas Rose have lately been mentioned as rivals in the columns of THE GARDEN, and in "Veronica's" notes of last week *H. n. angustifolius* had the best of it. I know the variety well. I will admit that in soils that suit it it deserves all the praise "Veronica" gives it. I have had beautiful pure white flowers of it sent this Christmas by Mr. Brockbank and from several other gardens; but with me it simply drags out a miserable life, whilst *H. n. maximus*, by its side, has produced fine flowers from the first week in November to the end of January. This was not the case with one plant only, but with many of each variety, and their constitution is very different. The common Christmas Rose and this variety, *H. angustifolius*, cannot stand autumnal damp or cold soils, which rot their leaves and make the crowns bare, and the flower buds become abortive. But the stouter

substance of the leaves of *maximus* resists the damp, and so the flowers come to perfection. I would advise those in whose gardens other Christmas Roses fail to try *H. niger maximus*. A few words about the origin of this variety. "Veronica" says it is "sacred to the memory of Miss Hope," of Wardie Lodge, and let it be so, for the lady is well worthy of the plant, and no one ever deserved more to have perpetual spring upon her grave; but I happen to know the history of the variety in Miss Hope's garden, which may be interesting to some. The original plant was planted, according to the label, in 1863, and was given to her by Mr. Hogg, of New Liston, who got it from Aberdeenshire. Miss Hope admired it so much that she sent a man to Aberdeenshire, who obtained some dozens of large clumps, and Wardie Lodge garden soon became a centre of distribution of it. Now, I have had too many pleasant days grouse shooting and salmon fishing in Aberdeenshire to say anything disparaging of the country, but I think it hardly likely that this giant Hellebore originated there. Mr. Archer-Hind, than whom I know no one better acquainted with Hellebores, tells me that when he went to live in Devonshire, twelve years ago, he found *H. niger maximus* an old-established plant in his garden, and that he could not trace its origin there. As far as I have observed, its distribution in the country is limited, and in the greater number of nurseries it is not known at all, but it probably was raised in some Continental nursery. By far the largest leaves of it I ever saw were from Mr. Archer-Hind's garden. It is a most distinct form, and to those who are not botanists seems worthy of specific honours.

Edge Hall, Malpas.

C. WOLLEY DOD.

DRAINING AND TURFING LAWNS.

MANY lawns on clayey soils seem to require draining; but is it under all circumstances expedient to do so? Some have been drained, involving needless expenditure, for in a few years the work has been rendered nugatory. Lawns are usually studded with trees and clumps of shrubs, and the roots of these find their way into the drains and effectively choke them up. A drain several feet deep of glazed pipes, such as are used for sewage, upon being recently opened was found to be choked up by the roots of a distant Horse Chestnut. When the pipes were laid about three years ago the puddling in the case of one of them was not effectually done. The roots entered, and when taken out were found to have completely filled the pipe. It thus appears that draining lawns with pipes is a delusion. We will assume that when the lawn is made trees and drains are so disposed that there is no possibility of interference on the part of the roots. In a few years changes occur either of gardener or proprietor, or both; trees are moved for reasons which we need not discuss, and the probability is that one or more may be placed where in a year or two its roots will clog the main artery. Even drains made in walks in the vicinity of trees to carry off surface water are frequently taken possession of by roots. I have observed, however, that, as a rule, lawns furnished with trees and shrubs seldom remain wet for any length of time. In summer the water is soon absorbed, and in winter the roots act as conductors to convey it downwards a certain distance.

Turf-laying.—This is an operation which engages attention more or less at this season. The actual work is usually delegated to handy labourers, and consequently gardeners acquire little experience in the matter. For instance, I observe directions given to cut the turf into pieces about 18 inches square. Now, I have always considered that the standard measure of a turf was 1 foot by 3 feet. A handy man will certainly cut two of this size whilst another is still thrusting and struggling to get up an 18-inch one. In directing how the turf should be laid, writers usually say the sods should be beaten slightly with the spade. Many years ago we were engaged in laying turf in that way, and I well recollect that most of the time was spent in be-

labouring the turf or obliterating our own foot-marks with the rake. In very wet weather the work had to be abandoned, for our feet stuck fast in mud of our own making. The most effectual and expeditious way of doing the work is as follows: The workman should commence at the part where the turf is likely to be brought; he will prepare his ground, *i.e.*, assuming that it has been roughly levelled before. A small sized half worn shovel is the best tool for the purpose. With this he can chip and chop and beat any slight hollows he may have to fill. Another man may follow, laying the sods. After he has completed a stretch or two he should have boards such as are used for scaffolding to lay on the top to stand upon whilst laying some more; he has only to turn them over as he proceeds. Another set is requisite for the barrows containing the turf. If advantage be taken of fine weather to prepare the ground, turf laying in this way can be carried on with ease and comfort, even in wet weather provided the men can withstand the rain. Turf cannot under most circumstances have too much beating, and if well done there will be no necessity to run about filling cracks later on. The beaters I have here are made of Oak, convex on the top side, with a beating surface of 8 inches in diameter; each has a 2-inch wide iron band round it. They have 4½-feet and 5-feet handles, inserted perpendicularly, of course, in the centre of the convex side. A mason's mallet will give some idea of it. This is a man's lift high or low, with one or two hands according to the force he wishes to apply. If it is a croquet lawn or terrace he should have a line stretched and move it every yard or two; in this way he can make the surface quite level. When turf is cut from ground of a stony character, there are frequently small stones left on the surface of the sods after they are unrolled, and in that case the whole surface should be swept before being beaten.

W. P. R.

Shrubby St. John's worts.—Allow me to mention the common Tutsan (*Hypericum androsaemum*) as a worthy companion to those named in THE GARDEN (p. 158). Apart from its handsome foliage and flowers, it bears a very attractive berry-like capsule, and as a British wild flower will bear comparison with even exotic *Hypericum*s. It is unfortunately getting scarce in the vicinity of London, but is still to be found plentifully in Devonshire and the adjacent counties.—J. W. ODELL, *Barrow Point, Pinner*.

Gladiolus failure.—Upon this subject I propose to add but a few lines; but the point is most material, *viz.*, the wintering or winter treatment. "Delta" says (p. 140): "I cannot say I see the advantage of 'W. J. M.'s" plan of storing, even if one had room . . . for the disease goes on until the whole bulb is destroyed." In taking up my stock in November, say, I cannot remember having seen a partially diseased (if I may use the term) *Gladiolus*. If one failed, it went before then; and if then sound, neither this year nor any other have I ever lost one from rot by my system. I mention this as many growers find the storing their greatest difficulty.—J. W. M., *Clonmel*.

Six-petalled Hellebores.—A short time since I sent you some blooms of *Helleborus niger* showing six sepals from bract conversion. I now send you a specimen of *H. purpurascens*, somewhat pale coloured, also having six sepals. To me this is even more remarkable than the *niger* divergence, inasmuch as in this case there is not the provision of sepal-like bracts on which the flower can steal a march. As will be seen, the floral leaf is not only perfect, but relatively in its proper position. The difference in the two appears to be this: in *niger* it was a converted bract, but here we have an entirely new or surplus member. In all other respects the flower is perfectly formed, especially the petals. I see Mr. Archer-Hind considers such sports accidental; but are they not capable of being turned to account?—J. WOOD, *Kirkstall*.

Myosotis dissitiflora alba.—It will probably interest Mr. Fish and other admirers of this lovely Forget-me-not to learn that I have the

pure white form of *dissitiflora* in bloom under glass, and charming it is. My plants have been hard propagated, having been little better than cuttings but a month or two since, and therefore the sprays and blooms are not so large as those of the blue kind under ordinary culture; but I have no fear whatever but that strong plants will always furnish large flowers. I mentioned last year that I had got a small sport of the white form. It was, indeed, when found, but a tiny speck, a single spray of white amidst a field of blue. It was lifted out with the greatest care, planted out by itself, and then forgotten. However, very early in the new year my attention was recalled to the plant, which had then grown into a big clump, by observing that the expanding blooms were white. Then I remembered my sport of the previous season, and at once lifted the clump, pulled it to pieces, and potted it up. I observe that Messrs. Veitch offer seed of this white kind, so that it will soon, doubtless, become abundant; and, indeed, I venture to prognosticate that in a very few years it will become a most popular market plant, and be grown in vast quantities in pots. The blue variety will come reddish pink in colour under glass, until solar light becomes strong enough to create the desired blue tint. Thus it is a disappointing plant in warmth. On the other hand, the white kind comes out in a gentle heat of the purest hue, and I think it will be soon universally ranked amongst the loveliest of our hardy spring flowers.—D.

THE CHRYSANTHEMUM AND ITS CULTURE.

Hints on exhibiting.—Cut blooms for exhibition will keep fresh longer and look better if cut the evening before the show and placed in cups of water on a cool, moist cellar floor. Intending exhibitors must be especially careful "to read, mark, learn, and carefully digest" the words and meaning of the schedule and regulations of the exhibition or society offering the prizes. If the slightest doubt is felt, call upon or write to the secretary of such exhibition or society at once and gain a clear idea as to what is meant, or 'disappointment may result, owing to your having unconsciously shown in a wrong class; or you may be disqualified for showing "clusters of flowers as grown" instead of the three best flowers, "clusters or bunches of three," which you have on your plants. The following will explain what is to be guarded against: "At a recent exhibition a class was provided in the schedule for 'twelve Pompones, not less than six varieties, to be shown in bunches of three, with foliage.' The chief prize was awarded to an exhibitor with three individual flowers of each variety. The second prize was awarded to another who staged three trusses of each variety, each bunch of three trusses probably containing over a dozen individual blooms. According to the reading of the schedule, ought not the latter stand to have been disqualified? We state this question in order that our reply may be better understood and of more service generally, as the subject has much more than a personal significance. The second-prize stand referred to could not have been disqualified, as 'bunches' certainly were staged—a 'bunch' meaning a cluster. A number of the same kind growing together, or a number of stems containing single flowers tied together, would form a bunch. In the Kingston schedule the stipulation is 'twelve bunches of Pompones, distinct, three stems as cut to form a bunch (Anemone Pompones and hybrids excluded).' Mr. Moorman was rightly adjudged the first prize in this class, each of the stems having six or more fine flowers. According to the extract from the schedule first referred to, the judges might, perhaps, have disqualified the first-prize stand, as blooms, not bunches, of three varieties were staged, but they no doubt, as judges usually do, exercised their discretion in reading ambiguous conditions. According to the Kingston schedule they could neither have disqualified bunches of three single blooms as cut from the plant nor bunches containing several blooms on one stem. Whatever is meant by committees should be stated. Either 'three single blooms to form a bunch,' or 'three

bunches of flowers as cut, number of blooms not limited,' would make the matter plain to all."

Dressing Chrysanthemums.—On this subject Mr. Douglas, Loxford Hall, writes as follows: "Those intending to exhibit cut blooms will find it necessary to obtain dressing tweezers. These are made of ivory, steel, or iron. The ivory tweezers are not quite strong enough to remove the badly formed petals or green scaly substance that is sometimes to be found in the centres of the flowers, so that steel tweezers will have to be provided for that purpose. The ivory tweezers are used mainly for arranging the petals, but one pair made of steel or iron may be used for both purposes. The large-flowered incurved section is that from which the exhibition blooms are selected, but on careful examination of the various varieties named in this section it will be found that the petals of many of them are irregularly formed, and some of them are badly placed. If we take an incurved bloom as a model, the best for our purpose would be Mrs. George Rundle or the primrose and yellow sports from it. The petals of this variety are sufficiently broad and incurved so that they meet in the centre of the flower, forming what the florist would term a perfect flower; this variety does not require any dressing. John Salter is a large and good flower often seen in stands, but it requires a good deal of manipulation to make it presentable, owing to the number of badly-formed petals in the flowers. It may be added parenthetically that the flowers of this variety and others of the same type come better formed if they open near the glass roof; the worst of the petals must be removed first with the tweezers, and those that remain must be carefully arranged to meet in the centre. Cherub is another type of flower that requires a good deal of work to make an exhibition bloom; unlike John Salter, which is weak in the centre, this variety is generally too full, so much so that the outer petals are thrown back sometimes against the stem; in this case the tufts of small petals in the centre have to be torn out, and the wooden cups are used to draw the flower together. Every one of the blooms must be set up in these cups, which are furnished with a stem to fit into the water tubes; there is also a hole through the stem of the cup through which the flower-stem is passed, and the stem must be wedged in to keep the flower in position. Another fault some incurved flowers have is the tendency of some of the petals to reflex; these have to be brought into position by working them through the tweezers. The outer petals are usually the best, and should, if possible, be carefully preserved; when a number of them are removed by decay or for the purpose of improving the flower the chances are much against such flowers winning in a close competition. I would say to an intending exhibitor, first take every pains to preserve the blooms from damp, and thus save the outer petals until the blooms are fully open; second, take Mrs. George Rundle as the model of an exhibition flower, and bring the others up to that form by dressing; and thirdly, let no one go away with the idea that badly grown flowers can be dressed to beat those that are well grown. Good cultivation must go hand in hand with good dressing to obtain the best results."

"Various opinions," says Mr. Moorman, "will always exist on the propriety of dressing flowers. At the present time it would be useless for any exhibitor to stage a collection of undressed blooms against others of equal size and substance that were dressed. Nearly all societies allow flowers to be dressed, which consists, in the case of an incurved flower, of merely drawing out with a pair of tweezers all short, curled, and irregular florets from the centre of the flower, or in any part of the flower that they can be found. The centre of most flowers will be found shorter than the outside, and by pulling out the short florets a more even outline is produced; the remaining florets are regulated and the blooms placed in hollow wooden cups, in which position they are tightly fastened. One point may here be advanced in favour of dressing, that the more a flower is dressed the smaller the bloom is made; therefore,

the more substance the flowers contain the better chance the exhibitor has in gaining the premier position; hence the success of the Liverpool growers over growers in the neighbourhood of London. The incurved flowers of the former are always of better build and contain more substance than the southern growers appear to be able to obtain."

I am informed on good authority that at the Jersey Chrysanthemum Show no dressing is allowed, each bloom being exhibited as it is grown. Although the above directions may be useful, yet I must say that formality is not beauty in the eyes of artistic, or even tasteful, people, and all that dressing can do for us is to give to the florets a slate-on-a-roof kind of regularity—a stiff formality which does not deserve toleration.

Large blooms.—On the subject of bud selection for large blooms I note the following in a recent number of the *Gardeners' Chronicle*: "About London cultivators generally are in favour of growing their flowers upon the terminal bud, meaning thereby the bud actually latest in course of development, but not terminal in the sense intended by the botanist, who uses the word in relation to position, not time; while north-country growers prefer the crown bud, or crown terminal, as it is called about Liverpool. Thus, while one set of plants are growing, making wood, the other set are forming and developing flower-buds, a fact which upon the face of it will clearly account for the difference in the size of the flowers."

"In the interests of the uninitiated we will endeavour to explain these technicalities, and start with the cutting taken in the spring, say in February or March. Cuttings are rooted, potted off, and grown upon one stem until July, in the early part of which month a bud will appear which is called the July bud, which if taken is rarely of any worth—at any rate not as an exhibition flower. In a vigorous growing plant this bud (the terminal bud of the botanist), if it is closely observed after its formation, will be seen to gradually decrease in size, and at the same time three young shoots, at first not much larger than pin-heads, will be seen to come away from below its base. As these shoots increase in length the first bud will disappear altogether, and there will now be three shoots to a single stem. In August another set of buds will appear, which, if properly formed, and the vigour of the plant pretty well expended, should be taken, or, in other words, the growth of the plant should be stopped. Immediately upon the appearance of the bud it will be found that three tiny growths are in process of formation at its base, which would develop into shoots, as before explained, and these should be removed at once if the buds are to be retained."

"The next set of buds appear about the first days of September, and these are what cultivators call the 'terminal buds,' as undoubtedly, in one sense, they are, being the last effort of Nature after the plant has ceased to make shoots. If for the sake of argument we assume that one cultivator disbuds his plants in August, and another disbuds his at a considerably later period, we have a substantial gain on behalf of the former for the process of bud-development. This we consider the simplest way of elucidating the technicalities of the bud business, but the practice is not now generally followed in growing large flowers."

"The system to which we now allude is more intricate in its details, but it offers great advantages to the exhibitor, inasmuch as it gives him a wider selection of buds. It is done in this way. When the plants are about a foot high they are pinched, viz., the extreme points of the shoots are 'rubbed off,' not cut back, as an old hand once sarcastically put it to a young beginner. This early pinching gives a stout stem, and three young shoots break away from the point, all below these being removed as fast as they are formed. Upon this system the first buds that appear are taken, if they do not show too early. But suppose there is a doubt about the matter—one bud is taken for a chance flower, and the remaining two are treated upon a different principle. The bud upon the second shoot may also be taken, but, as a measure of precaution, instead of rubbing out the three

growths at its base one is left temporarily to divert the flow of sap from it until it is clearly seen that the force of the sap is not strong enough to spoil the bud, when of course the growth must be pinched out. The third shoot would be allowed to grow on, taking care to remove its two weakest companions as soon as the strength of each could be recognised. Thus the cultivator who adopts this system has three chances from the same plant, so that if he misses the mark with one flower he is sure to hit it with another. We have seen three distinct characters of flowers upon the same plant over and over again, the variations being due to nothing else than the time and manner of disbudding. The next point of importance in the production of large blooms is the theory of the ripening of the wood, which in the case of the Chrysanthemum will not hold water. There must be strength of stem and large green leaves down to the rim of the pot to produce good-sized, well-formed flowers."

Mr. Lynes says that after "Having cultivated the Chrysanthemum for some years I do not know of any one system which may be laid down as a hard-and-fast line to follow and guarantee results. What is termed the natural system is to let the plants grow as they will until they show the summer bud, which will generally be from the middle of June to the end of July. This bud is useless. Several shoots are produced below it, when as many may be left as the cultivator deems fit—from three to eight, variety and strength of plant to be considered. These shoots, being left to grow, will each show another bud, which is termed the crown bud, and that is the bud to produce fine flowers, provided it comes at the proper time. When first seen it is very small, and has three vigorous shoots around it. These should be at once pinched off, likewise all after growths, to direct the whole resources of the plant to the flower. The difficulty is to induce the plants to show this bud at the proper time, for upon this (provided the plants are healthy and vigorous) depend the future results. Take three plants of any one variety, treat them alike in every respect; the probabilities are one will show the crown bud in the middle of July, another in the middle of August, the third not until September. My opinion is, the time for them to show this bud is between the 10th of August and the 7th of September. Seasons vary, but from several years' experience I have no hesitation in saying a great percentage of buds taken between the above-named dates will prove satisfactory. If taken before, they are apt to become hard and not open properly.* I know at least one celebrated grower of large blooms for exhibition who, having struck the cuttings in the usual way, grows them on by planting them out in the border of a cool orchard house, where they are trained to single stems, each bearing one enormous flower at its apex. Under this system there is less danger of the plant suffering from drought at the root, and some of the varieties attain a height of 10 feet to 12 feet, the stems and foliage being enormously stout and healthy, and the flowers exceptionally fine."

French seedlings.—The following notes on French seedlings have been kindly furnished by M. Victor Lemoine, the well-known nurseryman and hybridist of Nancy: "I am not actually a raiser of Chrysanthemums, although I grow them rather extensively for commercial purposes, and have sent out some seedlings of merit. One of our earliest raisers of this popular flower was the late M. Lebois, of Toulouse. He it was who effected such a marked improvement in the Pomponne or Chusan Daisy race, and the late M. Mielley, a nurseryman of Lille, introduced them to the trade. Since the death of these two enthusiasts this small-flowered race has been somewhat neglected, although Madame Lebois for some years after her husband's death continued to raise seedlings, which she sent to the late M. Verschaffelt, of Ghent, and several of the finer kinds were figured in *Illustration Horticole*. Bona-fide raisers who have most distinguished themselves since that time

* Paper read at the Wimbledon Gardeners' Society, December, 1882.

are M. Pertuzes, of Toulouse, and M. Boucharlet aîné, of Lyons, both of whom have sent out some desirable early blooming varieties. M. Charles Huber, of Hyères, for some time turned his attention to raising seedlings, and sent out some good kinds. Some twenty years ago Messrs. Bonamy frères, of Toulouse, effected considerable improvements, but nearly all the raisers above mentioned are now replaced by others, of whom the following are most worthy of note: M. Lacroix, of Toulouse; M. Boucharlet aîné, of Lyons; M. Schwartz, of Lyons; M. Bernard, of Toulouse; M. Marrou, of Toulouse; M. de Reydellet, of Valence; and above all by M. Délaux, of St. Martin du Couch, near Toulouse. M. Délaux has been most fortunate, and his seedlings continue to improve year by year. One great fault may be found with the southern raisers: They secure fine varieties, but as but little attention is paid to constitutional hardihood, it is often disappointing to find that they do not bloom well in cold localities. The first of the early Pomponé race were raised in Paris by the late M. Pelé.

Jersey and Guernsey varieties.—The following is compiled from original notes and lists kindly furnished by a noted Chrysanthemum grower in Jersey: "Having resided in Guernsey for twenty years, during which time the Chrysanthemum has been an especial favourite of mine, I may say I am personally acquainted with all the raisers in that island, and have seen some thousands of seedlings, some exquisitely beautiful, others, alas! not so attractive from a florist's point of view, and so doomed to be cast aside. The raiser of the first seedling Chrysanthemums in the Channel Islands was a baker, the plants being trained on a wall behind his oven. The varieties of that time were, of course, very different from those raised more recently in Guernsey by such men as Clarke, Davis, Pethers, and Smith. Mr. Smith has sold as many as sixty new varieties in one year to the late Mr. John Salter, of Hammersmith. These were named and brought out a few at a time, so as not to overstock the market. In Mr. Salter's catalogue a number of them are marked Smith, while many are marked S only. I recently paid a visit to some old friends in Guernsey, and while there, speaking of Chrysanthemums, they seemed unanimous in thinking that by far the greater number of the large flowered varieties in Salter's list were of Guernsey origin bought from the stock of unnamed seedlings. Crimson Velvet was first exhibited by Pethers, and is still one of the best of rich dark coloured kinds. Among the modern Japanese varieties several have been raised by Major Carey's gardener, while those two favourites, Elaine and Fair Maid of Guernsey, were raised by Mr. J. Downton, gardener to Mr. Saumarez Carey, of The Grange. Jersey Pompones were sent by M. V. Langlois and myself to Mr. A. Forsyth, who then lived at Stoke Newington. They were mostly of French origin. Dick Turpin is a Jersey seedling named by the judges at our fourth exhibition, it having been given by the raiser to his postman, J. Turpin. Major Carey now seems almost alone here as a raiser of new kinds from home-saved seeds. As to

Seed-saving, I have observed two methods of treating the plants. A common plan is to train them against a sunny wall, protecting them above by a weather board. Here they are left to ripen until the end of January, when the old flower-heads are cut off and the seeds separated and saved by rubbing them in silver sand. Others are grown to single stems in pots placed in a greenhouse. February is the best time for seed-sowing, but Mr. Beckford tells me he has sown as late as April, and even then has had blooms the same year. Some years ago I tried the Chrysanthemum seeds advertised by different seedsmen, but never could obtain from them a variety worth keeping; indeed they resembled Ox-eye Daisies more than anything else. Not having attempted raising seedlings of late years, it is quite possible that the seeds now advertised are of better quality. Mr. C. Smith, of the Caledonian Nursery, Guernsey, once told me that he regretted having thrown away many single and semi-double varieties that would now be

gladly purchased, although totally unappreciated at the time he had them growing and in bloom.

Chrysanthemum societies.—Chrysanthemum culture is much fostered and improved by the aid of local societies specially devoted to that end. They enable cultivators to meet each other in friendly rivalry; new flowers are brought forward; the merits of these, as of older kinds, for certain purposes are brought out and discussed; and visitors to such shows not unfrequently are led to take up the culture of this popular flower by seeing well-grown plants or cut blooms who would otherwise never have thought of it except as a miserable bush tied up to a fence in the open air, or starved and poor in a pot in the greenhouse. The Chrysanthemum is literally the last show flower of the waning year, and deserves notice as coming at a time when decorative plants in bloom are scarce. Wherever two or three or more growers are found in any district a Chrysanthemum society should be formed, and the interest of the exhibition may well be augmented by holding a fruit and vegetable show in conjunction with the exhibition of Chrysanthemums. The formation and organisation of such a society must be taken in hand by growers and admirers of the Chrysanthemum themselves in this way. They must band themselves into a working committee, and then some nobleman or gentleman popular in the locality must be solicited to allow his name to appear as president, and eighteen or twenty gentlemen who have good gardens must be induced to become vice-presidents. Lady patronesses, treasurer, and hon. secretary must likewise be secured. A subscription list must be opened and subscriptions solicited from ladies and gentlemen who have gardens in the locality, or who are known to be fond of horticulture. Make up your mind to give money prizes, if possible, and nothing conduces more to the long life and prosperity of a flower show of any kind than prompt payment of prizes on the very day the awards are made. The rules of the Kingston and Surbiton Chrysanthemum Society may serve as a model for others. In districts like Kingston, Camberwell, Stoke Newington, Highgate, and other suburbs of London, and near Liverpool, where the Chrysanthemum is even more popular, a few extra classes should be added to the schedule here given. Thus prizes might well be offered for the finest new flower or variety of the season in each class or section—Incurved, Pomponé, Japanese, Anemone, quilled, Reflexed, &c. A special class should be made for seedling kinds raised by the exhibitor. Another for the best bridal bouquet of Chrysanthemum flowers (foliage *ad lib.*), best ball-room bouquet, and for a vase arranged for the drawing-room. An interesting class might be made for dwarf plants bloomed in 6-inch pots, grown from tops of plants struck late.

The rules and regulations for the exhibition itself must be clear and explicit, and it is the duty of the committee to see that they be carried out by the exhibitors. A little supervision on the morning of the show on the part of one or two members of the committee will often prevent errors on the part of new exhibitors, who in all cases deserve encouragement. The following rules are those of the society just named:—

I.—All productions entered for competition must be in the place of exhibition by 9 a.m. on the first day of the show, and each correctly named and placed ready for the judges by 11 a.m., at which time the building will be cleared.

II.—No exhibits entered for competition to be removed before 10 p.m. on the second day of the show.

III.—The judges will be empowered to withhold prizes where the productions exhibited are by them considered below the standard for the lowest prize, and their decision shall be final.

IV.—All cut blooms must be shown on boards of the following dimensions, viz.: boards for six, 1 foot long by 18 inches wide, and 3 inches high in front and 6 inches behind; boards for twelve, 2 feet long by 18 inches wide, and 3 inches high in front and 6 inches behind; boards for twenty-four, the same width, but double in length. Labels, on which the names of all cut blooms must be written, will be supplied by the secretary.

V.—No exhibitor will be allowed to compete in two classes for the same thing, or with the same letters, or take more than one prize in a class.

VI.—Any protest must be entered during exhibition hours, and in the event of disqualification the prize shall be awarded to the next exhibit in order of merit, if considered worthy.

N.B.—Any exhibitor not complying with these regulations will be disqualified.

A printed schedule of classes and prizes offered, together with rules and regulations, and a printed form for the exhibitor to fill up (specifying number and description of his proposed exhibits therein) should be forwarded to all exhibitors in the locality. For the sake of neatness and uniformity all boxes or stands for cut blooms should be of the same dimensions, and all names should be written clearly and neatly on cards provided by the society.

GARDEN FLORA.

PLATE CCCLXXVIII.

CYPRIPEDIUM SPICERIANUM.*

THIS is one of the most recently introduced of all the Indian species, and one that is very distinct from its numerous Eastern relatives. In neatness of habit and in the oblique pose of the flowers there is some little suggestion of *C. Fairieanum*, and to some its partial resemblance to *C. Druryi* is also apparent, but, broadly speaking, it is one of the most characteristic of the genus, and as such is highly prized in all gardens where Lady's Slippers are generally cultivated. Mr. Spicer is to be congratulated on having been so fortunate as to introduce this novelty a few years ago, a correspondent having sent it home to him along with other plants, and we can well imagine the interest caused by its first blooming. I think it was in November, 1878, that Mr. Harry Veitch showed me a single flower of this new *Cypriped*, which I remember was very much admired, and Mr. Chandler made a very effective and faithful coloured sketch of it—now, no doubt, in the voluminous orchidæ archives at Chelsea. At that time the plant had another charm—the individual specimens in cultivation might be counted on the fingers of one hand, and I am afraid to say what was offered to Mr. Spicer for "the stock." At Stevens' rooms a solitary plant brought something like £80 or £100. But then came importations, and there was a good deal of excitement during the first few sales. I remember Mr. Low examining one of the importations very critically, and the little bundles of clay-covered roots and flaccid leaves were eagerly bought up at high prices. Other importations in quantity have, however, now lowered the price, so that the plant is readily obtainable for shillings where pounds were formerly paid, and it is now quite commonly met with in most good gardens.

The best of Lady's Slippers seem peculiarly fated to accidental introduction. Apart from our present species, take, for example, *C. Stonei* platytænium, from Borneo, and the dainty little *C. Fairieanum*, which appeared at Stevens' rooms in 1856 or 1857 in an importation received from Assam. One would think that the collectors who so successfully tracked *C. Spicerianum* to its "native lair" would have long ere this have

* Drawn from a plant in Messrs. Veitch's nursery, Chelsea.

Growers or introducers of new plants will oblige us much by early intimation of the flowering of new or rare species, with a view to their representation in our "Garden Flora," the aim of which is the illustration in colour, and in all cases where possible life size, of distinct plants of high value for our gardens.

CYPRIPEDIUM SPECTABILE

brought us plants of *C. Farrieanum*, which is just now a desideratum in most gardens. *C. nævium* was another beautiful waif, and there are a few others which have from time to time cropped up as it were in an accidental way. Some day let us hope that *C. Fairrieanum* may accidentally crop up again. *C. Spicerianum* grows quite freely in a warm plant stove or Orchid house, in a compost of loam, fibre, and Sphagnum on a well-drained bottom of crocks and lime rubbish, which, as in the case of *C. concolor*, seems peculiarly congenial to this species also. The coloured plate represents a fairly good variety of this now popular Orchid, which flowered in Messrs. Veitch and Son's nursery at Chelsea some months ago. The purple markings on the upper sepal and on the staminode are peculiarly beautiful, all of which, however, the plate well illustrates. F. W. B.

SEASONABLE WORK.

FLOWERS AND PLANTS IN THE HOUSE

WE gladly welcome the flowering season of the Indian Azalea, a plant so good for ornamental purposes. It decorates a long dinner table for eighteen people, chiefly by means of three well-grown plants, about 16 inches to 18 inches through, in silver vases. The centre plant, the tallest and largest, is a rosy red, the other two pink. Round each plant is a group of four silver cups, holding flowers and foliage of the same red and pink Azaleas, the two colours grouped together in every cup. No other flowers and foliage are needed. The table is lighted with large silver candelabra standing between the flowers. For a round dinner-table cut Azaleas may be arranged in a ring of fish globes round a central lamp, red and pink flowers alternately. If the glasses are of two sizes, so that every other bouquet may be a little more important, it will be all the prettier. The same arrangement suits red and pink Camellias. The fish-globes may also be grouped in threes, two small with a larger between, the three glasses touching; all the smaller dressed with pink, and the larger with red, forming an interrupted circle, a space being left between each group of three. Tips of shoots of common Laurel, if the pieces are chosen as small-leaved as possible, make a good garnish for dessert dishes; large single leaves, as commonly used, look coarse and unmeaning, but the points of shoots with three or four leaves, of which the largest is not more than $3\frac{1}{2}$ inches long, are very suitable. They may be found towards the base of Laurels that stand free and are not over-grown with other shrubs. Twigs of Bay are still better, but so liberal a supply is not generally available.

FLOWER GARDEN.

Gladioli and other bulbs.—As a rule, in warm sandy soils Gladioli winter safely when left in the ground, and old-established bulbs produce flowers far more profusely, though not so fine individually, as when the bulbs are selected and replanted annually, but for effectiveness, give us the long-established bed with its long season of flowering and irregular heights of the flowers. Those not favourably located as to climate would, however, do well to keep to the more general plan of lifting the bulbs in autumn and planting afresh at this season. We are now planting out a few in clumps of five and seven among herbaceous plants, putting them near those kinds that will have done flowering when the Gladioli begin, in this way maintaining the gaiety of the border. Anemones, Ranunculuses, Lilies, Schizostylis, &c., are used in exactly the same way; these should now all be planted. In heavy soils the bulbs should be placed in a handful of sand, and the depth should be less than in light soil, say about 2 inches deep for Ranunculuses and Anemones, and 3 inches for Gladioli; but 1 inch deeper for all kinds in sandy soil may be allowed.

Lilies, of course, must be planted in depth according to the variety and size of the bulbs, but it may be well to remark that they are generally not planted sufficiently deep. Where ground can be afforded to plant each kind in beds by themselves they will repay the space and labour by the quantity of cut flowers they will produce, and of course can be had finer because of the convenience of being able to specially prepare the soil for them by trenching and manuring.

General work.—Complete all alterations, specially such as necessitate the removal of turf, as it is important that this gets re-established before drought and bright sunshine become excessive. Edgings or verges of turf should also be cut: they will presently be too hard to be operated on nicely, not to mention the longer time which they take to cut when in that state. Planting, too, should be pushed to a close, at least as regards deciduous subjects, but if needs be most evergreens may safely be removed for some weeks yet, but even with these were we certain of a dry summer, our experience is such that nothing would induce us to transplant at all after the beginning of March, and those moved as late as that should be kept thickly mulched with Bracken or litter during summer. Hedges and belts of any kind may now be clipped, and young hedges be encouraged to grow by pricking up the soil and clearing it of weeds. Laurels and Hollies that have got naked at bottom should now be headed down to any height that may be thought desirable; younger plants may be kept in compact form by pruning back the more straggling shoots. We have far too much of this kind of work, but though at the time we are apt to begrudge the labour, there are few operations that give us an equal amount of satisfaction.

THE ROCK GARDEN.

RESERVE stock wintered in cool frames should be lifted, and the usual watering, recommended after a long winter, deferred until the pits are drier. All hardy annuals and some of the hardy perennials should be sown now in a cool frame, but many of the latter class should be kept for sowing out-of-doors later in the year. We can often save ourselves a good deal of work in spring when we are busy by gathering and sowing seed as soon as it is ripe in the open ground. It is necessary only to give a covering of sand and a few Yew twigs in hot weather. We have sown seeds of various Drabas in pots, especially *D. cuspidata* and *D. Kotschyi*, and have been unable to rear them, whereas plants have come up the same year from self-sown seed. *Aethionema coridifolium* has never come up in pots, but when self-sown the seeds have germinated freely. Other kinds which sow themselves are: *Arabis rosea*, *Arenaria norvegica*, *A. verna*, *Armerias*, *Aubrietias*, *Cerastium Biebersteinii*, *Claytonia sibirica*, *Coronilla minima*, the majority of the Pinks, several *Erigerons*, *E. caucasicus*, *E. philadelphicus*, *E. glaucus*, *E. grandiflorus*, and *E. regalis*, *Erinus alpinus*, and several Heron's-bills; indeed, large numbers might very well be left for outdoor sowing in any odd bare spots on the rock garden. It should only be in cases in which one's knowledge does not justify outdoor sowing that the cool frame should be resorted to, or in the event of the quantity of seed being limited. If a plant has the reputation of being quite hardy, one may be sure that at some season of the year its seed will germinate either in a cool frame or out-of-doors. The hotbed should be tried in certain cases, as, for instance, if you want to get a few biennials to flower the first year; doubtfully hardy members may be sown in a cool frame a month hence, and those with which you are better acquainted now. The greatest difficulty we shall have will be with plants which bear an ordinary winter in this country, but, which, when we get a severe one, are killed or very much injured. These cannot be truly called hardy, and therefore should have a hotbed, as, for instance, *Calandrinia umbellata*, *Callirhoe involucrata*, *Chlora perfoliata*, and *Umbilicus spinosus*. Among plants in flower are *Saxifraga Burseriana*

major, *Cyclamen Coum vernal*, several species of *Croci*, *C. Imperati*, *C. Sieberi*, *C. biflorus*, *C. minimus*, and *C. vernus niveus*; Snowdrops, including *Galanthus Imperati*, *Elwesi*, and *plicatus*. A patch of that pretty Crucifer, *Ionopodium acaule*, has been in bloom from December until the present time.

INDOOR PLANTS.

Ferns.—See that the whole of the different species now begun, or about to begin, growth have the soil thoroughly moistened, or the fronds will have a crippled appearance and be deficient in size. At no time can Ferns be allowed to get so dry at the roots as the generality of other things will bear without injury, but whilst the fronds are in a tender, half-developed state the want of root-moisture is most injurious. Except comparatively few species, such as the *Gymnogrammas*, that require a high temperature, it is a mistake to give Ferns so much warmth as that in which they are often grown, the effect of which is to make the fronds long, weak, proportionately less enduring, and more liable to injury from insects. Use manure water freely, but in not too strong a state, to all that are under-potted, and to which it is not deemed advisable to give more root room. This does not apply to the creeping stemmed kinds, which must have space to allow their spreading rhizomes to extend, or they will suffer permanently. One mistake that has been too general in the cultivation of Ferns is the supposition that because they are mostly found in a state of Nature more or less shaded by other vegetation, or the positions they occupy, they will succeed in any sort of dark structure. So treated, strong-growing species that require anything above a greenhouse temperature attain an undue size and smother the weaker kinds. Do not have fixed shading on the roof where it can be avoided, and use no more than is necessary to prevent scorching, with enough air daily to solidify the growth as it is formed. By following this course the plants will preserve a much fresher appearance than they otherwise would do through the latter part of the year consequent on the increased substance imparted to the fronds. Todeas are often spoilt through being syringed overhead. The condensed drops of moisture with which the fronds are usually studded when confined in cases in which these and other filmy species do best leads to the idea that watering overhead will benefit them, but this is fatal to their well-being. Keep them quite cool; the temperature of a cool greenhouse is much better than more warmth.

Potting stove plants.—Such portions of the stock as were potted some time ago for early blooming will now be making process, and should have an increase of heat as they begin to move freely. No time should be lost in completing the potting of the stock generally. It is well to consider what form the plants are to assume, whether to be grown into large specimens or flowered in as small a state as the nature of each individual species will admit of. Most stove plants are quick growers and will bear plenty of root room with large shifts, and where the object is to have large specimens this is the course to follow, but if the plants are required for standing in rooms, or to be removed to cooler quarters, such as a conservatory during summer, the small pot system of cultivation will be found most satisfactory, as under it the restricted leaf growth will better bear the adverse conditions under which the plants will have to be placed. The same holds good with regard to fine foliaged subjects; the smaller growing *Caladiums*, if grown in large masses, are all but useless for employment in cool places, and are amongst the best decorative plants when cultivated in small pots with abundance of light and air, and no more heat than is requisite to induce moderate growth. *Allamandas*, *Ixoras*, *Dipladenias*, *Gardenias*, *Clerodendrons*, *Aphelandras*, *Franciscas*, *Hibiscus*, *Hoya*, *Bougainvilleas*, *Medinillas*, *Jacarandas*, *Tobeyanæmontanas*, *Rondeletias*, *Thunbergias*, *Aristolochias*, *Eschynanthus*, and other flowering species, together with *Crotons*, *Dracænas*, *Aralias*, *Marantas*,

Pandanus, *Musas*, variegated, *Pine-apples*, *Cupanias* and *Dieffenbachias* should at once be shifted, giving them room proportionate to the size of the specimens and the respective purposes for which they are intended. See that the soil is in right condition as to moisture. To those who have not had much experience in plant cultivation it may be well to say that it is better to pot in soil that is a little too dry than the opposite. Another important matter is to see that all plants before being potted have the balls of earth well moistened, so that there may be no necessity for giving water for some days after the operation is performed. The effect of this is that the roots, more or less unavoidably broken in removal, have time to heal, and are less liable to rot than if water were given immediately the plants were potted. Pot moderately firm, but in the case of such stove plants as are partially shaken out at the annual potting, and which have the old soil removed to some extent, it is not advisable to ram the material so tight in the pots as with hard-wooded greenhouse stock where there is no annual renewal in this way.

Striking cuttings.—See that a sufficient number of the old plants of *Euphorbias*, *Begonias*, *Thyracanthus rutilans*, *Sericographis Ghiesbreghtii*, *Plumbago rosea*, *Pentas carnea*, *Jasminum gracillimum*, *Eranthemums*, and *Apelandras* are at once put into sufficient warmth to produce cuttings for use next autumn and winter. Plants to be thus treated should have been cut back a short time ago, and ought to be placed where they will have enough light to induce stout growth in the shoots intended for cuttings, for upon this depends in a great measure the character of the plants which they will afterwards make.

Luculia gratissima.—Wherever there is a warm greenhouse this should find a place, planted out if convenient; if not, in a large pot or tub. It is rather a difficult plant to strike, and the cuttings must be put in when they have arrived at the right age and size. If too young and sappy they are liable to damp off, and if too old they will not root freely. We found them to succeed best when about 4 inches or 5 inches long, taken off with a heel. Healthy plants in a genial temperature, say that of an intermediate house, start into growth immediately they have done flowering, and when the young shoots have attained the size just mentioned they should be put in pots filled with sand in the ordinary way, kept moist, and covered with propagating glasses, being careful that the cuttings are neither allowed to flag before being put in or afterwards. Should this occur the chances are that few will strike. In other respects this most beautiful and fragrant of autumn flowering plants requires no special treatment. It thrives in good turfy loam with a little sand, and makes more progress, especially in its early stages, if treated to an intermediate temperature than that of a greenhouse.

Pelargoniums.—The large-flowered and fancy kinds should have attention in the way of lying the shoots well out, so as to keep the plants open and stocky. With this view they should be placed where their heads will be close to the glass. Those that after flowering were cut down earliest last summer will now be about setting their bloom-buds, and, if the pots are well filled with roots, will bear the application of manure water once a week; the soil also will do to be kept a little more moist, but any excess in this way must be avoided. The flowers of Cape *Pelargoniums* are comparatively small, and by many looked upon as insignificant; yet amongst them there are many that possess both brilliancy of colour and elegance of form. Their propagation is not so easy from shoot cuttings as that of the better known varieties, but they strike freely from root cuttings, and their after treatment is similar in other respects to that of the ordinary sorts, except that, being weaker growers, they require less root space, 6-inch or 7-inch pots being large enough for most of the species. They occupy little room, and are very suitable for cultivation by amateurs who have small houses.

KITCHEN GARDEN.

We are now busily engaged digging and manuring Potato land. The late varieties we always plant before the earlier. Varieties of Potatoes are now so numerous that one feels perplexed what to grow and what to avoid. We stick closely to some of the old kinds for field work; the best are *Pater-son's Victoria*, *Scotch Champion*, *Scholmaster*, and *Beauty of Hebron*. *Magnum Bonums* are useless in some soils. Last season without a particle of manure they grew too large by one-half, while the quality was soapy and disagreeable. *Scotch Champions* are excellent, but that objectionable deep eye is against them. *Schoolmaster* if anything supersedes *Victoria*. *Beauty of Hebron* is simply unique as an early Potato, and it may be lifted and housed as soon as *Myatt's*, and so escape disease. A thorough cleaning and in many cases fresh planting of herbs should be made at this season. *Tarragon*, *Thyme*, *pot Marjoram*, and *Pennyroyal* may all be planted. That very useful herb, *Chamomile*, may also be parted and planted. *Mint*, perhaps the most useful of all, should be planted in the shape of cuttings when 3 inches high. *Sage* does best as cuttings put in in the first week in May. Seed of many herbs may be sown, but not at present. *Knotted Marjoram*, summer *Savory*, and *Sweet Basil* are much sought after in early spring; a small pinch for using in a green state may now be sown.

Forcing.—We are now sowing Canadian *Wonder Beans* for the last batch, and intend growing them in 8½-inch pots. Bear in mind a potful of healthy roots is what is required, and not a potful of soil alone. Young plants now showing in outlying frames should be aired regularly to keep them sturdy and strong, but do not be caught napping by giving air in the morning and at night find the crop gone. Always take time by the forelock and place a bit of old netting over the lights, making all safe before leaving. *Seakale*, *Asparagus*, and *Rhubarb* may still be brought forward in case of need. Our plan is to have *Asparagus* in in November and keep the stock well up until about the middle of February. In the first week in April one can have it outside, and after being without it so long it is relished and much more thought of than if the supply had been continuous. This also we do with *Seakale*, but always have one of these two if possible. Vegetables are plentiful this year. We are supplying beautiful *Spinach*, *Broccoli*, *Tomatoes*, *Artichokes*, *Seakale*, *Rhubarb*, *French Beans*, and *Asparagus*.

FRUIT.

Peaches.—In the earliest house still attend to the thinning, disbudding, and tying in of the young shoots intended to form next year's fruit-bearing wood. As we have before observed, the disbudding of house Peach trees is an important operation which requires daily attention, combined with a complete knowledge of the condition of the roots. If the latter have been recently disturbed, or the trees have been weakened by heavy cropping, a little delay will give them time to pick up before many of the shoots are removed, but as trees of this kind generally set freely, the timely removal of a great number of the least promising fruit may precede disbudding, when good mulching, followed by a moderate supply of warm liquid, will soon start them into growth. Vigorous young trees, after being divested of fore-right shoots, may have many of the side shoots pinched either to form spurs or to supply foliage where there is likely to be a scarcity; but it must always be borne in mind that the best shoot, which starts from the base of this year's fruiting wood, must have plenty of room for growth and exposure to the influence of warmth and light. Where young trees are trained upon the extension principle and last year's shoots are from 2 feet to 4 feet in length, the latter may be allowed to carry a Peach at every foot run, and, provided they were well thinned out at the autumn pruning, two or more shoots, also the leading point, may be laid in full length. See that the trees are well syringed twice a day, and regulate the quality of the stimu-

lating liquid by the condition of the tree. If well made and properly drained there is little danger of overwatering inside borders, as *Peaches* having a large breadth of foliage exposed to sun-heat and light will take immense quantities, provided it is a few degrees warmer than the house and can pass away freely. Let the temperature range about 55° at night and 10° higher by day from fire-heat, and make up for a low minimum by closing with plenty of sun-heat whenever that luminary penetrates the pall of which forcing gardeners have experienced more than enough for one season.

Figs.—A temperature of 60° to 65° at night and 70° to 75° in the daytime will not be too high in the early house during a continuance of this unusually mild weather, but in the event of a change to the long delayed winter, a lower figure, particularly through the night, will be advisable. Although the Fig delights in an abundance of heat and moisture, it does not succeed where there is not a corresponding supply of light and air; hence the importance of keeping the glass clean and stirring the fires early every morning in order to admit of a free circulation of fresh air. The enemies to which the Fig is most subject are *musel scale* and *red spider*; the first does not often become troublesome until late in the season, but the latter sometimes springs into life before the first crop is ripe. The best antidote or preventive is copious syringing with clean water, generous feeding with tepid liquid, and the maintenance of a constant supply of ammonia by turning the plunging material and surfacing the pots with fresh horse droppings. Continue to give the necessary attention to pinching, thinning, and tying out where there is trellis room for extension; also thin the fruit where too thickly placed. Pay attention to directions already given for the management of early pot trees in succession houses by feeding, mulching, and syringing, always bearing in mind that the timely and vigorous treatment which the good cultivator applies daily improves his prospect of excellence by making the position of the enemy untenable. Young trees in pots intended for next year's forcing may now be started, in order to give them a long season of growth and time to ripen their wood. If stock is wanted put in eyes or cuttings and treat as *Vine eyes*, using well-drained sandy soil and plunge in a sharp bottom-heat in a close pit. If well managed a fruiting plant may be grown from the eye in two years.

Cucumbers.—Since our last notes were written we have experienced a change to rather colder weather, which will necessitate extra firing to prevent the occupants of this department from receiving a check; and as few subjects are so easily and injuriously affected by sudden changes, the cultivator must be ever on the watch for the appearance of red spider and thrips, which invariably spring into existence when old plants are placed under the influence of overheated hot-water pipes. If taken in time the most effectual remedy is sponging with warm soap-water; but prevention being better than cure, frequent syringing with a weak solution of Gishurst on mild evenings or dull days, when hard firing can be dispensed with, will keep these troublesome enemies in check. If mildew, the outcome of insufficient bottom-heat, hard cropping, and a low, stagnant atmosphere, puts in an appearance syringe well with a clear sulphur water, renovate the beds, and stimulate the plants with copious supplies of clear tepid liquid or guano water. As young growths break away under generous treatment, gradually remove old leaves, crop lightly, fertilise the most promising fruit, and cut before they attain their full size. Ventilation and cleanliness—two important items in successful culture—must not be overlooked; but draughts being objectionable, the air should be conducted through ventilators placed in front of the pipes, and on a level with the surface of the fermenting material from which moisture and ammonia will be carried to the foliage and fruit. Cleanliness may be secured by the removal of all decaying matter and the frequent washing of the floors, shelves, and glass. Give every attention

to spring-sown plants intended for pits or houses, and pinch or train to suit the position they are to occupy. If not already sown, a few seeds of some good prickly kind may now be sown for fruiting in ordinary pits and frames. Although we have tried a great number of startling novelties, we have not yet met with anything to surpass a variety sent out by a Worcester firm, under the name of Smith's Frame. Many people think the prickly kinds superior to the smooth Syon House section. As consumers, we do not feel competent to venture an opinion; as growers, we prefer the first for frames in the summer, and the last for house work all the year round.

Hardy fruit.—Although fruit trees in the open air are in a forward state, yet, owing to the absence of sun, they are not so much advanced as we at one time expected to find them. Another retarding cause may have been the unusually late spring of 1882, which threw the ripening and resting period well into the succeeding autumn and winter. Be this as it may, the abundant blossom buds justify the expectation of an excellent crop of fruit, provided we can protect from the troublesome spring frosts, which generally follow mild winters. In all cases where movable screens can be adopted, no time should be lost in getting them fixed, as much may often be done by shading and so retarding the blossoms of Apricots and Peaches from bright sunshine; but, as we have before stated, the coddling system must be regarded as one of the greatest evils, when perhaps there is neither sun to force nor frost to kill. On the other hand, it will be well to avoid being lulled into carelessness by the favourable appearance of the early part of the night, as it is well known that the greatest depression frequently takes place shortly before and sometimes after daybreak. The first important item in wall covering is protection of the blossoms from wet either by the use of glass or boards, and as these checks to rapid circulation produce a dry, steady atmosphere, the flowers near the wall are capable of resisting several degrees of frost with impunity. The weather having been favourable for outdoor operations, it is hardly possible that any part of the winter routine can be in arrears; but where this is the case, no time must be lost in setting matters straight, as a busy time is at hand, and doing things at the right time is quite as important as doing them well.

FRUIT GARDEN.

CULTURE OF THE RASPBERRY.

OWING to the number of gardening journals, and the immense variety of subjects treated of in each, one finds it difficult to think of anything new to say on any branch of gardening, and of fruit culture in particular, not that I think for a moment that perfection of culture of any plant or fruit has yet been attained, but what I mean is some mode of writing on a subject that shall not be a repetition of anything that has been previously written, and yet shall tend to advance the culture of whatever is being written about. To my mind the only way of ensuring this is to record only one's own practice, but not to be so full of self as not to read and appropriate hints, &c., given by others, even on subjects that possibly we think we know sufficient about. Applying this rule to Raspberry culture as practised by myself, I have to say that a deep loamy

Soil inclining to clay is best, but it should be well drained, for though the plant luxuriates in a cool soil, anything like stagnation or sourness is soon perceived by weak and badly matured canes. This description of soil being the best, it follows that the various descriptions of soils that have to be made available for their growth must be treated from this standpoint, which means that sandy and gravelly soils should have an addition of clay, or, lacking this, a greater quantity of well decayed manure and be made firm by rolling or treading; on the other hand, clay and soils of a tenacious nature should have a liberal quantity

of old mortar rubble, charcoal, or burnt soil intermixed, and if manure at all be used when trenching, it should be in the form of half-inch bones, a manure that in such soils will last for years.

Planting.—Early in November is the best time, as then the plants get a firm hold of the soil before there is any danger of drought, from which they suffer if planting be delayed till February or March. Position and distance apart of plants must to some extent be regulated by numbers of other small fruits that have to be grown in kitchen gardens, and modes of cropping the same. I find the best aspect and form of growing them to be in straight lines running from north to south, the said lines being arranged as divisional lines for forming the principal quarters of the kitchen garden into convenient portions for cropping. By this arrangement the plants take up but little space, as cropping can be done within a yard of the stems, and if this space be annually re-covered with a thick layer of stable litter, as it should be by way of mulching to the roots, it forms a convenient alley each side of the row for getting at the vegetable crops. The distance from plant to plant in the row should be 15 inches, and the mode of

Training be to strained wires, fixed to stout poles, say about 8 feet long, which should be driven into the ground 3 feet; this will leave 5 feet for the height of the topmost wire, which should be secured to the poles by small staples; three other wires equidistant, beginning at 2 feet from the ground, make a most perfect fence, the canes to be tied either in upright or in oblique form to the wires with matting or yellow Willow. This latter form is generally adopted when there is a tendency to over-luxuriate in growth, and doubtless does to some extent check the current of the sap, and tends to the production of better lateral shoots, particularly at the lower half of the canes. The bundling together of innumerable canes to a single pole, under the impression that time is saved by using such supports, is a mistake; the plan here recommended is carried out just as quickly, and finer fruit and more of it is a certainty, in addition to the ease with which it can be protected from birds.

Varieties.—These are not numerous, and there is such a sameness about most of the kinds that if they were weeded down to about four sorts no one would be the poorer for the reduction. The best for general culture are Fastolf and the old Red Antwerp, and the best autumn bearer is Belle de Fontenay. The canes of this latter variety, and of all autumn fruiterers, should be closely cut down at the winter pruning, and as soon as the new growths have attained a foot in height the weakest should be thinned out till the canes that are left have at least 9 inches of clear space each.

General culture.—Surface dressings of manure are of first importance, and application twice a year is not too much, viz., of good rotten manure in autumn, and a supplementary addition of long stable litter in spring to serve both as a mulching and a path; no watering will then be needed, even in the driest weather, and the plantation will continue in a productive state for several years. The first symptoms of a change of ground being needed will be seen in the production of smaller fruit and weakly canes of a blackish green colour; when these appear, make new plantations at once. Digging immediately over the roots is very injurious, and should never be resorted to, except to remove Couch Grass and other troublesome weeds or portions of roots that have formed suckers a long way from the original stools. In pruning, if the canes are well ripened, they may be left almost full length, that is if there is plenty of training space, or they may be cut to such lengths as there is to be filled, but bear in mind that to overcrowd them with the expectation of getting a greater quantity of fruit will tend in the opposite direction.

W. W. H.

Pear Fondante Thirriot.—This, of which a coloured illustration is given in the *Bulletin*

d'Arboriculture, is highly praised by M. Rodigas, who asserts that its merits are by no means so well known as they should be. As a fact, it is, although by no means new, but little grown, but now that it has been adopted by the French Pomological Society, its good qualities will probably receive their just recognition. The flesh is white, fine, melting, and buttery, juice abundant, very sweet, relieved by a slight acidity, and highly perfumed. Habit, vigorous; branching, pyramidal; fertility, great and remarkably regular; it succeeds equally well on the Quince and on the Pear stock. Its season commences at the end of October and lasts until the middle of December. Altogether it is pronounced to be a first-class variety.—J. C. B.

NEW PEACH.

IN a recent number of the *Journal of the French National Horticultural Society* considerable space is devoted to the description of a new seedling Peach, and which, if one may believe what is there said of it, is likely to prove one of the very best varieties hitherto raised. Its origin is curious, and is thus related by M. Guyot, a well-known grower at Montreuil: "A young Peach tree sprung up in a bed of Pæonies, the produce of a stone thrown there in a chance way. Remark its fine growth and handsome foliage, we, in the hope of obtaining something good, budded it on a strong Almond which had once formed the stock of a Peach. Carefully tended, in the course of several years it yielded the fine fruit now before you." The above account was furnished by M. Guyot on the occasion of his exhibiting a very fine collection of Peaches at Montreuil, pre-eminent amongst which was this new kind, and which so impressed the Peach growers of that place with its beauty as to induce them to call the attention to it of the National Horticultural Society, which deputed a commission of its members to inspect the tree, amongst them being M. Lepère, M. Bertant, and other well-known experts in Peach culture. The following is an extract from the report of this inspection: "We believe that this Peach is destined to become very popular, both on account of the luxuriant growth of the tree and the flavour and beauty of the fruit. It should certainly be placed amongst the best Peaches generally grown." The exceptional hardiness of this Peach should recommend it to English growers, as it is stated that the winter which proved so destructive to the Peach trees of Montreuil scarcely affected it, and it would now be difficult to find such a large and healthy tree in that locality. It is called Belle Henri Pinant.

Byfleet.

J. C.

Grubs on fruit trees (p. 150).—Some of the grubs on "C's" fruit trees are, I should imagine, those of the Apple weevil (*Anthonomus pomorum*), a small beetle scarcely a quarter of an inch long, which lays its eggs on the swelling flower-buds. The beetles pass the winter under stones, Moss, rubbish, and loose pieces of bark on the trees. They do not fly much, but crawl up the stems to the buds. Remove all rough, useless bark, Moss, &c., from the stems, and all stones and other shelter for the beetles near the trees, and before the weevils leave their winter quarters, tie strips of sacking, dipped in tar, round the stems, which will prevent the beetles crawling up them.—G. S. S.

Temperature in the shade.—In "Notes and Readings" (p. 147) "Peregrine" alludes to an experiment by M. Macagno as to the difference in temperature of the air round Vines exposed and covered. "In other words, the mean temperature was higher in the shade than in the sun—a wholly abnormal condition of things." This surely cannot be gathered from M. Macagno's experiment. He proved that the mean temperature during three months was 70° round Vines left exposed, 82° round those covered with a white cloth, and 92° round those covered with a black cloth, and he, I imagine, is quoting the average temperature during the whole time, both day and night, and not the mean temperature in the sun, which during the

three months that Grapes are ripening must be considerably more than 70°, for in Johnston's Physical Atlas the mean annual temperature of Italy is given as 60°. One can easily understand that the coverings alluded to would prevent the radiation of heat at night to such an extent as to so equalise the temperature during the twenty-four hours that the average was higher under the covering than it was outside, but this is not a "wholly abnormal condition of things."—G. S. S.

Fruit trees in hedges.—In some portions of Kent, notably at Cuxton and Bush, near Rochester, many of the hedgerows are planted at short intervals apart with Damsons, which thrive luxuriantly, and produce heavy crops of this desirable fruit. According to a writer in a late number of *Farm and Home*, many of the cottagers in the above-named districts make sufficient from the Damsons cultivated in this way to pay the rent of their house and garden. In planting new hedges the trees may be very easily introduced; they should be planted about 10 yards apart for Damsons and 12 yards for cider Apples. Wherever the Damson will succeed preference should be given to it, as the Quickset will thrive better under it than under the Apple, and there are very few stone fruits which are more in demand or more profitable than Damsons. A most excellent hedge may be formed by planting the Cherry Plum (*Prunus Myrobalana*). It will succeed in almost any soil, grows quickly, is perfectly hardy, and thoroughly proof against cattle. It is a most suitable stock for budding or grafting Damsons and many varieties of Plums upon, so that by using this for a hedge, the owner has only to have Damsons budded or grafted upon it at whatever distance apart he may think proper, and await the result, which will far exceed his expectations.

BOOKS.

VINES AND VINE CULTURE.*

WHEN a practical man like the able director of the Royal Horticultural Society's Gardens at Chiswick sits down to commit his experience to paper it is hardly likely that the information conveyed will fail to gratify and enlighten his readers; but when he avails himself of facilities and advantages which few private individuals can command, and combines them with sound practical knowledge, horticulturists of all classes will look for teaching which they can put into practice with security. In this respect readers of Mr. Barron's book will not be disappointed, as it is undoubtedly the most exhaustive volume upon Vines and Vine culture ever published.

In the opening chapter he gives an interesting history of the Vine from the time of Noah down to the present day. The succeeding chapters, extending over more than 100 pages, with numerous illustrations, are devoted to propagation, hybridising (a most interesting and instructive chapter), the formation of borders, the best structures for Grape growing, heating, and the general management of vineries, the weakest point being the twelfth chapter, which is devoted to the thinning of the fruit, the figures representing to our mind bunches considerably overthinned; chapter 13, upon the Grape room, with numerous illustrations, and chapter 14, upon packing for transit by rail, convey a vast amount of information, which growers for home use or market may gather with decided advantage; indeed, the subject of the last-named chapter is so imperfectly understood by many of our best practical growers, that hundreds of pounds worth of valuable fruit is annually destroyed or greatly deteriorated by bad packing. Passing on to chapter 19, giving a short history of the large Grape house at Chiswick, we would direct attention to the excellent contrivance invented by Mr. Barron, and shown in the accompanying illustration, for getting to the Grapes and Vines throughout the season of growth. As this is probably the largest vinery in the world, the fol-

lowing quotations from the author may be interesting to those who have not seen it:—

He says (p. 125), "This noble vinery, probably the largest structure devoted to the cultivation of Grapes in existence, was originally erected as a plant conservatory. It is 180 feet in length, 30 feet in width, and 26 feet high. In 1857 it was planted with Vines, and there was much speculation as to whether they would do in so large a structure. A great number of varieties was at first planted, affording an excellent opportunity for the determination of their distinctive characters.

dreaded Phylloxera in all its forms, winds up what may be termed the practical part of the work. This does not, however, nearly exhaust the contents of the volume, as we have a chapter on the selection of Grapes for special purposes, which, judging from frequent applications for information which reach us from private individuals, will be found invaluable to amateurs and others whose limited experience does not enable them to select the best kinds for themselves. A step in the right direction, now varieties have become so numerous, is the system of classifying Grapes, as by it the

Worthless kinds were cut out and grafted, a proceeding which afforded some interesting illustrations of the suitability of Vine stocks. At the present time good standard sorts best suited to the house are grown and give excellent crops, the greatest number of bunches produced in one season being 4500, the aggregate weight exceeding 2 tons.

"The ladder employed for getting to the Grapes is made of wrought angle iron and runs on wheels. It is so constructed that the men in whatever position are within easy reach of the Vines. From ten to twenty men may be at work on it at one time, and it has already effected an immense saving in labour and glass over the ordinary ladders formerly in use."

Diseases to which Vines and Grapes are subject have not been overlooked, and a beautifully illustrated chapter on noxious insects, including the

veriest novice may easily trace a Grape which he has never seen before to one or other of the sections or sub-sections to which it belongs.

The remainder of the book, some 60 pages, is devoted to illustrations and descriptions of thirty of the most popular kinds of Grapes in cultivation. The first of the series is the well-known Alicante, which, with the author's permission, we herewith introduce to our readers with his remarks.

Alicante.—An oval black vinous Grape. Season: Best suited for late use. Where Grapes are required after Christmas there are few sorts that keep so well as the Alicante, and it is more largely cultivated for market, perhaps, than any other variety excepting the Black Hamburgh. Merits: Quality third-rate, but valuable for its excellent keeping and free fruiting properties, its splendid appearance and fine constitution. Synonyms: Black Alicante, Black Lisbon, Black

* "Vines and Vine Culture." By A. F. Barron.

Portugal, Black St. Peter's, Black Spanish, Black Tokay, Meredith's Alicante.

VINE.—Growth very strong, vigorous, and free, the young growing shoots densely coated with down, giving them a whitish appearance, the ripened shoots being also downy, and especially so round the buds, which are large and prominent and of a dark purplish colour; the wood ripens freely and well; moderately fruitful.

LEAVES.—Very large, deep green, thick and soft, covered with down on the under side, giving them a silvery appearance; they remain long conspicuously green amongst others, being late in ripening and changing colour, and they die off yellow or occasionally tinged with red.

FRUIT.—Bunches large or very large, averaging from 2 lbs. to 6 lbs. in weight, broadly shouldered, sometimes regularly tapering, and of very handsome form, but more frequently divided or with large irregular shoulders that assume the appearance of a cluster of bunches; always very closely and well set, and requiring early attention in re-

observation, I am convinced that very few crops indeed fail from bad seed, especially if obtained from a reliable source, but failures are continually happening through mismanagement in sowing and planting, more particularly during wet weather. For the sake of experiment we have sometimes sown a short row of Peas very early in the season, when the ground was very wet, and the result was invariably the same, viz., failure, few plants showing above ground, and such as did struggle through were never robust and always deficient in fertility. On the other hand, seed sown in dry ground and in dry weather always grew luxuriantly and bore profusely. Let the ground only be dry and get the seeds snugly in, and it matters little what kind of weather may follow for a time. It is a common desire to get all seeds and plants in early, but this, in many instances, is disadvantageous. Many kinds of seeds sown under favourable conditions early in April with the soil in suitable order will be almost certain to give a supply as early and come to maturity as soon as those sown in Janu-

It will grow or succeed in any ordinary vinery, but the more heat that is given to ripen it the better the flavour. With ordinary care it is generally very fruitful, always sets well, and colours magnificently. After ripening it requires to be kept in a cool temperature, otherwise the berries are apt to decay.

This excellent volume is neatly and appropriately bound, and is printed on good paper. The type is large and clear, the text free from errors, and the illustrations good. We congratulate Mr. Barron upon the production of so instructive a book, the want of which has long been felt, and we are sure it will prove a valuable acquisition to the library of every horticulturist. W. C.

KITCHEN GARDEN.

SOWING IN WET WEATHER.

JANUARY and February have been two of the wettest months on record here, and according to

The Great Vinery at Chiswick.

gard to thinning. Stalk stout and strong, very short, the bunch frequently resting on the shoot.

BERRIES.—Large, of a true oval shape, quite black and covered with a dense blue bloom. Their foot-stalks thick, short, and slightly warted. Skin, thick and leathery. Flesh rather squashy, with a tinge of red, and adhering somewhat to the skin. Flavour in general somewhat earthy and disagreeable, but when well ripened, and after hanging a long time, they are more briskly and pleasantly flavoured, but seldom rich.

HISTORY.—There is no authoritative record of the introduction of this Grape. The name is Spanish, but it is applied to several varieties of Grapes coming from Spain. Dr. Hogg ("Fruit Manual") states that he has met with it in the vineyards of the south of France under the name of Espagnin Noir. It is no doubt the same as Speechley's Alicante; but it is to Mr. Meredith, late of Garston Vineyard, that the credit or popularity of this Grape is due. His excellent and extensive cultivation of it led to its being called Meredith's Alicante, in order to distinguish it from Kempsey Alicante, at that time much praised and recommended, but which was ultimately proved to be Black Morocco.

CULTURAL NOTES.—There are very few better constituted or more easily cultivated Grapes

all accounts the rainfall has been excessive throughout the country. This has doubtless greatly retarded kitchen garden operations, and should rainy weather continue to be the rule much longer many vegetable crops early in some seasons will be unusually late this year. Further than this, a general deterioration in quantity and quality may be expected. Nothing is more against the ultimate success of a crop than sowing or planting when the soil is in a pasty condition. In large places where work under glass can be forwarded by all hands in wet weather, and the same can be done in the kitchen garden when a favourable chance occurs, the ill consequences of working wet soil are not so liable to be encountered as in small gardens, as although many may take delight in attending to their frames or small conservatory, few will, I apprehend, take to the digging and cropping of the kitchen garden, this being mostly left to a "jobbing man." This useful individual has generally his time fully taken up at this season, and to meet all demands must push on with his work at each place, let the weather or consequences be what they may, hence disappointing results. Strange to say, however, these are hardly ever attributed to gardening in the wet, but are, as a rule, put down to bad seeds or some such plausible cause, but, from experience and close

ary or February in wet, retentive soils. I have known Onions sown in January irrespective of weather beaten by those sown two months later when the crop was harvested in September. I attach the utmost importance to having the ground in the very best of order for the reception of seeds, and I have a decided objection to anything like kitchen gardening during wet weather. We have no fixed dates for sowing anything; the weather alone is our guide. Some years we have had a good patch of spring Onions from seed sown by the middle of January, and at other times not a seed has been got in until the middle of March, but in the end the crops were about equally good, thus showing the advantage of waiting for fine weather. Considering the number of wet days which we have had lately, I fear many will be tempted to put crops in now when the soil is really not in the best of condition for sowing. In all such cases I would certainly bespeak patience. In wet seasons, changeable weather, or showery times it is an excellent plan to dig or fork and sow or plant as that goes on. A long piece may be turned up to-day with the intention of cropping it to-morrow, but a wet night may follow and prevent this being done for days, and even weeks, when the soil will have lost the sweet, mellow

surface which it possessed when first moved, and it may be necessary to dig again before the crop can be got properly in the ground. In cropping and digging at the same time I would begin say with early Potatoes. Let an opening be taken out at the end of the border or piece of ground, and plant one row very near the end, then as every 18 inches or 2 feet of the ground is turned over make a notch in the opening and put in another row, and so on to the end. Rows of plants may also be planted in this way, and seed beds may be formed whenever sufficient ground has been turned over to give the desired width. Lastly, if a stock of dry soil can be secured, covering over all seeds with it in a wet season will be a great benefit to them. During winter, or indeed throughout the whole season, we never throw away any of the old soil which accumulates in our potting shed; on the contrary, it is all sifted and put away in an odd shed to be kept dry for covering vegetable seeds. When drills are opened, 1 inch or 2 inches deep, we hardly ever fill them again with the ordinary soil, but use this material from our store heap, and as it generally contains a good deal of sand, leaf soil, and well decayed manure, the young seedlings push freely through it and thrive remarkably well in it, more especially in wet seasons. J. MUIR.

Margam.

A SELECTION OF POTATOES.

IN the following selections the choicest of the Potatoes in cultivation are arranged according to the purposes and soils for which they are best suited:—

FOR PRODUCTIVENESS AND HIGH QUALITY.—*White Rounds*: Bedford Prolific, Early Border, Early Market, Feltham White, Fenn's Standard, Lady Truscott, Premier, Early White, Rector of Woodstock, Sharpe's Victor, Sutton's Favourite, Sutton's Fiftyfold, Sutton's Early White Regent, Reading Hero, and Wiltshire Snowflake. *Coloured Rounds*: Adirondack, Beauty of Kent, Johnston's Downshire, Matchless, Reading Russet, Triumph, and Vicar of Laleham. *White Kidneys*: Myatt's Prolific Ashleaf, Avalanche, Bresee's Prolific, Cosmopolitan, Covent Garden Perfection, Edgecote Seedling, King of Potatoes, McKinlay's Pride, Magnum Bonum, Myatt's Prolific, Pride of America, Sharpe's Duke of Albany, and Sutton's Magnet. *Coloured Kidneys*: American Purple, Beauty of Hebron, Manhattan, Mr. Bresee, Queen of the Valley, Salmon Kidney, Sutton's Prizetaker, and Trophy.

BEST FOR GARDEN CULTURE.—Ashleaf, Bedford Prolific, Cosmopolitan, Covent Garden Perfection, Early Border, Fenn's Standard, Magnum Bonum, Myatt's Prolific, Rector of Woodstock, Sutton's Early White Regent, Sutton's Fiftyfold, Reading Russet, Reading Hero, Sharpe's Victory, and Woodstock Kidney.

BEST FOR COLD WET SOILS.—Beauty of Kent, Bedford Prolific, Bresee's Prolific, Covent Garden Perfection, Fortyfold, Johnston's Downshire, Magnum Bonum, Reading Hero, and Scotch Champion.

BEST FOR SAND AND CHALK.—Beauty of Hebron, Bresee's Prolific, International Kidney, Early Rose, Manhattan, Matchless, Mr. Bresee, Pride of America, Schoolmaster, Reading Hero, Triumph, and Trophy.

BEST FOR EXHIBITION.—*White Kidneys*: Avalanche, Bresee's Prolific, Cosmopolitan, Covent Garden Perfection, International Kidney, King of Potatoes, McKinlay's Pride, Magnum Bonum, Model, Myatt's Prolific, Pride of America, Snowflake, Sutton's Magnet, and Woodstock Kidney. *Coloured Kidneys*: American Purple, Beauty of Hebron, Crimson Ashleaf, Garibaldi, Heather Bell, Manhattan, Mr. Bresee, Salmon Kidney, Sutton's Prizetaker, and Trophy. *White Rounds*: Bedford Prolific, Early Border, Feltham White, Fenn's Standard, Lady Truscott, Lord Mayor, Porter's Excelsior, Pride of Wilts, Rector of Woodstock, Sutton's Favourite, Sutton's Fiftyfold, Reading Hero, Schoolmaster, and White Emperor. *Coloured Rounds*: Adirondack, Beauty of Kent, Blanchard,

Grampian, Matchless, Radstock Beauty, Red Emperor, Scotch Blue, Reading Russet, Triumph, and Vicar of Laleham.—*Gardener's Magazine*.

DOUBLE CROPPING.

IT is a time-honoured practice with many to occupy the soil with two distinct crops, one of which is intended to be cleared off by the time the entire space is required by the other, or most important crop. Thus Radish seed is frequently sown thinly along with Onion seed, and the Radishes are generally cleared off before the seedling Onions have made much progress, while the gradual withdrawing of the Radishes tends to loosen the soil, and benefits rather than otherwise the Onion crop. In some parts of the country cottagers invariably plant the Mazagan or some other Broad Bean between the rows of Potatoes in their gardens, and the Beans do not, as a rule, prove injurious to the development of the latter crop. But in addition to this the cottager entertains a belief that the presence of the Beans tends in some way to mitigate the virulence of the Potato disease. Summer Spinach is also frequently sown between the lines of Peas, as in the early stages of their development the necessary space between the lines is not required, and by the time this is the case what may remain of the Spinach crop may, if the weather is dry, be used with advantage as a mulching for the Peas, or, if cleared off, the space between the lines may be forked or dug over, bearing the soil to the right and to the left, so as to give increased depth of mould to the roots of the Peas. Celery is mostly planted in trenches, and the soil thrown out of them forms ridges, which, when levelled on the top, form excellent stations for Cauliflowers, Lettuces, or any crop of quick growth, which may be cleared away by the time the soil is required to mould, or earth up the Celery. The increased depth of surface soil afforded the roots of plants occupying these ridges induces a rapid and exceedingly succulent growth in such gross feeding plants as the Lettuce, consequently some of the finest summer Lettuces are thus produced.

This dual system of cropping may with advantage be followed in the case of winter Broccoli, which not infrequently during severe winter, is entirely cut off by frost, a serious loss, as during early spring, the period when Broccoli is expected to come into use, culinary vegetables are as a rule seldom plentiful. The process mostly practised with the view of preventing the destruction of this crop is that known as laying, an operation effected by removing a portion of soil from one side of a row and pressing the plants down until they assume a somewhat horizontal position. The stems are then covered with soil taken from the side of the next line of plants, and so on until the entire plantation is laid down. The stem is found to be the most vulnerable part of the plant, hence the necessity of protecting it in some way, and a covering of soil is mostly found to have the effect of preserving it from the effects of very severe frost. The operation, at the same time, gives a salutary check to the plants, rendering them less susceptible to the injurious influence of a very low temperature than when in vigorous growth. On some light and poor soils, however, this check has also the undesired effect of inducing the plants to produce heads of smaller size than would otherwise be the case, and on this account the precautionary process of laying the plants down is frequently omitted, while by adopting the following plan the stems are protected and no check whatever is given to the development of the plants. The winter sorts of Broccoli intended to come into use during the following spring should be planted in lines, say 4 feet or 5 feet apart, and between the lines should be planted at the same time lines of Walcheren Cauliflower, Veitch's Autumn Giant Cauliflower, early Savoy, or Coleworts, which should be all cleared off by the middle or end of November, when the winter sorts should be at once moulded up close to the lower leaves, and in a manner similar to that practised with Celery. They thus sustain no check, and at the same time the stems are effectually protected,

and the trench thus formed between the rows tends to keep the soil in a dry and healthy condition. Plantations of winter Broccoli thus treated generally produce heads of the finest quality, and are seldom greatly injured during even the most severe winters. P. GRIEVE.

FORCING SEAKALE.

FEW who see the delicate white bundles of this vegetable lying in greengrocers' windows, or who enjoy it for their dinners, have any idea how it is grown, or of the great change that has taken place of late years in the mode of forcing it, a change which, by rendering the work much less laborious, has cheapened the article produced and placed it within reach of those who rarely, if ever, could taste it before. The old plan of managing Seakale was to have beds of a certain size with plants in clumps, so that they might be covered with large costly pots, made with lids at top for the purpose. This was only a very small part of the preparations required for forcing, as the more serious portion had to follow, which was the getting together of a huge mass of fermenting material to surround and cover the pots. This big pile of manure and leaves had then to be watched by inserting trial sticks to test the heat, which would perhaps get to a violent pitch, when, to prevent the Seakale being burned and spoiled, the whole heap had to be shaken over and turned. This turning at once effected the lowering of the temperature, and very often lost the heat altogether, when more manure had to be got and added to start fermentation afresh. Things would go on in this uncertain way, when, after a time and much searching, some of the pots might be found to contain a few crowns ready to cut, while plants in others had not moved at all, or were just beginning to push. Instead of the mountain now going to Mahomet, Mahomet has to go to the mountain, or rather the Seakale is taken where the heat is, which is much easier than the other way, as the roots may be dug up and wheeled in a barrow or carried in a basket, and packed together in a very small space.

By adopting this method, almost anyone can find a suitable place to force it in, as all that is needed is warmth, for no light or air is required; indeed, they must be excluded, or the Kale will not blanch. Where only a small quantity is wanted, a large deep flower-pot or tub is as good as anything, as the roots may be put in either, and filled in between with fine soil; and if then covered quite close over the top, the Seakale may be forced under the stage of a plant house, in a stokehole, cellar, or shed, in a stable, or anywhere that waste heat can be had. If there is no place available, the pot or tub containing the Kale may be buried in a bed of fermenting leaves or manure, where, if the heat does not run above 80°, it will shoot quickly and come very strong. Those who have only a limited quantity of roots and cannot spare any to take up for forcing, may still forward what they have by turning any spare flower-pots over the crowns, as the pots absorb and conduct the warmth from the sun to the air within, the temperature of which is raised considerably, and this excites and brings on the Kale. To have this bright and white, the pots must be well pressed on the ground and the holes in the bottoms blocked by dabbing a piece of clay over them so as to shut out light, otherwise the Seakale will be of a purplish hue. A good way of retarding this excellent esculent is to cover the beds with straw litter, which, by keeping off the sun from the ground, retards the roots considerably, and thus prolongs the season's supply much beyond the time it could be had without having recourse to this practice. Some use cinder ashes and others earth up the crowns of their Kale to blanch it, but when so buried the heads are generally stained and the Kale is never so good. Those who have not beds of this vegetable will find this a good time to make and start them, work which should be set about first by well preparing the land. The way to do this is to manure heavily and trench or dig deeply, as the roots of Sea-

kale go far down, and like plenty of rich stuff to feed on. Plants of Seakale may be raised in two ways—the one by means of thongs, or portions of the old roots, and the other by seeds, the former being preferable, as by adopting that plan very fine crowns may be got in a season.

In the selecting and making of the sets, the strongest parts of the lower roots should be chosen and cut up into lengths of 3 inches or 4 inches, but care must be taken when doing so to make a distinction in the two ends by making the top flat and the other sloping, as being of the same size all through, many of them would be likely to get planted upside down, and thus fail to grow. The distance at which the sets should be planted is about a foot, and 18 inches from row to row, which will give ample room for the spread of the foliage, and enable the plants to develop fine crowns. The way to put in the sets is to have a line, when by the use of a small dibble to make the holes the sets may be dropped in, and the holes filled up around them by raking the ground after, or by casting in a handful of sand, which is always advisable if the land is at all wet and stiff, as the sand preserves the root pieces from rotting. Seakale, being a maritime plant, is fond of salt, and if a sprinkling is sown over the beds when the plants are growing it will not only help them greatly, but be of much use in keeping down weeds, and therefore save both time and labour in hoeing. If seed is sown the earlier it is got in now the better, as it is important to give a long season's growth. The seeds being large may be sown in drills in rows the same distance apart as advised for the plants, and the seedlings thinned out when large enough, leaving the young plants about 10 inches or 12 inches asunder. S. D.

NOTES AND READINGS.

THE CATTLEYA WRANGLE.—Probably none besides the pedantic section of Orchid fanciers reads a line of the discussion now going on in all the papers relative to Cattleya "Percivaliana." If any do, it must be a source of profound wonder to them why so much ink should be spilled over a variety which the disputants label "miserable, inferior," &c., and as only fit for the rubbish heap by comparison. A perusal of what has been written on the subject suggests the idea that there is no such a thing as a "Percivaliana," and that it does not matter in the least whether there is or not. There are probably numbers of the same variety, hence the confusion. If the present reckless system of naming varieties of Orchids be followed much further, the Latin tongue, which has hitherto been considered inexhaustible for such purposes, will fail to specify the numberless distinctions the Orchid fancier professes to see. What subtlety of distinction, for example, and scholarly appreciation of the Latin adjective is manifested in the naming of six of the thirty or forty Cattleya Mossii in the list—*grandiflora*, *grandis*, *magnifica*, *majestica*, *splendens*, and *superba*. One would like to know where the comparative and superlative begin and end here. The truth is these so-called "varieties" differ from each other about as much as half-a-dozen wild Daisies gathered at random might do. Many other similar examples could be furnished showing the little weakness of our Orchid scholars. There are good reasons for supposing also that many of the so-called

*

RARE VARIETIES OF ORCHIDS are not by any means exclusively in the hands of a few growers. We were standing the other day before a rosy-looking spike of a Vanda, in an extensive trade collection, in company with a well-known private grower of the species, who professes to be one of the few favoured mortals who possess a limb of the grand "Gloriosoni" variety described and figured no end of times, and we asked, "Now, what do you call that?" "Oh, that is —'s variety," was the answer; "exactly the same as my own." "No," put in the nurseryman, "that is *amabilis*; we got it out of the private collection

of Mr. So-and-So, who named it himself." A fabulous price had of course been declined for this variety. The London trade, those sly fellows who are always supposed to be on the scent of novelties, had tried to get possession, but had failed. No doubt "*amabilis*" will help on the confusion of fine varieties soon. The finest of all the Vandas is *suaavis*, which should be grown at the rate of six to one of all the others. The bold, grand way it projects its spikes out from the stem, and the "excelsior" expression of the whole flower would strike a Doré. It is a free grower and flowerer too; it is said not to throw out side shoots very freely, but some finely-furnished specimens of it have been shown before now.

*

LAPAGERIA PROPAGATION.—We revert to this subject to say that a collection of young plants now to be seen at Handsworth Nurseries is well worth attention. Twenty-two plants, in pots the size of tubs, and none of them exceeding four years of age, very nearly cover the whole roof, a 32-feet span, of a house 100 feet long, many of the shoots being 30 feet in length or more. These plants when taken up as rooted layers probably filled 12-inch pots at once, from which their growth, root and top, not long afterwards necessitated their removal to pots nearly a yard in diameter. Talk of cuttings!

*

CRACKING GRAPES.—It is by no means certain that the cracking, not bursting, of the berries of certain Grapes like the Madresfield Court can be prevented by keeping the Vine dry at the root, or incising the branches, as has been stated. Professed experts have failed to do this in the case of Madresfield Court Vines growing in inside borders and perfectly under control in every way at the root. The theory that the cracking is caused by distension from within, owing to the force of sap, will not do at all, physiologically or otherwise. When anything bursts the contents run out, but who ever saw the sap running out of a cracked Grape berry? And why is it that when a berry is rent its entire length or for half its circumference the crack will continue to extend, and perhaps take a transverse direction if distension is the cause of cracking? When the Chasselas Musqué Grape cracks it does so like a mealy Potato exactly, and the Madresfield Court splits deeply, allowing the stones and flesh of the berry to protrude as if the disease was caused by some kind of vegetable scurvy. Hard forcing seems to aggravate the disease considerably.

*

THE LATEST AUTHOR BUT ONE ON VINES recommends the canes to be trained a long way indeed from the roof. He has a span vinery 216 feet long and 30 feet wide, and the Vines are trained about 4 feet from the glass on the average, calculating that the wide lantern roof (a perfectly needless and expensive encumbrance on any vinery because it can hold nothing and is of no value otherwise) rises 7 feet or 8 feet above the trellis; the latter in a lofty house of this kind is only 8½ feet from the surface of the border at the highest part, and the practical man may therefore guess what length of rod, and consequently hundreds of pounds weight of good Grapes, are lost by such an arrangement in a vinery 216 feet long. Every foot of available bearing wood lost means weight in fruit. This is the serious disadvantage of a short trellis. The chief advantages are, according to the author, that "he can reach every bunch in the house without a pair of steps, except those immediately over the pathway." This is the set-off against the odd quarter of a ton of Grapes or so lost thereby. We do not believe one Grape grower in a hundred will be found to favour this idea. Four feet or even 3 feet from the glass is too far for Vines, and means a dead loss of space and nothing else, and it has besides been proved by some of the best growers of the Vine in this country that such waste of space is wholly unnecessary; nor has the author in this case shown, nor can he show, anything to the contrary. And it may be confidently stated

that an accurate gauge of his crops would demonstrate this fact conclusively.

*

ROOTS & TOPS.—We have lately been reading up on this subject, and have come upon a curious problem. A recent writer advises cultivators who may be driven to such an alternative as to have to sacrifice either the roots or tops of their Vines to choose the tops for future operations and let the roots with all their stored-up energies go. It certainly presents some notable advantages, this plan, because when the cultivator has to flit he can take his Vines on his back along with him like a bundle of faggots. This plan is, we believe, going to be introduced into France in a very short time, and it is supposed to have been the method adopted by the apostle to the Britons when he planted the Glastonbury Thorn. The author of this notion bases his idea on the fact that Vines root with equal freedom at either end, although he never read of Mr. Wildsmith's double rooters. That excellent cultivator will, therefore, not feel aggrieved at having been anticipated, but it would be interesting to know what he thinks of the plan, or if he has heard of it. We look forward with some anxiety to Mr. Barron's book, which growers are waiting to welcome in order to see if he also adopts this certainly "original" idea.

PEREGRINE.

OAK LODGE, THORPE, NORWICH.

FOUR years ago the land upon which this tasteful residence stands was a grass field. The house, a very pretty modern villa, is placed in the shade of a group of fine old Oaks, from which its name of Oak Lodge has been derived. The place is not large, scarcely more than two acres in extent, but it contains many interesting features. The old trees partially screen it from the public road, and a small strip of lawn and shrubbery surrounds the front door and extends northwards till it meets the terrace, on which the block of glass houses is built. A handsome conservatory is attached to the house on the northern side, lighted with gas, and very tastefully laid out, the beds and borders being raised and planted with Ferns and Palms, flowers not doing well in the gas-light. The collection includes several handsome Dicksonias, imported by Mr. Sendall direct from Australia, the trunks of the tallest pair being 8 feet high, with well furnished heads of fronds. I may mention as an instance of the skilful manner in which everything is made the most of here that this beautiful conservatory is built over the coal cellars. Minton tiles are laid in the paths, and have the advantage of being easily cleaned without raising any dust. In front of the conservatory is a small circular flower garden, approached by an arch covered with Clematises, which in summer must be a bright and striking feature. Round the flower garden, shutting it in, is a belt of fruit trees and evergreen shrubs, which include pyramidal Pears and standard Apples, intermixed with evergreens for winter greenery, the ground being raised into a broad based mound, which furnishes the fruit trees with a great depth of soil. By and by, as the seasons roll round, and they get well established, the little flower garden will be completely hidden from the kitchen garden beyond by a bower of fruit tree blossoms in spring and of fruit later on. On one side of the house facing the entrance is a fine collection of Roses; the soil here being specially suitable for their culture, a grand bank of blossoms is enjoyed in summer. The ground rises in a line from the house, the acclivity increasing till the wood-crowned summit of a hill in the distance is reached. Amongst

The glass houses on the terrace is a span-roofed orchard house, furnished with trees in pots—Plums and Cherries chiefly—and, judging from the state of the buds, there will be an abundant crop of blossoms. Tea Roses are trained along wires under the roof. The glass in this house is cut in a slightly circular form, a plan which gives more elasticity and prevents the frost cracking the glass by freezing the water between the laps; moreover, this mode of glazing does not

add to the expense of the building. Next came three span-roofed forcing houses, just the kind of houses with which any one would be pleased for forcing flowers or fruits, being light and well heated. They were full of plants either in flower or approaching that condition. Amongst them were handsome examples of *Imantophyllum miniatum* nicely in blossom, showing what a grand thing it is for forcing at this season. Numbers of double *Primulas*, including Gilbert's varieties, and a very fine assortment of zonal *Pelargoniums* bearing grand trusses of flower. The double white *Bouvardia* was in blossom, and its flowers are found to be valuable in a cut state. One of the late Mr. Nelson's *Lachenalias* (*L. pendula*) was furnished with a spike of flowers greatly superior to those of any of the old varieties. These houses also contained a good assortment of new *Coleuses*, *Begonias*, and some grand plants of *Eucharis amazonica*. The next house we entered, also a span-roofed structure, contained Pines on one side (I should mention all these houses had a path down the centre and forcing pits on each side) and *Gardenias* and other plants on the other; Tomatoes also were being led up to the roof and showing clusters of blossoms. The other houses included a range of lean-to's, furnished with Vines and Peaches, which were in good fruiting condition. A fernery under glass contained a good collection of all the best varieties of *Adiantum*, *Cheilanthes*, *Asplenium*, *Alsophila*, *Lomaria*, *Gymnogramma*, &c. But the most remarkable plant in this house was an *Allamanda Hendersoni*, and its mode of growth shows in a marked manner how little solid food plants require if well supplied with heat and moisture. In the centre of the house (a three-quarter span, 50 feet long), on the north side, is a tank which receives all the water that runs from the roof, and it is also supplied from another source in dry weather when the rain water fails. This tank is heated by means of hot-water pipes passing through it, and is covered in with slates; on the latter is a couple of inches or so in depth of shingle. Three years ago a small mound of peat was placed on the shingle over the tank, and a small *Allamanda* planted on it. There was nothing to keep the small mound of peat from crumbling down, and it gradually wasted away until now there is only a thin stratum 6 inches thick, and none has been added since the first basketful was placed over the tank. The *Allamanda*, nevertheless, has developed marvellously; right and left along the roof it has spread. It was not in flower when I saw it, but I was told that the flowers had been very fine and abundant, and so bright in colour as to attract special attention. The wood, I could see, was remarkable for substance and shortness of joint. Such wood will bear abundance of blossoms for a long period if well fed; but where were the roots to nourish the blossoms? Well, on closer examination they were found in great flaky masses floating on the water—sufficient, indeed, to support the great golden blossoms which for six months of the summer and autumn had hung in clusters from the roof. The roots, not finding food enough on the slates, had crept down the sides of the tank until the tepid water was reached, when all difficulties as regards culture were at an end. There is, however, nothing new in this; many a story has been told and many others might be narrated of the way in which roots take possession of drains and other sources of moisture, and how the appearance of the plants thus circumstanced undergoes a marked change for the better. A plant stove with its roof covered with creepers contained, amongst others, the useful old *Ipomœa Horsfalliae*. The space under the stages and the edges of the paths in this house were prettily ornamented with the variegated foliage of such plants as *Panicum variegatum*, *Fittonia argyroneura*, *Gymnostachyum*, &c., the back wall being planted with the curious clinging plants *Scindapsus pictus* and *Ficus repens*. In two other houses a collection of Orchids has been formed, all the best genera being represented, many of the *Odontoglossums*, *Dendrobiums*, *Cypripediums*, &c., being in flower. Oak Lodge, indeed, is a *multum-in-parvo* kind of place, well worth a visit at any season. The houses, thir-

teen in number, are well warmed by one of Messrs. Boulton and Paul's improved saddle boilers, which heats 5000 feet of 4-inch pipe. E. HOBDAV.

ORCHIDS.

ODONTOGLOSSUM CRISPUM.

(STRIPED VARIETY.)

THE accompanying woodcut represents a flower of *O. crispum*, sent to us a short time since by Sir William Marriott, The Down House, Blandford. As may be seen by the illustration, the petals, sepals, and labellum are all spotted and striped on a white ground. These spots and stripes are a bright violet-purple, and there are also flushings of the same colour on the outer surfaces of the flower segments, the whole giving it an uncommonly beautiful appearance. We have frequently seen flowers of this Orchid flushed with purple, but not till Sir William Marriott's specimen came

limited in numbers, were known by repute, as well as by those who had seen them, to be of an extraordinary character, and certain to bring buyers enough of the right sort to enable them to reach their value. As to the importers of Orchids, there is not much needed to show them what would be conducive to their interests in the matter, as I fancy those who have already tried sales at some of the places named have seen sufficient to show them what to do. I have known imported stock in good condition sent long distances from London to be thus sold that I do not suppose made much more than the expenses attendant on the sale, leaving out of account the cost of collecting and transit to England. The name Orchid, according to many people's ideas, must necessarily be associated with extravagant prices; this, coupled with the mistaken notion that to grow Orchids well houses specially devoted to their cultivation were indispensable, has deterred more people from beginning to cultivate them than the whole number of those who have

Striped flower of *Odontoglossum crispum* (Alexandrea).

had we seen a striped flower. This is another instance of the wide variation of *O. crispum*, and, moreover, one of the most beautiful, and it is to be wished that the sport will become fixed. Each flower in the spike sent us was similarly marked. The form and size of the flower may be taken as typical of what orchidists now term a good form of *O. crispum*.

ORCHID SALES.

IN THE GARDEN (p. 147) it is suggested that Orchid sales might with advantage be held in the large provincial towns in place of being, as hitherto, mostly in London. I presume it is imported stock or such as is only partially established that the writer means. Anyone having a collection of established plants to dispose of, even if living in the immediate vicinity of one or other of the large towns in question, would be likely to think twice before sending them to any other place than London, for reasons that Orchid buyers are well aware of, having, as many of them have, those at hand, in or near London, who buy for them if they do not attend themselves. The fact is, London sales of these plants always bring more buyers than ever appear elsewhere, unless the plants have an especial reputation, such as the Manley Hall collection or those sold at Edinburgh belonging to Dr. Paterson, the latter of which, although

gone in for them. The latter of these mistakes is every day now being dispelled, for, as has been so repeatedly urged, not a few of the finest examples of Orchid culture that have ever existed have been grown in houses partially devoted to the growth of other plants of a nature wholly different from Orchids. But as to the other obstacle, price, a clearer conception is fast being arrived at, *i.e.*, with the exception of rare species which often do not produce flowers a fraction handsomer than others as plentiful as need be. Orchids in the shape of imported or partially established plants can now be bought at the nurseries of those who cultivate them largely at little more cost than ordinary trade-sized *Camellias*, *Azaleas*, *Heaths*, &c., and less than is paid for new varieties of *Fuchsias*, *Pelargoniums*, *Begonias*, *Roses*, and similar plants. The high figures constantly being heard of as obtained for individual plants of Orchids are often taken by the uninitiated as representative of the ordinary value, to which they are nothing more than an exception, and simply bear evidence of the lengths to which those who are enthusiasts in these as in many other things will go. Nor should anyone find fault with the spirit that actuates such buyers. Those who can afford and make a special hobby of Orchids merely act as people do in scores of other matters. Amongst instances continually occurring, only the other day at Stevens' room, where a number of

Cattleya Trianae were sold in flower, there were many that went for about £1 apiece, whilst one or two plants no larger fetched eight or ten times that sum, and yet anyone who had no particular acquaintance with them, but was only an admirer of beautiful flowers, would not have seen as many shillings' difference in the value as there were pounds in the actual price obtained. T. B.

CATTELEYA LABIATA PERCIVALIANA.

ANYONE who has had an opportunity of seeing, as I have had, a good many plants of this *Cattleya* in flower, and has not had the luck to meet with more than one example that could be set down as better than extremely poor, cannot fail to see the justice of the complaints that have been made about it. Take, for instance, the three washed-out looking examples shown at the last meeting at South Kensington, and, allowing for the somewhat better condition in which they may appear when more strength has been attained, and those acquainted with imported plants know tolerably well how much to allow on that head, even those who are the greatest appreciators of novelty could not have set them down as above third rate, judging them by the standard of the many fine *Cattleyas* in cultivation, and the examples in question appeared to be of the average that may be looked for. The plant evidently varies a great deal, in this respect quite as much as *C. Trianae*, with a preponderance of poor varieties. Before this *Cattleya* had received such a glowing character it should have been remembered that in addition to the old *C. labiata* we already had such magnificent kinds as *C. gigas*, *C. Reineckiana*, *C. Mossiae*, *C. Dowiana*, *C. Mendeli*, *C. Warneri*, *C. Trianae*, and *C. speciosissima* in their numerous beautiful forms; then *C. labiata Percivaliana* might have been put in about its right place. In the matter of Orchids, as in other things, demand begets supply, and are not those to blame who go in for collections, and rush indiscriminately after everything new, regardless of its merits compared with others already in their possession? This, I venture to suggest, has something to do with the indifferent species sold under such exaggerated characters. Not that this is by any means sufficient justification for the proceeding; still, so long as there are buyers determined to have something new, so long will indifferent plants be forthcoming under characters they do not deserve when really fine novelties are not to be had.—T. BAINES.

— Four weeks having elapsed since January 27, the date my description of *C. Percivaliana* appeared in THE GARDEN, I thought Mr. Burbidge had come to the conclusion that this *Cattleya*, which has now been so fully discussed for and against had turned out better than he expected. But now I see by his letter in THE GARDEN of February 24, 1883, he is still as "of yore." In it he uses a new comparison, viz., *C. Warneri*. This is getting a little off *C. Mossiae*, and perhaps a step nearer identifying *C. Percivaliana* with the *labiata* section of the genus. Mr. Burbidge says I gave "a good many measurements of *C. Percivaliana* and a good deal of description not to the point." The whole actual description and measurements of the flower itself occupied but twelve lines in a column of THE GARDEN of January 27, 1883, though, of course, my letter on the subject was longer. Had it been much less it would have been a very little one, especially as the flower was that of a new plant, of which, I presume the public who took the pains to read my letter would like as accurate a *résumé* as I was able to give, leaving out the long words so much used in the authorised descriptions of the professors of botany, to whose language I never aspire. Had I had the help of a coloured plate, as Mr. Burbidge so often has, I would have dispensed with it all. I could have also given measurements of "the old *labiata*" had I thought Mr. Burbidge would have liked them, but as my letter was principally addressed to "F. W. B." (who I am pleased to see signs in full in THE GARDEN of 24th of February, 1883), I thought he would thank me if I spared him the tedious repetition so often seen in re-describing well-known things. As to my courage of

which hespeaks, that did not fail me in the awful moment of writing a letter for a public newspaper, and I can now, as he seems to wish it, say, "firmly and decidedly" (to use Mr. B.'s own words) on my own part, that I consider *C. Percivaliana* to be handsomer than "the old *labiata*." I, of course, may be wrong, but there are others with me, and I am not alone. To what section of *Cattleyas* would Mr. Burbidge refer it, if not to the "*labiata* section?" *Mossiae* is of that section, and if *Percivaliana* is a *Mossiae*, then it must belong to that section also. I think if Mr. Burbidge had seen some of the fine varieties of it lately sold at Stevens' rooms, and also the blooms sent up by growers, and last, but not least, the collection of bulbs and flowers sent by Mr. Sander, he would not have formed quite such a hard-and-fast opinion of it as he has. He does say that he will publicly acknowledge he is wrong if I or others can convince him with fresh flowers. This I had hoped sometime to do, but, unfortunately for me, he says in the next sentence, "I distinctly refuse the evidence of a writer who acknowledges he had two flowers of the true old *labiata* before him." Now this will be seen to be written in my letter printed in THE GARDEN, January 27, 1883; therefore that pleasure is denied me; but if I ever come across Mr. Burbidge I do hope to have a talk with him on this plant and Orchids in general, as he has them at heart. The main point between us originally was whether it was more like a *labiata* than a *Mossiae*. On his part Mr. Burbidge will find it hard to reconcile Prof. Reichenbach's description in *Gardeners' Chronicle*, January 27, 1883 (which, oddly enough, corroborated mine appearing in THE GARDEN of same date), and also his further remarks in ditto, February 24, 1883, with his own opinion of the plant and also that of Sir Trevor Lawrence, who says, "I speak of those which have flowered out of the numerous plants that I myself bought." Therefore we all write on what we see, and have each formed our opinions. There is always a great divergence of opinion on new and old things. For my part, I should like not only one "un-biased" grower to compare the opposite descriptions (he could only say which he agreed with, after all), but I would like the opinions of twenty-five well-known growers, whose names should be drawn by lot from all those who have bloomed it, and then we should see the preponderance. It would be very interesting to see such a conclusive bit of evidence. When the plant has thoroughly established itself and shown its full vigour it will show who are right. When once established all writing will be superfluous, and will be only the expression of individual opinion.—D. B. CRAWSHAY.

Phaius grandifolius.—The finest examples of this old and well known Orchid we have seen for a long time come from Mr. Field, gardener at Stanley Hall, Bridgenorth. The spikes measure between 4 feet and 5 feet high, and carry from fifteen to twenty blossoms. The foliage, too, is uncommonly large, being about a yard long and 6 inches in width. Mr. Field says he finds it a most useful Orchid for winter and an easy one to cultivate, but few grow it so well as he does. With this come some flowers of *Cattleya Trianae* cut from plants imported last season. These measure 5 inches and 6 inches across with broad sepals, petals, and lips, and in point of colour, too, represent very fine varieties, thus showing what beauties one may sometimes turn up from a batch of imported plants. An uncommonly fine variety of *Lycaste Skinneri* is also sent. It is remarkable for the large massive blooms, the deep purple-crimson of the sepals and petals, and a broad white lip, also spotted with crimson.

Substitute for Orchid peat.—As good Orchid peat is now very difficult to be got, more especially on account of the excessive rainfall, I am going to try the outer shell of the Cocoa-nut chopped up into pieces suitable to the size of the pot. Will other growers give this a trial and let us watch the result?—ALEX. PATERSON, *Fernfield, Bridge of Allan.*

Oncidium phymatochilum.—At page 161 this *Oncidium* is spoken of as difficult to flower. I cannot quite agree with the writer on this point. We have a plant here which flowers freely annually, and has two flower-spikes showing at the present time. It is grown in a pot close to the glass in an intermediate house; it is in robust health, and has produced a quantity of roots outside the pot. My opinion is that if it is properly treated it will not be found difficult to flower. The greatest mistake is repotting this plant when it gets to the side of the pot; if let alone it will grow and flower freely.—EDWARD WILSON, *Fernside, Bickley Park.*

Lælia harpophylla.—A good variety of this richly coloured *Lælia* is now in flower in the Orchid house at Kew. There have been many amongst plants recently imported whose flowers have not come anything like up to the expectations formed by those who have had the pleasure of seeing Sir T. Lawrence's fine plant, which was exhibited at Kensington some five years ago, and excited so much admiration. No doubt the large numbers of this plant sent home were the result of the successful *début* of Sir T. Lawrence's plant. This Kew variety is quite as good as the best seen yet, the width of the sepals and petals, substance and depth of colour being specially marked in this plant.—B.

Orange-striped Cattleya Trianae.—A very remarkable variety of this Orchid, one that we have not hitherto seen, has been sent to us by Sir Alexander Ramsay, Cheltenham. Its peculiarity consists in the two lowermost sepals, which are pale mauve, having a thick bar of bright orange-yellow running down the middle of each, which gives the flower a distinct appearance. There is a good deal of orange in the throat of the labellum, and this, in combination with the rich magenta-purple of the other part of the lip, and its frilled edging, makes a most attractive flower. It is large, measuring just 6 inches across. Sir A. Ramsay certainly possesses a most curious variety, and one if it should become fixed will be sought after.

Phalænopsis grandiflora aurea.—Of this rare and beautiful variety Mr. Vicary sends a very fine flower from Mr. Peacock's collection at Sudbury House, Hammersmith. The flower is $3\frac{1}{2}$ inches across, the lateral petals very broad and more rounded than in the type, while the side wings of the labellum are almost entirely of a rich chrome yellow, which makes the flower so attractive in contrast with the snowy whiteness of the sepals and petals. We see in this variety that the peculiar slender appendages to the labellum are also bright yellow, a character we have not observed in any other *aurea*. With this comes a spike of a splendid variety of *P. amabilis*, remarkable for its large, broad-petalled blossoms, and some of the deepest tinted varieties of *P. Schilleriana* we have seen. Among the latter is one with flower just upon 3 inches across, which is large for the species. A specimen of the lovely *P. Stuartiana* is also sent; it is as lovely as it is uncommon. It has flowers nearly as large as an ordinary *P. Schilleriana*; the three upper sepals are white, while the labellum and half of the lower sepals are beautifully spotted with cinnamon-red on a yellow ground. Quite different to any of the foregoing is one called *P. Manni*, a somewhat inconspicuous species, with flowers about an inch across with a tiny white lip, and narrow sepals and petals barred with brown on a yellow ground.

Phalænopsids.—I send you flowers of a variety of *Phalænopsis grandiflora* which some would call *aurea* on account of the yellow markings of the labellum, but, in my opinion, it is not so good as the varieties of *P. amabilis*, a bloom of which I enclose from a batch imported last midsummer. The plants were then entirely without leaves, but now have made stout leaves, and I have no doubt when the plants get stronger the flowers will be even finer. Some of them now have borne flowers considerably over 3 inches across. The petals are broad and full, and the lower sepals beautifully spotted; the lip is also much larger than that of the best *P. grandiflora*. We

have some varieties entirely without a blotch on the lower part of the lip; the markings on the lateral lobes of the flower sent are also much brighter than in most of the varieties. The flower of *P. Schilleriana* is of the ordinary type; we have several varieties as regards size and colour, but this one is very fragrant. Can any of your readers tell me why this one should be scented and not another among a hundred. The *Cœlogyne flaccida*, of which I also enclose specimens, is just coming in to take the place of *C. cristata* now past its best.—A. F. GORDON. [The *P. amabilis* alluded to is not often seen so fine; it is identical with that sent us by Mr. Voss, mentioned lately. The variety of *P. grandiflora* is not so fine as the typical form named *aurea*, the yellow blotches on the labellum not being so large. The *Cœlogyne flaccida* is a pretty and elegant plant, particularly useful for cutting, as the drooping spikes fall gracefully over the sides of a vase.]

AMERICAN NOTES.

The Washington Cedar.—As is now tolerably well known, the Mammoth tree of California was at first supposed to be a new genus, and named *Washingtonia* by Dr. Kellogg. Lindley also supposed it to be distinct, and, either ignorant of or ignoring Kellogg, named the supposed new genus *Wellingtonia*. But neither of these determinations stood the test of botanical rules, and the plant was finally referred to a genus already established, namely, *Sequoia*. Dr. Kellogg now claims, at least, priority for his common name, Washington Cedar. He says, "As historic truth demands it, it is but just to state, I, myself, took Mr. Lobb to the California Academy of Sciences, and showed him the first specimens he ever saw of this marvellous, now world-renowned, Washington Cedar, which was so named by me before he ever saw the tree. The fact is well known to the old charter members of the Academy, several of whom are still living. It is, therefore, the earliest among common names, and claims precedence, by all courtesy, in point of time, as also in appropriateness of honour. Our relations to its earliest identification we leave to the historian of the future."

Fertilising Moss.—The agent of the Dumesnil Moss Company called on me in June, and I consented to test the claims of his "secret." Accordingly he sent me a package of the Moss which we gave a thorough comparative test with our mixture used for Moss mulching, which is composed of about fifteen parts of Moss to one part of pure bone dust. Also to make the trial more thorough, the same number of plants were potted in ordinary soil. We used 12 plants of *Lantana borbonica*; 12 *Colens*, one sort; 12 *Caladiums*, one sort; 12 *Pandanus*, one sort; and 12 *Crotons*, one sort. We washed the soil from the roots and potted in 5-inch pots four plants of each with the Dumesnil Moss, four of each with our Moss and bone mixture, and four of each with ordinary soil. The plants were placed together on one of our greenhouse benches and were given exactly the same treatment. No difference was apparent in any of the three lots from first to last and all grew well, but there was no superiority whatever in those grown in the French Moss over the others. I last month invited the New York agent of the Dumesnil Moss Company to examine them, which he did, and expressed himself as being unable to see any difference in the three lots. The matter can be easily tested by any one. Moss and bone-dust can be got almost anywhere, and if it proves to be as useful for the purpose claimed as this French Moss, whose fertilising principle is a secret, then it is difficult to understand where the value of the "secret" comes in.—P. HENDERSON.

Is the Kalmia poisonous?—I have been observing the controversy regarding the poisonous qualities of *Kalmia*. I confess I cannot understand why chemistry fails to show that it is a most deadly poison. My earliest recollections are coupled with the aid the boys of my native

village gave to the men who drove cattle and sheep across the mountains before the days of railroads. Our village was at the base of the mountain, which was three miles to its summit, and the pike lined on either side by dense thickets of *Kalmia*—the especial dread of sheep drovers. The boys of the village were employed by the drovers to assist in keeping the flocks on the pike until the summit of the mountain was reached. I doubt if a large flock was ever driven across it without the loss of several from eating *Kalmia*. I have seen them lie down to die before they could be driven from the thickets into the highway. My grandfather kept large flocks of sheep, and I can remember one occasion when a deep snow fell leaving nothing green but the *Kalmia*, and the flock could not be found until late the following day (being in a very large range). When we found them a very large portion were dead with the *Kalmia* leaves in their mouths. They were found in groups about *Kalmia* plants; in one case five died just where they ate. Within two years my partner in the fruit farm had a valuable heifer in company with a small flock of sheep in a range where he had directed the hired men to cut out all the *Kalmia*. In a few places the *Kalmia* had sprouted up, and after a fall of snow looked temptingly green. The heifer was found dead with portions of the *Kalmia* protruding from her mouth. I could multiply these instances. But it seems to me that direct experiment would convince the most sceptical. Anyone willing to sacrifice a sheep by allowing it to eat *Kalmia* leaves could have it demonstrated to his satisfaction that it is a poison, chemistry to the contrary notwithstanding. Sheep accustomed to the sight of it were never known to eat it except when the ground was covered with snow; but flocks driven by it from the western country would eat it if permitted.—Q. A. LOBINGIER, *Steubenville, Ohio*, in *Gardener's Monthly*.

Kerosene for posts.—Please [state if refined kerosene will preserve fence posts as well as crude petroleum. I can get kerosene here at 15 cents per gallon, but the crude petroleum is quoted at 20 cents. Why is this?—R. I. H. [Kerosene is not so good a preservative for wood as crude petroleum, as the latter contains matter which becomes concrete after entering the pores of the wood, while the kerosene is more liquid and would not remain so long. There is no reason why dealers should charge as much for petroleum as for kerosene, except from a disposition to overcharge on an irregular sale.]—*Rural New Yorker*.

Starting tree seeds.—In these days of timber culture it becomes important to decide how to treat seeds as well as seedlings. Only nurse them through the first two or three years, and but little care will be necessary in the future. Some tree seeds, as those of the Oak and Maple, grow too readily, and occasionally the little radicle or first root in these may often, during moist weather, be noticed peeping out of the seed before dropping from the parent tree. Then again such seeds as those of the Holly, Juniper, and Yew will generally lie dormant in the ground for two or even three years. The proper treatment for the first is to dry them very slightly before committing them to their winter quarters; and for the latter class, place them in damp sand as quickly as possible after removal from the tree. It is an excellent plan to wash off all the fleshy covering from pulpy seeds, as this acts more as a preservative than as an incentive to germination. A proper care of the tender seedlings justifies us in protecting them from the direct rays of the sun and from the trying effect of high winds. This may best be effected by making frames of common, cheap boards, so as to form beds, say about 6 feet wide and of any length necessary. These are covered with lath racks or "shelters," 4 feet by 6 feet in size, with ordinary plastering lath tacked across them, leaving three-quarters of an inch between. Here may be started all seeds of difficult germination, as well as the rare species that we desire especially to grow. Many kinds, depending greatly on the size of the seed, must be covered very slightly with sand; in fact, merely

hiding them from sight would be desirable. Others, again, of larger size require rather more soil over them, and those of larger dimensions, as the Walnuts, must be placed beneath the surface for 3 inches or 4 inches. An excellent rule to observe, however, is to cover too little rather than too much, as seeds during germination decay very easily. Sharp, gritty sand or light, sandy soil are about the best for covering seeds, although when peat or leaf-mould are readily procured they will be found very serviceable for the purpose. When the young seedlings are two years old they must be transplanted, or if very close in the beds they may be pricked out into other beds at one year old. Pinch off the tips of all long tap-roots and dip in thin mud before dibbling in their new homes. Again cover the lath shades, and mulch with Moss if very valuable. Should dry weather set in water thoroughly with a coarse rose or sprinkler, but towards autumn take off the racks to hasten the ripening process by means of the sun's rays.

Potato fibres.—Dr. Sturtevant made an examination of the depth to which the roots of the Potato run. A plant was selected which grew on a high ridge, the seed having been planted 6 inches deep. A trench was dug at the side to expose the soil, and the roots were washed with a stream of water turned against them, laying the fibres bare. One root was found to reach 34 inches below the top of the ridge, or 28 inches below the tubers. The deeper roots appeared most fibrous. Very few roots were found above the tubers. The soil did not allow the tracing of the finest roots. This experiment seems to indicate the importance of a deep soil for the Potato, an indication which repeated experiments fully corroborate, and in very dry seasons the crop on deeply trenched soils has been more than double that on ground ploughed at common depths, and both equally fertile.—*Prairie Farmer*.

PLANTS IN FLOWER.

CHRYSANTHEMUM NUIT D'AUTOMNE.—I send you the last of our Chrysanthemums. It is the variety *Nuit d'Automne*, a Japanese sort, with long narrow plum coloured petals. We have had Chrysanthemums in flower since the second week in August without a break. We then commenced with *Illustration*, *Mexico*, *Cassy*, and *Nanum*, and very useful we found them throughout the autumn months.—GEORGE KEMP, *Edgeley House Gardens, Stockport*.

VELTHEIMIA VIRIDIFOLIA.—Some unusually fine specimens of this old Cape of Good Hope plant reaches us from Mr. Field, Stanley Hall, Bridgenorth. The stout flower-stems are 15 inches high, and are terminated by a dense cluster of flowers, each about a couple of inches long, after the manner of the Flame Flower (*Tritoma Uvaria*). The colour of the flowers is a kind of glaucous pink, very attractive, and contrasting finely with the broad green foliage. It is a capital greenhouse plant of easy culture, and it possesses the advantage of continuing to bloom for months in succession.

RHODODENDRON EARLY GEM, one of the early flowering or *davuricum* class, is the finest we have seen. Like other varieties of this type, it is dwarf in growth and very floriferous. The blossoms, produced in dense massive trusses, are fully 2 inches across, and of a beautiful rosy lilac hue; the petals being wavy-edged, add to the attractiveness of the flower. As it is so dwarf and compact in growth, and, moreover, a very early bloomer, it is particularly adapted for pot culture, and a few plants interspersed with others in a conservatory have a pleasing effect. It is now beautifully in flower in Messrs. Veitch's nursery at Coombe Wood, where we believe it originated a few years ago.

A NEW WHITE VARIETY of *Cydonia japonica* now in full bloom in Messrs. Veitch's nursery at Coombe Wood, under the name of *nivalis*, is among the most chastely beautiful of early flowering shrubs. The flowers are identical with those of

the ordinary kind, but are as white as driven snow, and it retains its purity throughout the flowering season, thereby differing in an important degree from the common white variety of *Cydonia alba*, which changes to a pinkish colour by age. This variety *nivalis* is, like the original, a very free bloomer, and long shoots are perfect wreaths of white, so abundant are the blossoms. Beautiful as these snow-white flowers are on the bush, they seem to reveal additional beauty when cut and associated with a little greenery, and they last a considerable time in water and half-opened buds fully expand, though not such a pure white as those that expand in the open air. As a companion plant to the high coloured varieties of the favourite Japanese Quince the plant under notice is recommended. For wreath and other floral devices it is invaluable at this season.

CORBULARIA CITRINA.—A bunch of flowers of this charming Hoop Petticoat Daffodil has been sent to us by Messrs. Collins & Gabriel, who received them from the south of France. It is scarcely known in English gardens, yet it is so beautiful and so distinct from any other variety of *Corbularia* that it should be grown by every body. It is just like the ordinary Hoop Petticoat in size and form of flower, but the colour, instead of being bright yellow, is of a soft pale lemon hue. The rim of the crown, too, is cut off straight. Judging by the quantity of flowers which this firm has, it is not a rarity in the south of France, where it evidently grows to perfection. It of course is a variety of *Narcissus Bulbocodium*.

NARCISSUS MINOR.—After the Hoop Petticoat *Narcissus* this is the first to bloom. In Messrs. Barr & Son's unique collection at Tooting it may be seen in all its glory, not in little tufts, but in spacious beds with hundreds of little golden flowers nodding as if they had not strength to hold up their heads. It is very dwarf, never more than 4 inches or 5 inches high, but usually only 3 inches. The cup, which is the most conspicuous part, is a bright golden yellow. As it is so dwarf, so that, as Parkinson quaintly says, "its nose for the most part doth lie on or touch the ground," it is advisable to plant the bulbs beneath a surface of some trailing plant such as *Spergula*, thereby protecting the flowers from dirt. It is the "least Spanish yellow Bastard Daffodil" of Parkinson.

COLCHICUM CROCIFLORUM.—Flowers of this newly introduced species come from the New Plant and Bulb Company, Colchester. It is not a large nor very showy species, but very interesting, as it is so different from the other kinds. The outspread flowers are about 1 inch across, and the six segments are white within and stained with reddish purple on the outside. It flowers before the foliage appears, and its resemblance to some species of *Crocus* no doubt suggested its specific name. It is a native of Southern Persia. Another interesting new plant is also sent from Colchester; it is called *Bulbocodium persicum turkestanicum*. It has small white flowers produced with the half developed leaves. It is much like the true *Colchicum montanum*.

ANEMONE FULGENS.—A basketful of flowers of this brilliant Windflower comes to us from Messrs. Collins & Gabriel, Waterloo Road, to whom they were sent from the south of France. The sight of such a charming gathering indicates plainly that the climate of Southern France even in February is a most genial one for flowers, reminding us of April and May here, when this Windflower unfolds its brilliant blossoms in our open borders. Three forms are sent, the single, the semi-double, and one called *multipetala*, which has numerous narrow petals arranged in two or three rows; all are beautiful, and we hardly know which to admire most. The colour in all is of that refulgent crimson-scarlet such as one sees in no other flower in the open air.

ANDROMEDA JAPONICA.—Flowering so early in the year as this shrub does, it is particularly welcome, and its flowers combine a delicacy of colour with elegance of habit seen in no other *Andromeda*. In this country it usually is a dwarf bushy

shrub, furnished with leathery bright green foliage. The flowers, which remind one of those of Lily of the Valley in size and colour, are borne in a branchlet of cluster terminating the shoots, each branchlet of the cluster being a long one-sided spike, all the flowers being arranged on the under sides of the stalks. It is an uncommonly pretty shrub, quite worth growing in pots for conservatory adornment, though we never remember seeing it treated in that way. It is one of the most interesting hardy shrubs in full bloom in the Coombe Wood Nursery. Another species belonging to the same subgenus (*Pieris*) is also worthy of mention. It is *A. calyculata*, a North American shrub, with small bronzy foliage and leafy racemes of white blossoms.

ERICA CODONODES.—There is no hardy Heath so beautiful as this when well grown. It forms a small shrub from 2 feet to 4 feet high; the branches are slender and erect, and clothed with small foliage similar to that of *E. hyemalis*. At the present time each of these slender erect shoots is completely wreathed for about a foot in length with myriads of tiny bell-shaped blossoms. The unexpanded buds being of a deep rosy pink, and the open flowers pure white, there is a pretty contrast in colour such as we have seen in no other Heath, and each shoot being terminated by a few inches of green foliage, its effect is heightened. Such an extremely pretty shrub as this only needs to be seen to recommend itself for cultivation, and the fact that it is hardy adds greatly to its value. In the Coombe Wood Nursery it is now beautifully in bloom with other hardy kinds, among which the well-known *E. herbacea carnea* and *E. mediterranea alba* are the most noteworthy, and both admirable plants especially for the rock garden.

THE FIRST BOUQUET this season from Mr. Joseph Stevens' garden at Grasmere, Byfleet, contains many beautiful and interesting hardy flowers and shrubs. Some of the most noteworthy are *Forsythia suspensa*, a pretty Chinese shrub, whose long slender shoots are wreathed with bright yellow blossoms. It is an excellent plant for planting against a sunny wall, though perfectly hardy to stand in the shrubbery. No garden should be without it. Branches of *Berberis Darwini*, profusely laden with blossoms, is among the brightest in the bouquet, but it is too well-known to need describing, and the same remark applies to the old *Cydonia japonica*, *Andromeda floribunda*, and *Veronica imperialis*, a deep magenta variety of *speciosa*, which Mr. Stevens assures us has been in flower throughout the winter. A sweet-scented Honeysuckle, *Lonicera Standishi*, is worthy of note; and among herbaceous plants are *Doronicum cordifolium*, a bright yellow, Daisy-like flower; *Hepaticas*, double red and single blue, both charming; and the true *Helleborus orientalis*, which has large cup-shaped flowers, the sepals of which are greenish white.

FREESIA LEICHTLINI MAJOR.—Of this charming Cape bulbous plant Mr. Smith sends from his Caledonia Nursery, Guernsey, some wonderfully fine flowering specimens. The flower-spikes measure 15 inches high, and are branched at intervals of 3 inches or 4 inches. The main stem carries a one-sided spike, consisting of from nine to twelve blossoms, all looking sideways. The side branches are also terminated by flower clusters scarcely less numerous than those of the main one. The tubular flowers are some 2 inches long, pale yellow, with a conspicuous blotch of orange on the lower petal. Not the least noteworthy point is the delicious perfume emitted by the blossoms, a combination apparently of that of Primroses and Violets, but much more powerful than either; indeed, the scent of one spike alone diffuses itself throughout a good-sized room. In these remarkable specimens we have an additional proof of the skill with which bulbous plants are treated in Mr. Smith's nursery, and they show well what good culture, combined with a genial climate, may do for *Freesias*, which, singularly enough, seem to be very little known as yet. As regards the variety Mr. Smith sends, there is no doubt that it is decidedly a major form of *F. Leichtlini*, larger in every respect than the type.

CAMELLIA C. M. HOVEY.—This new variety fully sustains the high opinion which its American raisers had formed of it before it crossed the Atlantic. It is now pronounced by competent authorities to be without exception the finest *Camellia* of its colour in cultivation—in short, the very ideal of perfection; such were our thoughts on seeing a specimen of it about 8 feet high the other day in the *Camellia* house at the Royal Exotic Nursery, Chelsea, where, though surrounded by every variety of note in cultivation, it has no peer, whether we take into consideration its size, growth, floriferousness, or the size, form, and colour of the flowers. The bush in question was carrying a score or so of blooms, some of which measured 5 inches across. The flowers are perfectly circular; the petals, though not large, lap over each other in a beautiful way, and the centre, often the weak point, is not coarse in any stage. The colour is a sort of crimson-lake, with a peculiar and indescribable brightness about it which makes it so much admired, particularly when seen on the plant associated with the broad, lively green foliage. Mr. Hovey, of Boston, the raiser of this variety, might well be proud of having sent to Europe one of the finest *Camellias* as well as having stolen a march upon Italian raisers.

QUESTIONS.

Flower beds.—Will any of your readers kindly furnish me with the names and arrangement of any really pretty flower beds in any of the London parks last summer?—H. M.

Striking Japanese Privet and *Garrya elliptica*.—May I ask the help of your correspondents as to how best to strike the broad-leaved Japanese Privet and *Garrya elliptica*?—R. H.

Blinds in plant house.—Can any reader of THE GARDEN advise me as to the best blinds for a house 60 feet long facing the south? Should they be inside or outside, and on rollers?—SUB.

Edging tiles.—Can any reader give me any practical suggestion as to the best kind of edging tiles for a kitchen garden? I require about 600 yards, and wish to combine economy with efficiency. I thought of having Staffordshire blue tiles with a plain rolled top, as being least liable to be broken by a wheelbarrow passing over them. Where can these be procured to the best advantage?—E. L. M.

Onion and Carrot grubs.—Will some of your readers be good enough to tell me how to cure grubs in Carrots? They attack not only the main crop, but even the bed of Horn Carrots, which we sow in August to use now, when not much larger than Radishes. The soil is light, and formerly we piqued ourselves on Carrots and Onions; the latter are also now much injured by a different grub in early summer. Soot and salt we have tried, but fear to overdo salt in these cold wet seasons.—R. H.

Lilies.—I should be greatly obliged if some of THE GARDEN readers who know anything of *Lilium concolor* *Parthenion* would tell me if it is distinct from the variety *Cordion*; and if so, in what way and what kind of soil does it require for its best development. I am led to make these inquiries from the fact that I have received two Lilies under this name, which are not only unlike each other, but are also quite unlike the *L. concolor* *Parthenion* or Japanese Lady's Lily, as it is sometimes called, and which is said to bear only white and yellow coloured flowers.—H. H.

Stove shelving.—I have built a greenhouse which can be brought up to almost any heat, and as I think of converting it into a stove, will some of the readers of THE GARDEN kindly tell me what is the best sort of shelf for stove plants—wooden spars, slate, stone, or what? It is heated with hot-water pipes. What flowers easy of culture would be suitable for a stove? I have only one other conservatory; therefore require flowers in bloom all the year round. If the shelves are of wood, stone, or slate, must the pipes be high or low near to the ground?—EUCHARIS.

* * Our readers will greatly oblige by replying, so far as their knowledge and observation permit, to these questions. The title of each query answered should be prefixed to each answer, and replies will be printed in the department of the paper under which the subject falls. The questions that arise and must be solved are so many in these days, that it is only by a general interchange of ideas and experiences among practical men that we can hope to answer them satisfactorily.

GARDEN DESTROYERS.

APHIDES IN ADVANCE OF THEIR FOOD.

It is bad enough to have these or other pests pounce upon and devour the flowers or tender leaves of Peach, Cherry, Plum, or other fruit trees or plants as soon as they are partially developed, but it is worse to find them prowling about in wait for them while they are yet in a state of rest. Such trying phenomena are more common than usual this spring, alike indoors and out. These early flights of aphides are also harder skinned and more difficult to destroy than those fed on more tender and succulent food; this is rather singular, considering that it is by no means obvious what they live upon. They are mostly found clinging closely to the bark in close proximity to the buds, but they do not seem to eat the latter, at least to any extent. Still, I do not quite believe these pests live on nectar, and it is not safe to leave even unopened fruit buds at their mercy; hence one or more heavy smokings should at once be given where the plague of aphides are found on fruit trees early in the season under glass. In the open air tobacco water or a dusting of damaged snuff are among the surest remedies. But prevention is far better than cure, and the best mode of preventing the appearance of these early aphides is to clean the trees in the early autumn and dress them with some sort of smear. Its character and composition are of far less moment than its quantity. Its beneficial action is chiefly mechanical, though a little tobacco juice, snap, soot, lime, nux vomica, or Gishurst adds to the adhesive and penetrative properties and killing or preventive power. The latter quality is of great importance, for aphides, like most other insects, seem to have rather sensitive organs of smell and taste, and hence arises the usefulness of nauseous compounds and the efficiency of tar as an ingredient in any plant smear. Notwithstanding, however, the high authorities that have recommended tar in Vine smears, I have seen so many cases of injury from its use as a preventive to hares and rabbits, that I still hesitate to use it. Neither has anyone, so far as I am aware, recommended tar as a smear for stone fruit; the flower buds of these being so prominent and so early developed, would be more easily injured than the skins of the buds of berries. The bark is also of quite a different character and far more susceptible of injury from strong and pungent smears. These facts also point to the prudence and importance of applying such dressings in the autumn or early in the winter, though not a few cultivators smear their Peaches and Plums on the walls in February or even March. Of course this ensures that such smears shall be stronger as well as thicker than those applied in or before winter. But on the whole the earlier after the fall of the leaf these anti-aphide smears are applied the better. The buds being dormant are less susceptible of injury, and this part washed off will serve a useful purpose in clearing the trees of Mosses and Lichens, and probably will find its way into nooks, cranies, or crevices, where insect larvæ or eggs have been deposited.

D. T. FISH.

Slugs.—I find nothing better to get rid of slugs than hemispherical traps made of the peel of an Orange (often recommended in your columns), especially at this time of the year when the ground is little occupied. By placing these near newly-planted small subjects the slugs will go to them in preference to the plants. They should be examined each morning, or oftener, and the slugs destroyed; large numbers will thus be caught. One day last spring I found twenty-eight under one trap, and six more close by. This morning (February 28) I found twenty-three under one trap. Water made milky with a little Fir tree oil is an excellent mixture to put them in. The same mixture will last for some time.—A.

Ants.—Some few years since, being much troubled with ants, I tried chloride of lime as a cure and found it perfectly effectual, and am now

of the opinion that sixpennyworth of this article is quite sufficient to drive away all the ants from a very large establishment, or at least from such parts of it as they may be at all troublesome in. A pinch or so taken between the finger and thumb and rubbed into the wall round about and near to the cracks from which they emerged, or dusted about their runs, was sufficient for each colony. As much as will lie on a shilling or a two-shilling piece at the utmost is enough for a large colony. Their entire disappearance will follow a few hours after the application. This is so simple and easy a remedy, and does not seem to be generally known, that I think it may be a valuable one to many of your readers.—J. E. EWING.

RAINFALL IN 1882.

It may be of interest to see a comparative statement of rainfall in two places—one (Belvedere House) in the centre of Ireland, near Mullingar, the other in one of the midland counties of England, Belvoir Castle, near Grantham; both are furnished by competent and intelligent men, but the curious result is that while at Belvedere, which is on the limestone plain, near a large lake, the rainfall is 42.46, that at Belvoir is 35.73, and in the former the days are 189 against 226 at Belvoir Castle, so that there were more rainy days in Leicestershire than in Westmeath.

BRINSLEY MARLAY.

Rose insects (*E. S. S.*).—Your Roses are attacked by a species of frog fly, an insect very nearly allied to the common frog-hopper or cuckoo spit insect. Take the plants out-of-doors and shake them well, and then syringe them with soft soap and water or tobacco juice; in the course of a few hours wash the plants clean. A cloth might be thrown over the plants before they are moved, so as to prevent the insects flying about the house. They disfigure the leaves by sucking their juices from them.—G. S. S.

Rosa berberifolia.—I think Mr. Wm. Paul must possess this Rose, because I sent him seed of it just two years ago. I had received it from Teheran, Persia, where it grows on sandy hills. I

have sown some of it, but I lost the plants last year. It is very delicate. I also sent some seed of it to Mr. Ellacombe, who, I hope, will have been more successful with it than I have been. If your correspondent cannot obtain *R. berberifolia*, I would recommend him to procure *R. Hardyi*, which is a seedling of *R. berberifolia*, a cross from *R. clynoophylla*, raised by Mr. Hardy about fifty years ago. Although delicate, it is much more robust than its parents, and must be in the possession of English rosarians. If not, it can be procured in Lyons.—JEAN SISLEY, *Monplaisir, Lyons*.

—“K.” will find this in Messrs. Paul & Son's catalogue. I had it from them two years ago, and it grows and flowers freely in the open border.—J. R. DROOP, *Stamford Hill*.

RECENT PLANT PORTRAITS.

THE January number of Regel's *Gartenflora* contains coloured portraits of the following plants:—

Aphelandra pumila var. splendens.—A fine dwarf-growing species, with handsome velvety foliage resembling that of one of the Gesneras, and brilliant orange-scarlet flowers borne on a short stout stem.

Delphinium cashmerianum (Royle).—A handsome large purple-flowered hardy perennial Larkspur, which possesses the great merit that slugs will not touch it, whereas they usually particularly affect this ornamental family of hardy border plants.

The second number of the *Révue Horticole* for February contains a coloured plate of hybrid varieties of Hellebore in several shades, from pure white to rosy purple.

The February number of the *Illustration Horticole* contains coloured portraits of the following plants:—

Dendrobium bigibbum (Plate 476).—A beautiful Orchid said to be one of the most ornamental of its family, and bearing a spray of large rosy purple flowers; a native of Torres Straits.

Aralia gemma (Plate 477).—A charmingly graceful and most distinct foliaged stove shrub, introduced from New Caledonia, in 1875, by Mr. Linden's collectors, Messrs. Pancher and de Maerschalk; said to be admirably adapted for table decoration, and a welcome addition to collections of elegant stove shrubs.

Cypripedium Lawrenceanum (Plate 478).—A fine plate of this very handsome Lady's Slipper, which was sent to Messrs. Veitch, from Borneo, by Mr. F. W. Burbidge, and flowered at Chelsea for the first time in December, 1878.

W. E. G.

Tuberocées (p. 179).—In the fourth line from the bottom instead of “as dry as possible,” read “as dwarf as possible.”—W. C. T.

Tussilago fragrans.—During a lovely walk to-day (Feb. 25) I came across two grand plots of this fragrant weed. One was just on the borders of Hanbury Churchyard, Worcestershire, and another on a roadside bank between Hanbury and Stoke. In both cases this plant was quite at home and growing vigorously.—H. M.

Mistletoe Oaks.—Allow me to add one to the list of Mistletoe-bearing Oaks. I discovered it about twenty years ago on the estate of Mr. P. W. Godsal, Iscody Park, Flintshire. The tree was a young one, and the parasite had a stem about as thick as my little finger. I have not seen it since.—J. OFFLOW (hall keeper), *Mechanics' Hall, Nottingham*.

Names of plants.—*R. Sp. ncer.*—Both Orchids you send are *Dendrobium Wardianum*; No. 2 is the finest variety of it we have seen.—J. Mitchell.—*Dendrobium barbatulum.*—J. B.—*Odontoglossum odoratum.*—W. B.—*Calogyne flaccida.*

"This is an Art

Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

CAMELLIAS AT WALTHAM CROSS.

The display of Camellias just now in perfection in Mr. William Paul's nursery at Waltham Cross is a striking proof that the Japan Rose—the scentless Rose of spring—receives as much attention as the fragrant Roses of summer, for which this nursery is so justly celebrated. The Camellia collection here is indeed a grand one, richer in varieties and finer in every respect than any we have hitherto seen. It represents no fewer than 220 sorts, omitting unnamed seedlings and others, a number which may be fairly said to represent the Camellia in every important variation from the typical variety to the beautiful new sorts raised during the past few years. Such a full collection as this is not only an imposing sight, but one of considerable interest, inasmuch as it shows what strides have been made with regard to the improvement of this flower. Here side by side, and in direct contrast, are the representatives of the very earliest varieties imported over half a century ago and those of the present day. When we compare the flower of the typical *Camellia japonica* with one of our new varieties, the zealous labours of our florists become manifest. In Mr. Paul's collection one may single out almost the identical type figured by Curtis in the *Botanical Magazine* as far back as 1790,—one of the earliest figures of it. It was then no stranger to botanists, but was known chiefly by Thunberg's "*Flora Japonica*," where it is described as "growing everywhere in the groves and gardens of Japan, where it becomes a prodigiously large and tall tree, highly esteemed by the natives for the elegance of its large and very variable blossoms and its evergreen leaves. It is found there with single and double flowers, which also are white, red, and purple, produced from April to October." Thus it may be seen that the Camellia even in its natural state is a most variable plant, and this variability has been taken advantage of by florists, and a long work of seedling raising and intelligent selection of the finest has brought the flower to the high state of perfection at which it has arrived. Advantage, too, has been taken of the plant's liability to sport, and by fixing these sports most of the best varieties have been secured.

The greatest help the Camellia improvers have had has been that received from the Japanese and Chinese gardeners, who have doubtless cultivated the Camellia from time immemorial. A large number of their garden varieties were introduced to Europe about the end of the last or the beginning of the present century, and it is a remarkable fact that these include even now the very cream of our finest varieties. Among those imported at that early date were *alba plena*, the old white *fimbriata*, the fringed white *anemonæflora* (the Waratah Camellia), *myrtifolia*, *atrorubens*, *Sabiniana*, *Parksi*, *imbricata*, *pæoniæflora*, and *incarnata*, or Lady Hume's Blush. These are only a few of the Chino-Japanese varieties, but they have been the most useful in forming a basis for the hosts of beautiful varieties now to be found in gardens. The greater number of these old varieties may be seen in flower side by side in the Waltham Nursery, thereby add-

ing much interest to the collection as a whole. Probably the greatest worker in the improvement of the Camellia was Mr. Chandler, whose nursery (still in the memory of many) in the Vauxhall Road was almost exclusively devoted to this popular flower, and whence many a beautiful variety was sent out. Since then the Camellia has been steadily improving, though not so much in this country as in sunny Italy, where the climate is peculiarly suitable to the Camellia, and where seed saving and seedling rearing may be carried out advantageously; hence the greater part of our finest varieties have been christened with Italian, not always euphonious, names. From America has emanated some good sorts, but all previous varieties have been surpassed by the two or three that have within the past few years come from Mr. Hovey, of Boston. This Waltham collection represents all these; indeed it has for years been the aim of Mr. Paul to collect from every available source any variety of Camellia of importance, so that those interested in them may be able to judge for themselves of the merits of any particular variety, and there can be no better plan to further this object than to collect the whole series under one roof.

The culture and propagation of this vast collection take up an extensive amount of house room; the bulk of the specimen plants is housed in two capacious span-roofed houses 120 feet long by about 30 feet in width. As it is important not to have the entire collection in flower at one time, the plants in one of these houses are induced to flower some weeks in advance, thereby extending the Camellia season over a long period. The later crop of bloom is just now in full beauty, and a magnificent sight it is, there being thousands of flowers in all stages of development and representing every conceivable shade of colour from the purest white to the deepest crimsons. The majority of the flowering plants are huge specimens exclusively in tubs or pots, so as to be readily moved at any season. The plants form two solid masses corresponding to the angles of the roof of the house, which runs north and south, in order the more equally to distribute the light. Though no Camellias are planted out here, nothing could well surpass their luxuriant growth. This is a good proof that planting out in free soil is not an essential condition of Camellia culture. However, there is no doubt but that greater care and attention are necessary in pot culture than when the plants are in borders. It is interesting to observe how a few particular varieties predominate in the stock plants. For example, scarcely too many plants can be grown of the old Double White, which is always in demand, and about a score of others are almost as popular. The propagation is chiefly carried on by grafting, and for stocks the old single red is used.

The routine of culture practised at this nursery is as follows: As soon as the flowering season is past, which is about the end of March, the Camellia houses are kept closed and artificial heat applied, in order to obtain a temperature of about 65° by day and 55° by night. The plants are freely watered to encourage vigorous growth, and are thoroughly syringed with a garden engine every morning. After about six weeks, in genial weather the air from the outside is gradually admitted, at first during the day only, and afterwards at night also. This ensures the hardening of the wood and the formation of flower-buds. At about

the end of June the plants are all taken out of doors and placed in a shady position under a hedge with a north aspect, where the process of ripening the growth is perfected. The plants are returned to the houses early in the month of October, and are kept entirely without artificial heat until the commencement of frosty weather, when just sufficient warmth is given to prevent the frost from spoiling the flower-buds. The plants are then allowed to flower naturally, no forcing being resorted to. A few flowers are produced in November, and the number continues to increase till March, when the plants are at their best flowering state, some of the largest specimens being then literally loaded with blossoms. When the flowering season is at its height, air is given to the plants from the top inside ventilators throughout the day, and if the weather is mild, at night also. This tends to preserve the freshness of the flowers considerably.

A selection of varieties from such a full collection as this is no easy task, but as a list of a score or so may be useful, it may be as well to name some of the most prominent in flower at the present time. Some of the old varieties with single or semi-double flowers make grand bushes and are highly effective, as most of them are high coloured and extremely floriferous, but unsuitable for cutting as the flowers lack that refined symmetry so much admired in a first-class Camellia. To this class belong such well-known varieties as *Donckelaari*, *Chandleri*, *corallina*, *elegans*, *picturata*, *tricolor*, *punctata*, *reticulata*, and *conspicua*, most of which have been in gardens for at least half a century. In selecting from what may be termed the florist's class, it is convenient to range them according to the predominant colours. Among

Whites there is no peer to *alba plena*, or the old Double White, as it is oftener called. It is too well known to need describing; it may be easily recognised by its large flat flowers, with snow-white petals neatly lapping over each other. Some, perhaps, would like the fringed white (*fimbriata*) quite as well, for there is a peculiar charm about the fringed petals seen in no other Camellia. Mr. Paul considers *Ninfa Egeria* to be one of the best whites he has. It is a vigorous grower and has large and beautifully formed flowers with closely imbricating flat petals of snowy whiteness. *Alba elegantissima* is also a good white, as is also *Casoretti's White*, and both may be classed as first rate. Other whites of note are *Innocenza*, with large and regular flowers; *Princess Charlotte*, which sometimes comes striped with pink; and *Targioni*, also inclined to a suffusion of pink. *Montironi* and a form of it called *vera* is also a good sort.

Peach or pale pink colours are somewhat scarce. The finest are *Marchioness of Exeter*, one of the best; *Principessa Aldobrandini*, *Mdme. de Strelaloff*, and *M. d'Offoy*, all with large and well-formed flowers produced plentifully. For bouquets and cutting, one called *Principessa Rospigliosi* is an admirable sort, the flowers being small, but of good shape and abundantly produced. The finest of this colour in flower in the whole collection was *Contessa de Hainaut*, with large and beautifully shaped flowers and closely imbricated petals. A plant of this covered with bloom was quite a floral sight in itself.

Reds and crimsons are plentiful, and it is difficult to select the best of the old kinds. *Mathotiana*, *Eximea*, *Imbricata*, *Manara*, *Cœquet*,

tina are among the finest, and other admirable sorts in these colours are C. M. Hovey and C. H. Hovey, the two new American kinds alluded to in THE GARDEN last week; Comte Botourlin, large and fine; Henri Favre, an extremely richly-coloured variety, first-rate in every respect; Mme. Lebois, one of the best of its colour; and Leeana superba, an old, but admirable sort.

Striped and edged varieties are also abundant; among the best are l'Avenir, one of the finest Camellias grown; Auguste Delfosse, Archiduc Carlo, Lucrezia Gazzarrini, Passimiana, Teutonia, l'Insubria, Leopoldo Benucci, all of which are pink or red, banded with white. Of the pink and rose are Eugène Massina, and Vicomte de Nieuport. The finest of those flaked with red or pink on a white ground are Lavinia Maggi, very fine, Bonomiana, Jubilee, Adelina Benvenuti, Princess Clothilde, and Adamo.

Blush-tinted varieties are very lovely; one of the best is Cup of Beauty, which is inclined to more white than others. Lady Hume's Blush is well known.

These form but a fraction of the entire collection, and probably some worthy sorts have been omitted not being in flower at the time these notes were taken, but by far the best way is for everyone to see for themselves such an imposing exhibition of this popular spring flower as Mr. Paul has now on view.

W. G.

NOTES OF THE WEEK.

PROTECTION OF OPEN SPACES.—A committee has been formed to protect the common lands and open spaces in the parishes of Mitcham, Beddington, Wallington, and neighbourhood. A guarantee fund is being raised for the protection from building on Mitcham Common at Beddington Corner. The committee does not propose to limit its labours to the defence of the land at Beddington Corner, but intends, if sufficient support is forthcoming, to get the whole of the common, some 500 acres in extent, placed under proper management, so that it should no longer be spoiled by being turned into a gravel pit. This common has suffered from time to time from encroachments, which show how desirable it is that some new Act should be passed restraining lords of manors from selling parcels of common or waste lands.

EARLINESS OF SPRING FLOWERS.—The following list of the dates at which some of the earliest spring flowers have bloomed may, perhaps, interest some of your readers. The plants are all grown on heavy clay soil in the north of England exposed to fogs, smoke, and north-east winds.

	Flowered.

—M. P. F.

A GROUP OF PERNETTYAS in Mr. G. F. Wilson's gardens at Wisley is about the prettiest sight we have seen in the way of hardy shrubs for a long time. The group forms a large oval mass several square yards in extent, and is composed of about a dozen distinct named varieties of *P. mucronata*, differing from each other in the colour of the berries with which each shrub is abundantly furnished. In all the berries are of the size of large Peas, and hang in massive clusters all along the erect branches. In some the colour is a deep crimson, and there is well-nigh every

intermediate shade between that and pure white. The varieties thus intermixed make a most attractive group such as is rarely seen, and the dark shining green foliage shows the colours off finely. This group is planted in full exposure on the hillside. The soil used is an admixture of peat with the natural soil of the hill, and with some of the black vegetable mould from the adjoining wood garden. Treated thus, the plants seem to luxuriate, and will in future form a fine feature to the place. On seeing such a group as this it occurred to us that the *Pernettya* must be very imperfectly known, or one would oftener meet with it. There is assuredly no finer winter shrub, and it is attractive from autumn throughout winter till spring, for the berries if untouched will remain intact. Mr. Wilson has besides the group in his Wisley garden a similar one in his wood garden at Weybridge, but, singularly enough, the plants have been stripped of their berries, presumably by pheasants or other birds. This teaches us not to plant the *Pernettya* where its chief attraction may be spoilt; on the other hand, it may prove to be a good covert shrub.

SUPPLEMENTARY CARNATION SHOW.—Mr. Dodwell, now located at Oxford, inaugurated a supplementary exhibition of Carnations and Picotees in that city last year, and a very successful one it was. It is therefore intended to hold a similar exhibition on July 31 this year in the Royal Nurseries, Slough. In 1849 a large exhibition of Carnations and Picotees was held in Mr. Turner's nursery. Mr. Dodwell, in a note to me, says that he took part in that exhibition, and that it was the finest display of this flower that he had up to that time seen. The date is a suitable one for north and south to meet together, and it is to be hoped that this exhibition, supplemented as it would be with Mr. Turner's collection, will surpass any that has been hitherto held. Mr. Dodwell, Stanley Road, Oxford, is collecting prize money, and will be grateful for any help which he may receive from lovers of these flowers.—J. DOUGLAS.

NEW PARK AT BEDFORD.—The corporation of Bedford, having recently decided to appropriate sixty-one acres of land adjoining the cemetery for the purpose of forming a public park, offered a prize of twenty-five guineas for the best set of plans for laying out the same. The Park Committee met on Friday last and unanimously decided to adopt the plans of Messrs. Barron & Son, of Elvaston Nurseries, Borrowash. The site is admirably adapted for a public park, the ground sloping gradually to the south. The prize plans provide for a piece of ornamental water in the south-east or lower portion of the park, about three acres in extent. Large open spaces are devoted to cricket, football, and parade grounds. The two main entrances are at either end of a new road 100 feet in width, which the corporation propose to construct along the southern boundary of the park. A refreshment pavilion, surrounded by a flower garden, occupies a conspicuous central position, leading from which is an avenue of Lime trees, terminated by a fountain. Tennis lawn, bowling green, an archery ground, and a gymnasium are provided; also designs for an entrance lodge, band stand, and rustic shelter.

EDINBURGH ROYAL BOTANIC GARDEN.—Mr. Robert Lindsay has been appointed curator of this garden, a post for which he is well qualified. The world-wide fame of the Edinburgh Medical School necessitates a well-appointed botanic garden and class rooms; and while the latter are now almost all that could be desired, the former, under a succession of able curators, has long been maintained in a high state of excellence. If the appointment which has just been made, we confidently anticipate that this satisfactory condition of things as regards the Botanic Garden will not only continue, but that with advancing science and the adoption of better methods of cultivation progress towards greater perfection will be made. Mr. Lindsay has had all the advantages of a thoroughly practical training, having been connected with the Edinburgh Royal Botanic Garden from boyhood, now nearly a quarter of a

century, with the exception of a short period spent in the Botanic Garden, Chelsea. For a number of years he was at the head of the propagating department, under the late Mr. McNab, by whom he was held in the highest estimation. Mr. Lindsay's skill in this important branch of work is well known, numerous interesting and successful experiments in hybridisation, propagation by root cuttings, &c., having been performed by him. On the appointment of the late Mr. Sadler to the curatorship, Mr. Lindsay continued to act as principal foreman, with credit to himself and benefit to the garden. His wide knowledge of plants and his thorough mastery of their culture, the result of close study and long application, joined to a love of his profession, all combine to prove the wisdom of the present choice.

ORCHIDS.

Cattleya Gaskelliana.—We saw the first blooms of this new *Cattleya* at Stevens' Rooms on Thursday last, they having been sent by Messrs. Backhouse, of York. It is a splendid variety, with flowers as large as those of *C. gigas*, being 7 inches across, with wide petals of a soft lilac-mauve tint, and the lip is broad and shallow, frilled at the edge, and of a rich magenta-crimson. It is stated to be a variety of *C. labiata*.

Orchids in bloom.—Among a host of Orchids in flower at Mr. William Bull's nursery, Chelsea, are the following rare kinds: *Cirrhopetalum picturatum*, *Cymbidium Devonianum*, *Cœlogyne cristata*, Chatsworth variety, a plant between 2 feet and 3 feet over, producing a magnificent effect; *C. cristata alba*, pure white; *Odontoglossum cristatellum*, *O. facetum*, *O. crispum-roseum*, *O. blandum*, *Phalæncopsis Stuartiana nobilis*, *Masdevallia Estradæ delicata*, *M. xanthina*, and *M. militaris*.

Pilumna fragrans.—Amongst Orchids now in flower few are better worth a word of praise than the fragrant *Pilumna*; it combines an elegance of growth with chaste purity of bloom, and a powerful, yet delightful, perfume which can be likened unto no common scent. It is an ever-green species, having long narrow leaves produced in a dense tuft, from the base of which the flowers spring. These are borne on spikes about 6 inches or 9 inches long, carrying four, five, and six blossoms, which are snow-white save an orange spot in the throat of the ample labellum. We have rarely met with this Orchid better grown than in Mr. Southgate's garden at Selborne, Streatham, where it is evidently a great favourite; numerous fine specimens are grown in an intermediate house. These plants are now in full beauty, bearing numerous spikes of bloom, the odour from which pervades the entire house. It is a plant of tolerably easy culture, and one that can be cheaply bought.

Varieties of Cœlogyne cristata.—There are now three distinct varieties of this popular Orchid besides the common typical form, and we had an opportunity of seeing all in flower the other day at Messrs. Veitch's nursery, Chelsea. These varieties are *alba*, with pure white flowers borne as profusely as in the ordinary form. The spotless white blossoms of this are lovely, very few flowers being so entirely without a trace of colour. It is as yet very rare, even tiny plants of it commanding high prices. A second form is *Lemoniana*. This is at once recognised by the hairy crest of the labellum, being of a pale primrose-yellow instead of orange-yellow. This likeness is a lovely variety, the colour of the crest being so delicate in contrast with the snowy whiteness of the petals, and it is a singular fact that by artificial light this pale yellow is scarcely visible, so that the flowers may take the place of really pure white blossoms. A third form is called the Chatsworth variety; it is remarkable for the flowers being much larger than ordinary, the sepals, petals, and lips broader, and in producing more flowers on a raceme, often as many as nine or ten. The variety *Lemoniana* takes its name from Sir Charles Lemon; not from the lemon tint on the lip, as some suppose.

ANGRÆCUM SESQUIPEDALE.

THROUGHOUT the numerous tribes of orchidaceous plants now to be found in gardens few are so interesting as this *Angræcum*, a native of the hot jungles of Madagascar. When introduced some years ago by the Rev. W. Ellis, a missionary in that island, it was considered to be a wonderful production, nothing in its way having hitherto been seen. It remained for years a rarity, only to be met with in the richest plant collections. Now, however, it is comparatively common, and its large, grotesque-looking creamy white flowers may be seen in most Orchid houses during the early part of the year. Its culture, too, is better understood than formerly. It succeeds best in a hot, moist atmosphere such as that maintained in what is termed the East Indian Orchid house, and

ance. Some plants, too, flower when only about 6 inches or 9 inches high, while in others the flowers

cut was sent us by Mr. Kemp, Dunlop, Ayrshire, who had a plant about a month ago bearing fourteen flowers on three spikes, an unusual number, and the fact shows that Mr. Kemp thoroughly understands the requirements of this Orchid.

CATTLEYA PERCIVALIANA.

THERE is in this discussion something a little deeper than "individual opinion" on a new *Cattleya* which, poor as some of us think it to be when

compared with the true old autumn flowering *C. labiata*, might well have been introduced on its own merits. Especially is this so if Mr. Crawshay's individual opinion be justly true, and this *Cattleya* is really "handsomer than the old *labiata*," as Mr. Crawshay states it to be (p. 211). As to Professor Reichenbach's description to which he alludes, I simply pass that over for what it is worth. The plain fact is that the Orchid-buying public are not quite so fond of "descriptions" as they used to be a year or two ago. Indeed, some of us think that there has been a little too much of "description," and lately a great deal too much of—well, of something else. Take, for

Flower-spike of *Angræcum sesquipedale* (half natural size).

ing found mostly on trees in its native habitat, it does not like to be hampered with much solid potting material about the roots. A very light soil, consisting of lumps of turfy peat and live Sphagnum Moss, is the best compost in which to pot it. It particularly objects to be overpotted; indeed, the pots used for it should be small compared with the size of the plant. It requires abundance of watering when in active growth, but should be kept drier in winter. When well grown a large specimen of this Orchid is very handsome, even when not in bloom, for it has deep green leaves about a foot long, prettily arranged one above the other in two rows on either side of the stem. It is a slow-growing plant, taking years to form a good specimen, that is, one about 2 feet in height. A well grown plant is usually furnished from the base to the top with healthy foliage, but in some cases the bottom leaves decay despite the efforts of the cultivator, rendering the plant what gardeners term "leggy." This defect may, however, be remedied. The stem may be cut through just beneath the foliage, and the top placed in the soil, in which it will strike root, but it is always best to have a few live roots attached if possible to the top portion thus cut off. There are two recognised varieties of this *Angræcum*, one having larger flowers than the other, produced later in the season and in greater abund-

are only produced when the plant has attained a foot or 15 inches high. The subject for our wood- example, those modest little sketches shown in auction rooms of new Lilies, Irises, Orchids,

and other plants. If Mr. Crawshay has *C. Percivaliana* in flower he can get a fair and unbiased opinion of it from the floral committee at South Kensington. Perhaps the plant has been certificated there already; if not, it is a great pity its light has been hidden so long. Mr. Crawshay firmly and decidedly asserts that the plant in question is handsomer than the old *labiata*, but of this we desire proofs. We have heard the same statement made elsewhere, but I, for one, did not give it credence.

The flower of *C. Percivaliana* referred to in *THE GARDEN* (February 24, p. 171) as being the finest as regards colour which had been seen was sent to me, and I at once made from it and other living material a carefully coloured drawing, and I took particular pains to make it faithful in all ways, and all who saw the drawing and flower in direct comparison agreed that it was so. This drawing I sent to *THE GARDEN* office for inspection, so that Mr. Crawshay will perceive I am as anxious to be just and unbiased in this matter as he is himself. After all, the plant must stand or fall on its own merits, and yet it is interesting to know what professional and practical men think of it. Here is the advertised account of *Cattleya labiata Percivaliana* (Rehb. fil.) from the *Gardeners' Chronicle*, January 23, pp. 102–105 (1882). In years to come, even if not just now, this advertisement will have a niche or corner in Orchidæic history: "*Cattleya labiata Percivaliana*, true autumn-flowering *labiata* . . . a wonderful importation of this magnificent *Cattleya*. It is well known there are numerous varieties among the old *Cattleya labiata*, such as *Pecatorei*, *picta*, &c., and the varied bulbs show that many varieties are among the lots offered. It is true autumn-flowering. Flowers will be on view of this, the finest Brazilian *Cattleya*; sepals and petals broad, deep rose or light purple; lip broad, large, splendidly fringed with deep velvety purple; in some varieties quite one half of the lip is dark, throat golden yellow. We have never previously imported a *Cattleya* so floriferous; there is hardly a bulb which has not flowered, and whose spike does not show three and four flower sheaths. Mr. Seidl, the lucky discoverer, states that one mass alone had 380 flowers fully expanded when collected, and many others had faded. This piece had to be cut into four to facilitate its transport to the far distant coast. We are extremely pleased at being able to offer it to the public, having looked for it without success for many years. The green and red-leaved varieties are among the importation, which is altogether in simply superb condition. The whole will be given into Mr. Stevens' hands, and will comprise all that could be found, and none sold privately; but Mr. Sander earnestly invites prior inspection."

After the plant had bloomed we find the following advertisement of it in *THE GARDEN*, p. 2, February 3, 1883: "The first flowers* of this grand *Cattleya* opened in the middle of December last, and there is no doubt that the established plants will flower in November and December this year, and a little later than the old *labiata* flowers; it is, however, a far grander species—the superb coloured lip and its freer habit making it such. If the time of flowering, its exceeding floriferousness, fine and free habit, and the fact that among *C. Percivaliana* is never found what may be termed a bad variety are taken into consideration, we think that we do not say too much in stating that it is the finest Orchid we have had the pleasure to introduce. Petals larger and far rounder than in any other *labiata*, and often of that magnificent plum colour so rare in *Cattleyas*; its lip is grand, and it is hardly possible to describe it."

In the *Gardeners' Chronicle* of March 3, 1883, p. 288, the editor states in reply to "F. S. & Co.": "Its claims to be a variety even are open to doubt, for it seems from the specimens we have seen to have more variety than constancy about it."

Here is another advertisement from the gardening journals of January 6, 1883, respecting which I make no comment: "*Cattleya labiata*,

extraordinary double-sheathed form. . . On Thursday next, Jan. 11, at half-past twelve precisely, a grand importation of *Cattleya labiata*, nearly the whole with double sheaths, and found in a district where no previous traveller collected; the plants are in most superb health and found in flower; the latter will be on view, and are exceptionally beautiful. They have every mark of the old *labiata*, of which the double sheath also reminds. This, together with the time of flowering and the long leaves, remind us stronger of the true old form than any *labiata* we have ever imported before." Messrs. Veitch & Sons in their plant catalogue for 1882, p. 21, offer *Cattleya labiata Percivaliana* from a guinea each, and remark that "although at present thought to be so near the true *C. labiata*, we are inclined to think it will eventually prove quite distinct from that species." In *THE GARDEN*, March 3, 1883, Mr. T. Baines, having seen a good many plants, all save one being "extremely poor," considers it a "third rate" novelty. These are a few unbiased opinions on both sides of the question, and Orchid amateurs and others interested must draw their own conclusions respecting it.—F. W. B.

—I must confess that I was greatly disappointed with the flower of this *Cattleya* sent to Mr. Burbidge from London. It was a poor wretched, crumpled-up thing. The lip is good in colour, but so small as to be scarcely worth calling a lip. As to its being a form of *Mossia*, I must differ from other correspondents; the flower before me shows close relationship with *C. Trianae* or *C. labiata pallida*, and if a natural hybrid, I should say that *C. Dowiana* was the pollen parent. To compare it with the old autumn flowering *C. labiata* is like comparing a counterfeit sovereign with good gold. Under cultivation *C. Percivaliana* may improve, and if it had been allowed to stand on its merits no one would have had cause to be dissatisfied.—T. BEDFORD, *Stratton, Kildare*.

COCOA-NUT HUSKS FOR ORCHID GROWING.

I FEAR Dr. Paterson will not succeed with growing Orchids in this material. On one occasion, a good many years ago, I had a quantity of imported *Cattleyas* and *Laelias* that arrived in excellent condition. Early in the spring, as soon as they began to grow, I attached them to pieces of these husks, on which they did well so long as the season's growth continued, and through the winter whilst dry and at rest. Before they began to move in spring I placed the whole of them in pots just as they were attached to the pieces of husks, but as soon as they were again freely supplied with water, the whole mass of fibry matter became white with mould in which the roots refused to move at all, and I had no recourse but to take them off and fasten them to pieces of wood for the season. I do not like this material in any shape for growing any plant in, much less allowing it to come in contact with the roots of valuable things such as Orchids. There is no difficulty in getting good peat in the south of England that does well for Orchids, for which I may say there is no need to be quite so particular as many growers suppose; if it contains plenty of fibre, even if this does not consist of the roots of Ferns, which alone satisfies some cultivators, it will answer just as well, as I have found by trying it. Peat and Sphagnum are the only materials that I ever found free from a disposition to mould when water is given after it has undergone the drying process consequent on withholding water whilst the plants were at rest. I once thought I had met with a commodity that could not fail to answer—the fibrous roots of a *Tillandsia* that had been used for packing some plants from Brazil. Nothing could have looked more likely to suit the purpose. I put a few plants in it mixed with crocks in the usual way, but in a few weeks after they began to move and receive water the whole of the material was quickly a mass of mould, out of which I was at once obliged to move them. T. BAINES.

Cattleya Trianae at Cleveland.—Cleveland at Southport, the residence of Mr. R. P.

Percival, is so gay at present with glorious flowers of this *Cattleya*, that the sight will not easily be forgotten by those who have seen them. No fewer than 300 flowers were to be seen there last week, their great variety and grandeur producing a brilliant display. The varieties having been selected with judgment, are, with few exceptions, excellent; and if it be taken into consideration that these *Cattleyas*, already good sized specimens, have been purchased as imported plants during the last two years only, some conception may be formed as to the skill with which Orchids are cultivated here. All the plants of *Cattleya Trianae* are abundantly rooted, have plump, strong bulbs, and leathery, healthy, dark green leaves. It is difficult to pick out of a collection such as this the best variety, but one struck me as being particularly beautiful. It is a plant marked 94 with very short thick bulbs and broad leaves; it had 18 flowers on it fully expanded, and individually large; petals broad, wavy, of fine texture, and of a lovely rose colour; sepals rather lighter in shade, broad, and possessing the rare merit of being flat to the very tip, the upper half not turning back, as the sepals in so many examples of *Trianae* do; lip broad, open, flat, and heavily fringed, the edge and exterior of the throat being of a uniform rose colour; the lip itself is velvety maroon-crimson, a colour which advances well towards the throat, and terminates in a deep yellow slightly lined rose at both sides.—VISITOR.

FERNS.

ASPLENIUMS.

(Continued from p. 186.)

A. caudatum.—This gracefully pendulous species from the East Indies is very well adapted for large hanging baskets. It is a good and easily grown plant, producing from a succulent and slightly creeping rhizome its elegant pinnate fronds from 2 feet to 4 feet in length and about 8 inches in breadth; the pinnae, long and comparatively narrow, are attenuated towards their extremities. The whole plant is of a beautiful dark, glossy green, and its beauty is also enhanced by the very conspicuous sori, making, too, lines parallel to and close to the mid-rib. The fronds being of a coriaceous texture possess the advantage of remaining a long time on the plant. This is one of the few species which prefer a mixture of peat and sand only without any loam whatever. Stove.

A. cicutarium.—A very handsome Fern from Tropical America, whose numerous feathery fronds are produced from an upright, short stem. They grow to about 15 inches or 18 inches long, are very finely cut, of a delicate green colour and of a nearly erect habit; they are lanceolate in shape, tripinnate, with the pinnules very small. Stove.

A. Colensoi.—This very pretty and highly decorative species from New Zealand has long been grown under the erroneous appellation of *A. Hookerianum*, also a New Zealander, but to which it does not bear the slightest resemblance. This is much more in the way of the well-known *A. bulbiferum*, but more compact, and of a much smaller growth in all its parts. The fronds are produced from a thick fleshy rhizome in great quantities. They are of a bright green colour, and studded all over with young plants, which render them very effective; they very seldom reach more than 10 inches in length. Greenhouse.

A. contiguum fissum.—A variety of comparatively recent importation from the South Sea Islands. It is a distinct-looking and very interesting addition to the list of cultivated Ferns of evergreen habit from these islands; it has ovate, smooth fronds of leathery texture; the pinnae, few in numbers, are distinctly placed and stalked, with two basal segments and an elongated, attenuated, distantly toothed apex, the teeth of which are simple, or sometimes forked. The basal lobes or pinnules are wedge-shaped and unequally toothed at their extremity. Stove.

* The first plant of *C. Percivaliana* bloomed in Messrs. Shuttleworth & Carler's nursery, at Clapham, in June (17th) 1882 (vide *GARDEN*, Vol. XXI., p. 419).

A. dimorphum (biforme, diversifolium).—These significant synonyms under which this very fine Norfolk Island Fern is found in cultivation are all three very applicable names for a species, whose barren and fertile fronds, or portions of fronds, are so entirely different. The gracefully arching fronds of this noble-growing kind are produced in great abundance from a fleshy creeping rhizome, which keeps on the surface of the ground. They are of a shining bright green colour, and often reach 24 inches to 30 inches in height. The barren ones are bipinnate, with broad and somewhat toothed pinnae, whereas the fertile ones are very finely divided and tripinnate. It is not unusual to find that part of the same frond will be barren while other portions are fertile. As an evergreen decorative plant very few Ferns indeed can rival it for elegance and strength of constitution combined. It is also very prolific and of easy propagation. Greenhouse.

A. ebenneum.—A charming small-growing species from North America. Its fronds, which are pinnate and lanceolate, are produced from a slightly underground creeping rhizome. They are provided with a beautifully shining black stem, and generally reach 8 inches or 10 inches in height. The pinnules, of a dull green, are slightly dented, and set far apart. The general appearance of the plant is that of an erect-growing form of our own common *Asplenium Trichomanes*. Greenhouse.

A. elegantulum (obtusilobum).—This pretty dwarf trailing species from the Fiji Islands is an excellent plant for Fern cases, and also for baskets of small dimensions, as each frond is proliferous at its extremity where it roots freely, and makes a dense, compact mass, rarely exceeding 6 inches high. The fronds, which are elegantly cut, are produced in profusion; they are pinnate, and from 3 inches to 6 inches long, with pinnae deeply cut and wedge-shaped. The whole plant is of a bright dark green colour. Greenhouse.

A. Fabianum (foeniculaceum).—A fine ornamental species from Australia with fronds produced from a thick fleshy rhizome; they grow from 18 inches to 24 inches in length, and are of a dark, shining green colour, besides being gracefully arched, as every pinna becomes beautifully pendulous from the weight of the mass of young plants borne upon it. It is a plant admirably adapted for table decoration, for vases, &c., as very good sized plants can be grown in comparatively small pots, and as it is perfectly evergreen. This species, although growing very well in the mixture recommended for *Aspleniums* in general, thrives more luxuriantly in peat and sand alone, in which soil it will be found to produce fronds of larger dimensions, and especially of a much brighter green. Greenhouse.

A. Fernandezianum.—This very pretty little species, native of Juan Fernandez Island, is exceedingly useful wherever decorative plants of small dimensions are required as also for planting in a Fern case for the room, as it is not at all particular as to the temperature to which it is subjected. Its pretty pinnate fronds of a deep sea-green colour are produced in great abundance from a short upright stem; they rarely reach more than 8 inches in length and are proliferous at their extremity. The pinnae, closely set, sometimes overlapping, are incised at the margins and frequently, especially when the plant is in a very vigorous condition, are also lobed at their base. Stove.

A. ferulaceum.—A beautiful species from New Guinea, and one possessing very little of the general appearance of an *Asplenium*. The fronds, which are of a very light and pleasing colour, are very minutely divided, and resemble much more those of the rare and beautiful *Gymnogramma Pearcei*, or those of the well-known *Pteris scaberula*, than any of the other *Aspleniums*. They spring from the crown of a short stem, making a miniature little Tree Fern; they are broadly triangular, spreading, arched, or curved, and ovate acuminate in outline, the pinnae much divided and finely cut; the pinnules are linear, slightly flattened, and very delicate and fine in texture.

It dislikes loam and grows more luxuriantly in peat and sand, and enjoys its stem being kept constantly moist. Indeed, to grow this beautiful plant in perfection a close, moist place is required in the stove.

A. flabellifolium.—This extremely pretty, slender-growing New Holland species is wrongly put aside by many amateurs, its merits being generally underrated by most Fern growers. Yet it is well adapted for growing in baskets of small dimensions, where the peculiarly filled or fringed appearance of its slender fronds shows the plant off to perfection. It is also very useful for covering the ground of small Fern cases, as it makes fronds from 12 inches to 18 inches long, proliferous at their extremity, where they root very freely when in contact with the soil. They are pinnate, the pinnae fan-shaped, dented all round with reddish brown sori on the underside and of a bright green above. Indeed, it is so very distinct from anything else that no collection should be without it. Greenhouse.

A. flaccidum.—A popular Tasmanian evergreen species, and one of the best appreciated of all cool basket Ferns, for which it is well suited on account of its long pendulous fronds being produced in great abundance, and often reaching 18 inches long. They are bipinnate, with narrow pinnae, leathery, and of a rich deep green colour. Greenhouse.

A. fœcundum (compressum).—This very robust growing Fern, native of St. Helena, is an evergreen species with thick, fleshy, pinnate fronds, from 18 inches to 24 inches high, rising from an erect, scaly rhizome. It has a very peculiar appearance, inasmuch as the pinnae, which are large and flat, of a light green, have their upper surface studded all over with young plants. Greenhouse.

A. formosum.—This elegant tropical American species soon becomes a favourite with whoever comes in contact with it, yet it is not very commonly found in cultivation. Its beautiful fronds are produced in great numbers from an upright stem; they are of a delightful green and grow from 12 inches to 15 inches long; they are pinnate, with pinnae deeply cut and opposite, borne on slender, wiry, shining black stalks. It is a very pretty evergreen, bearing always a mass of fronds curving outwardly in a very elegant manner. This species does not like loam, but it is greatly benefited by a little crock dust being added to the mixture of peat and sand. PELLÆA.

GARDEN IN THE HOUSE.

SCREW PINES FOR INDOOR DECORATION.

The Pandanads, or Screw Pines, furnish us with excellent subjects for indoor decorative purposes. Though they thrive best in our stoves, yet they can be successfully grown in a temperature that does not often fall below 55°. When grown thus, in what might be termed a cool stove, they need less water at the roots, and likewise overhead, than when in a higher temperature. We have found them to damp off in the heart if this precaution is not taken. The Screw Pines are a class of plants that will be found to put up with a good deal of rough usage. The foliage retains its healthy character exceedingly well, not being so liable to turn brown and decay at the points, as that of some Palms, for instance. Once, however, a fair stock of the most approved varieties is obtained, it matters but little if an occasional plant is sacrificed by being kept in a disadvantageous position too long. Young plants are easily raised from offsets or suckers, and such losses are therefore easily repaired. All the Screw Pines usually grown are graceful in habit and elegant in outline, making, when in a small state, excellent subjects for the dinner table. Later on, when too large for this purpose, they will be found useful for large vases and various receptacles in other rooms, in entrance halls and corridors; in any position, in fact, where not too much exposed to violent draughts of cold air. All the stock set aside for decorative uses should have their pots well filled with roots, and as large heads of foliage as

can be had in comparatively small pots. It is astonishing to what a size *Pandanus Veitchii*, for instance, can be grown in a 4½-inch or 6-inch pot. These plants when thoroughly pot-bound will be found more hardy and durable than when such is not the case. If used frequently after a recent shift the young rootlets are apt to suffer and the plant thereby weakened.

The best kind is *Veitchii*, without doubt the finest of the genus. To obtain this in its best condition for table decoration, propagation should be proceeded with whilst the suckers are very small, about 3 inches in length being quite sufficient. In the case of a tolerably large plant these can be found pushing forth from among the roots just above the soil. These take longer to establish themselves than larger material, but when this has been secured they are preferable to larger growths, inasmuch as they develop foliage of a more graceful, drooping character, and the variegation is brighter and better, and to such an extent is this so that when in a small state a plant thus grown might easily be mistaken for one of another variety. *Pandanus javanicus variegatus* is a pretty kind, but not equal to *P. Veitchii*. It will not be found to be so compact in habit as that kind. The spines also with which it is furnished on the underside of the mid-rib (in an opposite direction to those on each edge of the leaf) render it a difficult subject to deal with when syringing is resorted to. *P. graminifolius* we find to be a most serviceable kind. It is not grown so much as it deserves to be, making as it does a very pleasing change as a dinner table plant. Being slender and delicate in growth, pairs of this kind can be advantageously used. We find this species to be about the hardiest of any. *P. Vandermeerschii* is very distinct and handsome; its foliage somewhat narrower than that of *P. Veitchii*; the spines with which it is armed are an ornament to the plant, being dark crimson. It is a useful variety, quite different from any of the aforementioned. *P. ornatus* is pretty when small, but it quickly grows out of bounds if not starved at the root. *P. elegantissimus* is preferable to *P. utilis*, being less robust. Unless there is an abundance of accommodation, neither of these two last named kinds will be found of great service. We find the Screw Pines to thrive in a compost of good peat and fibrous loam, with plenty of silver sand; frequent potting is, however, quite unnecessary. When an abundance of water can be applied, never allow the plants to become dry at the root.

Gunnersbury House.

JAMES HUDSON.

RECENT PLANT PORTRAITS.

THE March number of the *Botanical Magazine* contains portraits of the following plants:—

Caraguata musaica (Plate 6675).—A fine Bromeliad from New Grenada, with brilliant red and yellow flowers, and remarkably veined and marbled foliage, which bloomed for the first time in Mr. Bull's nursery in 1875, and has been already figured in the *Belgique Horticole* by M. Morren under the name of *Massangea*, by Mr. Moore in the *Florist* under the name of *Tillandsia*, by M. Dallier in his "Plantes à feuillage ornementale" under the name of *Vriesia*, and by Dr. Regel in his *Gartenflora* under the name of *Bilbergia*, so it has plenty of names.

Eucharis Sanderi (Plate 6676).—A beautiful new variety of this lovely family, intermediate in size of bloom between the well-known *E. amazonica* and the more recently introduced *E. candida*. It was introduced by Messrs. Sander, of St. Albans, after whom it is named, and flowered at Kew for the first time in November, 1882.

Thunbergia Kirki (Plate 6677).—A small slender growing stove shrub with pretty tubular violet flowers, sent by Sir John Kirk to the Royal Gardens, Kew, from Mombasa, near Zanzibar, and bloomed for the first time in September, 1882.

Fraxinus Mariesi (Plate 6678).—Native of North China. A small tree which is likely to become a favourite in our parks and shrubberies from its profusion of white flowers, which are

more conspicuous and ornamental than those of the Manna Ash (*Fraxinus Ornus*) of Southern Europe, to which it is nearly allied. Seeds of this new flowering Ash were sent to Messrs. Veitch by their collector, Mr. Maries, from the province of Kiu-Kiang, and it bloomed for the first time in their Coombe Wood Nursery in May last.

Comparettia macroplectron (Plate 6679).—Native of New Grenada. A rather dull-coloured Orchid, with spikes of pendulous pale rose-coloured flowers, said, however, to be the handsomest of its family.

Saxifraga cortusifolia (Plate 6680).—Native of Japan, a dull, white-flowered Saxifrage nearly allied to the old Strawberry Saxifrage (Plate 92 of this work), and also to *S. Fortunei* (Plate 5377, figured from specimens sent by Messrs. Veitch, who raised it from seed sent to them by Mr. Maries). The *Revue de l'Horticulture Belge* for March contains a coloured plate of

Two new varieties of Ageratum likely to be useful for bedding, as their colours seem to be distinct, and their habit, especially the blue one, sufficiently compact and dwarf. They bear the names of *Perle Bleue* and *Perle Blanche*, and are now being sent out by M. G. Bruant, of Poitiers, Vienne, France. These novelties, which I hope to be able to prove by comparison with others during the coming summer, seem to be a decided improvement on anything yet introduced in this way.

W. E. G.

NOTES.

Willow catkins or palm.—Will some kind reader be so good as to inform me of the best kinds of Willow to grow for catkins or palm or "pussies," as they are popularly called? Is it the weeping Kilmarnock Willow, which is bearing buds like burnished silver—at a distance they look like pearls—in a corner of my garden just now. The soft, downy yellow "pussies" of *Salix lanata* were much admired here last season. They reminded me of little chicks fresh from the shell; someone said they were like "baby canaries," so soft and golden were they just as they emerged from the hard brown sheath which envelops them in their early stages. I am so pleased with these two kinds, that I wish to know if there are others equally good or better in cultivation. Alder catkins are, as a friend writes to me, quite as beautiful as are those of Willows.

The winter Heath.—Standing in the early spring sunshine before a spreading mass of *Erica carnea*, I cannot help wondering that it is so seldom seen in even the best of gardens, public as well as private. There is a white variety, but I prefer the pink one with its dark brown cluster of anthers thrust outside its little flask-shaped bells. It lasts long in a cut state; its sprigs and slender sprays of rosy pink flowers are useful for bouquets, and it is as hardy as a bit of the granite rock beside which it nestles. Perhaps this is one reason of its having gone through the "middle ages" of neglect.

The mountain Saxifrage, both carmine, purple, and white, are now lovely draping water-worn boulders and sandstone alike with its delicate tracery of tiny green sprays and star-like flowers. From mountains in Britain or Ireland it goes pretty nigh the North Pole—need we say of such a pretty little arctic explorer that it is quite hardy.

Among the Crocuses—golden, purple, and white—on a sunny border, there are here and there glints of a vivid scarlet Poppy-like blossom swaying and fluttering in the brisk spring breeze. It is the scarlet Pyrenean *Anemone fulgens*, than which few spring flowers are more showy or more welcome. What has become of Mr. John Poë's splendid *Anemone* from the Lemon terraces above Mentone?—the one with vivid scarlet petals and an amber ring around its black centre. Where are now the late Mr. Nelson's very fine seedlings with velvety scarlet blossoms 6 inches in

diameter, and petals (forgive me, oh botanist!) over 1 inch in breadth? "Measured, or guess work?" I hear someone say. Yes, actually and truthfully measured. Oh! for a day in the Vine fields of Pau, where this gorgeous beauty is "at home to all visitors."

The common purple Crocus (I mean our native one, which now, or perhaps a little later, will throw a hazy mist of lilac over the fresh green meadows at Nottingham) is of all the best for naturalising on lawns and sunny nooks in gardens, or even in grass fields near to the house, or in churchyards, or anywhere where a glint of spring beauty is desired. At Nottingham, I remember, it grows very deep down in the clay; it is submerged for weeks, months sometimes in winter. It is most beautiful and abundant in spring, albeit that its leaves are mown off with the grass in the most matter-of-fact way. Verily do they "bloom to-day, and to-morrow are cast into the oven."

Prickly Ivy.—A lady wishes to know to what particular Ivy this name is applied, and asks what kind of leaf it produces. The accompanying

Spray of Smilax aspera.

woodcut will show it better than any description in words. The species is *Smilax aspera*, of which both leaves and stems are prickly. Some kinds are nearly smooth, but the tendency to asperity is indicated in most of them. I did not allude to the economic interest of some South American species, because I thought the fact of *Sarsaparilla* being their produce was generally known. When raised from berries we are informed that the seedlings vary much in size of leaf, as well as in general habit, and in the silvery markings characteristic of this species, and one or two other kinds.

The Holly-leaved Hellebore (*H. argutifolius*) is now putting forth its large and shapely pea-green flowers; when cut and arranged in fresh wet Moss with *Anemone fulgens* or crimson *Rhododendron* flowers, it is a great treat, its colour being, perhaps, well-nigh unique amongst flowers. It is a strong growing perennial easily raised from seeds, and makes a pretty foliaged plant the first year, and flowers quite freely the second and third, and so ad infinitum. As one of the most distinct and effective of the evergreen Lenten Roses, it well merits good culture. Speaking of the

Hellebores, now is the time to hybridise the late flowering kinds, or to fertilise them in order to obtain plenty of their shining black seeds.

From seed they grow freely, and generally bloom the second year. Mr. Frank Miles, I think, told us to sow in a box or pan as soon as ripe in early summer, and to cover with a slate or tile, which preserves equable moisture, keeps away slugs and birds, and—quite stops the growth of adventurous weeds, ever eager to poke their noses up among one's pet seedlings.

Rough stone edgings to beds, borders, and garden walks are in many ways preferable and much cheaper than Box, and the wonder is that they are not more generally employed. Such edgings, well made, last for years, and when planted with Sedums, Saxifrages, *Sempervivums*, and other dwarf rock or alpine plants are as interesting as they are beautiful. Box is ever a nidus for slugs and snails; it costs sixpence a yard to purchase and something more in labour to plant it and keep it in good order. A cart-load of granite from the quarry here costs us three shillings; a load makes thirty yards of edging, and two men will lay a hundred yards of it per day. We must perforce purchase our stones, but in many places they cost nothing, and so this edging becomes still cheaper. A stone edging made three years ago, and planted with different mossy Saxifrages, is now much admired. Such edgings are especially suitable for positions where Box will not grow, as under trees and tall fences.

The Daffodils are now coming into bloom. *N. maximus* opened its first flower on the 24th, *N. minor* on the same day, and the pretty *Tenby Daffodil*, *N. obvallaris*, is opening to-day (26th ult.). *N. eystettensis* is also opening its buds, and a variety of *N. Tazetta* is likewise in full bloom on an open border. This variety is floribundus, the same having come to us from St. Michael's Mount, Penzance, in Cornwall, where it is abundantly naturalised. In pots in a cold greenhouse, the best are *N. bicolor Horsfieldii* and the true *N. Tazetta* var. *Bazelman major*, perhaps best described as "the best of the *Tazetta* race."

Nuttallia cerasiformis is an old white blossomed shrub now rarely seen. On a wall it has just produced its fragrant white clusters of flowers among the soft green leaves. Why is it not more generally grown? Does it ever fruit in Britain?

Pleione humilis var. tricolor is a perfect little gem amongst rare Orchids now in flower. Why is it so rarely seen? It seems to be the one most amenable to cool-house culture of all the varieties of Indian Crocus, and so perhaps a high temperature has caused an exodus of it from our collections. It has the smooth dark purplish green shining bulbs of *P. humilis*, and bears pale, rosy lilac flowers 3 inches to 4 inches in diameter, the segments glistening like frosted silver in the sunshine. The lip is widely expanded at the mouth, and deeply fringed around its trumpet-shaped mouth. It is suffused with warm chome-yellow, and profusely blotched with brown or brownish red in front, these blotches and the lines of the crest vanishing into dots, which become smaller and smaller as they approach the base of the column. The idea of perspective distance thus given is very pleasing—indeed, one observer, remarking the perspective himself, said the lines of the crest reminded him of the straight lines of a railway as seen under a bridge, the bridge being represented by the column and over-arching sides of the lip. It is a dainty little beauty, well worth more general culture.

The Pau Anemone (*A. fulgens*) is now in full blaze of beauty, but how comes it that we so seldom see the glowing, broad-sepalled form from the Grecian shores? "Ah!" said a lover of all hardy flowers, and of *Anemones* in particular, "if we only could get hold of a few ounces of the cottony seeds of *Anemone fulgens*, and of the long awned ones of *A. alpina* and *A. sulphurea*, we should soon get a stock of these in our gardens."

The two latter and *A. Pulsatilla* more especially are difficult of increase by division, and it does seem a pity in one way that the seed should be blowing about so plentifully on the Pyrenees and so little of it procurable either for love or money here at home. Where are now all the varieties of *A. Pulsatilla* of which we used to read accounts years ago. White, violet, purple, ruby-purple, and lilac were only a few of the colours named as belonging to seedling forms of this sun worshipper among Anemones. At Biarritz, where the sulphur *Corbularia citrina*, *Anemone fulgens*, and other beautiful plants grow, I am told "the summer sunshine is almost tropical, followed by drenching dews at night," conditions under which most bulbs and tuberous-rooted plants flourish.

The best Snowdrops.—For hardihood and floriferous vigour none are better than the typi-

Flowers of *Galanthus Imperati*.

cal *Galanthus nivalis*, as grown by the acre in the lowlands of Lincolnshire. In stature and size of individual flowers, however, the type is exceeded by three or four other kinds, no matter whether species or varieties. Here with us *G. Imperati* is the largest and best; then comes *G. Elwesi*, good forms of it being very fine, but some imported roots of this plant which I obtained from Erfurt (misnamed *G. Imperati*) are very poor and weedy, albeit they have the characteristic blotch at the base of the inner segments. Our engraving represents accurately a fair average flower and bud of *G. Imperati*. It is curious to note that here the slugs are very fond of *G. Elwesi*, while they leave *G. Imperati* entirely unmolested. I never saw *G. Elwesi* finer than in Barr's grounds at Tooting soon after its introduction, the bulbs being part of Mr. Elwes' own importation. *G. nivalis* var. *Melvillei* is a giant form of the type, the flowers large, having widely expanded segments, and the whole blossom dangles from the scape at the end of a long flaccid pedicel in quite a peculiar way. The above and *G. plicatus* are the best five Snowdrops in cultivation, and my estimate of them is in the order named from an all-round point of view.

Cultivators and botanists are both divided in opinion as to whether the above are specifically distinct or merely varieties of one widely distributed and divergent kind. Be they

species or varieties, however, they are readily divided into two sets or sections by their leaves. Thus *G. Imperati*, the great Neapolitan Snowdrop, is so like *G. plicatus*, the Crimean, in port and leafage, that I look on them as simply geographical forms. *G. Melvillei* is avowedly a seedling raised at Dunrobin Castle from the common *G. nivalis*. *G. Elwesi* has also narrow leaves, and may be to the typical *G. nivalis* what *G. Imperati* is to *G. plicatus*, but the deep green blotch on its inner perianth segments is a most characteristic and sure distinguishing mark. *G. Redoutei* (= *G. latifolius*) is also distinct, and the early and late forms of the type, although not showy, serve to extend the Snowdrop season in our gardens.

Snowdrops are rarely too abundant in even the best of gardens. For cutting, they and Violets are especially welcome. They should be planted in all sorts of positions in sun and shade, on borders and on grass, and in the shelter of Holly bushes, in places where the dead leaves may blow around them, as in this way their season is much prolonged.

Daphne Blagayana, from the woods on the Austrian Alps, is now in flower—dwarf, sweet, white, and pretty for rockwork, or the front of a sheltered shrubbery border.

Ferula communis is now springing from the mossy turf beneath our Pine trees, as fresh and as finely cut and as tender in its greenery as any Todea or Filmy Fern whatever. (I hope Dr. Cooper Forster and Mr. Neill Fraser may not happen to see these notes.) We have yet much to learn as regards all branches of the garden art; but as to gardening on the grass, we are yet only in the most rudimentary state; scarcely through our A B C, in fact.

Chionodoxa Lucillæ and the pretty white-flowered Rush Lily form a pretty contrast just now; so do also *Narcissus minor* and the Siberian *Scilla* on a carpet of common green mossy Saxifrage.

Scarlet-berried Aucubas are now at their best. In pots in cold houses they are especially bright and attractive, being quite distinct from aught else in their way. Small bushes in pots are very useful for indoor decoration, or for contrast with early flowering bulbous plants.

Forsythia suspensa.—A lady writes to say that this plant in blossom always reminds her of "a swarm of golden bees." It is now most lovely, and the paler blossomed *F. viridissima* now bears it company. I rather like the idea of the "golden bees." It is truthful and also suggestive.

Saxifraga Burseriana is most lovely; also another, and as I sometimes fancy a more vigorous and satisfactory species, *S. coriophylla*, which bears its white blossoms from a little spire or rosette of deep green leaves. It grows like a weed here; whereas its allies *S. juniperina* and *S. Burseriana* are always rarities with us.

Anemone coronaria of various kinds from seed, scarcely two alike, are now very pretty in the early sunshine. For cutting both half-opened buds and the finely-cut leaves are highly valued.

Dentaria digitata and its white variety are now very pretty in sheltered sunny nooks, along with Hepaticas and Hose-in-Hose Primroses, Galagiskins, Jackanapes-on-horseback, and other quaint old varieties so common in our grandmothers' days.

Cocoa-nut husks for Orchids.—I am very pleased to see that Dr. Paterson intends to try this material, and no doubt there are many others besides myself who would like to know where the entire husks may be purchased. Mr. Burbidge tells me that in the gardens of the

eastern colonists and Government officials Phalænopsis and other Orchids are commonly grown in these husks suspended as baskets from the verandahs, or fixed in the branches of Orange trees, or in those creeper-laden tabernacles of wood which so often do duty for glass houses in the Tropics. Mr. Burbidge says that he had *Cypripedium Lawrencianum* growing in this material—simply rough coir fibre—for some months, as they were tied up in bundles, leaves outwards, for transport, and that they rooted into it with evident satisfaction. Mixed with clean Sphagnum Moss, or with charcoal, or with crocks, according as the rooting medium it affords is desired to be wet, moist, or moderately dry, I feel very sanguine of its proving a success for many things, and especially for *Cypripedes*, *Vandas*, *Aerides*, *Odontoglossums*, and *Masdevallias*; and yet, when I remember Dr. Paterson's splendid plants and their superlative vigour, I can only wonder if improvement is possible with him in his culture.

Alnus cordata and its allies *A. macrophylla* and *A. rubro-nervia* yield beautiful male catkins at this season, long tails drooping gracefully and laden with that golden dust of life-giving power we call pollen. The last named has dark brown catkins, *A. cordata* has pale green or golden ones, both long and graceful for decorative purposes, such as fringing an Etruscan tazza, or for dangling gracefully from the rim of a bit of old Venetian glass. These Alder catkins come in at a time when those soft grey tassels of the male *Garrya* fade (where may female plants of *Garrya* be obtained?); and in a vase with silvery or golden Willow buds, *Clematis cirrhosa* blossoms, or a spray or two of the rosy magenta flowered *Rubus spectabilis* they are all most ornate and lovely indoors.

White Rush Lily.—No more dainty spring blossom opens its eyes to the sunny days of March than this little beauty, which now reminds one of St. Bruno's Lily, as it blossoms beside *Narcissus minor* and *Chionodoxa Lucillæ*. It is a real gem among spring blossoms.

Hardy Primulas as annuals.—Primulas and Polyanthus of Clapham's strain, a mere pinch from a generous friend, are now flowering

Seedling Polyanthus

quite freely in sheltered nooks and corners. Some few individuals are very pretty rich violet or

plum-purple selfs, or rich crimson-maroon with gold specks around the margin of the corolla, as in the variety known as Rockery Gem. Some of the fancy Polyanthus varieties are most lovely in the spring sunshine, and, as I think, these seedling plants, albeit not as yet a year old, are far more vigorous and free flowering than are divided plants or old-established clumps with us, and then their variety is infinite. Mr. Wolley Dod long ago told us that *P. capitata* especially and some other species never did well unless treated as biennials by raising batches from seed, and I am convinced that we shall never enjoy the full beauty and variety of which our own native Primrose and Oxlip or Polyanthus is capable unless we save seed by carefully crossing good varieties and treat them as annuals. So treated, the large sulphur white and orange race of Oxlips may be increased *ad infinitum*; and the gold-laced section even yields some little variety in this way, the plants being especially vigorous and free.

Aponogeton distachyon, or Cape Pondweed, is now flowering in our tiny pond, and *Primula japonica* and *Iris Kämpferi* planted around its margin are now coming up fresh and strong, although they have been entirely submerged for months together. *Richardia æthiopica* thrown in last autumn is alive and healthy, and is now making new leaves.

VERONICA.

FLOWER GARDEN.

NARCISSUS MONOPHYLLUS.

AFTER reading Mr. Wolley Dod's note (p. 164) in reply to "Veronica" (p. 130) on *Narcissus monophyllus*, I referred to Gerarde and was disappointed on failing to find any mention of *Narcissus monophyllus*, or of *Corbularia*. In chapter lxxvi. "Of the Bastard Daffodils" there appears: "*Pseudonarcissus anglicus* and *hispanicus*—common yellow Daffodilly," over a woodcut of what plainly represents our common wild Daffodil, and a variety thereof. The letterpress reads as follows: "The common yellow Daffodilly or Daffodown-dilly is so well known to all that it needeth no description. We have in our London gardens another sort of this common kinde, which naturallie groweth in Spain very like unto our best knowne Daffodil in shape and proportion, but altogether fairer, greater, and lasteth longer before the flower doth fall or fade." Gerarde further says: "The yellow Spanish Daffodils doth likewise decke up our London gardens where they increase infinitely," and later on in describing "The Vertues," he proceeds: "The distilled water of Daffodils doth cure the palse if the patient be bathed and rubbed with the said liquor by the fire. It hath been proved by an especial and trustie friend of mine, a man learned and a diligent searcher of nature, Master Nicholas Belson, sometime of Kings Colledge in Cambridge." It will be seen that the description has as little reference to *N. monophyllus* as Master Nicholas Belson's use of Daffodil water has to the cultivation of the plant. It is true that my copy of Gerarde, alas! lacks title page and contains some evidence that it is not of the original edition, yet I would prefer to learn that "Veronica" has made a rather curiously amusing slip in transcription rather than to find that my old volume is an unfaithful reprint. Another word. I am sure that many readers of THE GARDEN must be puzzled like myself by correspondents sending notes relating to the hardness or the reverse of doubtfully hardy plants without specifying the locality of the observation. For instance, in a recent issue there is a note to the effect that *Dracena indivisa* has stood for two winters unprotected and is unhurt. Does the writer date from the Land's End or John o' Groats? Locality is the essence of the information to us who live in unfavourable spots with a high rainfall.

Since writing the above it has been pointed out to me (by the kindness of Mr. Brockbank) that in the later edition of Gerarde, enlarged by Thomas Johnson, and published in 1636, the

white Hoop Petticoat *Narcissus* is figured as *N. omnium minus montanus albus*, and is one of the editor's additions. It does not, however, appear in the same chapter with the reference to Master Nicholas Belson. The 1636 edition of Gerarde makes considerable use of Parkinson's "Paradise."—RHO.

I am afraid my knowledge of the requirements of this pretty little plant will not enable me to offer much that shall be really useful to its admirers, but as the plant has been growing at Kew for several years both under glass and out of doors (with protection), a few words on the treatment it has received here may perhaps be of some little value. Some five years ago about a score of bulbs of this *Narcissus* were sent to Kew, where they were planted in a bed in the herbaceous ground along with other members of the genus. The soil used was equal portions of loam and peat with a good sprinkling of silver sand. Beneath this a good layer of drainage was placed. A small hand-glass was placed over the bulbs after planting, the top of which was removed in warm weather and replaced during the wet and cold season. Under this treatment almost every bulb produced a flower. There has been a slight decrease in the number of bulbs through death, and several of them have been presented in exchange for other plants, so that at the present time there are perhaps not more than half the number originally planted. These, however, are in good condition and at the present time there are half-a-dozen good sized flowers on them. From the above it may be reasonably inferred that there is not much wrong in our treatment, the protection from the excessive wet afforded by the handlight and good drainage being perhaps the chief cause of success, good soil also, no doubt, playing an important part. This *Narcissus* is also grown as a greenhouse plant, and so far it has thriven fairly well under treatment similar to that enjoyed by like bulbous plants. Mr. Joad, who adopted what, judged by its results, was certainly an excellent plan for the cultivation of this and many other small bulbs of a delicate and miffy nature, grew this *Narcissus* fairly well. Anyone looking over that grower's collection could not fail to admire the beautifully grown terrestrial Orchids, Cape bulbs, *Arisemas*, and other Aroids, and many other rare and choice plants all thriving in beds, none, or at most very few of them, being grown in pots. I am of opinion that we have yet to learn much in the direction of Mr. Joad's system of cultivation before we shall succeed with many choice little things of the nature of *Narcissus monophyllus*. Of course it is a question of space, but where a house can be spared in which beds of well prepared soil may be made for the reception of such plants as those above mentioned, so that after planting they can be let alone, the excellent plan of planting these little things out instead of keeping them in small pots is bound to prove satisfactory. So taught that keen cultivator, Mr. Joad, and in many, very many, instances the plants proved the wisdom of his views by finer and healthier specimens than was ever becoming possible in pots.—W. WATSON, Kew.

With reference to this plant, I may mention that I have referred to Gerarde's "Herbal," and for the information of Mr. Wolley Dod can state that the name given by Gerarde to the white Hoop Petticoat *Narcissus* is *N. omnium minus montanus albus*. From the description given of this plant on the same page it is evident that Gerarde adopted the name from Lobell, because he says Lobell calls this last described *Narcissus* by the name I have just quoted. I have made a hasty glance at the figures in Parkinson's charming old book, but I do not find this plant figured there.—J. C. CLARKE.

I quite well remember the friendly advice which Mr. Rawson gave me about the cultivation of *Narcissus monophyllus* some four or five years ago. Before that time it was an insolvable puzzle to me; since then it has been an annual blessing. I insert this note just to say that the same bulbs unquestionably blossom year after year (p. 164). Any secret that I possess about this matter

came entirely from Mr. Rawson himself. He has moved northwards, and *Narcissus monophyllus* declines to follow him. That is all that has happened. I cannot think that the hand of so skilful a master has lost its cunning as yet.—H. EW-BANK, *St. John's, Ryde, Isle of Wight*.

Mr. Wolley Dod says, in answer to "Veronica," that Gerarde's "Herbal" was written half-a-century before Parkinson's "Paradise"—not after, as "Veronica," by a slip of the pen, seems to say. Now, in chap. lxxvi., Gerarde says: "Now those that require all their figures (of Daffodils) and more exact descriptions, may find full satisfaction in the late work of my kinde friend, Mr. John Parkinson, which is intituled '*Paradisus Terrestris*.'" Here Gerarde alludes to the late work of Parkinson. I rather fear joining issue with Mr. W. Dod, so, perhaps, he will reconcile the paragraph for me.—M. LOCKWOOD, *Harlow*.

HELLEBORUS MAXIMUS AND ANGUSTIFOLIUS.

HAVING recently received a plant of *H. angustifolius* from a friend in Lancashire, I am quite ready to endorse all that "Veronica" claims for it as to beauty and purity of colour, but it is no disparagement to say that it is not equal to *maximus* in massive foliage nor in the larger wider-spalled flower of the latter. My reason for drawing attention to the difference between the one and the other was that in consequence of "Veronica's" notice in THE GARDEN I was applied to for some distinguishing characteristics of *maximus*, and I gave them. As regards the exquisite coloured figure given in THE GARDEN, I cannot agree with "Veronica" that the flowers were past their best, too old for figuring—on the contrary the artist reproduced bud, perfect flower, and fading bloom, all pink, all true to Nature, as they are occasionally, but not, as regards the perfect flower, of the usual colour, which is white. In this respect it was misleading, and actually did mislead, since in this case also I was applied to by an unknown correspondent to say whether any such pink variety existed, and whether it could be had. My answer was, of course, in the negative. While in momentary conference with "Veronica," may I ask whether he (or she, as the pseudonym would seem to suggest) can give any information as to the first appearance of *H. maximus*? It seems to be always assumed that it came from Scotland; but is this a fact? Did it travel from north to south or from south northwards? I suggest the doubt, because ten years ago *H. maximus* was the common Christmas Rose of this part of Devon, and niger was absolutely unknown. The plant was then common, and the clumps old and long established. I remember an old friend, and no tyro in gardening, complaining that he had just paid five shillings to a London nurseryman for what he called *H. maximus*, and that he had sent only the common Christmas Rose, of which he had quantities in his own garden. The plant sent was, however, quite correct, but my old friend had never seen niger. Perhaps some one of the old Devonshire authorities can throw some light on this matter. May I take this opportunity to correct an error in my enumeration of Hellebore species (GARDEN, Feb. 3). I inadvertently placed *foetidus* with the non-persistents. The mistake was too palpable to mislead, since *foetidus* is the most persistent of all we have, more so even than *argutifolius*, *foetidus* preserving both old foliage and old stem; whereas in *argutifolius* the stems and leaves are the growth of the season, and in other persistents the leaves only remain through the winter.—T. H. ARCHER-HIND, *South Devon*.

Since writing the above Mr. Wolley Dod has been able to inform me that *Helleborus maximus* was first introduced into Miss Hope's garden in 1863, from Aberdeenshire, but I have a letter from a very early collector of the family (I do not know that, like mine, his collection began more than forty years ago), and he tells me that what is now niger *angustifolius* he bought twenty years ago from Mr. Salter, of Hammersmith, as

niger major; and, with regard to *H. maximus* in 1879 he saw a plant in Torquay in the garden of a gentleman who said he had had it as long as he could remember, which must have been over half-a-century. From this testimony and from the fact that *H. maximus* prevails not only all over Devon, but extends also into West Somerset, I think we may fairly conclude, so far as present information goes, that Devon, and not Scotland, is the earlier habitat of the great Christmas Rose, and that niger angustifolius is the niger major of earlier date.—T. H. ARCHER-HIND, *South Devon*.

HEPATICAS.

In the *Horticultural Cabinet* for 1835 will be found a very excellent article by "Snowdrop" on the culture of the Hepatica, and it is curious to note how little has been added to our stock of knowledge or of varieties since. He commences with "the double white Hepatica being still a desideratum and its existence doubted," precisely as we should state the case to-day. There is a sort of lingering belief that the double white exists somewhere, but I have never yet been able to find it or to hear of any florist who can say that he had seen it.

Rumour stated that it grew in a quaint old garden where the present Sheriff of Newcastle-on-Tyne lives, but my friend Mr. Henry Clapham writes me: "My gardener tells me there is the tradition that it existed in our garden in 1881, but before I bought this place, about that date, there was a sale of all that was valuable, and he supposes the double white Hepatica went also, as we have not got it now. This is coming very close to the present, and I hope some of your readers in the neighbourhood of Jesmond Cottage will see if by any chance it has strayed into their precincts, or if it can be heard of and its actual existence in 1881 vouched for. An old Yorkshireman says he remembers seeing it in the garden of Sir Marmaduke Wyvill, at Burton Hall, near Leybourne, when he was a lad; but here again the trace of it is lost, as the place has changed hands and the old garden has been broken up, no Hepaticas surviving at this time. Another lost Hepatica is the single yellow figured in the "*Hortus Floridus*," published at Arnheim, in Holland, 1614; there are also figured the double blue, single white, and single blue. What has become of the yellow? Will our friend, Mr. Krelage, try to hunt it up, if it ever existed?

Parkinson ("*Paradisus*," 1656) gives the following list: 1, great single blue; 2, small single blue; 3, purple, or dark blue; 4, lesser white; 5, great white; 6, ash coloured, or argentine; 7, white with red threads (stamens); 8, red blush or pale red in the description; 9, double purple; 10, double blue. It will be seen that this is a pretty full list of sorts still in cultivation. We have the following which are not mentioned by Parkinson: 11, white with pale anthers; 12, Hepatica angulosa, the grand single blue, with flowers larger than half-crowns; 13, double pink. There are several shades of pink, one a rich carmine, and there is the purple Hepatica Barlowi, which I do not possess. If there are any others I shall be glad to hear of them. There is no prettier and no more welcome flower than the Hepatica; it is one of the earliest heralds of spring.

"Some like stars to tell us spring is born," may well be taken as Longfellow's allusion to the Hepaticas, coming as they do out of the dark ground so star-like and so lonely-looking without their leafage. In old gardens where they are to be seen in masses the effect is most lovely. They ought to be planted in the most sheltered nooks, alike protected from the coldest winds and the hottest summer sunshine. They like to nestle behind a Box edging or under the lee of a big rockery stone, or at the foot of a west wall. The soil does not matter so much as the situation, and they do not like to be divided or disturbed; leave them alone under proper conditions and they thrive apace. The strongest variety is the double pink, and it carries the strongest tuft of leafage. Three weeks ago

so dense was the clump of leaves on our plants that I wondered how the flowers could possibly be seen when they came; but by-and-by the old brown leaves fell to the ground, encircling the dense mass of buttons which were just visible, and which soon sprung up and burst forth into the most lovely rosettes of rosy pink. They are just now the gayest plants we have, and will last some time in great beauty. We have a Scotch variety of *H. angulosa*, the great Hepatica, which is the most beautiful single; the petals are more rounded than the English variety and set closer. It is larger than a half-crown. The Scotch white variety has very small flowers. The large white variety has the pink anthers noted by Parkinson. *Brookhurst, Didsbury.* WM. BROCKBANK.

ALPINE AURICULAS FOR BEDDING.

We make a bed of these every year, as they give but little trouble. Our stock is not composed of the best and choicest varieties, but in the first place the sorts were named. They may therefore be considered to be superior to ordinary seedling plants. Be that as it may, they are very acceptable plants in the spring garden, as they make variety and are interesting to many. Our course of management is very simple. At the end of May we shall lift them from the beds; the largest plants we shall divide into two, and leave the small ones as they are. They will then be taken to a north border under the shade of a high wall. There they will be carefully planted about 9 inches apart each way, placing some fine soil pressed firmly about the roots. It is necessary to take them up carefully and plant them in their fresh quarters without any delay, as they will be in active growth, and rough treatment might weaken them. During the summer, more especially during the months of June and July, they must have an occasional watering, and water must be given in sufficient quantity to moisten the whole of the soil about their roots, and as a matter of course they must be kept free from weeds; with these little attentions the plants will go on until the time comes round for planting them where they are to flower. We reserve a bed for them in autumn, because I do not like to plant them at that time, having found from experience that, although hardy plants, if they are put out in the autumn they suffer more from damp than when left undisturbed until spring. I therefore defer planting them where they are to flower until the middle of February, or as soon after that time as the condition of the ground will allow. A fairly rich soil broken up rather fine is better for them than a poor sandy or heavy staple. J. C. C.

PENTSTEMONS AND THEIR CULTURE.

THAN the Pentstemon, thanks to the hybridist, few plants have of late years made more rapid strides in the way of improvement. The individual flowers are very much larger and opener than formerly. Many of them, too, are placed stiff and erect on amazingly long dense spikes. Pentstemons, moreover, are free, continuous flowerers, numerous beautiful spikes of bloom following their predecessors in rapid succession. They are very easily grown, and will do well in any good garden soil—the richer the better. They are not liable to insect pests or disease, and where a good selection of varieties is grown, coupled with even average cultivation, they are strikingly effective even when looked at from a distance. Our mode of cultivation is very simple; in fact, very much the same as that for a crop of Cauliflowers. The ground is trenched 2 spits deep in autumn. If poor, a good layer of manure is spread on it and trenched in. In that state it is left until planting time, which usually takes place about the latter half of March. A good layer of well decomposed manure is then wheeled on and carefully dug in. Young, soft, well-rooted plants are then selected and planted about 15 inches apart; care is taken to thoroughly water in very dry weather, as if this is not attended to their tendency is to run prematurely to flower before they have gathered sufficient

constitution and strength to carry good spikes. The only attention they now require is to stake and tie them as they increase in growth, and of course keep the ground clear of weeds, &c. Cuttings taken off any time during August or September, and inserted from 2 inches to 3 inches apart in light, sandy soil in a cold frame, will strike freely. They should be about 4 inches in length, and if taken off with a heel will strike all the better. After being inserted give them a good soaking of water, put on the lights, and shade from strong sunshine for a few weeks until they show signs of growing, when air should be freely given them. They may remain there until planting-out time. Plenty of air should be admitted during the winter whenever the weather is sufficiently open to permit of it. The following are selected as being very choice from a collection of nearly 200 varieties, viz., Henry Cannell, Andrew Sinclair, Mrs. A. Smith, Sir William Forbes, Helen Wood, Climax, Decision, Hebe, Mrs. McKelvie, James Begg, James Eddie, Walter Scott, James Leadbetter, Lady Sinclair, John Fairlie, Czigane, Inimitable, Corsair, William Milligan, James Gowans, Mrs. Melville, William Saddler, Robert Osborn, Miss Annot, and Mrs. J. Allan.

Harwich.

JOHN FORBES.

SPRING NOTES.

THE Snowdrops and other bulbs peeping above the Grass at this season show one how necessary it is to plant all such subjects in dense masses if planted at all. Snowdrops scattered thinly over the ground are really and truly "lost," and it is years before they multiply sufficiently to produce a noticeable effect. We say, therefore, confine your planting to masses a yard or two across, and dibble in thickly, allowing an inch or two between the bulbs only. A mass like this even will look thin for a year or two, but it will be visible and striking compared with the "scattering" system. Crocuses produce a better effect than Snowdrops, and some of the white and silver varieties are excellent for lawn planting, producing a fine effect. They should also be planted thickly in the ground, and the different colours should be kept by themselves. The same advice applies to Daffodils and all the Narcissus family thus planted for naturalisation. We put in a lot of the better kinds last autumn, putting two or three dozen in a patch, and filling the spaces between the groups up thickly with Primroses, so that we shall have a body of colour—at least of harmonising tints. We notice they are just pushing up amongst the Primroses, the latter seedlings of last year, and all showing flower. Primroses like a good soil to grow in, and it is quite surprising what strong crowns they make when well done, too, in that way, and what a quantity of flowers they produce. The little Narcissus Bulbocodium is pushing its slender leaves up also, but it remains to be seen how it will do in our climate. This variety has a doubtful reputation as a grower, not that it is not hardy enough, but it is particular as to soil and situation. We hear of it doing well in Ireland and in Cumberland, and failing altogether in places where the climate and soil are both better.

Plants on rockeries are putting forth growth in sunny situations, and care should be taken to mark and preserve the better and weaker species. The surface of the soil and crevices should be cleaned and hand-weeded, and everything done to give the surface a clean and neat aspect as far as that can be done without interfering with a rusticity of aspect. Cleanliness is a great matter even in a rockery, which should be covered in every part with its proper subjects, but not by weeds and litter.

We have been noticing this spring the difference between Holly trees planted at different seasons of the year. Several trees moved by the woodman here during mid-winter of 1881 have hardly recovered yet from the effects of removal, and some have died outright. It was a case of urgency the moving of these at that time. On the other hand, several large trees, perhaps forty years of age, which were transplanted in May have hardly shown

the least sign of a check, but are green and growing, and made good foliage the same year they were planted without losing their leaves. It is always a better sign, however, in transplanted Hollies losing their leaves altogether than their withering and remaining on the tree. In the first case there are good hopes of the tree recovering, but none in the other.

Scarcity of birds.—For some years back our singing birds, especially blackbirds and thrushes, have been unusually scarce, and this spring they appear to be fewer than ever before. We do not remember to have seen or heard so few of the last species for many years back. Not many years ago our pleasure grounds here used to swarm with them, as none were ever killed, and hardly a thick bush was without a nest; but it is different now. The deep snows we had in December starved numbers to death, no doubt.

Forced Forget-me-not.—We are trying to force this pretty subject this year in the cool greenhouse. Thousands of self-grown seedlings of *Myosotis sylvatica* came up in our borders last year, and in November we potted up a couple of hundred tufts in 5-inch pots and placed them on a ledge near the glass in a cool frame, where they are making excellent progress and throwing up their flower-stalks. If this plant will only do well in the greenhouse, there is no prettier subject, for a Forget-me-not plant grown in rich light soil makes a fine bush and produces its beautiful turquoise flowers in thousands. We advise those who have plants in their borders to take some up and try them.

The Cape Hyacinth (*Hyacinthus candicans*).—We once praised this subject in your pages, but have to modify our opinion concerning it a little. It is hardy enough, and flowers well in the open border, but it has not been tried long enough in this country to test its enduring capabilities. It is of little good, however, planting it singly. To look well and be effective it must be grown in masses some yards square. In the rather exposed and cold Handsworth Nurseries, near Sheffield, I saw a fine mass of it last September. J. S. W.

Clematises.—*C. florida* is one of the most charming plants imaginable, its beautiful white, single, Anemone-like blooms lasting for a month or six weeks at a time. At a place in Norfolk one was planted against an Apple tree standing in the pleasure ground. It climbed all over the top of the tree, and when in bloom was a sight not soon to be forgotten. How beautiful it would be in the wild garden climbing about everything with which it comes in contact. *C. flammula* is another lovely old plant for the wild garden, climbing about as it does on everything it can get hold of; it is so useful for cutting, too, for lighting up bouquets or vases in rooms, or for the hand.—E. SENDALL.

Tropæolum speciosum (p. 191).—After two or three failures we have succeeded in growing this *Tropæolum* in the south of Ireland and on a dry gravelly subsoil. It has established itself on a part of the rockery which is partially shaded in summer by a Sycamore. As few summer plants grow on this shaded bit of rockwork, it can come up when it pleases (by no means always in the same spot), and scramble over anything it can lay hold of. It looked especially pretty climbing up the tall flower-stalks of *Campanula pyramidalis*. It receives no particular treatment; the soil is not rich, but a top-dressing is annually given. Once the plant is established it should be left undisturbed. This *Tropæolum* grew well against the house amongst Ivy on a north wall, but disappeared last year, probably killed by slugs, which were more than usually destructive last spring.—C. M. OWEN.

Imported Anemone flowers.—Can anybody tell us the name of the double and semi-double narrow-petalled scarlet Anemones which are now being sold by the florists? At Southport a lady friend of mine was told by the flower seller in the market, who had it in quantity, that it was a

Pyrethrum, and he booked her order for many dozens of plants of it, to be delivered in about four weeks. I daresay he thought it was the double *Pyrethrum* Captain Nares, which it somewhat resembles; but the flowers are those of Anemones, and I suppose they are imported from the sunny regions of the Mediterranean. It would be worth forcing in our greenhouses, as its bright blossoms are most valuable at this season. Since writing the foregoing I notice your notes respecting imported Anemones in last GARDEN (p. 213), and suppose the flowers to be the multipetala variety of *Anemone fulgens*. I enclose specimens of each for your inspection.—BROCKHURST.

[The flowers sent represent an inferior double form of *Anemone fulgens*.]

Calceolaria Kellyana.—Mr. W. Dod (p. 199) asks for information respecting the hardiness of *Calceolaria Kellyana*; my experience of it is very short, but it has a direct bearing on the point raised. Suspecting its hardiness, I at once divided somewhat severely a strong specimen sent to me from Edinburgh by the late Mr. John Sadler. The divisions were potted separately in sand and peat, and plunged in sand in a north aspect, but otherwise quite exposed. In such a position they have been all the past winter, and to-day they are fresh and growing, being still in their winter quarters. What may happen when planted out or during a more severe winter I cannot say, but I am sure that this *Calceolaria* is capable of enduring 23° of frost under the above conditions.—J. WOOD, *Kirkstall*.

Surface stirring flower beds.—We make it a practice every year about the end of February to stir up the surface soil between spring-flowering plants, especially such as *Violas* and *Pansies*, *Forget-me-nots*, *Daisies*, *Polyanthuses*, *Silenes*, *Saponarias*, &c., and we have done so again this year, but I do not remember the beds requiring it so much as this season. The heavy and continuous rainfall had beaten the surface into a hard, battered crust, so much so that after the first few dry days the soil had so run together that with a pointed stick it could be lifted up in cakes half the size of a man's hand. To a greater or less extent the same thing will have occurred in most gardens not only amongst spring-flowering plants, but in mixed borders as well. The inexperienced should therefore take note of the condition of their beds, and if anything like what they may expect to find them, they should have them seen to at once. Amongst plants such as *Wallflowers* and *Polyanthuses* a small Dutch hoe may be used to break up the surface crust, *i.e.*, if used with care, but amongst smaller growing plants a pointed stick is best to prick up the open spaces with. If the seeds are on Grass the edges should be clipped, and any dead leaves and other rubbish removed; any plants, too, that are partially drawn out of the soil by the action of the frost should be pressed into their proper positions—all necessary alterations at this season. I can already see a marked difference between the appearance of the plants thus treated and others not operated on.—J. C. C.

SHORT NOTES.—FLOWER.

Primroses (*J. S. S.*).—A very prettily striped variety, and one well worth propagating, particularly as you say it flowers early in February.

Hybridising hardy Cyclamens.—Could you induce some skillful person to improve the various hardy Cyclamens, especially *Comm. vernum* now in bloom? its tiny size is the flower's only fault.—R. H.

Narcissus viridiflorus (pp. 164 and 189).—After seeing the correspondence between Mr. Maw and Mr. Rawson I much doubt whether my bulbs are true to name. However, my authority was M. Durando, of Algiers, and I shall hope, on the flowers decide the question.—A. KINGSMILL.

Mentha arvensis purpurascens.—There is no doubt that this will soon become a plant that will be found in everyone's garden, owing to the relief given by its oil and crystallised camphor in cases of neuralgia. It is rapidly propagated by the roots as well as by means of cuttings.—W. H. CHRISTY, *Malvern House, Sydenham*.

Oenothera eximia.—"T. H. D." asks for some further information as to this plant. I first saw it some years since at Mr. Ware's nursery at Tottenham, but failed to obtain it thence. Subsequently I got a plant from a friend's garden at Enfield, who had previously had it from his relative, the Rev. John Nelson, of Aldborough. My plant flourished exceedingly, and seemed to me to answer "T. H. D.'s" description, as far as I now recollect. It differed from *O. acaulis* and *taraxacifolia* in not being of a trailing habit, but running underground. I think that the leaves were larger than those of the former species, and not divided, as those of the latter, and my impression is that the flowers were larger and more opaque. I did not, however, keep it long enough to find out if its travelling habit rendered it such a nuisance as *O. speciosa*. Mr. Nelson had lost it himself, but thought he knew where it was still growing, and had promised to obtain it for me just before his death.—E. H. EGLES.

GARDEN FLORA.

PLATE CCCLXXXIX.

ABUTILON VITIFOLIUM.*

THIS most beautiful and free-flowering hardy shrub or small tree (as it has attained a height of

Abutilon insigne.

30 feet in one shrubbery that I know of in the county Wicklow) is a native of Chili, whence it was introduced to European gardens in the year 1836 by Captain Cottingham, of Dublin. Seeds of it were also sent in 1844 to Messrs. Veitch by their collector, Mr. Lobb, and they bloomed it in a greenhouse in a small state in the following year. It is also known under the name of *Sida vitifolia*, and is figured under that name in the 72nd volume of the *Botanical Magazine*, tab. 4227. The late Dr. Moore, curator of the Glasnevin Gardens, always maintained that its more correct and appropriate designation was *Sida malvæfolia*, and a large bush of it formed for many years when in

* Drawn from a plant in Mr. Gumbleton's garden, Belgrove, Queenstown.

Growers or introducers of new plants will oblige us much by early intimation of the flowering of new or rare species, with a view to their representation in our "Garden Flora," the aim of which is the illustration in colour, and in all cases where possible life size, of distinct plants of high value for our gardens.

ABUTILON VITIFOLIUM

flower and covered with its large cupped porcelain-blue blossoms one of the most conspicuous and beautiful objects growing in the open border of those interesting and well-stocked gardens, and when at last it died it was not, if I recollect rightly, from any severity of weather, but simply because by nature it was apparently not a long-lived plant. With me it is by no means a quick-growing plant, but blooms profusely on the tops of all the young shoots about the month of May, and occasionally, but rarely, sets and ripens an odd pod of seed, which is of the true Abutilon form. Its foliage before falling towards the end of the year assumes a fine golden hue. When grown under glass it is subject to red spider, but is quite free from this pest in the open air. W. E. G.

OTHER KINDS OF ABUTILON.

As in the case of many others of our most popular garden plants, some of the most beautiful of Abutilons owe their origin to the judicious selection and skill of the hybridist, who has succeeded in raising some very distinct and useful kinds, both as regards habit and colours of the flowers. In Vol. XIX., p. 524, were figured some of the handsomest of these, for most of which we are indebted to Mr. George, of Putney Heath, whose success in the hybridisation of Abutilons has been most marked. Of the species of Abutilon, of which there are some fifty or sixty described, there are about a dozen good garden plants known to us, most of the others, although by no means lacking useful qualities for the cultivator, being hardly worthy of mention here. The following are, however, well-proved plants, most of them being valuable both for indoor and outdoor summer gardening. It may therefore be worth while to offer a few descriptive and cultural remarks on them for the guidance of those who are not already acquainted with them.

The plate for this week is a representation of one of the most beautiful of the species of Abutilon. Although the introduction of this plant dates back some fifty years, it is still a rare plant in gardens. In the *Botanical Register*, vol. xxx., p. 57, there is an excellent figure of this Abutilon, where it is spoken of in the highest terms by Lindley, who describes it as being hardy in Ireland and a very ornamental plant for the shrubbery. From Ireland came the specimen from which the annexed drawing was made, Mr. Gumbleton, whose love for choice plants equalled by his success in their cultivation, having it growing in his garden, where it proves itself to be a useful and handsome plant. For the cool greenhouse or conservatory this plant will prove a worthy subject, its shrubby habit, floriferousness, and the singularly coloured flowers being especially serviceable during the autumn and winter. Lindley figures it with half a dozen flowers on one small shoot. Besides the lilac of its flowers this species is remarkable in the absence of the long stamens which in most Abutilons are united so as to form a sort of club, but in this, as will be seen in the figure, they spread much the same as in the *Sidas*, to which it has been by some referred.

A. Darwini is a handsome, large green-leaved plant of good habit, growing into a large shrub, and producing an abundance of large, bell-shaped, orange-red flowers, beautifully veined with blood-red, and produced in the axils of the Sycamore-like leaves. As a winter-flowering plant this species may be specially recommended;

by growing it freely out of doors during the summer months and placing it in a warm greenhouse in the autumn it produces its useful flowers all through the winter. For the introduction of this Abutilon we are indebted to the great naturalist after whom it has been named, Mr. Darwin having received seeds of it from S. Brazil, and flowered it in his garden, where a figure of it was made in 1871 for the *Botanical Magazine*. This species is the progenitor of many of our finest seedlings. The variety *tessellatum* is a beautifully variegated plant of great value for summer bedding, for which purpose it is freely used about London, and in combination with the Castor-oil Plant, Tobaccos, &c., it proves very effective. As a stove or warm greenhouse plant it may be used with satisfactory results.

A. insigne.—An excellent garden plant, with large green heart-shaped foliage and white and dark maroon flowers, reminding one of those of the rich coloured *Pelargonium* Captain Raikes. These flowers are produced in axillary pendulous racemes very freely, even small plants 18 inches high flowering well. This plant might be used with good results by the hybridiser. It produces its flowers in the winter, and therefore should be grown as advised for *A. Darwini*. It forms a handsome shrub when liberally treated.

A. pæoniæflorum is a red-flowered plant with large ovate green leaves. The flowers are not as large as those of the kind previously mentioned; but from their distinct colour they are very attractive on well-grown plants.

A. striatum.—One of the most useful of plants for training up a back wall or covering a pillar, being a quick grower and very free flowerer. It also forms a handsome greenhouse shrub if freely pinched back, and when so grown there are few plants more attractive. The rather large lobed green foliage, with long slender petioles, forms a good background to the richly coloured flowers, which hang so gracefully on their long curving stalks, and are orange-yellow with a thick reticulation or veining of blood-red. It is a useful autumn bloomer, though, like most of the species, it may be had in bloom at almost any time of the year if skilfully managed.

A. venosum.—This is distinguished by its palmate Ricinus-like foliage and unusually large flowers. It is a tall grower, serviceable for standing among shorter plants, over which its head of drooping yellow and red flowers looks very graceful. These flowers are 3 inches in length and bell-shaped, so that for cut-flower purposes this species is valuable.

A. megapotamicum and its variegated variety, known as *A. vexillarium*, are useful in a number of ways. The flowers, which are very pretty, the calyx being yellow and the corolla deep purple, may be used for bouquets and similar purposes. The foliage of the variegated kind also is useful in the same way; branches of this plant look very well among flowers and stand in water for some days. For covering rafters, pillars, trellises both kinds are of great value, and as standards, which may be had by grafting them on the tall stem of a stronger kind, they are useful greenhouse plants. The graceful drooping habit of this species makes it effective in either of the above positions, and as it is a free grower and flowerer it cannot fail to prove satisfactory. In the spring it is a good plan to prune the shoots well in, or they get long and naked. It flowers all through the autumn and winter.

A. Sellowianum marmoratum.—Grown in the stove, this is a most valuable foliage plant its large, tomentose beautifully marbled leaves being highly ornamental. It may be used for table decoration when in a small state, and by gaslight the yellow and green leaves have a pretty effect. We grow quantities of it every year both for the stove and for summer outdoor bedding; used for the latter purpose in a favourable manner, there are few plants to equal it. It is easily propagated, and a very free grower.

A. Boule de Neige.—I am unable to trace the origin of this plant. Perhaps some of our readers may be able to enlighten me. It is very distinct, although most likely a garden hybrid. The merits of this—one of the most useful of all plants—are so well known and appreciated, that little need be said respecting them. As a greenhouse plant we all know its worth, and for bedding it is almost as useful. The pure white flowers are useful to the bouquetist, who pinches out the stamens and turns the petals back, making them more serviceable and lasting. To this and *A. Darwini* Mr. George and others owe their first successes in hybridisation. Although there are other whites in cultivation, there is none of so much service as this the "Snowball" Abutilon.

Turning to the hybrids and seedlings, we have a great number of kinds—white, all shades of yellow, pink, red, scarlet, and verging even on to violet colours, while in habit and foliage the variety is almost as great. To attempt anything like a description of these would be out of place here, and perhaps quite unnecessary, as the characters of the best of them will be found described in any good nursery catalogue. Continental hybridisers have been working as hard and quite as successfully on these plants as their brethren on this side the Channel, and the result is a large addition to our winter and spring-flowering plants. Mr. Barron has rendered signal service to horticulture in getting together so many of these popular garden plants for trial, and, by growing and exhibiting them at Chiswick, has provided such excellent means of judging as to the merits of each, that it is hardly possible to make a bad selection. The following list includes some of the most useful:—

Reds coloured flowers.	Yellows.
Cleopatra	Reine d'Or
Venorum roseum	Blandi
Rosina	Phyllis
Richesse	Lemoinei
Roseoflorum	Couronne d'Or
Louis Marignac	Zara
Reds.	Variegated.
La Lorraine	Mignon
Louis van Houtte	Roi Soleil
Firefly	Tritute
La Grande	White.
	Boule de Neige

Hybridisation is easily effected in the case of Abutilons. The stamens of the seed-bearer should be carefully removed and pollen from the other intended parent placed on the stigma. This should be effected in the morning of a sunny day, fertilisation being easier accomplished then than when the operation is performed on a dull day. When the seeds are ripe they may be sown in a mixture of loam, leaf-mould, and sand, and placed in a warm house, where they will soon germinate, and if sown in the spring plants may be had to flower in the following autumn. Cuttings of the whole of Abutilons strike freely. All of them delight in a rich compost.

B.

Spring flowers.—With the bright sunny weather of last week spring flowers are making

their appearance in numbers, and every day adds something fresh. Snowdrops on grass and in plantations are making a grand show. Winter Aconites and Primroses are increasing daily. In herbaceous borders and in the rock garden I notice the following already in bloom, viz.: *Anemone blanda*, *Hepatica angulosa*, *Bulbocodium vernum*, *Cyclamen Coum vernum*, *Crocuses*, *Draba cuspidata*, *Daphne Mezereum*, double Daisies, *Erica carnea* and *carnea alba*, *Galanthus Imperati*, *Houstonia cœrulea alba*, *Hepatica triloba rubra fl.-pl.*, various *Hellebores*, *Jasminum nudiflorum*, *Leucojum vernum*, *Myosotis dissitiflora*, *Pansies*, *Polyanthuses*, *Primula denticulata*, *P. pulcherrima*, *Polygala Chamæbuxus purpurea*, *Scilla sibirica*, *Saxifraga oppositifolia maxima*, *S. Burseriana* and *Burseriana major*, and should the present mild weather continue, in a few days the number just recorded will be doubled, including *Narcissi*, *Iris reticulata*, *Sisyrinchium grandiflorum*, and other interesting plants.—J. SIMPSON, *Hurworth Grange, Darlington*.

SEASONABLE WORK.

FLOWER GARDEN.

Bocconia cordata.—This hardy perennial in deep sandy loam grows to a height of 8 feet. The foliage is large and deeply serrated, and the flowers, which are produced in panicles on the upper portions of the stems, are of a whitish brown colour; under favourable conditions as to shelter from wind this plant will continue in flower from July to the end of September, a fact that justifies its being placed amongst the best of the taller growing section of hardy flowering plants. It is well adapted for planting in large masses in the back lines of herbaceous borders, but undoubtedly seems more at home on turf, something after the way in which the Pampas Grass is generally planted, i.e., in separate tufts in front of shrubberies to break or relieve the oftentimes unavoidable formality of straight lines. For the "wild garden" it is every way suited, for the less the roots are disturbed, the better the plant grows. It is increased by division, which requires to be done with great care, the best time being just as the plant is starting into growth.

Violas and other bedding plants.—Where spring bedding is not practised and the beds vacant, several kinds of hardy flowers may now be planted, each bed, as regards manure and digging or trenching, being given such treatment as the intended occupants demand to produce the best results. *Violas*, *Pansies*, *Calceolarias*, and *Verbenas* never thrive satisfactorily without abundance of manure and deep digging, but, given these, failure is all but impossible; on the other hand, it should be remembered that it is possible to have too much of a good thing; for instance, in rich soil many kinds of *Pelargoniums*, though they will grow like weeds, refuse to flower, and the same may be said of *Ageratums*, *Heliotropes*, *Lantanas*, and many others. Still, it will not be safe to follow this line of treatment too severely; there are always exceptions to rules; for example, fine foliaged *Pelargoniums* must have as liberal treatment as *Violas* and *Calceolarias* if they are to grow and colour to perfection. But to return to *Violas*; plant them out as early as possible in the richest soil, and no other spring or summer flower will be able to match them for free and continuous blooming, and few kinds equal them either for massing or edgings. The best all-the-year-round varieties are *Bluebell*, *Tory (blue)*, *Crown Jewel (blue)*, *Princess Teck (light mauve)*, *Snowflake (white)*, and *Lutea (yellow)*. On the terrace at Hampton Court Palace one summer the blue varieties were used more effectively than we ever before saw them as a carpet or setting for the tall variegated *Abutilons Thompsoni* and *Darwini*. Several large oblong beds were so planted, and though there were most elaborate carpet beds, grand beds of *Pelargoniums*, *Verbenas*, &c., none were half so beautiful as these, and it should be added that the simplicity of the arrangement in no small

measure enhanced the general effect. Had the beds in question been planted with an outer marginal edging of golden variegated *Arabis*, the arrangement would have been as near perfection as it is possible for any bedding arrangement to be. Once arrangements are completed, there are sundry other kinds of hardy bedders that should be planted at this early period, not only because the plants will be likely to do better, but also because much precious time will be saved when the busy season arrives. Among these are the variegated *Arabis*, *Ajugas*, *Cerastiums*, *Golden Feather*, variegated *Thymes*, variegated *Lamiums*, *Lavender Cottons*, *Veronica incana*, and *Euonymus radicans*. This last makes a striking and permanent edging and is especially well suited for edgings to beds of *Cannas* and *Ricinus*, or indeed for any fine foliaged plants.

Annuals and biennials.—It is now time to sow many of these, and especially those intended to be used in the general bedding arrangements. The endless varieties of good kinds of *Pelargonium* have pushed to the rear many good old annuals that twenty years ago did excellent duty on the parterre, foremost amongst which may be named *Sanvitalia procumbens*, compact and dwarf, with light yellow flowers having a black disc; *Saponaria calabrica*, similar in habit of growth, but slightly taller; *Brachycome iberidifolia*, same habit as the last, but having bright blue flowers; *Portulacas* of several colours, but all of low dense growth, and alike suitable either for outer lines of beds or for massing in small beds; *Silene pendula compacta*, not unlike the *Saponaria* just named, but, owing to the habit of the plant being tufty, the effect produced by the two plants is very different; *Tagetes signata pumila*, bright yellow—in poor soil it is dwarf and keeps in flower for months. These are a few only of the many kinds of annuals that may be relied on for summer bedding, and which, if used in fair proportion to other kinds, will tend to obviate the charge of sameness often made against bedding arrangements. They should be sown now on a south aspect in the open garden. If lights can be placed over them till fairly well out of the ground, all the better; but after this the more they are exposed, the more robust will be their growth. If sown thinly, no transplanting will be needed till they can be placed in permanent positions. *Asters*, *Stocks*, *Zinnias*, *Phloxes*, *Indian Pinks*, and *Everlastings* should also now be sown in frames; and *Wallflowers*, *Antirrhinums*, *Sweet Williams*, *Larkspurs*, &c., in the open air. To guard against loss through slugs and birds whilst the plants are in the seedling state, when possible all the kinds should have the protection of frames or hand-lights; lacking such structures, sow the seeds on a plot of ground by themselves, and as soon as sown sprinkle the ground thickly with wood ashes and soot, the best preventive against injury from slugs; and against injury from birds, net over the entire plot.

FLORAL DECORATIONS.

On a recent occasion, in order to provide an arrangement as a centrepiece for a dinner table of considerable size, a shapely, handsome plant of *Geonoma gracilis*, furnished with about seven leaves, the plant itself being nearly 3 feet high, including the pot, was selected. This *Palm*, having been grown in a 4½-inch sized pot, was well adapted for my purpose. It was turned out of the pot on to the centre of an oval meat dish measuring 2 feet 3 inches in length, and made secure in its position with sand, filling up to the edges of the dish. After this we plunged six or seven small plants of *Asplenium Veitchi* that had been grown in 2½-inch pots around the base of the *Geonoma*. At the two ends we used two very small plants of *Pandanus Veitchi*, nicely variegated and well developed; also four small growths of *Pandanus graminifolius* at the sides. As a base to rest on the cloth we secured small leaves of variegated *Begonias* and of *Alcascia metallica*, and a few fronds of *Nephrodium molle*. In order to hide the sand we covered the surface with fresh green Moss. Having some spikes of *Eucharis*

amazonica with the last flowers just expanded, we used four with five flowers in all, and stems from 1 foot to 15 inches in length, placing them around the centre plant, not too closely. To harmonise with these we had several stems with fresh foliage of *Cyperus alternifolius*, and some spikes of *Narcissus* (Paper-white and early Roman), and growths of the same cut off close to the soil. Around these we dotted some growths and good spikes of *Lily of the Valley*. A few spikes of Chinese *Primula*, chiefly white, completed the arrangement, which, when on the table, which was lighted with candles, had a very pleasing effect. Had the room been lighted with gas, it would not have looked nearly so well; the foliage of the *Geonoma* would then have cast a shade on the surroundings. Two small plants of *Cocos Weddelliana* were placed in two soup plates, and secured there with sand and green Moss, amongst which were dotted a few *Tulip* blooms and a base of large growing forms of *Adiantums*, with a few fronds of the *Malden-hair* among the *Tulips*. Blossoms of *Camellias* in various colours were used in specimen glasses. No costly epergnes or valuable glass were used, yet the entire arrangement gave every satisfaction. Those of us who have much bouquet work to do ought to grow *Staphylea colchica*, for which purpose it appears to be a valuable plant. Choice cut *Roses* should be made the most of; individual flowers look well in specimen glasses, but should neither be set in a draughty place, nor where there is too much heat; in either case they will soon fade.

ROSE GARDEN.

THOSE who have not had their *Rose* beds dug and well dressed with manure should now lose no time in doing so. All Hybrid *Perpetuals* may now be pruned, leaving the *Teas* until later in the season. Here we never saw *Roses* in the open air so forward before. Indeed, plants which have not been disturbed have been full of life and activity all winter, many varieties remaining evergreen. Under these circumstances they will, when pruned, bleed freely and lose much of what we would rather was retained, but the longer the delay in pruning the greater the evil. Should no break in the present mild weather occur, we shall have an early flowering season.

INDOOR PLANTS.

Bulbous plants, such as *Hyacinths*, *Tulips*, and *Narcissi*, as well as hardy shrubs used for flowering in pots, do not require much forcing after this time, as they naturally come into bloom under glass without much fire heat; where there is any deficiency of the ordinary spring-flowering greenhouse stock to keep up the requisite supply of bloom to follow the forced plants, a portion of bulbs and other hardy subjects may with advantage be kept back by giving them no more warmth than that afforded by greenhouse treatment. The indifferent usage which forced bulbs frequently receive after flowering makes them of little use subsequently; whereas if fairly cared for, *Tulips*, *Narcissi*, *Crocuses*, and even *Hyacinths* answer well for outdoor cultivation. With their foliage soft and tender, consequent on the forcing to which they have been subjected, they are often at once put out in the open air; whereas if turned out into a bed of prepared good soil in a frame and well attended to until their growth stands a chance of getting matured, they will do good service in after years planted where they are to remain.

Hardy shrubs.—These are also often badly used when they have done blooming under glass. *Lilacs* and *Laurustinus*, especially such of these as have been prepared for pot culture along with double *Prunus*, *Ghent* and the mollis varieties of *Azalea*, and *Rhododendrons*, should have a place in a pit or any spare structure where their growth can be fairly matured before being exposed to the open air. *Deutzia gracilis* should, if room can be found, be kept in warmth, such as that afforded by a vinery at work, until the wood is hard and the next year's flower-buds visible.

Camellias.—As these go out of flower they should, if affected with white or brown scale, at once be cleared from it, as it will increase apace under the warmer treatment to which the plants ought to be subjected whilst making their growth. I have found nothing better to assist them during the time when growth is being made than soot water, which not only has an invigorating effect and improves the size and colour of the leaves, but also banishes worms from the soil, should these be present. A little shade will now be beneficial to those that are making growth, and also to those that are in bloom, as the flowers will not last long if subjected to bright sunshine. In the case of examples that are turned out in beds as well as in pots or tubs, be careful that the whole of the soil is sufficiently moist, for Camellias more than most plants cannot endure drought at the root, particularly whilst their flowers are opening and their growth is being made.

Azaleas.—Such of these as have been forced to come in during the winter and have done blooming should immediately they are out of flower have the seed-pods picked off, as the production of seed exhausts the plants even more than the flowers. If they are not at once placed in a little heat, and kept growing until their bloom-buds are fully formed, the time of their flowering next season can be accelerated. The course here advised is different from that of keeping the plants after flowering for a time in an ordinary, dry, cool greenhouse temperature, and then placing them out of doors early in the summer with the season's shoots only partially matured. So managed they will bloom in a certain way, but the fact of Azaleas flowering at all under such treatment only shows their accommodating nature; the growth and bloom so produced are extremely meagre and poor compared with that which is attainable under more liberal management. In all cases care should be taken that the plants before being started into growth are quite free from their worst enemy, thrips. Tobacco water is the safest and best remedy out of the many I have tried for the destruction of these pests and their eggs. It is much better not to shift any plants that require potting until the young shoots have made some progress, as the roots of Azaleas do not begin to move nearly so early as the top growth. Plants required for late blooming, to come in say at the end of May and the following month, should now be moved to a north house, and kept as cool as possible without subjecting them to absolute frost.

Roses, such as are grown in conservatories, or in any structure along with other plants, require especial care at this season to see that they are free from aphides. Where planted out, if the soil needs manurial assistance, this should at once be given, as on this mainly depends the successional crop of bloom. Where Hybrid Perpetuals are used in quantity for forcing they should now be introduced to the Rose house in succession; these will give flowers at a time when the Tea varieties that have been earliest at work are beginning to fall off more or less, but even in the case of the latter it is surprising how they will keep yielding a succession of bloom if they are regularly supplied with manure water from the time when they are first started; without this the after growth comes too weak to bloom strongly.

Lilies.—Any of these that have been wintered in cellars and under plant stages should, immediately the shoots appear above the soil, be placed in a light position, or they will become drawn and weak, a condition that no after treatment can rectify. See that the soil is sufficiently moist, but not too much so. The different varieties of *L. speciosum*, *L. auratum*, and a few others as soon as they begin to grow do well in a cold pit where they can be kept near the glass. In this way they make strong, sturdy growth, calculated to flower well. *L. eximium*, than which there is no more useful species, coming in as it does before the other kinds, should be grown by all who have a greenhouse. From this time forward it will bear a little warmth if its early flowering is desired. It is most serviceable when two or three

good strong bulbs are grown together in a 7-inch or 8-inch pot.

FRUIT.

Pines.—By this time the most forward Queens will have reached the flowering stage, and if well ripened plants were selected the remainder of the first batch will be showing their fruit. So far mild weather has favoured the maintenance of steady temperatures, and we may now hope that brighter days will enable us to strengthen the plants and economise fire heat by running up to 85° or 90° after closing with atmospheric moisture. The latter may be produced by damping all available spaces and gently dewing the plants about the axils of the leaves in preference to overhead syringing, but care must be observed, as plants which are closely plunged in tan or leaves are often injured by having too much water at this critical stage. It will of course be necessary to examine them regularly and to keep them moderately supplied with weak liquid or guano water, otherwise they will suffer from the opposite extreme. Let the bottom heat range from 85° to 90°, maintain a steady night temperature of 70°, and stir the fires early every morning in order to admit of timely ventilation when the warmth of the house approaches 80°.

Succession plants.—If the strongest of these were selected early in February and plunged in a bottom heat of 85° they will be making the growth which usually precedes the appearance of the fruit. Gradually raise the temperature to 70° at night and 10° higher by day, water carefully, and defer overhead syringing until the fruit is well above the foliage. If not already done, get the strongest successions shifted into their fruiting pots. Let the crocks, pots, and soil be dry and warm, ram the latter very firm with a blunt-pointed stick, plunge in a sweet bottom-heat of 85° to 90°, and withhold water from the roots until they begin to work in the new compost. It often happens that this department at this season contains a number of good plants in rather large pots which they have not filled with roots. These should be examined, and if crocks, roots, and soil are not quite satisfactory, shake out and repot in pure loam, using pots one or two sizes smaller. Plunge in a sharp bottom-heat and treat as spring suckers. Examine the first batch of suckers which were potted about the middle of the past month, and give them a little water when the roots reach the crocks; also dew them over with the syringe on fine days and close early with sun-heat to start them into growth. If the heat in the bed has not receded below 85°, but little fire-heat will be needed in mild weather, as it will not be wise to force an elongated growth before the roots get well established in the new soil. Keep the young plants near the glass, ventilate on all favourable days, and cover up with mats at night.

Vines.—Practical Grape growers who have to keep Mrs. Pince, Black Alicante, and Lady Downes fresh, black, and plump until new Hamburgs are ready will not have to be reminded that the houses should now be closed and the buds fairly moving by the middle of the present month. Assuming that the roots have the run of external and internal borders resting upon ample drainage, the inside roots, previously watered with cold water, may now be mulched and copiously watered with diluted liquid at a temperature of 90°; and as well matured wood has a great deal to do with compact shows, perfect fertilisation, and finish, a little extra fire-heat combined with early closing on fine days will enable the cultivator to steal a march upon the spring, and give more time to the colouring and finishing process, which should be complete by the month of September. Having so often drawn attention to the importance of an early start, a repetition of the above remarks seems uncalled for; but when we find Grape growers inquiring how they must proceed to make their Mrs. Pince indifferently coloured, and their Lady Downes become shrivelled to insure their keeping, one begins to feel that some at least are still in urgent need of the practical

advice which will be found reiterated in the Calendar. When the buds begin to swell a higher temperature than that recommended for early houses may be indulged in; indeed, to have Lady Downes thin skinned, full flavoured, and capable of keeping fresh and plump until May, the Vines should receive Muscat treatment until the Grapes begin to colour, when Hamburg treatment will insure colour. Black Morocco and Gros Colmar, when properly managed and allowed a long growing season, are valuable to use from January up to March, but they should be ripe in September. Gros Colmar should hang for some time on the Vines after the leaves fall, and a few weeks in a warm Grape room will remove the earthy flavour which makes badly ripened examples uneatable. A promising late Grape, Mrs. Pearson, is well worthy of a place in every autumn and winter vinery. As a grower it is quite as free as its inferior relative, the Golden Queen. It shows an abundance of handsome bunches which set well, and my experience justifies me in saying it will keep for a long time and improve in quality after it is ripe.

Early houses.—When all the Grapes are thinned and the berries begin to swell away freely give the inside borders another liberal supply of warm diluted liquid and maintain a healthy growing atmosphere by damping the walls and floors with the same. Let the night temperature range from 65° to 68°, with a chink of air when practicable, and ventilate freely through the early part of the day to maintain the colour and texture of the foliage. A rise of 10° by day when fire-heat is applied will be quite sufficient, but 85° for a short time after the house is closed with sun-heat will add greatly to the size of the berries without distressing the Vines. If any part of the trellis remains uncovered, tie down the laterals in preference to hard stopping, and let all, with the exception of the strongest, have full play when the stoning process sets in.

Pot Vines.—The above treatment applies to fruit-bearing canes now swelling off crops. If all has gone well fresh roots will now be abundant and capable of taking warm diluted liquid at every watering. Encourage laterals where space admits. Shake out and repot cutbacks when they have made 2 inches of growth. Place them over a bed of fermenting leaves in a close pit and train near the glass.

KITCHEN GARDEN.

WHERE the ground is not too wet more Peas may be sown. We like the round better than the wrinkled ones at this season. Pride of the Market is a thoroughly good Pea but as yet scarcely cheap enough for the million; we are therefore sowing Telegraph, an excellent variety. Another sowing of Broad Beans may also be made; the giant class of Beans, of late so fashionable, we are not in favour of. We sow Early Mazagan and good old Green Windsor. Few vegetables have come to the front more of late than Broad Beans eaten when about the size of Peas. Our first spring Cucumber plants will be in their places on Monday. We grow the first lot at the top of a stage where we place about a peck of soil in hillocks under each light, and as the roots come out more soil is added. Always have some in the house warmed. We have not grown Cucumbers long in this way, but can recommend the plan. Last year they did really well, and doubtless they will do so this season. Tomatoes should be staked at once to lead them up to the roof of the house; the latter should be kept at from 60° to 65° at night, and there should be a proportionate rise with sun heat in the daytime, giving air when the temperature has risen from 70° to 75°, but screen the air through canvas if possible.

Self-help for gardeners.—"Peregrine" is in error when he states that the gardening fraternity can as yet boast of no benefit association of its own. He is not, I presume, aware of the existence of the United Horticultural Benefit and Provident Society, a society that is doing

good work among gardeners in various parts of the country, and which deserves the support of every one who is eligible for election, and who prefers to join a club specially constructed for his benefit. It is, I am glad to say, making good progress, seven new members having been elected at the last committee meeting, over 100 being now on the books. The funds invested in the Bank of England and in the hands of the treasurer amount to £2500 odd. Balance sheets, rules, and further information will be gladly afforded on application to the secretary, Mr. J. F. McElroy, Moray Lodge, Campden Hill, Kensington; or by the treasurer, Mr. James Hudson, Gunnersbury House, Acton.—J. H.

ROSE GARDEN.

ROSE LA FRANCE.

THE plate of this Rose in THE GARDEN of February last (p. 180) was really superb, and in the description of it not one word too much is said in its favour. There can be no doubt about La France being one of the most beautiful Roses that can be grown, and from experience I have proved it to be one of the most useful. When thoroughly known by those living in the suburbs of our large towns—I mean those who have a garden, but do not keep any regular gardener—it is sure to become the most popular Rose in cultivation. It is not generally known that this variety is one of the best to succeed in the smoky neighbourhoods of large towns. This locality is one of the worst that could be found for the cultivation of the Rose, yet La France luxuriates amazingly, and produces in a season ten times more blooms than any Hybrid Perpetual growing by its side. In manner of growth it resembles the Tea varieties; as soon as one flower is over it breaks into short growths and flowers again, the most puny shoot producing a fine large flower. Its perpetual habit of flowering from early in the season until cut off by frost renders it doubly valuable for massing in large beds in suitable places in the pleasure grounds.

Like Mr. D. T. Fish, I am thoroughly convinced that this is one of the many Roses that flourish best on their own roots. I have it growing on the seedling Brier and Manetti, but get more blooms of a richer colour from the plants upon their own roots. I have carefully tested them on the two stocks above mentioned against those growing on their own roots by keeping the union of the stock and Rose above ground, and the superiority has always been recorded in favour of those on their own roots. La France will live much longer on the Manetti when the union is left above ground than many other varieties, simply because it is only of moderate growth. Those growing upon their own roots are more luxuriant than upon either of the stocks just named; at least such is its character here, where the soil is naturally lighter than we should recommend for Hybrid Perpetuals, and the rainfall is very heavy. There is no coloured Rose with which I am acquainted that is so well adapted for early forcing in pots, and can with the greatest ease be had in flower early in February. It will go on flowering continuously for eight months out of the twelve, that is if the plants are provided liberally with stimulants.

For autumn flowering after Roses are over outside until Christmas this is invaluable if rooted during the month of March from plants that have been forced into flower early. It strikes readily from cuttings when the wood is scarcely half ripe if inserted in coarse sand or sandy soil and covered with a hand-light or bell-glass, and placed in a temperature of 60° to 65°. They will become rooted and ready for potting in about three weeks, and if grown on through the summer until they are in 6-inch or 7-inch pots they will be found most useful for late flowering, and will continue for a long time in a night temperature of from 50° to 55°.

MANIFESTO.

Rosa berberifolia (p. 214).—My experience of this Rose agrees with M. Jean Sisley's. I reared the seeds he sent me, and gave away some nice

little plants; but all of them, I believe, failed after the first year, as mine did. It is certainly not only tender, but difficult to cultivate, and I cannot help thinking your correspondent Mr. J. R. Droop has not got the true plant if he finds it to grow and flower freely in the open border at Stamford Hill.—HENRY N. ELLACOMBE, *Bitton Vicarage*.

PROTECTING AND PRUNING TEA ROSES.

TEA ROSES are not only the most delicately beautiful and fragrant of all Roses, but likewise the most sensitive. They shrink from contact with severe frosts, and rush forth to welcome early sunbeams with equal alacrity. Hardly has the sun shone upon Teas with any heat than they begin to grow, and welcome the warmth with peeping buds and unfolding leaves. Such is the present state and dangerous condition of many of our Teas. Their early excitability has placed them at the tender mercy of March weather; and what cultivator has not painful memories of what that means? How best to fortify the plants to bear the coming strain is now the most trying of all problems to rosarians. To leave them alone is one method, and probably once in a dozen times it may answer. Last season was one of those exceptional springs, when those who either pruned their Teas in winter, or not at all, reaped an early and beautiful harvest, for in most localities even the early buds escaped destruction. But it is dangerous to confide in the genialities of March; for once it is genial, it is harsh, stern, and destructive a dozen times. The majority of Teas have had more or less protection. Already, on this 26th day of February, not a few of the plants have grown through it, having made from 1 inch to 3 inches of growth. What is to be done under these circumstances? Probably the best course is to remove the protection and cut off most of the more forward shoots, thin out all weakly and superfluous growths, and retain a little protection. The latter can hardly be too slight and thin. Spruce or Yew boughs or Fern fronds are the best protective materials. The effect of slight screens is twofold: they keep out the heat as well as the cold, thus avoiding the two extremes that cause the destruction of Tea Roses. It must also be admitted that they shut out the light if used in excess, and that deprivation of light leads inevitably to weakness. But, on the other hand, it is possible to screen out a good deal of heat and cold from our Roses without obscuring the light very seriously; it is astonishing what flimsy screens suffice to baulk the heating power of sunbeams and check the energy of radiation.

Besides, the screen may be so skillfully disposed as to give it a maximum of protective with a minimum of obfuscative force. To this end it should crown the plants rather than closely envelop them. So placed, plants may be protected without being sensibly weakened, the lower buds being as much as possible still exposed to the light. To ensure this twofold purpose, however, no merely haphazard mode of protection will suffice. On the contrary, the material used must be nicely adapted alike in quality, quantity, and position to the objects aimed at. The difficulty and delicacy of these needful adjustments of protection have decided not a few rosarians to do without it. In mild springs like these they run heavy risks of failure. They, however, trust mostly for safety in the knife. The more and earlier the growth of these Tea Roses, the more severely they cut them back. There is a double advantage in this; the lower they cut, the more dormant the buds left, and consequently the longer they will be in breaking. Some carry this severe pruning so far as to cut Teas back almost to the growing line. This latter plan answers well for late bloom, as Teas on their own roots mostly respond to this severe surgical challenge with a vigorous output of suckers or crown stems, that grow with vigour and bloom profusely. But such slashing prunings are more like recipes for the rejuvenation of exhausted Roses than the rational treatment of plants already in existence. The waste of time and material involved is too great for general adoption.

The time for pruning Teas is hardly yet, unless in exceptional seasons, such as this promises to be. Towards the middle or end of March most Teas may be pruned and wholly uncovered without serious risk. This season the compromise here recommended of immediate pruning and partial re-covering seems the best method of treating Teas running wild in the end of February. Permit me also to state that Maréchal Niel, being altogether a special Rose, is not included in any of these suggested methods of pruning Teas.

D. T. F.

FRUIT GARDEN.

VINE FORCING.

VINES may be forced into growth and to bear fruit at any season of the year, provided—and provided always—that the wood is properly ripened. Early forced Vines of one season force more easily the following year, and established Vines always more easily than young ones; indeed, young Vines, excepting pot Vines, should not be hard forced. To secure early Grapes, say in April, the Vines should be started into growth in November. The period of time required from the commencement of growth to the ripening of the fruit is for the Black Hamburgh about five months. Thus Vines started in March should have fruit ripe in July, and those coming naturally into growth by the end of March in August and September. The Muscat of Alexandria, Alicante, Lady Downes Seedling, and other late Grapes require nearly six months to ripen and finish properly. All Vines should be started sufficiently soon to have the fruit ripe in the early part of September, for Grapes ripened later than September require a great amount of firing to finish them, and do not keep well through the winter. The Grapes ripened in September are the latest that arrive at full maturity. If, say on January 1, we take as an example a vinery from which ripe Grapes are required to be cut in the month of June, the management necessary to secure this end may be stated in general terms as follows:—

1. TEMPERATURE.—At the commencement a night temperature of about 60° will be sufficient until the Vines have started to grow. The heat should be raised gradually to 70° by the time they come into flower. When the Grapes are fairly set a lower temperature may be maintained until after the stoning period, when, if necessary, a rise of a few degrees may be allowed. When the Grapes commence to colour a lower temperature may be maintained, but fire heat is almost always required in order to maintain a bracing atmosphere. For day temperatures a rise of 5° by fire heat may be allowed in dull cold weather, and of 10° or more, if by sun heat up to 80° or 90°, as the season advances. In very cold weather, however, it is better to have a lower temperature than to maintain a high one by overheated pipes.

2. VENTILATION OR AIR-GIVING.—The object sought to be obtained by ventilation is not merely the maintenance or regulation of the temperature, but also the admission of fresh air, which is a most important factor in the well-being of plants. The night temperatures are mostly regulated by the amount of firing or heat applied, but the day temperature, or amount of sun-heat, is regulated by ventilation. In vineries a little air should be given at the top ventilators early in the morning, or as early as it may be observed that the temperature has risen or is rising above the required point, and this air should be gradually increased as the day and the temperature advances, and later on should also be reduced in a like manner, endeavouring, if possible, to shut early enough to secure a slight rise in the temperature after doing so. We prefer shutting up early at all times, and "bottling up," as it were, the sun's warm rays, to the rigid rule of keeping to a given temperature, and the consequent early application of fire-heat for its maintenance. As the Grapes begin to colour air must be given freely both by day and by night on both sides of the house, &c., so that a bracing atmosphere may be secured.

3. **MOISTURE**, in its relation to the atmosphere, is of the greatest importance to the healthy progress of the Vine, and demands special attention. A close moist atmosphere is necessary to induce the buds to break freely, and afterwards it is necessary to assist in supplying nutriment to the Vines through the leaves. A very great proportion of the vital energies of plants is absorbed through the leaves. Again, moisture is necessary to prevent the destruction of the leaves by the inroads of insects, such as red spider, &c.

From the commencement, then, a moist atmosphere must be maintained, and the higher the temperature the greater the evaporation, and the greater the amount of moisture required. It is difficult to supply too much. When the Vines are started they should be syringed regularly several times a day, especially if the weather be bright and warm, beginning as soon as it may be noted that the temperature is rising, and so on, varying as to time according to season, &c.

tables of temperature for both day and night, to be followed strictly during the season, but never having seen, or having derived any benefit from the use of such tables, we prefer to state general principles that may be understood and followed out by everyone as circumstances may admit.—A. F. BARRON, in *Florist*.

EXTRAORDINARY VINE AT ROCHE-SUR-YON.

At a time when the Phylloxera has done and is still doing so much damage in vineyards, the following account of a Chasselas de Fontainebleau (Royal Muscadine) Vine whose fertility has been a matter of surprise to many cultivators may not be without interest. It belongs to a shoemaker, who has furnished the following particulars concerning it. As will be seen from the accompanying illustration, taken from a photograph, it is planted in the pathway in front of the house; the surface

refer to his acknowledged sources of information on such subjects, viz., the *Gardeners' Chronicle* and *GARDEN*, he will discover that he has not drawn the above accurate description of this method of propagation from any communications signed by Mr. Thomson (who, on the contrary, explained at the time that it "had nothing in common" with his plan, which Mr. Barron does not allude to at all in his book), but from those signed by the writer of this letter.—JAS. SIMPSON, *Hortley*.

ARE ORCHARDS PROFITABLE?

ANY remarks of mine on this subject may seem out of place, inasmuch as my forte is rockwork; but as doubts have been expressed as to whether orchards are profitable, I hope that what I am going to say after seven years' experience may show that they are. My orchard consists of about an acre. I have five good-sized Apple trees and three Pear trees, which this year, though a bad season,

Prolific Vine at Roche-sur-Yon.

This treatment may be continued until the Grapes come into flower, at which period a somewhat drier atmosphere should be maintained until they are fairly set. Syringing the Vines overhead must from this time be discontinued, as, on account of the lime present in almost all waters, the Grapes become spotted and soiled by its use. Young Vines on which there is no fruit may, however, be syringed with advantage. Every portion of the house and border should be freely syringed at all times, and the atmosphere thus kept well charged with moisture. When the Grapes begin to colour, a somewhat drier atmosphere is required, and by the time they are ripe the atmosphere should be kept as dry and bracing as possible. After the Grapes are cut, if it be during the growing season, the syringe should be again freely employed, to thoroughly cleanse the leaves and wood, and its use continued until they ripen off thoroughly. All Vines in vineries, at whatever period they may be started into growth, will require treatment or management on principles somewhat similar to those here laid down. It has been the custom of most writers on the cultivation of the Vine to give

soil near the stem is dug up twice a year and mulched with horse manure. All the previous year's wood is spurred in as closely as possible, an operation which is performed between the 1st and the 15th of April. The new shoots are stopped at the second leaf from the base, and during the whole of the year all the shoots which grow too large are taken off, in order that they may not rob the fruit. Thus managed, in 1882 this Vine yielded 2115 fairly sized bunches of Grapes, and in order to encourage so heavy a crop to ripen early, a good deal of the leaves are taken off in July, so as to expose the bunches more directly to sun heat.

Mr. Barron's book on Vines (a correction).—At page 55 of this work Mr. Barron says: "Mr. Thomson, when at Dalkeith, adopted the plan of raising Vines from eyes struck in square pieces of turf instead of in pots; in these the Vines rooted, and were planted out into the border without disturbance, a very simple and efficient method." It is not a matter of much importance, only it is better to be right than wrong in such matters, and I feel sure that if Mr. Barron will

yielded me twenty-eight bushels, and last year over thirty bushels. Now what I want to state is that from this same acre I had a good crop of hay, which was got up earlier than that of anyone else in this neighbourhood; in a very few days afterwards Grass was cut and this was repeated day after day till the end of October. I therefore had abundance to keep a good-sized pony in grass and hay daily for about six months. About 30 fowls, too, had the run of the ground on which the Grass grew close up to the trees. It seems to me, therefore, that if a few trees are planted irregularly, leaving large spaces between them, that Grass or hay may be obtained in quantity as well as fruit, thus making the result profitable; and as to the amount of capital laid out in forming and maintaining an orchard, it need not be nearly so much as some of your correspondents have asserted. In addition to the trees named I have on the same acre several trees recently planted coming into bearing, the cost of which was 12s. 6d., and these will take the place of the old trees when worn out. Both trees and Grass receive the manure from the stable, including liquid manure, which is poured under

the fruit trees. This is but a small experiment; but what is there to prevent its being carried out on a large scale, when I feel sure it would pay? I may state that the trees are pruned and otherwise well cared for, the branches never being allowed to crowd each other, thus encouraging insects, blight, and the growth of Moss and Lichen. In ill-managed orchards all these evils occur, and Apples are necessarily small. Looking at the barrels of fruit that come annually from America, it would seem that we are unable to make orchards pay. Grass orchards, however, ought to do so, the secret being the having two crops on the ground at one time—hay and fruit. Under the present tenure of land I suppose the landlord should plant the trees, and therefore the tenant would be freed from that expense.

Double cropping of the ground is what I apprehend is wanted, so that if one crop fails there is another to fall back upon. Where orchards are not laid down in Grass, bush fruits take the place of the hay crop, and these often pay better than the produce of the taller trees.

Broxbourne.

JAMES PULHAM.

[We have seen Mr. Pulham's Apples, which were unusually large and fine, and when we saw the trees they were loaded with fruit.]

KITCHEN GARDEN.

VEGETABLES ON BOG LAND.

TRAVELLERS by railway between Preston and Liverpool pass through a wide extent of flat country, chiefly bog land. The bog, in the summer season, is cut into bricks 7 inches by 10 inches, and about 2 inches thick, for fuel, and when dried, it is put together in conical stacks, allowing as many interstices as are compatible with the safety of the pile. The centre of the cone is hollow, and in this way it remains until disposed of. Turf cutting is discontinued when the water line is reached, generally about 8 feet deep. A foot or two of the top is thrown down into the cleared space. This, in consequence of being furthest from the water, as well as being ameliorated by the action of the elements, is sweeter and more suitable for the roots of plants which will shortly occupy it than the soapy lower strata. The lumpy pieces are collected with all other refuse and burnt, and spread on the ground. Pits are dug until the marl is reached, and thrown out and distributed over the surface, and ultimately mixed with the bog by the spade or plough. Ditches are dug as deep as is consistent with the security of an outlet. The drains laid 2 feet deep in the ground empty their contents in the ditches. The absence of sufficient fall in the latter is the greatest obstacle with which the cultivator has to contend. During the operation of ditch-making, several stumps of trees, as well as now and then a trunk, are come in contact with. The wood, in one case that of an Oak, which we examined was as hard as ebony; it laid across the ditch, and must at one time have been 12 feet below the surface. Those who undertake to instruct us as to the cultivation of vegetables often are at some trouble to describe the particular soil most suitable for each kind, a useless kind of information, gardens being as a rule not composed of more than one sort of soil. For instance, I have seen excellent crops of Strawberries growing on land into which a walking stick might be thrust at any time up to the handle; again on bog land we find Onions growing two successive seasons, and the last crop decidedly the best. Few cultivators have any conception of the capabilities of such soil for vegetable culture. Potatoes are generally the first, second, and even third crop; Turnips, summer Cabbages, and Celery follow, some of them such crops as have not been produced on land selected by the most skilful cultivator.

Celery, it would appear, is likely to be an important crop for bog land, not being particular as to soil. Plenty of moisture and manure are what it requires, a fact demonstrated by its being sometimes grown in little else. The seed is sown the first week in March in frames, and pricked out when the plants are sufficiently large to safely

handle. The final planting is done on the surface, the trench system, for obvious reasons, being abandoned. The manure, too, is confined to the surface, and as the rows are 6 feet apart, the roots have plenty of space in which to travel. To dig trenches and plant in them would be placing the roots in a cold, wet, and otherwise unfavourable situation. Surface planting, indeed, should receive more attention than it does in most gardens, especially in the case of the latest crops. Had we not adopted this plan we would be badly off for Celery during February and March, during such seasons as the two last have been. I have seen trenches dug 18 inches deep and little more in width than that of the spade. Six inches or so of manure have been put in and covered over, or dug in with the subsoil, which is usually the worst material. Under such circumstances, unless the ground had been recently trenched, the sides of the trenches are in most soils impenetrable by the roots, even if their quality was inviting. The Celery grows well enough until its roots have filled the trench; after that its growth is slow instead of rapid. The Celery grower on bog land has no occasion to water; he can earth up at any time provided he has two or three dry days, and the Celery when dug comes out as clean as if it had been washed, and free from slug bites or other blemishes. Growers on heavy soils often experience a difficulty in earthing Celery. The soil is either wet and sticky, or hard and lumpy. In very dry weather we have even had to water the soil so as to render it workable with a fork, and enable us to add a few inches of mould to pack round the Celery heads, the banking up having to be done with soil in still worse condition, so stiff and tenacious is our clayey soil. Even when tolerably well pulverised, then there is no comparison between the appearance of our crops and those produced on bog land.

Best show Celery.—Someone asked in THE GARDEN a short time ago which was the best variety to grow for show. The following as well as many others have been amongst the prize-takers, viz., Ivery's Nonsuch, Major Clarke's, Leicester Red, Sandringham Dwarf White, Incomparable Dwarf White, and Wright's Giant White, kinds, however, scarcely known in the neighbourhood of Preston. Two or three growers save their own seed which may or may not be identical with that of recognised kinds. The greatest weight that I have heard of has been attained by Troughton's Ne Plus Ultra or White Prizetaker, as most growers call it, and the heaviest weight recorded is 10½ lbs. Celery grown in this part of the country enjoys perfect immunity from the ravages of the Celery fly (*Tephritis onopordinis*), of which I have had sad experience, notably a few miles from London. The plants have even been attacked before they were planted in the open ground. W. P. R.

EDGING TILES.

I HAVE made many kitchen garden edgings with bricks and tiles, but the best I ever made was with blue-black Staffordshire bricks made for the purpose; they are 10 inches long, 7 inches deep, and 3½ inches thick, bevelled at the top, with holes in the ends to admit small pieces of galvanised wire about 3-16ths of an inch thick to hold them together. I took out the soil to the required depth, and rammed it well down to get something like a solid bottom; then I laid the bricks down to the line, inserting the wire in each, so that when I got to the end of the walk my edging appeared like one solid piece. I well rammed in the soil against it on one side, and black engine cinders on the walk side, thus fixing the bricks firmly. I then gave their tops a coat of tar, and there they are now, neat, clean, and durable; the cost, exclusive of labour, was 6d. per yard. Another good plan is as follows: I got some Staffordshire rough, hard bricks, about 27s. to 30s. per 1000; took out a trench as before, put one brick flat at the bottom, then another on the top upon its edge. I bedded the top one in a little mortar mixed with cement. Any ordinary gardener can do this, but I had a

bricklayer. I forget the cost now, as it is some twenty years ago since I did it. I know the first cost was much less than that of the former plan, but then I was within a few miles of the brickfields. The advantage as regards the first plan is the fact of the bricks being all tied together, so that by digging or wheeling you cannot well break or displace single bricks. I may mention that if "E. L. M." resides near the Staffordshire blue brick-makers, he would be enabled to get the bricks which I speak of much cheaper than the price just given. RUSTIC.

SOME NEW POTATOES.

IT is satisfactory to find that the useful work done by the committee of the International Potato Show at Chiswick last year is, with the assent of the council of the Royal Horticultural Society, to be continued this summer. Already a considerable number of new seedling Potatoes have been sent there for growth under Mr. Barron's care. Last year some thirty or more kinds were grown for the inspection of the committee, all being of home origin, and of these only two or three were esteemed good enough to receive certificates of merit, so severe was the test to which all were subjected. This consisted of two inspections at a month's interval of lifting and judging as to cropping qualities, distinctness, freedom from disease, general value, and finally testing table quality by careful cooking. If after this samples were put on the exhibition table that were handsome or at least meritorious, then a certificate was granted, but not before. It need hardly be said that could such a test as this have been applied earlier, many indifferent kinds of Potatoes might never have got into commerce. It may be said that after all this is but work which the fruit committee has performed at Chiswick in years past, but it is obvious that the fruit committee, consisting, as it does, of persons not one of whom perhaps possesses any considerable practical knowledge of Potatoes, cannot have, in the estimation of Potatogrowers and traders, that prestige which is enjoyed by the executive committee of the International Potato Show, all the members of which have made the Potato a special study, and are from long experience more familiar with its kinds and their characters than perhaps any other body of men in the kingdom. There is a determined effort being made to keep back inferior kinds, and specially to give the prestige of the International Potato Show only to such new sorts as shall fully merit the honours they may secure. Of course it is not possible to govern the entrance into commerce of all new kinds, as some, and possibly meritorious ones, may not be sent to Chiswick. Still the public may some day come to ask whether such a kind has gone through the Chiswick ordeal, and if it has not, to conclude that its raiser has not that confidence in its qualities which is desirable. Of

New kinds which came before the committee last year Pride of the Market has been put into commerce, the raiser having a large stock. This, though a capital late Potato, was thought to be too much alike to Magnum Bonum (as indeed were several others) to be worthy a special honour, yet the raiser has confidence in its distinctness as a valuable late Potato, and certainly let it resemble Magnum Bonum ever so much in other respects it is very superior in table quality. One other kind, Alderman, a large, flat, white kidney, a seedling from the Early Rose and Early Market, also put into commerce this season, received the highest number of marks at Chiswick, but failed to secure a certificate because it was not shown at the Crystal Palace. It will probably make a reputation as a good garden variety. Several kinds will probably be tested again this year, but raisers will do well not to send kinds that bear striking resemblances to other and well-known kinds except they possess some very special and valuable improvements. Of other new sorts put into commerce this year, Standwell, a robust late white kidney, is a seedling from the Vicar of Laleham and Woodstock Kidney, and in addition to having what so many like, a rough, netted skin, certainly has flesh of the finest quality. It proved last year to be of

disease-resisting power and a great cropper. Only one American kind, Vermont Champion, seems to have been put into commerce here this season, and that is a white sort and spoken of highly. It seems evident that the popularity of

The American sorts, once so great, is now decaying, for in the trade the demand for many once famous kinds is now poor—the Potato-growing public, finding that fine new sorts of home rearing are coming in, seem to claim for them a preference. Lady Truscott, certificated at the Crystal Palace in 1881, a capital flat round white kind, is now in commerce, as is also Favourite, likewise a white round, but of which nothing further is yet known. The list of new kinds or varieties put into commerce this season is a small one so far, and it is difficult to make it complete, but if any are fearful that we are in danger of being flooded with new kinds, at least they may take heart for the present year, as the number is few. Of sorts put into commerce last year several have proved to be first-class kinds, and will make popular reputations: of these, Cosmopolitan is one of the best white kidneys in cultivation. Prizetaker, pale red in colour, is of superb table quality, and is a great acquisition to the coloured kidney class. Fifty-fold is a first-rate round kind of white skin, and excellent table quality; and of coloured rounds, one of the very best and handsomest of the section is Reading Russet. In the previous year there was put into commerce under the name of Surprise, a handsome flat white round kind, very like Porter's Excelsior, but larger and of far better table quality. This has since had its name altered to First and Best, and is, without doubt, one of the handsomest and finest show white rounds we have. Queen of the Valley proved last year to be a large, flattish, pink-skinned kind, a great cropper, and producing handsome tubers; its quality is of the true American type, as is that of Adirondack, another coloured American, handsome, and a great cropper. America has given us so many coloured kinds, that it is a relief to find that the only one of that country put into commerce this year has a white skin. Duke of Albany is a white Beauty of Hebron, very early, and a great cropper. Early Cluster, Early Border, Premier, and Victor are white kinds with dwarf tops, admirably suited for pots, frames, or early borders, and are all of capital quality. A. D.

SOWING VEGETABLE SEED UNDER GLASS.

Of late years I have adopted the plan of sowing under glass seeds of many kinds of vegetables that require to be transplanted in preference to the more general practice of sowing on sheltered borders or in the open. For this purpose any old lights or rough frames, to which I have previously alluded, are available, and I know of no better use to put them to. Raising plants in this manner may entail a little extra labour; but, admitting this, it is yet, for several reasons, much the most satisfactory and economical practice. In the first place a much less quantity of seeds than will suffice in the open may be sown, as the little warmth assures germination in the case of many old or imperfectly ripened seeds, which would perish if committed to a cold soil. Then, again, birds and slugs are very destructive among seedlings of the Brassica tribe, and though we may to a certain extent guard against the former by coating the seeds with red lead, or by soaking for a short time in paraffin, it is only partially preventive in the case of birds, and will not affect the slugs in the least. Last season small birds were not so very troublesome; but slugs were simply irresistible, and had we not anticipated them by sowing the seeds under glass, we should have fared badly for plants of various winter vegetables.

Not only did we sow seeds as usual of such kinds as Veitch's Early Forcing, Erfurt Mammoth, Eclipse, and Autumn Giant Cauliflowers; Snow's, Veitch's Autumn, Osborn's White, and Leamington Broccoli; Brussels Sprouts; Ellam's and Reading All-Heart Cabbages; Black-seeded Bath Cos, good strains of Paris White Cos, and Early Paris Market Lettuces, and Parsley under glass; but it proved

absolutely necessary to sow similarly the later kinds of Broccoli, Savoys, and Kales. Twice were these latter sown in the open, but do what we would in the shape of trapping or destroying the slugs, the weather was all in favour of these pests and they cleared all before them. This season slugs give promise of again being very abundant, and though we use quicklime unsparingly and intend keeping a number of young ducks in the garden, as has been our practice in previous years, we shall again sow both early and late varieties under glass.

For the former several shallow hotbeds are formed; these are about 2 feet high at the back and rather less in front. The heating material, being previously well prepared, is soon in a condition to receive the soil, and of this we employ about 6 inches of light sandy mould, obtained by sifting over the heap old potting soil. From this the seedlings can be drawn without much injury to their delicate roots. We have no particular date for sowing, everything depending upon circumstances. Last season the seeds were sown late in January; this year they will be a month later and still be early enough. They are sown broadcast and rather thinly, are pressed into the soil with the back of a spade, and are then lightly covered with more of the fine soil. The soil is generally moist enough, but if dry it is watered through a roset pot prior to sowing the seeds, and this is found sufficient till the seedlings are in rough leaf. Air is freely given to the young seedlings, and on warm days the lights are drawn off. They are gradually hardened off, and as soon as safe in this respect the lights are dispensed with. Early in April the required number are pricked out on a west border in rather light soil and about 4 inches apart each way. By the end of May all the first batch are transplanted to their final position with good balls of soil attached. In this manner they move without flagging greatly, and are, therefore, less liable to be preyed upon by slugs, besides being well established before hot, dry weather may reasonably be anticipated.

A successional sowing is made on a warm border early in March, and in this case the seeds are protected and the soil warmed by the aid of lights supported on bricks. This batch includes Leamington, Cooling's Matchless, Veitch's Spring White, White Cape, and Osborn's Broccoli; Autumn Giant and Erfurt Mammoth Cauliflowers; Little Pixie and Dwarf Elm Savoys; and Kales of sorts. I have no doubt I shall be correct in also adding Gilbert's Chou de Burgley to this and the previous list, as it evidently requires several months to grow it to perfection. The plants in every instance will be pricked out, and later on transplanted when the ground is at liberty or the weather is favourable. Late varieties, such as Cattell's Eclipse, Sutton's Late Queen, Model, Miller's Dwarf Late White, Ledsham's Late White, and Carter's Champion Late White Broccoli are sown at the beginning and again at the end of May. The last sowing of Savoys, such as Dwarf Elm and Drumhead, and Brussels Sprouts which sometimes prove very servicable when planted late, is generally made early in May. I have a decided objection to mixtures, and for this reason find it advisable to sow the above seeds myself, and I take care to properly separate the many sorts that are similar in appearance. Strips of wood are employed for this purpose, but in the case of Cauliflowers and Broccoli in frames, these can be divided by Sprouts, Lettuces, or Cabbages. It is only in comparatively large gardens where it is necessary or rather advisable to sow in frames or hotbeds. Those in charge of smaller places are advised to sow a few seeds of the earliest kinds thinly in pans, and dispose these near the glass in a warm frame, or on the shelf of a house, and otherwise treat the plants resulting as advised in the case of larger sowings. Successional sowings may be made in boxes, these being covered with strips of glass, and set under a warm wall; while the later sowings may be treated similarly or sown on an open border, and, if the season necessitates it, be covered with spare lights or hand-lights. W. J. M.

New way with Potatoes.—I have been a very successful grower of fluke Potatoes, and as my method has a feature of peculiarity in it, I am induced to ask you to give me space for making it publicly known. The peculiarity in my process consists in my using no manure, commonly so called, but placing in the bottom of the trenches in which the Potatoes are planted a mixture of dry coal ashes and recently slaked lime, two-thirds of the former and one-third of the latter, from 4 inches to 6 inches in thickness. In other respects my Potatoes are treated in the ordinary way, unless I may name, as an exception, that I allow more room for growth than most persons I believe do, for I plant not less than 3 feet distant from row to row, and from 20 inches to 2 feet apart in the row. My Potatoes thus planted have produced in each of three successive years a remarkably large crop of excellent flavour, nearly, I may say practically, free from disease. Thus grown, my flukes, too, have not had attached to them the stringy substance which often forms a part of the substance of the fluke. What renders my success the more remarkable is that the soil in which the Potatoes were planted is of a close, clayey nature, unfriendly to the growth of Potatoes when cultivated in the usual manner. The plot of ground planted by me has been the same from year to year, and comprises nearly half-an-acre. I may mention that in the same ground I have planted and treated a few Magnum Bonums in the same way, but this kind of Potato seems to be nearly disease-proof wherever grown; their flavour is poor at all times, but I think it improves when they are grown as I grow the flukes. I have planted flukes in preference to every other kind of Potato, because when they can be had of prime quality, like those I produce, my opinion is they are for the use of the table the most valuable of all the Potato tribe. —G. B. BROCK, *Bryn Syfi, Swansea.*

INDOOR GARDEN.

THE CHRYSANTHEMUM AND ITS CULTURE.

WILL you allow me, an amateur, to supplement "F. W. B.'s" account of the Chrysanthemum by a record of the way in which I grow mine? I am one who considers it to be a gardener's duty to help Nature to do that which she would not otherwise do, and, therefore, I protest against the cramping system of Chrysanthemum culture now in force. I also dislike the practice of removing all but the crown buds. I hold that Nature is capable of doing more than we are aware of, and therefore I allow some of my plants to have their own way, and large plants that will carry, say, a hundred flowers must be more than one year old. I take the best plants after blooming, cut them down, and put them in a cold frame safe from frost and cold winds. If obliged to put them out of the frame before frost has broken up, I carefully protect them. I stop all plants that are likely to grow strong while they are in the pots in which they have bloomed, and about the middle of March, if the weather is favourable, I shift them into their blooming pots, taking care not to stop them after they are thus repotted, and in this way I get strong plants. I may here state that I have a plant which I have grown on in this manner for six successive years, and during the last four it has borne no fewer than three hundred and forty blooms. I have another which I have grown these four years, and last year it had over 200 blooms on it. I find that there are several varieties which succeed well under this treatment; in fact, I believe the most of them would do so; the only drawback I experience is want of room. I feel sure that those who have at command large cold structures, with plenty of light and little heat, might have Chrysanthemums say 7 feet in circumference; such plants, when in full flower, would have a grand appearance. The Chrysanthemum, I find, does not want a large quantity of soil. In order to show this I may state that one of the

plants I have mentioned, a white flowering one, bore eighty blooms one year when repotted, whereas the following year it had 120 blooms on it when not repotted, and the individual blooms were better than in the previous year, plainly showing that Chrysanthemums, like other plants, can be over-potted.

Soil and potting.—I pot my plants in a mixture of good loam, leaf mould, rotten manure, and a little sand; but let me say there is a possibility of growing wood at the expense of flowers, and that although Chrysanthemums are gross feeders they may be fed too much. When that is the case, instead of the wood being ripe and well hardened by autumn, it is anything but that, and so I would say, if any of your readers are inclined to try plants year after year, they must avoid putting them in too large pots. After being put in their blooming pots I allow them to remain without manure water till they have become well rooted; in fact, I believe they would be as well without such help till their buds begin to show themselves, and then give it till the flowers are fully expanded. I do not agree with the plan of withholding manure water as soon as the flowers show colour, as many do; if withheld, then the flowers experience too great a check. Some recommend giving manure water as often as twice a day. I give my plants manure water if they require it every other day. I use guano; but allow me to state that although I use it as a stimulant to all kinds of plants, Peas, Celery, and Roses, as well as Chrysanthemums, I have only used in six years 15s. worth, and we have plants under glass which have been fed with it ranging from 1 foot to 14 feet in height and as much in circumference. At a glance one may see that our Chrysanthemums have not been over-fed. Now as regards the

Flower buds. I take off those which I know will never come to anything, but I never remove a bud that will make a flower. Last year we had blooms over 15 inches in circumference, although the buds were never thinned at all. It is bad practice to take off the buds so much as is done. The secret of having good blooms is well ripened wood and never stopping the plants after they are in their flowering pots. I do not mean to say that those who take nearly all the buds off their plants do not get the finest blooms for the purposes of exhibition; but which is best—about four good blooms on a plant, or a hundred or more? If a fine display is the object in view, a large plant is best; and if economy is studied, it is also best, as it takes up less time and labour than cramping and disbudbing. My mode of growth may, however, not please everybody; but I would like to see the day when those who have the management of our Chrysanthemum exhibitions would discourage the cramping system and favour, as much as possible, natural modes of growth.

JOHN HARDING.

Bedford.

BULBS AFTER HAVING BEEN FORCED.

ALL experienced cultivators know that it is not possible to force such bulbs as Hyacinths and Narcissi in a satisfactory manner after the first year, but that is no reason why they should not receive some attention after they have done flowering, in order to assist them to retain their strength for other uses. Very much of their future value depends upon how they are managed after they have done flowering. Too often they are roughly treated by being brought into the open air from conservatories and other warm houses, and set about in cold, draughty corners during cutting March winds, with very little care as to the state of the soil in which they are growing. I do not assert that even the most painstaking treatment after they have flowered will make them the second year equal to what they were the first, but if well cared for now they will flower the second year fairly well.

The proper treatment after they have done flowering is to give them the shelter of a cold pit or frame or corner in a cool Peach house, where

they can come under the eye sometimes, in order to make sure that they do not suffer from want of water. The right treatment may be described in a few words, viz., keep the roots well supplied with water, and take care that the leaves are not injured in any way, as flowering next year depends mainly on the condition of the leaves while maturing the bulbs. If the leaves are seriously injured or thoughtlessly cut off, the future condition of the bulb will be impaired. In the case of Hyacinths and Narcissi, directly the blossoms have faded the flower-spike should be cut off. If I had my choice in selecting a suitable place in which to ripen off the bulbs, I should select a cold pit or frame in which there was a bed of rich soil about 15 inches from the glass. As the bulbs go out of flower I should cut off the flower-spike, turn the plants out of their pots, and remove the principal part of the drainage. I would then plant them carefully with the ball of earth intact in the bed of soil in the frame; then by careful watering and shading from very bright sunshine, they would soon root into the bed, and in due time ripen a well matured bulb. I have tried various expedients in dealing with Hyacinths after flowering, but I have found none to answer so well as frame treatment. When planted in beds or borders such roots flower the next year in a very satisfactory manner.

J. C. C.

BLINDS FOR PLANT HOUSES.

As this is the time of year when people will (like your correspondent, p. 213) be seeking for information respecting blinds for plant houses, a few words on the subject generally may not be out of place. The chief mistake lies in selecting materials so close in texture that they half shut out the light, which together with heat, moisture, and air, combined with a root-run of suitable soil, is essential to the well-being of plants of most kinds. Everyone who begins to garden seems to have an intuitive knowledge that all of these, except light, must not be stinted if success is to be attained. But amongst many even of those who might be expected to know better the need of all the light we can give to ninety-nine out of a hundred of the plants in cultivation seems not to be fully understood. No further evidence of this is needed than the fact of so many using fixed shading, put on in the spring and let to remain until autumn through the untold number of days when we never see the face of the sun at all, and the many hours, morning and evening, even in bright weather, when every ray of unobstructed light is little enough. Smearing the glass with whitening, lime, or similar substances all tend in the same direction, and though largely employed, are makeshifts to effect that which with so much more advantage to the plants can be done by the use of movable shading. The thickness of the material that is required to a very great extent depends on the position the house stands in; the plants in a house either span-roofed or lean-to that stands full side to the south will bear blinds of a little closer material than if the ends stood north and south, for the obvious reason that in the former position the sun at noon, when most powerful, strikes the glass when the sash-bars or rafters offer the least obstruction to it.

For most things the thin material is best that goes under the name of gauze canvas or scrim, composed of hard-twisted threads like fine wire, not woven close. There is much difference in the quality; the right stuff is all flax, but there is a deal made of half jute or more than half; these last will not wear near so long as the former. A thick inferior canvas composed of uneven, lumpy threads, too closely woven, is often sold as scrim, but although lower in price is much dearer in the end, independent of its shutting out too much light. The blinds should by all means be on the outside of the roof. The way to work such blinds is now pretty well known, but for the information of those who may be unacquainted with it I may mention the best method of arranging them. One side of the blinds must be tacked to a 3-inch wide lath temporarily screwed on up to the ridge of the house, with a

deal roller 2½ inches in diameter, to which the opposite side of the blind must be in like manner tacked; this roller requires to be furnished at one end with a reel, 7 inches or 8 inches in diameter, so as to take a cord that will work it up and down, something like the drop scenes on the stage of a theatre. The roller must be a little longer than the house to admit of the reel running clear of the roof.

In making all blinds of this description it should be borne in mind that the threads of which they are composed that run lengthways, that is, the warp, are much stronger and more durable than the crossway threads, that is, the weft; for this reason, in cutting them out the material should run up from eave to ridge, not lengthways from end to end of the house. This will make a year's difference in the length of time they will last. To fully carry out the intention of movable shading it is needless to say that the blinds should always be rolled up when the sun is not so powerful or directly shining on the glass as to endanger the plants.

T. BAINES.

ROOF HEATING.

I HAVE waited to see if Mr. Cannell himself would reply to "W. C. T.'s" questions (p. 77), and though I doubt not that "Peregrine" is quite able to answer "A. D." if he chooses, I venture for one to refer thereto, as the latter's remarks (p. 198) tend to make confusion worse confounded. "Peregrine" said the principle was that of placing the fire, not the boiler, at the top instead of bottom of a chimney. This is what would be being done if all the pipes were above the body to be heated, and practical experience alike with scientific teaching would quickly show the folly of it, while "A. D." would be one of the first to denounce its practical application at home if his sitting-room fire was above his head. There is no clashing whatever between science and experience at Mr. Cannell's, nor are all preconceived notions (if scientific) set at defiance, but, on the contrary, confirmed. It is more a question of the amount of ventilation or movement of air that may be required in these houses than anything else. Science, like practice, teaches that if an opening is made in the upper part of a room and the air inside is hotter than the outside, the hot air will rush out, while cool air will come tumbling in unless there is an opening below at which the cold air can be drawn in sufficient quantity to let the upper opening be an outlet only. The coldest air lies ordinarily along the floor, and we build walls there to keep out the cold. In winter the cold penetrates the thin glass, causing condensation of the moisture within, and the cold air also falls in at the laps by its own weight to the ground, and so the whole atmosphere becomes about equal. Warm the pipes near the roof only, and no perceptible difference takes place, but warm the lower pipes alone and an upward current is created and must ascend, whether precisely columnar or as a shapeless body is immaterial. That motion is infinitesimal or rapid according to the degree of heat in the pipes and the facility with which cold air is drawn in, whether from laps above or openings below.

If the cold air comes in mostly from above, it will find its way down the sloping roof to the sides and on to the plants, the heated air below the stages, if made close, being drawn out next the path, and rising to the ridge or highest point without benefit to the plants on the stages. If the stages are of open laths, the warm air rises through the openings and among the foliage. Mr. Cannell's stages are, I believe, all close, and if so, and he has no bottom ventilators (the houses joining together without any spaces between), this simple thing alone will show why a 2-inch pipe part way up the roof is of great advantage. The lower 4-inch pipes are, I suppose, near the side walls, and there will be a small space between the edge of the stages and the outer walls. The bottom pipes heat all the air below, setting it in motion, while the hotter roof pipe draws this air up along the walls and across the plants in its endeavours to escape above, which it does, there being sufficient current created to force it out at the ventilators provided

for that purpose. This is all scientific, and what practical experience also proves to be correct. But there are no top ventilators at Mr. Cannell's, I shall be told; this I deny, for what is every lap of the glass but a ventilator, and the most effective ones, as a rule, all the year round in every house. Let Mr. Cannell or anyone else glaze his roofs with one long pane of very thick glass, or putty up all the laps for three months and then report on the Pelargoniums; or let "A. D." place two 4-inch pipes in the roof and none below the stage, "creating motion" with a vengeance by drawing all the cold lower air across the plants, and then watch the results in the case of Primulas. On the other hand, increase the heat in the lower pipes, use open lath stages, and as good results will be obtained as now, especially if there are some openings lower than in the roof.

In "A. D.'s" previous remarks (p. 146) he says it is in "the drying of the air more than in the heating" that success is to be found. This may be so (I am not a cultivator); but is the air really drier? for I believe the amount of moisture in the house will be the same with the same heat, whether from top or bottom pipes. In the steeper pitch, certainly, the moisture will be drawn off more rapidly with the surplus warmth near the ridge. One of the reasons why moist houses for Orchids, &c., are made with a low pitch of roof is, that moisture cannot escape so readily, and it will also help to account for much injury from damp and want of ventilation in vineries with flat roofs. There is less drip where there is top heat, because the glass itself becomes warmed, and so the moisture is not condensed thereon, as it would be with greater heat below and a cold surface above. No erroneous speculations, therefore, are necessary to account for Mr. Cannell's success; but whether he has, or has not, arrived at his practice by scientific calculation, he will succeed only so far as his practice is scientific, for the laws of nature cannot be entirely changed, though often adapted or forced for a time out of their usual mode of application. One word as to the roof pipe being a return pipe; it may seem so, but in practice its water must be hotter than the lower pipes, and therefore it is a flow pipe until it begins to fall from its highest point; if it was a cool return pipe it would have no effect one way or the other on the movement of air in the house.

33, Highgate Road. B. W. WARHURST.

SHELVING, OR STAGES FOR PLANT STOVES.

I SHOULD by no means advise "Eucharis" (p. 213) to use wood for this purpose, for although its first cost is much less than flags or slates, it is immeasurably more costly in the end. I have seen deal of fair quality completely rotten in four or five years in a moist stove. If your correspondent is in a neighbourhood where flags are cheap these will be the best to use, stood on brick piers, allowing an inch cavity between the outer wall and the stage. Slate slabs are neater, but are no more lasting. A strip of iron should be fixed lengthways back and front of the stage, standing up about 2 inches above the surface of the flags to hold the material with which they should be covered, such as sand, fine ashes, or something of a like description that will hold moisture for the plants to stand on. This is of the greatest use to the plants, as it counteracts the dry, ungenial heat that is ever rising from the pipes. Where these side stages are not too wide, say not more than 2 feet, I have used strong roofing slates which may be had in some places above double the thickness of the ordinary kind employed for roofs. These supported on iron strips resting lengthways on the brick piers, and laid so as to over-lap each other, will hold the ashes or sand equally well as the flags or slate-slabs and cost less. Where appearance is an object these side stages can be supported with iron Γ -shaped, one end let in to the outer wall, the other acting as the leg standing on the floor. If there are 9 inches or 1 foot between the top of the hot-water pipes and the under side of such a stage as is here named, it will do; the material

mentioned to go on the top will prevent any ill effects from the heat that rises off the pipes. The less wood used in plant stoves, or other description of houses where heat is employed, the better; and for all kinds of glasshouses, cold or hot, the all but general use of ordinary deal is as great a mistake as could well be committed. Pitch Pine, which costs no more per foot, will last three times as long.

As to the plants for growing in such a house, a fair portion of which will give flowers in the winter, they may consist of *Sericographis Ghiesbreghtii*, *Stephanotis floribunda*, trained on the roof; *Toxicophila Thunbergii*, *Tabernaemontana coronaria* fl.-pl., *Dipladenia boliviensis*, trained on the roof; *Begonia insignis*, *B. fuchsoides*, *B. Ingrami*, *Eschynanthus grandiflorus*, *E. splendens*, *Allamanda Chelonii*, trained on the roof; *Anthurium Scherzerianum*, *A. Andreanum*, *Aphelandra aurantiaca* Roezli, *Hoya bella*, *Bougainvillea glabra*, *Euphorbia jacquiniiflora*, *Gardenia intermedia*, *G. citriodora*, *Eranthemum pulchellum*, *Gesneras*, *Gloxinias*, *Achimenes*, *Jasminum gracillimum*, *Plumbago rosea*, *Poinsettia pulcherrima*, *Scutellaria Mocciniana*, *Clerodendron fragrans*, *Eucharis amazonica*, and *E. candida*. Many others there are that will succeed in an ordinary stove, but for the quantity of flowers they will yield, and their suitability for cutting, the above selection may be relied on. T. BAINES.

STEVENSONIA GRANDIFOLIA.

IN THE GARDEN of the 24th instant an interesting account is given of the Herrenhausen Botanic Garden and Palm house, and special notice is taken of some of its inmates, one of which is *Stevensonia grandifolia*. As the account of this Palm is not quite correct, I submit the following extract from my "History of the Palms grown at Kew from the origin of the garden in 1760 to the year of my retirement, 1864": "*Stevensonia grandifolia* was discovered on Round Island, one of the Seychelles group, by Mr. J. Duncan, director of the Mauritius Botanic Gardens. It was growing in wet, marshy places. In 1855 he sent three seedling plants of it to Kew under the name of *Stevensonia grandifolia*, in compliment to the then Governor of the Mauritius, who favoured his botanical excursions to the different islands. In 1857 Mr. Wendland, director of the Royal Gardens, Herrenhausen, visited Kew, and was anxious to obtain a plant of this rare Palm. I had marked one of the plants for him, and on taking him to the nursery pit to show it to him, the plant was not to be found. This led to a strict inquiry, and it was discovered that it had been stolen by a German gardener then employed in the Garden, and sent by him to a nurseryman in Belgium. It afterwards appeared in a private garden at Berlin, and some years ago I heard that it had grown to be a fine plant. Mr. Wendland, being a writer on Palms, set aside the name *Stevensonia* and substituted for it *Pheniceophorium*, which means the stolen Palm, and which, I consider, he was not justified in doing; moreover, it was a very undignified name to give such a noble Palm, founded on such an ignoble circumstance. In 1864 the leaves of the other two plants had attained a height of 8 feet and a breadth of 4 feet, nearly entire, strong and rigid, having every appearance of, in a few years, becoming conspicuous plants." In the autumn of 1864 I, however, learned that through some untoward event they had both died. J. SMITH (ex-Curator).

Royal Gardens, Kew.

Saundersonia aurantiaca.—"B.'s" method of culture (p. 180) is certainly rational, but, judging from my own experience, I should think that anyone could grow the plant if they had but a frame to give it a little protection. The bulbs should be potted in March—six in a comparatively small pot, provided with a bit of drainage consisting of small pieces of charcoal. After well watering, the pots should be placed in the frame and kept airy and moderately moist. The bulbs will push, according to the weather, in the course

of from 14 days to 3 weeks and will have made nice growth towards the end of April, when they should be carefully taken out of the pot, leaving the ball of earth unbroken, and plunged in somewhat loose soil at the foot of a south wall. They will soon grow into fine plants and flower well. In autumn, when the leaves begin to turn yellow they ought to be protected from excess of moisture; the ripe roots should be taken up by October and stored in dry earth in some cool, airy, frost-free place. —MAX LEICHTLIN, *Baden-Baden*.

Rare Begonias.—"M. P. F." (p. 191) will most likely find the *Begonias* desired procurable either at Messrs. Veitch's or Mr. Bull's nurseries. The demand for such kinds as he names is so small as to make mention of them in catalogues uncalled for. The species alluded to are useful winter-flowering plants with noble foliage. At Kew there are many fine species of *Begonia* with which one rarely meets elsewhere, but which are well worthy of cultivation generally. I have made a few notes on some of the more desirable of these, and intend to say a word or two on the subject shortly.—B.

Dipladenias.—In answer to your correspondent allow me to say that *Dipladenias* when done flowering should be put into a cool house for about two months to rest in a temperature of about 45°. Give them a very little water; after they have had a good rest bring them into the stove to make wood. Syringe them well to induce them to break. After the shoots are about 3 inches or 4 inches long, train them on strings up to the roof. Thus treated, they should show flower at every fourth joint. When in flower, as much light and sunshine as possible should be admitted; no shading whatever should be given.—THOS. WM. BIRKENSHAW, *Christ Church, Doncaster*.

Blue Paris Daisy.—Many have bought this thinking they had got something new, but when unpacked it has proved to be their old friend *Agathæ cœlestis*, a pretty plant enough, but no Paris Daisy. I have no wish to decry the merits of this or any other good old plant, and am doing my best to popularise and bring back some of the nearly forgotten plants of my boyhood; but let us have things under their generally accepted names. If people have bought the blue Paris Daisy as something new, and have found on arrival that they have only been adding to their stock a plant of which they already had plenty, is it to be wondered at if they feel disappointed?—J. G., *Hants*.

A new Bomarea.—At the meeting of the National and Central Horticultural Society of France on the 25th of January last M. Edouard André showed for the first time in flower a new variety of this handsome family of trailing *Amaryllids* discovered by him in 1876 in New Grenada, and to which he had given the name of *Bomarea Kalbreyeri*. From the description of this plant given in the last number of the *Paris Revue Horticole*, in which periodical a coloured portrait of it will shortly be given, it most closely resembles the beautiful *B. conferta* recently figured in one of the coloured plates of THE GARDEN. When the coloured plate of *B. Kalbreyeri* appears we shall be able to compare them and see in what points they differ, as the flowers of the new-comer are thus far only described as of a very fine red colour.—W. E. G.

Juncus zebrinus.—I wonder how many of the readers of THE GARDEN who possess this plant have made the same mistake as I did with regard to its culture. To me most plants have a something in their appearance which suggests either cool or warm or intermediate treatment and plenty of water, or not much. Gardening instinct, perhaps some would call it, and therefore irrational, or, at most, a rather unsafe rule to be guided by. I looked upon this handsome Rush as a delicate plant that would like warmth and not too much water, but found that treated as such it was by no means happy, but began to dwindle away. A friend suggested that as it was a Rush it

might like plenty of water, and being also a Japanese plant, out-of-door treatment in summer might prove most agreeable to it. I acted on this suggestion, and found my plants soon showed signs of improvement under the altered conditions, so that the treatment I would now recommend for this plant is an open, rich soil, and placed with its pot half submerged in water either in an outdoor tank or a pan, with plenty of sunshine. During winter it should be protected from frost, but never dried off, not even taken out of the water. Under this treatment my plant is thriving, and I hope to have a fine specimen this year.—B.

Trichinium Manglesi.—Last year our plants of this were a great success, flowering freely and bearing along with the flowers fine healthy leaves. I attribute this to the effects of cow manure, of which in a fresh dried state I used one part to one of loam, with a good sprinkling of sand—a strong mixture, some will say, for a plant which Nature planted in the dry, sandy, sun-scorched deserts of Australia. "The proof of the pudding, &c.," applies in this case, and I would recommend growers of the *Trichinium* to use cow manure if they wish to make success certain. I have just repotted my plants, and found on shaking them out an abundance of healthy thick roots, some of which were taken off and cut up into lengths of 1 inch for cuttings. These will give us a large stock.—B.

TREES AND SHRUBS.

TRANSPLANTING TREES AND SHRUBS.

IN order to do this work well one requires an intimate knowledge of the special and distinctive characters of trees and shrubs as regards habit, size, colour, height, &c., and it is necessary, moreover, that soil and situation also be taken into consideration. My purpose now, however, is not so much to describe what should be planted in this or that position as to direct attention to the best methods of doing the work and the proper season at which it should be done. In all kinds of ordinary soils generally the best time for planting is considered to be, for deciduous trees and shrubs, the autumn and early spring months, and for evergreen trees and shrubs autumn, winter, and spring. Summer planting is not carried out to any great extent, neither is it considered judicious. No doubt there are many potent reasons why this should be so. One has an objection to see the pleasure grounds in a state of confusion consequent upon planting operations at that time of the year; there is also the liability of the roots becoming dried in transit, as, for instance, from a nursery, and the risk attendant upon delay, the scarcity of water, &c.; with care, however, these are preventable causes. Let us first consider the question of

Season. I am of opinion that in some soils transplanting may be done successfully throughout the whole year; in others autumn, winter, and spring are the best periods; whilst in the summer months and in certain soils the operation is more successful than at any other season of the year. The soils in which transplanting may be successfully carried on at all times of the year are those which are black, rich, and friable and rich deep mellow loams. Those which are preferable for autumn, winter, and spring planting are those which are warm, light, gravelly, sandy, and well drained, whilst in heavy wet clay the maximum of success will be attained in summer. This will, on reflection, I think, appear to be perfectly reasonable and natural, the desideratum being to maintain the roots in a healthy condition, heal up the mutilated parts and induce new growth as soon as possible. The conditions of soils and seasons mentioned above will materially tend to produce such results. The following are the results of experience of planting in various soils and at different periods of the year. Conifers, including *Abies canadensis*, *Douglasi*, *Cedrus Deodara*, *Liliani*, *atlantica*, *Cupressus Lawsoniana*, *Picea nobilis*, *Nordmanniana*, *Pinus austriaca*, *sylvestris*,

and *Thuja*s, in rich black soils and deep mellow loams.—Summer, 2 per cent. died; autumn, winter, and spring, 1 per cent. died. In sandy, gravelly, and light warm soils.—Summer, 28 per cent. died; autumn, winter, and spring, 6 per cent. died. In heavy and wet clays.—Summer, none died; autumn, winter, and spring, 30 per cent. died. It will thus be seen that in heavy and wet clays summer planting was highly successful. The trees transplanted were from 8 feet to 20 feet high, and many had made growth from 4 inches to 12 inches in length; every one was moved with balls of earth varying from a quarter to one ton in weight; an average of a cartload of good soil was put round the roots of each, all were mulched with well rotted manure, and an occasional soaking of water given. These trees showed no signs of suffering in either colour or quantity of foliage; indeed, many benefited by the change, and all are in a most promising condition. The reason of success is perhaps not far to seek, the earth being in a warm and moist state, and therefore in a condition most conducive to root formation and nourishment; dull, warm weather is best suited to the operation.

Planting in winter, it will be remarked, was a partial failure, and should in all cases be avoided wherever it is desired to move valuable trees; in this instance the soil being cold and wet was therefore not suited to produce new roots. The feeding points rotted, the roots decayed, and no new roots were formed; the whole became attacked as by a contagious disease, and total inaction took place. This was followed by the stems becoming affected, rendering the sap putrid, in which state trees are soon preyed upon by insects, causing certain death. The cause of all this is coldness, excessive moisture, the imperviousness of the soil to air and the dormant state of the sap, which soon becomes incapable of performing its functions. Well drained, sandy, gravelly, and light soils are best suited for planting in autumn, winter, and spring, for the very good reason that they are warmer, better aerated, and not liable to become excessively dry as in summer. These soils contain but a small percentage of vegetable constituents and without the aid of moisture in moderate quantities are incapable of producing the necessary nourishment for the formation of rootlets, and consequently are unable to maintain the trees in a growing condition. In summer these soils are too hot and dry for the purpose of transplanting; the roots wither and perish, the foliage becomes deteriorated, a general disorganisation takes place, and even should the trees live, they take some years before they regain their normal condition and become thoroughly re-established. Soils of this description are unsuitable to transplant from, the roots being generally less fibrous, and by reason of their want of adhesiveness it is almost impossible to maintain a ball of earth intact, which is so necessary for success in transplanting trees. I am acquainted with no soils where mulching is so absolutely essential as with these; indeed, periodical mulching is necessary in order to maintain healthy trees and the foliage of good colour; mulching will likewise maintain the necessary degree of moisture.

In rich black soils and mellow loams the operation of transplanting may be carried on with success at all times of the year, assuming that ordinary care is taken in respect of drainage in winter and watering in summer; at other times the work may be done with an impunity almost amounting to carelessness. These soils contain the necessary constituents in the largest quantity and best possible condition for the food of trees; they are never excessively hot or dry, cold or wet, and are therefore practically in exactly the right condition—that which is most favourable for the formation of healthy roots and the supply of the best food necessary for their maintenance. Trees move well from such soils; the roots are usually more fibrous, and the earth clings tightly to them. Mulching is not absolutely necessary; nevertheless trees are benefited thereby, especially the first year after transplanting.

Shrubs.—With regard to shrubs, whether evergreen or deciduous, the difficulty is by no means so great as the transplanting of trees, except when they are very large, in which case the above remarks apply equally to them. The majority of shrubs are very fibrous rooted, and, therefore, in the best possible condition for transplantation, being much more tenacious of life than trees. Many of them, too, have a tendency to make new roots from the stem in the manner of cuttings. The necessity for large quantities of sap is not so great as with trees; there is no specially leading shoot to maintain, without which trees often lose their conformation, and are sometimes useless for the purpose for which they are intended, as, for instance, let us suppose an *Araucaria* without a leader. There are, however, several considerations which are necessary to be taken into account in transplanting shrubs. Thus, it would not be wise to transplant such shrubs as *Rhododendrons* and others of that class, which form their flower-buds at the point of a young shoot until they are perfectly ripened. Such a course would, in all probability, result in sacrificing the bloom for the ensuing season. Neither would it be judicious to move during the summer such shrubs as have tender and attenuated foliage, nor those with long, flexible, herbaceous shoots of very weak texture. We have instances of these in the sometimes tender shoots of the *Portugal Laurel* and the long ones of the *Tamarix*. The ordinary result of moving these in summer is that their shoots become blackened by heat, and, as a consequence, are unsightly. Most of those shrubs with strong ligneous shoots and coriaceous foliage move well at this season. Instances of these are some of the *Privets*, *Berberis*, and *Holly*. Shrubs of this class which generally ripen their foliage quickly and well and become, for the time being, deciduous are sure to succeed, throwing out strong shoots in the autumn. This is especially the case with the *Holly*, which often loses the whole of its foliage—a sure sign that new roots are being formed and that the new growth will be strong and healthy. Another important consideration is the time of flowering. Many shrubs which flower in early spring may be safely moved in summer, whilst it is better to move those which flower late in spring, summer, or autumn in winter and spring, that is, move as soon as reasonable after flowering and as long before the next blooming period as practical; by so doing the plants become thoroughly established before the strain of the flowering season comes upon them, and, be it remembered, this will very much enhance the blooms. Amongst the first may be mentioned *Daphnes*, *Ledums*, *Forsythias*, *Ribes*, and *Berberis*. The latter class are so numerous as not to need mentioning. Shrubs are sometimes "shy" of flowering; these should be moved at once without considering the season in order to induce them to make totally new growth. Under these circumstances they seldom fail to produce flowers. The causes which operate in preventing shrubs from flowering are that they may be soil-bound, or even in generally well drained soils they may have water at the roots, arising from an under-current; their roots may have decayed without, whilst those within may be struggling for moisture and nourishment, in which case they should be root pruned and thoroughly shaken out before transplanting. A cold clay under good soil will sometimes have the same effect, the remedy for which is deep trenching, lifting the shrubs, and cutting away the lower roots.

Soils for shrubs.—With respect to soils, shrubs generally speak are not particular; they will thrive in all kinds provided they are open, free from stagnant water, and have a moderate amount of nourishment in them. True, it is that some varieties grow luxuriantly in light and sandy soils, whilst others thrive best in peat and black vegetable deposits, and so forth. This, however, does not in a general sense apply to the general collection. Types of the first are the smaller *Conifers*, *Heaths*, and *Hollies*, whilst of the second the types are *Rhododendrons*, *Kalmias*, and nearly all American plants, many of these will also do well in rich loams. Hot, dry soils are

the most injurious, by reason of the surface roots which many vigorous shrubs make becoming exposed to heat and drought. This is especially the cause with Laurels, Lilacs, Privets, and Spireas, as anyone who has used the fork or spade amongst shrubberies cannot have failed to have noticed—a most reprehensible practice, by the way, except in the vicinity of populous towns, where the surface of the ground becomes coated with a substance of an oily, sooty nature impervious to air. Liberal mulchings and an occasional soaking of water are the best remedies for such soils; dressing with road drift and vegetable soil is also extremely useful. Cold, wet, and heavy clays are most benefited by deep draining and trenching. Of all soils these are perhaps the most unpropitious and troublesome. For complete success constant dressings of light and gritty materials are absolutely necessary. No opportunity should be lost, which in country places is frequent enough, of gathering up all the scrapings and cuttings from the public roads, first giving a dressing round the plants, and ultimately covering the whole ground. In such soils deep planting should be specially avoided, air being essential for the roots to perform their functions properly. Occasional mulching is also beneficial, and should invariably be put on in summer, when the surface of the ground is liable to become hard. Winter is not so suitable for the purpose, as the drier and more airy the surface is the better for the plants.

Rich black soils and mellow loams are best for all ordinary purposes, and with the addition of peat and sand may be made suitable for every known tree or shrub. Planting in such soils is most simple, as the most careless planter will generally meet with success. Should soils of this description become impoverished from any cause, as, for instance, the rapid and luxuriant growth of shrubs, or, in consequence of their vicinity to large trees and hedgerows, the most desirable kinds of surface dressing are well-rotted manure and leaf-mould. In these soils the least disturbance at the roots the better it will be for the shrubs. If the ground is properly trenched before planting, no further care will be necessary in the majority of instances for very many years, except the keeping down of weeds for the first two or three years. Although the practice of pruning shrubs indiscriminately is most injudicious and destroys their distinctive characters and individuality, in rich soils the pruning knife may in some cases be used freely; this would be the case with shrubs which are desired to produce the maximum quantity of flowers, and which would produce an abundance of foliage only unless they were pruned and thinned out. Overcrowding in rich soils should be especially avoided, being both injurious and unnecessary. Planting of nursery stuff should be done as expeditiously as possible after being received, and the same rule applies when transplanting. The practice of laying in by the heels, as it is termed, and allowing trees and shrubs to remain so for any length of time, is not advisable, the effect being that they are compelled to make new roots a second time when once would be more advantageous to them. It is not desirable to plant two or three shrubs together in order to make a mass at once, one well developed shrub being in every way better than two or more startlings.

E. D.

Mistletoe Oaks.—I note in THE GARDEN (p. 157) allusion made to a Mistletoe Oak two miles from Cheltenham, but in what direction from that town we are not informed. There used, however, to be a Mistletoe Oak on the Charlton Park estate, which is only a mile from Cheltenham on the Bath Road. In and around Cheltenham Mistletoe is abundant in Apple orchards, and it is also frequently found on the Black Italian Poplar. One instance I know in which two fine bunches are located on a handsome Sycamore, a tree, so far as my own experience goes, on which it is seldom found. I also know an instance where a solitary bunch is to be found on the Medlar. On the Whitethorn it is frequently found, and I once enjoyed the sight of a charming bunch of it

associated with the scarlet berries of that Thorn. Mistletoe is readily increased by rubbing the berries to and fro on the places which they are intended to occupy. First break the skin, and after that, owing to the glutinous matter encompassing the seeds, they may readily be fixed. Be careful, however, that they be not too much exposed, as they are liable to be washed from their positions by heavy rains.—E. JENKINS.

The Chili Pine.—I have sent specimens of seed cones that have this winter appeared for the first time upon a very large and beautiful *Araucaria imbricata* growing in the gardens at Ballynetray, Co. Waterford, the residence of the Hon. Charles and Mrs. More Smyth. This tree was planted where it now stands about fifty years ago, and the following are its dimensions just taken, viz., height, 65 feet 6 inches; circumference, 75 feet 8 inches; length of branches from trunk, 17 feet; girth of trunk at 2 feet from the ground, 6 feet. This *Araucaria* is most regular in shape and richly furnished with long and graceful branches sweeping down to the ground. The singular looking seed cones which appeared last November grow in clusters of two or three on the ends of the branches and shoots. There are, therefore, some hundreds of them on the tree and they add much to its unique appearance. For many years this *Araucaria* has been the admiration of all beholders from its noble size and beautiful form.—PUZZLE MONKEY.

A new hybrid Thorn (*Cratægus Carrièrei*).—The first number of the *Revue Horticole* for March gives a beautifully and delicately executed plate of the above named charming addition to our hardy shrubberies, which is now being sent out by the well-known French nurseryman, M. Baltet, of Troyes. It was raised by M. E. A. Carrière, when head of the propagating department of the Paris Museum of Natural History, from a seed of *Cratægus mexicana*, and is said to be extremely hardy, the severe winter of 1879-80 having left it entirely uninjured. It is valuable for its handsome bunches of large white flowers with conspicuous red-tipped anthers, produced freely about the middle of May, for the bronzy copper red tints assumed by its foliage in autumn, and for its handsome and brilliantly coloured berries resembling in colour those of the common *Arbutus*, but of a somewhat brighter hue. All these points are clearly set forth in the plate, half of which was painted in spring and half in autumn.—W. E. G.

QUESTIONS.

Cost of plant carriage.—Can anyone give me any idea of the cost of carriage from Baden-Baden for plants too large to come by post? Has anyone had plants from there by the Continental Parcels Express? Any information will greatly oblige.—MARCH.

Apples shrivelling.—Will some of your readers kindly give me their opinion on the following point? All my Blenheim Orange Apples of last year began to shrivel about Christmas. It could not have been that they were gathered too early, for nearly a third of the crop had fallen before I gathered the rest. These were hand gathered and placed at once in an airy cellar. Can anyone suggest a reason for their shrivelling? and could it have been that they were left too long on the trees?—E.

Unpruned Pear trees.—Early in January last I planted several pyramid Pear trees. As they were late put in, I thought it better not to prune them. They consequently have strong shoots of last year's growth, some of them several feet in length. These are in some cases (especially in that of Duchesse d'Angoulême) furnished with flower-buds at the extremities. What, let me ask of your readers, is the right way in which to treat these trees?—EWELENE.

* * * Our readers will greatly oblige by replying, so far as their knowledge and observation permit, to these questions. The title of each query answered should be prefixed to each answer, and replies will be printed in the department of the paper under which the subject falls. The questions that arise and must be solved are so many in these days, that it is only by a general interchange of ideas and experiences among practical men that we can hope to answer them satisfactorily.

PLANTS IN FLOWER.

THE FRAGRANT HONEYSUCKLES now in bloom are *Lonicera fragrantissima* and *Standishi*, distinct species, though in aspect somewhat similar. Both flower before the new leaves unfold, and both have small clusters of deliciously fragrant white blossoms produced in pairs on slender stalks. Neither are very showy, but for the sake of their sweet scent they are worth growing in the garden, especially if a small space against the walls of the house can be afforded them, though perfectly hardy enough to do without protection. Both are now in full bloom with Mr. Joseph Stevens at Byfleet, where we saw them a few days since.

RHODODENDRON PRÆCOX SUPERBUM is an extremely handsome hardy shrub, the more valuable on account of its flowering so profusely and so early. It has flowers 2 inches across, and the colour, a soft mauve, is very telling *en masse*. In each of Mr. Wilson's gardens at Weybridge it has for some weeks past been a beautiful object, so attractive when other flowers are scarce. Those who desire a pretty early shrub should make a note of this. Among other shrubs in flower in this garden are *Erica codonodes*, alluded to in THE GARDEN last week. Here it reaches 4 feet in height, and the long slender branches are covered with myriads of tiny blossoms. It evidently likes a little shelter. *Erica carnea*, now pretty common, is also attractive here.

SPIRÆA THUNBERGI.—The most elegant shrub now in flower in Mr. Stevens' shrub garden at Byfleet is this neat little Japanese species. It grows about a yard high, is very twiggy and spreads widely. Each twig is now furnished with numerous tiny flowers as white as snow, and they are accompanied by tender green leaves, which unfold about the same time as the flower-buds. Such an attractive shrub as this, flowering so long before its congeners, is worth knowing. It is a free grower in good soil, but hates being stuck in a thick mixture of shrubs. If given a good open place it will be a pleasing object in early spring. Some grow it well in pots under glass, where it blooms twice as freely as out-of-doors, and comes much earlier.

THE PRIMROSES in the Oakwood Garden, Wisley, are now a sight worth a long journey to see. For some years Mr. G. F. Wilson has turned his attention to raising and improving the Primrose, but it was not till he began gardening on his new ground at Wisley that he carried it out so extensively. His plan is to raise seedlings on a large scale and then select from them the finest, and so by these successive selections he has obtained an extremely fine strain. The seeds from the finest sorts are sown broadcast in beds of two or three square yards, and invariably the seedlings come up thick enough to cover the whole space. When in flower the best are singled out and planted in special beds. The seed saved from this selection is again sown as before, assortment made, and so on year after year, the result being the present richly coloured and large flowered varieties. The greatest break as regards colour is the blue variety named Scott Wilson, which was shown and certificated a few years ago. This is the nearest approach to a true blue yet obtained, and probably the slightly purple shade of the blue will eventually be removed. It is a beautiful flower, different from all the Primroses we know. As in the case of other fine varieties, it does not come true from seed, though some singularly fine seedlings have been obtained from it, but none exactly like it. Hence it has to be propagated by division, and Mr. Paul, of Waltham Cross, who possesses the stock, is, we observed the other day, making good progress in its propagation. Another fine variety is Hermann Wilson. It is quite different from the preceding, and is remarkable for large symmetrical flowers of a peculiarly rich velvety crimson, shaded with a paler tint. The bright golden centre is a fine contrast to the dark colour. The unnamed seedlings also include some striking kinds, which probably will be considered good enough to perpetuate. The strain of yellow

flowered sorts is an equally fine one, the shades varying from an intense yellow to pure white. Large size in the pip, clearness of colour, and a symmetrical, even-edged flower are the points aimed at in selection, and perfection seems to be well-nigh attained. A fine sight is a long belt of yellow sorts planted in a border skirting a hedge of the Myrobalan Cherry, which by the way is a capital hedge shrub. Mr. Wilson distinguished the Primroses of the Polyanthus type by the name of Bunch Primroses—a very good name. No less remarkable than the coloured Primroses is the collection of *Primula denticulata* and its endless varieties. This may be seen by the thousand here, and all being of seedling origin there is a remarkable diversity of colour in the flowers, there being every intermediate shade from a deep purple to white. Those who see such an assemblage of seedlings as here would hesitate giving specific rank to such forms of *P. denticulata* as *cashmeriana*, *pulcherrima*, and the like, for their counterparts may be singled out of a bed of seedlings of *P. denticulata*.

HARDY CYCLAMENS.—There could scarcely be anything more charming in the way of hardy plants than these sturdy little gems, of which some are now in full beauty of flower. The finest display we have ever seen of *C. Atkinsi*, *vernum*, and *Coum* is in Messrs. Barr & Son's grounds at Tooting. Here these kinds may be seen by the hundred, each plant being furnished with numerous tiny flowers. In *Atkinsi* they are white with a purple mouth, in the variety *roscum* a clear rose, and in *rubrum* a rich reddish crimson. The varieties of *C. Coum* are of similar colours. The difference between these two kinds may be seen at a glance in the foliage. In *C. Coum* the leaves are a deep green, while those of *Atkinsi* are marked with a silvery zone. This collection is grown in pots and protected in a cold frame, for which the plants seem grateful. They are, however, perfectly hardy, and during the week we have seen some fine tufts of them flowering beautifully in the open, notably in Mr. Wilson's garden at Heatherbank, Weybridge, where some are in an ordinary peaty border, others nestling in sheltered nooks at the base of a rookery, where they have been planted for years. No doubt such a position is best for the plants, which incur no trouble, save protecting them from the attacks of vermin.

NEW ZEALAND CLEMATIS.—Next to Camellias this beautiful climbing plant is the chief attraction in Mr. W. Paul's nursery at Waltham Cross. It is certainly lovely, and only needs to be seen to be appreciated. Its handsome shining green foliage contrasts effectively with the large, starry white blossoms, borne in abundance in clusters all along the young shoots. The flowers measure nearly 3 inches across, and so plentiful, that the plant is literally a sheet of white. There are two forms of this plant, and both may be seen here in flower. The typical *C. indivisa* is at once recognised by the leaflets having their edges quite entire, while the leaflets of the variety *lobata* have their edges deeply incised, a marked and invariable distinction. The name *lobata* is often attached to the type, as the variety is much the rarest. There seems to be not much difference in the size or number of the blooms. No one need hesitate to plant such a beautiful plant as this in a cool conservatory, and the fact that it habitually flowers in the early part of the year renders it all the more valuable. It seems to be somewhat partial to a shady position; on the other hand, we have seen fine specimens of it grown in full light. In Mr. Paul's nursery it is grown admirably in pots in a cool, shady greenhouse trained to upright stakes. It looks best when adorning a rafter of a house or hiding an upright pillar.

THE GLORY OF THE SNOW, as *Chionodoxa Lucilæ* is called, may now be seen in perfection in Mr. Ware's nursery at Tottenham. Here it fills spacious beds containing thousands of plants all in bloom, and their effect, as may be imagined, is extremely beautiful. No hardy flower of spring possesses such a glowing blue colour, and the white centres of the flowers add greatly to their beauty. Now that this charming bulbous plant can be pro-

cured at a cheap rate, there is no reason why it should not adorn every garden. It was figured in colour in THE GARDEN, Vol. XVIII., p. 12, and also the white variety of it, which is extremely scarce.]

CHRYSANTHEMUM CRY KANG.—Some excellent blooms of this Japanese variety are sent us by Mr. Wilson, from Longford Hall, Newark, who considers it a valuable late Chrysanthemum. The flowers are large, the florets long and narrow, collected in shaggy heads, and the colour is deep rose-purple, paler towards the tips. The specimens sent have four and five flowers on a stem.

FORTUNE'S YELLOW ROSE.—Some excellent blooms of this beautiful Rose have been sent to us by Mr. McClure, gardener at Hartley Grange, Winchfield, who says, "Those who do not grow Fortune's Rose deprive themselves of a great treat at this time of the year," and assuredly he is right; it is a charming Rose, different from any other with which we are acquainted. The flowers sent are three parts expanded and good in shape. The outer petals are a sort of tawny yellow, while the inner are flesh-coloured. It is, in short, a flower much to be desired, and, as Mr. McClure says, not half enough known, though an old introduction. Perhaps Mr. McClure will kindly tell us how he treats this Rose in order to get it into flower so early.

SCILLA TAURICA is indisputably the finest of all the vernal Squills, not even excepting the popular *S. sibirica*. It is no doubt a variety of *S. bifolia*, but it is larger and more robust than the finest variety of that Squill. The bulb is as large as a pigeon's egg, and the whole plant when well grown is just about a foot high. Like *S. bifolia*, the flowers are produced in pairs, but are longer and wider. The flower-spike carries on the average about fifteen flowers, each of which is three-quarters of an inch across and of a rich cœrulean blue. The reddish stalk is also a well marked character of this variety. There are two or three forms of it, but all are beautiful. Some remarkably fine specimens of it are now in full beauty in the Hale Farm Nursery, Tottenham, but the finest form as regards richness of colour we have yet seen was in Mr. Wilson's garden at Oakwood, Wisley. The tint of the blooms of these plants was intensely deep, but probably it could be accounted for by the clear, pure atmosphere there. One great point in the Taurian Squill is that it can be easily grown, while *S. bifolia* often fails.

PLANTS IN FLOWER AT BELGROVE.—We learn from Mr. Gumbleton that he has now blooming for the second time in his greenhouse, the handsome *Hæmanthus insignis* var. *superbus* from the Cape, differing from *H. insignis*, as figured in the *Botanical Magazine*, 1879, tab. 4745, in having dull red instead of green involucre, which are also much shorter and less developed, and in the brighter orange of its stamens with yellow anthers, in which the beauty of the flower consists. It is a very handsome variety. He states that he shall also bloom soon for the first time satisfactorily the blue-flowered *Lachenalia*, *L. atropurpurea*, which did not grow at all last year, though potted as usual, the bulb remaining quite dormant, apparently taking a rest. It is now, however, sending up a fine stout bloom spike. Mr. Gumbleton states that he had this very rare variety from Messrs. Henderson, of Pine-apple Nursery. The pretty little miniature *Narcissus juncifolius* is also now nicely in flower at Belgrove in a pot in the greenhouse, fifteen of sixteen spikes (three or four of which bear two flowers each) being borne by a dozen bulbs, which apparently like being taken out of earth and kept quite dry in a box during the summer and autumn months, and being re-potted about November, like *N. Bulbocodium*.

Prizes for early Peas.—I take much interest in Pea culture, and have tried myself both frame and outdoor culture on a warm border, and found the difference in the time of arriving at maturity so little as to make the growing of Peas in sods in frames not worth the trouble and

time involved. I want to ask (*vide* p. 192) what is the best test constituting an early Pea. Can competitors grow them how they like? or must they be grown in the open ground? I am trying an experiment this season with small quantities of Earliest of All and Earlier than the Earliest, grown both ways as above stated, and shall tell you the result later on.—W. J. M., *Clonmel*.

Soil for Anemones.—So far as my observation goes garden Anemones succeed best in comparatively light well drained soils. They are left in such soils all the year round, and seldom receive any attention beyond giving them a mulching of some kind. I have seen them flourishing in this neighbourhood by the sides of walls and houses in all aspects except north ones, and in open situations as well, all being alike thriving and flowering remarkably well. In some cases here the Anemone ground is covered during summer with ordinary bedding plants, such as *Pelargoniums*, which before autumn meet and cover the ground. Yet these do not injure the Anemones. The soil in this neighbourhood is generally black and comparatively open in texture, with a good admixture of stones in it, and it rests on gravel or sand. With us the case is different; we have made several attempts at establishing them, but hitherto without any good results, although, as we suppose, we have given them the best situation in the garden, viz., a comparatively high terrace on the south-west side of the mansion. Our soil, a strong rich loam resting on clay, seldom suffers from drought.—C. W., *Clarendon*.

Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ROSE GARDEN.

THE STORM AMONG THE ROSES.

WHATEVER may follow afterwards, the 6th and 7th of March will long be remembered among rosarians for their harshness and severity. The cold came with but little warning. Monday, the 5th, was almost summerlike in its sunny warmth, though in the shade there seemed a dash of iciness in the air. Next morning dawned with 7° of frost and a nor-easter of tremendous force that threatened to blast every green leaflet on Roses or other plants, and in fact it has done so in exposed situations. We had just finished pruning our Perpetuals, and had begun to uncover and prune our Teas, because the young shoots were boldly peering through the protections. The wind made short work with most of the protection left. It blew with such force against some of our Tea Roses on walls as to sweep off large Spruce boughs as if they had been straws, and for some hours yesterday it was hard work to stand for half an hour against the wind and snow and hailstorms that the Roses have had to endure for the last forty-eight hours. It is too early to write of results. Had I written on the 5th, I would have said that never had I seen Hybrid Perpetual and Tea Roses look better. They were rather forward for the season, but had a strength of bud and a regularity and number of good breaks seldom or never seen in March. Possibly even now the base buds may endure all this terrible harshness and hardness of weather and yet yield fine blooms. But this is somewhat doubtful, for I have observed where Rose buds are not absolutely killed by frost, the effects of it may often be met with in ill-formed and inferior blooms. Buds bitten through their hearts in embryo are mostly injured for life. Much, of course, depends on the stage at which they are injured. The more advanced are not only the more liable to damage, but it is also the more pronounced. Hence it is to be feared there will be a redundancy of inferior Rose blooms during the year. Fortunately, the present severities may not greatly affect the autumnal harvests of beauty; and yet, on the other hand, they may. If these exceptionally harsh winds and deep stinging frosts have seriously crippled the strength and impaired the health of our Roses, as is all too probable, they will hardly sufficiently recover to yield a good autumnal bloom, nor to recoup their vigour before winter.

Not a few of the sudden deaths among Roses, nor a little of that shortness of life that startles and bewilders our rosarians, arise from these sudden and severe frost-bites in the spring. The Roses often seem to break and bloom as if little were the matter with them. But these are but the last spasmodic efforts of enfeebled life, resembling the hectic flush and nervous and muscular energy of consumptive patients before the end of life. But we will try and hope better things for our Roses, and trust that the majority of them may even prove a match for this abnormally cruel weather, and come off conquerors on not a few

fields of contest and of glory next June, July, August, and September.—D. T. FISH.

—The rainfall between October and February was unparalleled; we then had what might be called spring weather; so bright were some of the days in February, that it seemed more like May than the sleety month, but the wind on the 5th inst. veered round to the north, bringing one of the most destructive storms on record. On the 9th we registered here 18° of frost, and the following morning, the 10th, 24°, and some of my neighbours say 28°. The result on vegetation, which was unusually forward, owing to the mildness of the winter months, is something appalling. To-day (14th) we have a partial thaw, with a little rain, interspersed with short gleams of sunshine; this, then, is the opportunity to note the results of such a severe frost. Roses, as is well known, were remarkably forward and full of vigour, many of the old plants being full of new growth, and the maiden buds pushing up with a rapidity that made one think we were in the month of May. Alas, for all our hopes of having a forward season; the cold north-easters have slaughtered all our innocents, and once more the rosarian looks upon his Roses for the coming season in despondency. All our Teas are killed, and many of the tenderer varieties of the Hybrid Perpetual class—that is down to the snow level; thanks for the ever welcome snow for covering our dormant eyes and for sheltering at the most important part our "cut-backs." So far as our observations have led to-day, the results of Saturday morning's frost have been as fatal to Roses as it was in 1880-81; indeed, where not protected by snow or other covering, such sorts as Annie Wood, A. K. Williams, Reynolds Hole, Prince Camille de Rohan, Sultan of Zanzibar, and other popular sorts are as black as one's hat. How Pear and Plum bloom will fare we cannot now say, not having examined other than Roses. Primroses, Hepaticas, and some other spring flowers were out in lovely form, but are drooping as if scalded.—W. H. FRETtingham, *Beeston, Notts.*

PRUNING MARECHAL NIEL.

THOUGH this peerless Rose has almost attained its majority, having been introduced in 1864, its pruning and general culture can hardly be said to be generally understood. The practice of pruning covers the entire distance from the most severe to none. Only the other day, when stating my views on this matter to several gentlemen, a clergyman asserted I was quite wrong about pruning, as he had beaten all his neighbours by pruning the Maréchal back to two buds. Two buds! and how long were his shoots? a yard or more? Well, what about the waste? He had not thought of that; he pruned for big blooms and got them, and that made him advocate a close regimen for Maréchal Niel; the few flowers were enough for him. But most rosarians are bound to have some regard to quantity as well as quality. And it is one of the most valuable characteristics of the Maréchal that both may be had abreast provided the plants are skilfully treated and liberally fed. Individual blooms of the most superb form and full size may be grown on plants that are weighted with enormous crops. And even were it otherwise the majority of cultivators would prefer a dozen, a score, fifty, or a hundred blooms to one were that one to be swollen to the size of a soup plate. Of course there will always be found specialists who will endeavour to concentrate as much golden beauty or riches as possible with as few buds or hoards as may be. But it holds good in Rose growing, as in political economy, that a wider distribution of wealth leads to the greater

happiness of larger numbers. Provided the Maréchal Niel Rose, tree or bush, is strong enough to bear its scores or hundreds of blooms, it seems something akin to sacrilege to slash them off in embryo with the pruning-knife with the hope of having the one or half-dozen blooms develop into enormous size. Unless

For show purposes, the largest flowers of the Maréchal are by no means the best or the most useful. The general run of the blooms or half-opened buds are too large for button-holes, and somewhat heavy for hand bouquets. The more in reason left on each plant the more useful the flowers for such purposes as well as for vases. Hence it is obvious that there is nothing gained, but a good deal of material and usefulness lost by pruning the Maréchal Niel severely merely to develop size of individual blooms. But others cut back buds to prevent exhaustion. As the Maréchal often proves short-lived, it has been too readily taken for granted that the plants have perished from exhaustion, or flowered themselves to death. Nor is this opinion to be wondered at by any who have seen the enormous heads of bloom carried by this Rose. The chief cause of the sudden deaths of Maréchal Niel seems to have nothing in common with exhaustion. The joint swellings or huge warts on the stems either at the point of union with the stock or of divergence of any of the main branches are the chief causes of the sudden destruction of this glorious Rose. These symptoms rather point to an excess than a paucity of strength or food. The Maréchal, if well fed, is capable of carrying an enormous crop of bloom and making good, strong growth simultaneously. While it does the latter it is not likely to succumb to exhaustion through any excess of blooming. Besides, the most reasonable mode of

Pruning Maréchal Niel possesses powerful recuperative powers. It consists in cutting out the blooming shoots so soon as they have finished flowering, and laying in young maiden shoots of equal or greater length to supply their place. As the roots in a good medium and abundantly stimulated with manure are pretty sure to keep pace or even run ahead of the tops, this method virtually provides a fresh blooming Rose every year, though springing from the same stem or root-stock. The time of pruning will vary according to the position and general treatment of the plants; as soon after blooming as possible is a safe rule for the Maréchal either indoors or out. Of course out-of-doors the weather seriously interferes with such matters, and also in seasons such as this violently disturbs the effects of this or any other method of pruning. The first week in March this year some Maréchal Nels on walls were examined. The entire shoots were breaking strongly from base to summit. Most of the latter, notwithstanding slight protection, are now quite blackened. But under glass each would be, as indeed they all are, hastening into bloom. When shoots are left very long, say several yards, it may be desirable to stop them back a little to secure a better and more uniform break right back to their base. But the Maréchal's power of breaking regularly along the whole line of the last season's shoots is unique. Even when left unstopped it is but very seldom that any of the buds refuse to break so as to form fine plants. It would, however, be most interesting to have the opinions and practice of other rosarians on their different modes of pruning this fine Rose, as well as the result of their experience in stopping the young wood and leaving it unstopped. Notwithstanding a few eccentricities, the Maréchal Niel is so profusely prolific, as to bloom well under various methods of culture. Nevertheless, as its commercial and decorative value probably exceeds that of any other Rose, it would be a matter of great importance to discover the best mode of pruning it so as to produce the most bloom and extend its longevity.

D. T. FISH.

Rosa berberifolia.—Mr. Ellacombe is right. My Rose is *R. berberifolia* Hardii, not *berberifolia*, but is yellow with a dark spot. It is probable that "K" referred to this one in his query (p. 151).—J. R. DROOP, *Stamford Hill.*

PLANTS IN FLOWER.

IRIS RETICULATA.—Alluding to this hardy bulbous plant, Sir William Marriott writes: "What a lovely thing this Iris is! Coming into flower at this time of year in the open air, it is worth its weight in gold. It really seems to be one of the few things that like the chalk, and I shall grow quantities of it."

FINELY GROWN LACHENALIA TRICOLOR.—The finest spikes of this bulbous plant we have seen come to us from Mr. Smith's nursery at Guernsey. They are all about a foot in height, and for two-thirds of their length are covered with yellowish green drooping blossoms; on one spike we have counted thirty-four flowers and buds. When grown thus this plant is an uncommonly pretty one, and the red tips to each of the spikes give them a bright appearance. Details of Mr. Smith's mode of cultivating Lachenalias appeared in THE GARDEN a short time ago.

NOTES FROM CORNWALL.—Our woods are now gay with Primroses, Daffodils, and Anemone apennina, and fragrant with Violets. Of Violets we have three distinct colours, blue, white, and a dull purple, the latter more curious than beautiful, but remarkably sweet scented. Among the Primroses there is a wonderful variety of colour, and some with several flowers on a stalk; unfortunately a hail shower has slightly damaged the blooms. The Anemone is coming up in patches here, there, and everywhere quite strongly, while the original clump seems to be losing its vigour. Is this usual?—JOHN C. TALLACK, *Prideaux Place, Padstow*.

HIMALAYAN PRIMROSES.—An attractive and interesting exhibit was made at South Kensington the other day by Mr. Llewellyn, Penllergare. It consisted of a group of varieties of *Primula denticulata*, together with what is considered to be the type, which has pale purple flowers gathered in a large and not very close head. *Cashmeriana* is distinguished by a dense head of deep purple blossoms, and *erosa* by the toothed edged leaves and pale mauve flowers. Some of the varieties have the foliage covered with a yellowish powder, but we are inclined to think that it is not a reliable character at all whereby to distinguish varieties.

RANUNCULUS GRANDIFOLIUS OF LOWE.—Mr. Kingsmill brings us from his garden, at Eastcott a handsome Madeiran Crowfoot, similar to *R. cortusæfolius*. The flower-stem is about 15 inches high, branched and furnished sparsely with hairy sessile leaves. Each branchlet is terminated by about three blossoms, each about 2 inches across, of a bright golden yellow, and shining as if the petals were varnished. Such a handsome plant as this is well worth the protection of a frame during its flowering season, which is always early in spring. Mr. Kingsmill grows it admirably in a cold frame. This species is synonymous with *R. megaphyllus*, now the accepted name.

IMANTOPHYLLUM MINIATUM.—Of this well-known Amaryllidaceous plant there is now in the Royal Exotic Nursery, Chelsea, a grand display of flowering specimens, representing nearly all the varieties in commerce. Between the flowers of the typical form and those of the finest varieties there is indeed a wide difference. In one they are comparatively small, the segments narrow and of a washy orange-red colour; in the fine new varieties the flowers are nearly twice the size, with broad almost overlapping divisions, and the colour is a brilliant orange-red, almost a scarlet. Messrs. Veitch's collection includes about half a dozen named kinds and about as many unnamed varieties and seedlings. One of the finest is *giganteum*, which is remarkable for the enormous trusses of flowers it bears—as many as thirty on one head. The flower is not remarkable for size, but the colour is rich and brilliant. As regards richness of colour, Madame Van Houtte is the finest; it has huge heads of well shaped blossoms. Perfection bears close heads of flowers of a brilliant colour; and maximum has very large

flowers, but the heads are somewhat loose and the colour washy. Some of the seedlings are uncommonly fine, and well worthy of distinctive names. It would be difficult to name brighter or more effective plants than these varieties of *Imantophyllum*, or any so easily cultivated. Moreover, when not in flower they are handsome, for they have huge tufts of elegantly recurved dark evergreen foliage. On the Continent, this *Imantophyllum* receives a deal of attention, and the finest varieties have been produced there. The great desideratum as regards the improvement of this plant is a wider range of colour. If some hybridist could infuse say a crimson, yellow, or scarlet hue in such a useful plant, his work would be much appreciated.

RHODODENDRON JAVANICUM.—We lately saw a fine bush of this now somewhat scarce species in flower in Mr. Rucker's garden at Wandsworth, and were much struck with its beauty. The flowers, which are produced in dense terminal trusses, are each about 2 inches across and of a warm orange, inclining to bluish tint. This plant, we presume, represents the typical form of the species, and if so we think it quite as beautiful as some of the numerous hybrids that have been obtained from it, though perhaps as regards the shape and substance of the flower the hybrids have the best of it. It is satisfactory to find type species of any popular class of plants, for in the eagerness for improved forms they are often annihilated.

PINGICULA CAUDATA.—The more one sees of this plant—undoubtedly the queen of all the Butterworts—the more is one charmed with its beauty, which rivals even that of any Orchid, not even excepting *Masdevallia Lindenii* and *Harryana*, which it much resembles in colour. It is only in a few gardens about London it can be seen. We saw a fine specimen of it a few days ago in Mr. Peacock's garden at Sudbury House, Hammer-smith, where it is grown admirably in company with the cool Orchids. From a dense rosette of thick, fleshy leaves, somewhat resembling an *Echeveria*, it produces from one to three flower-spikes, each about 6 inches high, terminated by a large, broad blossom of the brightest magenta hue, shaded with a deeper or carmine tint. Being a native of Mexico it is almost hardy, but it is best to treat it similarly to cool Orchids.

GUERNSEY DAFFODILS.—From Mr. C. Smith, Caledonia Nursery, Guernsey, come flowers of two extremely handsome varieties of *Narcissus*. One is called *N. cernuus*, but it is different from the variety known about London under that name. It differs in the rim of the crown being much reflexed and deeply and evenly lobed. It is a handsome flower of a uniform creamy white colour, or, in fact, nearly pure white. The petals and sepals are twisted, as in *tortuosus*. The other is a variety of *N. bicolor*, and may be best described as identical with that superb variety *Empress*, except that it is somewhat smaller. The golden yellow crown has a slightly recurved rim, and is much cut and crimped. The sepals are over an inch broad, and, with the slightly narrower petals, are of pale sulphur yellow. So far as we are able to determine, it is identical with *N. bicolor* anceps of Haworth. Its earliness is a great recommendation, for though the Guernsey climate has forwarded it, all the bicolor race flower so much later than others of the *Ajax* section of *Narcissus*.

A NEW EUCHARIS (E. Sanderi).—This new bulbous plant, lately introduced from South America, is entirely distinct from either of the other two species in cultivation, *E. candida* and *E. grandiflora* (*amazonica*), though it much resembles the latter in foliage and habit of growth. The flower-stem, which is stout and erect, carries from five to a dozen flowers each, arranged in an umbel as in the other species. The flowers have a curved tube some 2 inches in length, and the diameter across the perianth is about 2½ inches. The inner segments are ovate, an inch across, while the outer divisions are a third narrower and more pointed. The corona formed by the dilated filaments of the stamens is in this species almost entirely suppressed or rather united to the funnel

shaped tube; hence its great distinguishing character. The stamens are about half as long as the perianth segments, and the style protrudes half an inch beyond the anthers. The whole flower, save the yellowish lines in the tube, is of snowy whiteness and of firm wax-like texture. It is therefore a beautiful flower, and one that will doubtless become as popular as its congeners; it has a pleasant odour, and is said to be very floriferous. It was named by Mr. Baker, of Kew, in compliment to Mr. F. Sander, of St. Albans, who first introduced it. It first flowered at Kew at the close of last year, and is the subject of a coloured illustration in the current number of the *Botanical Magazine*. Some flowers have been sent to us by the Hextable Plant Company, Swanley, who are growing a large importation of it, received, we understand, through Mr. J. O'Brien, collected for him by the late Mr. Chesterton in South America.

TILLANDSIA LINDENI.—Those who wish to grow a few only of Bromeliaceous plants ought certainly to possess this species, one of the best of the whole tribe; indeed, there are few tropical flowers so beautiful in colour. We here speak of what is called the variety *Regeliana* of Linden's *Tillandsia*, the one with blue flowers and green bracts, not the true variety (*vera*) with purple flowers and large pink bracts. *Regel's* variety has, like the type, a dense tuft of elegantly reflexed leaves, from the middle of which is produced a tall flower-spike clothed with green bracts. On the upper part of the spike the triangular-shaped flowers (2 inches across) are produced, and these are of the richest gentian blue with a large and conspicuous white centre, the two colours blending beautifully together. We saw this plant in great beauty a few days ago in Mr. Rucker's garden at Wandsworth, where Mr. Pilcher grows it admirably in a close, warm stove.

ABUTILON VENOSUM.—Flowers of this extremely handsome species were among the most interesting exhibits at South Kensington on Tuesday last. They were brought by Mr. Green from Sir George Macleay's garden, at Pendell Court, Bletchingley. They are unusually large, being some 3 inches across when fully expanded, bell-shaped, with a long bundle of stamens and styles protruding nearly an inch beyond the corolla. The petals are a reddish yellow, strongly netted and veined with crimson; therefore the blossoms are highly attractive. The pedicels or flower-stalks are nearly 12 inches long, and being slender droop gracefully from the plant, which is a tall, vigorous grower. The leaves are very distinct from most other species, being large and deeply palmate. It is a handsome plant for greenhouse culture. Mr. George, the noted raiser of hybrid Abutilons, exhibited on Tuesday last an extensive series of seedling varieties, some of which were similar in colour to *A. venosum*, though it is doubtful if this species has been used in hybridising.

New hybrid Pink.—M. J. Sisley, of Lyons, sends us the following description of a new hardy mule Pink that has been raised by his friend, M. A. Aléatière, at Monplaisir: "To this new hybrid variety I have given the name '1881,' being the year in which I obtained the first plant of this new type. It was obtained from seed taken from a *Mignardise* (a variety of small Pink), crossed by a variety of new Stock Pinks known under the name of *Espoir*. The flower has a strong, yet delicate odour, and is of medium size; the petals are fringed, and of a pinkish lilac colour, darker in summer than in winter. If its form be not quite all that could be desired, the plant at least has the merit of flowering abundantly at all seasons. The flower-stalks become woody, so that they do not rot in houses the same as those of the Stock Pinks. Its culture is the same as that given to all Pinks, but if desirous of obtaining large plants in a short time, it is necessary to cut back each stalk at the base after flowering, that is to say above one, two, or three branches, which will not be long in their turn of giving many buds. This new Pink 1881 will be put in commerce this spring.

COUNTRY SEATS AND GARDENS.

DUPPLIN CASTLE, PERTHSHIRE.

THIS, the seat of the Earl of Kinnoul, has long been famous for the beauty of its site, the extent of its gardens, the length of its approaches, the number of its avenues, the largeness of its woods and plantations, and the richness and variety of its arboreal clothing and furnishing. The castle stands on a sort of plateau in the vale or strath of the Earn, amid some of the richest scenery in Scotland. To the north both castle and grounds are admirably sheltered by dense woods and plantations, while the extensive

Assuredly for many generations the Earl of Kinnoul must have acted on the advice given by the Duke of Argyle to his son John, "Aye be sticking in a tree, mon." And the planting is not yet completed, though Dupplin is without doubt one of the most charming sylvan retreats to be found in Scotland—that land so richly furnished with "brown beath and shaggy wood," as well as so grandly adorned with mountains and enlivened by floods. It is in this enlivenment of floods in which most of the fresh and absorbing interest of Scotch landscape consists. Even the Earn, which seems so soundly asleep in its rich and luxurious bed, made by itself in the lowest depths of Strath Earn, is every now and again thoroughly waked up by

nated with scarlet Thorns on the one side, and on the other with double-flowering Cherries, alternated with Thorns. The Araucarias are dispensed with on the left side, as when they got up their dark and dense masses would shut out or partially hide the charming view of the valley of the Earn. Bold masses of Rhododendrons in clumps are placed between the trees and the road on either side. In spring-tide and early summer, when the trees and Rhododendrons are in bloom, the effect must be peculiarly light and brilliant.

This blaze of colour, somewhat toned down by the dark shadows of the Araucaria, forms a charming interlude to the dense avenue of noble Beeches into which the carriage road plunges. As

Beech avenue at Dupplin Castle.

pleasure grounds sweep away down to the Earn, which occupies the centre of the valley on the southern side. Few demesnes are more favoured with an almost infinite variety of near and distant prospects of the most rich and varied character. The castle itself is surrounded, almost enclosed at some points, with noble trees and choice shrubs and flowers, and the middle distance is filled with still, peaceful sylvan and pastoral scenery, while in the distance the bold ranges of the Grampians may be seen closing in a valley of unique beauty, through which the links of the Earn coil and unwind themselves lazily, like a huge silver serpent travelling with uncertain progress from its lake or loch of superlative beauty, to begin a new and more stirring course among the more impetuous waters of the Tay some miles below Perth. But rich, varied, and satisfying as is the near and distant scenery around Dupplin Castle, the horticultural visitor is more deeply impressed by the number and size of the trees with which it is so richly adorned.

a spate, and the noise of its angry waters fills the valley as they roar down in tumultuous and foaming torrents towards the Tay. It is the same in degree with every burn and brook; as the poet laureate has it, they "chatter, chatter, as they flow, and not seldom scream and roar," on their course to join the brimming river.

But on visiting such domains as Dupplin, assuredly it is not the shagginess, but rather the stateliness and finished grandeur of the woods and the magnificence of individual specimens that fix attention and command admiration. Dupplin Castle is about five miles from Perth, and may be reached by two or more approaches, each distinguished by much variety of interest of outline and prospect, and adorned with a wealth of sylvan beauty. Entering by the east lodge, we pass along a carriage road, combining some of the most recent planting with that of the most famous of the old avenues for which Dupplin has so long been famous. The first part consists of an avenue, 60 feet wide, formed of *Araucaria imbricata*, alter-

it advances towards the castle the contrast is complete between the lightness of the vestibule and the semi-darkness and density of this noble avenue. As we advance we see and pass through a labyrinth of avenues of about equal age. On one point of the road an octagon of avenues converges. The effect is magnificent, and as one looks along first this one and then that in succession with a sort of bewildering admiration the Beech grows in importance and value as an avenue tree, and one wonders that it has been so seldom used for such purposes. And yet it has a massive dignity and a prodigality of grandeur of its own. Its wide-spreading tops afford ample shade at once dense and soothing, while its bold and sturdy stems are as straight as arrows, and well nigh as smooth as alabaster. The time, however, is rather inauspicious for advocating a revival of

Beech tree avenues just when the *Journal of Forestry* has virtually raised the cry of "No more Beeches" in its telling article in one of its latest issues on "Without the Beech." Without the

Beech, indeed! Take that tree out of the demesne of Dupplin and you would rob it of its sylvan beauty. The above authority, however, does justice to the ornamental qualities of the Beech while lamenting the inevitable decline and fall in the area of its cultivation. It remarks, notwithstanding its good qualities, the Beech is apparently doomed if not to gradual extinction, at least to a restriction of its sphere of usefulness. Though it stands alone in its unrivalled sylvicultural qualities, *there is no longer a market for its timber*. Fortunately, the words we have italicised do not furnish potent reasons for or against the planting of avenues. Few of these come to the hammer even in these degenerate times, when neither unique libraries, family paintings, historical papers, or personal articles of *virtu* are spared. Very few of those who have seen the Beeches at Dupplin or at Burnham but would venture to plant a good many for ornamental purposes. A giant Beech, 18 feet in girth a yard from the ground is worth going a good many miles to see; and this is the gigantic size of the biggest Beech at Dupplin, while many more in the various avenues approach a girth of from 14 feet to 16 feet 3 feet from their base. Soon after passing the octagon of Beeches the carriage drive takes a bold curve to the south and the castle is soon reached. This stands on a level plateau of lawn and gravel, that form a sort of secondary base to the house. The castle is a modern building replete with every convenience, and fitted and furnished with great beauty and refined taste. The old castle was burnt down in 1827, but was rebuilt in what the chroniclers justly describe a style of great magnificence. The view from the front door is open, extensive, bold, and rich in the extreme. Fine breadths of turf sweep back in all directions until lost sight of among noble trees. Other carriage roads and avenues are also seen from this commanding point. One ascends the rising ground in a straight line with the front door until lost sight of in a knoll a mile or more distant, which it is proposed to level down to show the line of road and form an avenue all the way till the carriage road joins the road leading over the Tippermuir to Perth.

Another grand avenue of Beeches proceeds from the castle westwards towards the parsonage. About the middle of this is a roundal or huge circle, in which are some very fine trees with a girth of from 12 feet to 16 feet, and near to this is the Beech alley 1000 yards long, consisting of four rows of very fine trees 25 feet between the central rows with a roundal also of Beeches. In the alley or roundal some of the trees are from 14 feet to 16 feet in circumference at 3 feet from their base. Highly distinguished, however, as Dupplin is for its Beeches, it must not be supposed that these exhaust its arboreal wealth; on the contrary, there are few trees that are not well represented either in its avenues, pleasure grounds, or woods and plantations. For example, on the north side of the castle there is a fine

Avenue of Oaks, terminating in a roundal or bold sweep of wide area. This is 25 feet wide, and contains many noble trees averaging from 11 feet to 14 feet in girth a yard from the ground. Yet another noble avenue is furnished with ancient Limes. This prodigality of avenues converging on the castle or on given points, some terminating in lodges, others in roundals, and several also interrupted by the latter, is only the most unique and striking features of the rich and beautiful grounds of Dupplin. It would, however, be a huge mistake to suppose that all the big trees at Dupplin were marshalled into avenues, or swept round in huge circles. No; fine timber abounds in all directions, and in close proximity to the castle giant trees may be stumbled against at almost every step. One of the noblest is a venerable Scotch Fir on the lawn 12 feet in circumference a yard from its base. Silver Firs also abound, ranging from 16 feet to nearly 18 feet in girth, the largest measuring 17 feet 10 inches; and of a group of Spanish Chestnuts near to the flower garden the largest girths 20 feet a yard from the ground, and several others from 16 feet to 18 feet. Several fine specimens of the Atlantic

Cedar girthed from 12 feet to 15 feet. Possibly, however, the greatest arboreal curiosity in these richly furnished grounds is that of a common Spruce just across the dell from the castle on the opposite side of the flower garden. This has a noble central stem with seven subordinate stems, all proceeding from and supported by the central bole, but looking from a distance like one large tree planted round with seven smaller. These subordinate shoots are evidently manifesting the same tendency to travel horizontally and rise again with yet other trunks, as the larger branches of the original bole. So with space and time there is no limit to the possible size that this Spruce may ultimately attain, especially as the original stem and all the subordinate ones are in robust health and full growth. I have seen the black Spruce develop this tendency to multiply stems, but not to the same extent as in this tree at Dupplin, which seems to differ in no way from the common Spruce, except in this singular multiplication of stems or boles. Close to the gardener's cottage, on the banks of the Earn, near to the ruins of the old church, where some of the family are buried, there stands a very fine Walnut tree of great age, and with a circumference of 14 feet a yard from its base.

Such are but a few samples of the ancient arboreal wealth of Dupplin Castle grounds. Fine trees in scores and hundreds abound in all directions. Nor is there any fear of its becoming less rich in noble trees in the future, than in the present. On the contrary, it is likely to be more so. The present Earl of Kinnoull and his late gardener, Mr. Oswald, are and were mighty planters, and the results are seen in groups and single trees of the rarer Coniferae growing up in all directions. Planting is still being prosecuted with such vigour that noble conifers have even, as it were, been helped over the walls of the kitchen garden. The finest *Araucaria imbricata*, over 50 feet high and a model of symmetry, is found in the kitchen garden, and near to this stands a noble specimen of *Cryptomeria japonica*, 40 feet in height; while close by, just outside the garden wall, a noble line of *Cupressus Lawsoniana* forms at once a living screen to shelter and a line of matchless beauty to the kitchen garden. Coniferous and other trees also abound in various directions, while the former have a pinetum all to themselves near to the castle, on the left of the long, straight carriage road already referred to.

The castle stands on the bank of a dell of considerable depth, which adds greatly to the charm and variety of the gardens. The flower garden sweeps up to the base of the building, and at the time of my visit, in the middle of September, was well furnished and still gay with the usual description of plants. From this upper plateau of beauty a balustrade stair leads down to the lower garden, which is occupied by beds of Rhododendrons and Ghent Azaleas. Most of the beds are filled with varieties of one colour, and the effect of the bold contrast of such masses of scarlet, pink, purple, yellow, and white when in bloom must be rich in the extreme. But I must confess that deep narrow dells profusely furnished with something like a tangled thicket of Rhododendrons, Sweet Bays, white and yellow Ghent Azaleas, &c., as a groundwork, with Laburnums, scarlet and other Thorns, *Cupressus Lawsoniana*, and other conifers, towering up as stavers from the mass of undergrowth, and other trees of a drooping character being added as the bottom of the dell is neared, and above all the quaint bridge and the tiny waterfall that leaps from the brow of the bank with such a dash and sound of freshness, singing a merry tune full of life and motion as it breaks into spray on its way to the brook or burn that carries it down the dell to the Earn—these form a perfect picture and a finished landscape of themselves. Doubtless this dell owes much of its charm to its close proximity to the castle and the more formal flower garden around it. Seldom or never, perhaps, has the unavoidable stiffness of art as seen in architectural lines of massive breadth and great length been more violently contrasted and so subdued and softened

by the flowing grassy slopes, natural foliage and flowers, while the sight and sound of falling water impart a freshness and a life all their own to the landscape. The peculiar Spruce already described is also a prominent feature from this point, while in the background masses of foliage of avenue or other trees are visible. But space would fail to do justice to this charming spot or to the

Flower gardens at Dupplin; suffice it to say that the flowers are by no means confined to this, on the whole, small flower garden; around are enormous quantities of flowers for cutting: old-fashioned herbaceous plants and Roses are grown in the kitchen garden. The demand for cut flowers for table, room, and chapel decoration is enormous, and without extraneous sources to draw upon, the flower garden would, indeed, soon be wholly flowerless. Wide flower borders skirt the central walk in the kitchen garden, and Rose and flower beds and borders are also found in other parts. In these enormous quantities of Phloxes, Pentstemons, Cloves, Carnations, Pansies, Violas, Mignonette, Zinnias, Asters, Marguerites, &c., are grown, while as for Stocks, especially the scarlet and white East Lothian, they are grown in blocks, brakes, or masses in a similar way, and almost to as large an extent as Carrots, Cauliflowers, or Cabbages. These are invaluable for decorative purposes, and the plants are lifted in the autumn and planted in the front borders of newly pruned orchard houses, where they flower throughout the winter and far into the succeeding spring.

The kitchen garden covers an area of about 8 acres, and faces the south in close proximity to the river Earn. It is thoroughly sheltered on the northern and western sides by the woods and plantations and pleasure grounds between it and the castle. It, however, lies fully exposed to the south and to the east, a less welcome aspect. A gentle inclination to the south is the *beau idéal* of a site for a fruit or kitchen garden. At Dupplin, however, the fall is so steep that in cases of sudden and severe storms and heavy thunder showers there must be considerable risk of finding soil, gravel, and seeds or growing crops mixed in a very inconvenient manner. The labour of manuring and of the general cultivation and gathering of the crops must also be considerably increased by the steepness of the site. Still, the soil and situation are evidently favourable for the culture of fruit and the growing of vegetables, and seldom have more promising fruit trees or finer crops been seen than in the kitchen garden at Dupplin. Where all the crops were exceptionally good it may seem invidious to specify any one in particular, though it is only a bare act of justice to Mr. Browning, the able and intelligent gardener, to say here that I had never seen Veitch's Autumn Giant Cauliflower so true nor so fine as in these gardens. There was also a full supply of all other vegetables in season. Fruit in the open air was scarce, as in other places, in September, for the failure was general north and south last year. In average fruit seasons, no doubt these fine gardens are equally distinguished for their fine fruit crops as for vegetables, and in any case the supplies from the glass houses are ample and unfailing. Before, however, entering these it may be well to linger a moment to note that here, as in most of the larger kitchen gardens in Scotland, the good old and safe plan prevails of growing large quantities of flowers within the kitchen garden. Here they are safe from the pest of rabbits and other game or vermin, and they form a useful as well or ornamental hedge or screen of beauty to less ornamental, though equally useful, crops. Their presence is not only salutary, but sanitary, where, as in the north, the daily constitutions of the family frequently extend through the kitchen garden. Few things are more distasteful to many than the strong odours of some vegetables, while the slightest approach to decomposition is unwholesome in a very high degree. There is no surer antidote to both nor safer security against the insidious germs of disease that too often follow close on the heels of decomposing vegetable matter than the sweet odour of Violets, Mignonette, and Roses. And hence a cordon of beauty carried

round or through a kitchen garden may often become a panoply of safety as well.

The chief range of fruit houses in Dupplin gardens runs a long way across them near their upper or higher side. The houses are large and numerous, and remarkably well furnished. A good deal of the stone fruit was gathered in September, but it was easy to judge of its probable quantity by the condition of the trees. The crops in the vineries and other houses where the fruit was still hanging were plentiful in quantity and of excellent quality, affording proof at once of the ability and success of Mr. Browning as a fruit grower. There are two Peach houses, one 100 feet long, and the other 60 feet long, each 10 feet wide. Nectarines have a house 50 feet by 10 feet; Plums another a trifle shorter and the same width. There are two fine vineries in this range, one of them 60 feet, and the other 40 feet by 10 feet; these are furnished with a mixed collection of Vines, all in robust health and carrying good crops. In another part of the garden, near to the block of plant houses, are two more vineries, each 48 feet long by 16 feet wide. One of these is devoted to Muscats, and the other to late Grapes, such as Lady Downes and Alicantes. Near these are the Cucumber and Melon houses, each 40 feet by 9 feet, and also several brick pits about the same length and 6 feet wide. From these facts it will be seen that pretty ample provision has been made at Dupplin for a good supply of fruits throughout the year. As showing that Grapes must be well grown and finished and give satisfaction, it may be noted that they are presented at table in a peculiar manner. The bunch is suspended before the Earl on a stand made on purpose. It can be raised or let down, so as to bring it within more easy reach of the scissors. It must be obvious, however, that each bunch and berry had need be pretty perfect for this prominent method of serving. It may be added that a handsome bunch thus suspended at the top of the table formed one of the most telling features in the dinner table decorations at Dupplin at the time of my visit, and that there this art may be said to have reached to the dignity of a science under the fostering influence of the Countess of Kinnoul.

The plant houses are even more numerous than those devoted to fruit culture, the demands made on them for plants and flowers for furnishing the castle and chapel being very heavy. Near to the west end entrance to the kitchen gardens stands a Camellia house 100 feet long by 17 feet wide, admirably furnished with healthy plants. This must prove a rare mine of wealth for cut flowers throughout the winter and early spring months. In front of this or another house near was a border of Gloire de Dijon Roses trained over a quadrant formed trellis, a charming picture of health and floriferousness that must yield a supply of flowers from May to November. Next to the Camellia house there is one or more roseries with Tea Roses planted out, yielding and promising to yield in succession abundant harvests of sweetness and beauty; then follows a nice greenhouse about 30 feet by 15 feet, chiefly devoted to the culture of semi-bulbous plants, and an intermediate house of the same length, but furnished chiefly with Lady's Slippers, and some fine plants of the useful and fragrant, but all too seldom seen, *Hedychium* fragrans. The flowers are white as a *Gardenia* or *Stephanotis*, totally unlike either or any other flowers in form, and fragrant as either or both of these favourites combined. Near here is a well-stocked Fern pit about 50 feet long and 6 feet wide, full of most useful and clean stuff for decoration or growing into specimens.

But the chief range of houses stands in a sort of block three deep, near the centre of the kitchen garden. Being on such a steep incline, of course the houses are built on different levels, like the steps of a stair, and a central corridor cuts them through the middle and connects them all together by a charming passage richly furnished with climbers. This was 200 feet long and 12 feet wide, and was being further extended at the time of my visit to run out on to the flower garden at its

lower or southern end. The effect is very striking going down this verandah, but still more ascending it, as the Jasmines, Fuchsias, and other climbers and the noble specimen of *Dacrydium Franklini* that forms such prominent features in its furnishing are better seen. Entering the verandah at the upper end, the first house on the right is the *Gardenia* house. At the time of my visit in the middle of September this house was worth a journey of 500 miles to see. The plants were without spot, pictures of health and cleanliness, and studded more thickly with bloom than such plants mostly are in February and March. With such a profusion of buds the plants must have continued flowering freely through the winter. The variety looked like *florida* or *intermedia*, only the flowers seemed more elongated at their base—a decided improvement of structure for mounting. Possibly this peculiarity might arise from the liberal treatment and skilful culture given to the plants. It is impossible to write too highly of the latter, as assuredly a finer house of *Gardenias* could nowhere nor at no time be found than that seen at Dupplin in September.

Next to the *Gardenia* house on the right was the *Orchid* house; on the left the plant stove, each 36 feet by 15 feet. In the former was a useful collection of *Orchids*, including some nice pieces of *Lælia anceps*, *Dendrobium densiflorum*, *D. d. album*, *D. thyrsiflorum* and others, *Cypripedium caudatum*, *Coeloglyne cristata*, *Dendrobium glumaceum*, &c. The plant stove was well furnished with a useful collection of the more popular foliage and flowering plants. Other houses diverge to the right and left of the verandah, while yet others diverge from those main ones into a semi-labyrinth of useful structures and pits, including Fern and forcing pits, intermediate houses, Palm houses. They were well filled with Palms, flowering and foliage plants for table and room decorations and other purposes. Here, too, the Muscat house and late vinery already named are also placed. Not far from the upper end of the verandah is the Melon ground with the Cucumber and Melon houses, pits, &c, and close by are found the most useful plant houses in the gardens. These are light, span-roofed houses, admirably adapted for the purposes to which they are applied. The first is 33 feet long and 21 feet wide, chiefly filled a good collection of *Azaleas*. The other three were each about 20 feet long and 10 feet wide. One was chiefly filled with a richly coloured collection of colour for table decoration; a second was chiefly occupied with *Heaths* and *Tuberoses*; and the third with sweet-scented *Rhododendrons* and soft-wooded plants. The roof of the house was clothed with the red and white *Lapagerias*, among the most useful plants in cultivation for decorative purposes, as with care the flowers will last fresh and untarnished for a fortnight or three weeks in water or damp moss after cutting.

Gardenias and *Hedychiums* are probably the most prized for cutting at Dupplin, and the castle at the time of my visit, was redolent with the fragrance of both. But enormous quantities of other cut flowers are needed for the drawing-rooms, boudoirs, and bedrooms, as well as for the chapel. Many Palms, Ferns, and other large plants are also used to furnish the lofty hall and staircase, while some large plants suspended in baskets heighten the effect of the architectural grandeur by their verdure of colour and gracefulness of form. The Earl of Kinnoul spends much of his leisure time in the garden, and takes a lively interest in all horticultural matters, as shown by the fact that his private or business room is connected with the gardens by the telegraph and telephone. He has also invented

A method of dry glazing, which seems at once cheap, simple, and efficient. Several houses are already built and glazed on the new plan, and it is intended to dry glaze the whole as the old roofs get out of repair. The weak point in most systems of dry glazing is found at that particular spot where the glass impinges against the wood or metal. The hardness of two such unyielding substances, and their unequal expansion at equal

temperatures, causes breakage. Hence the introduction of elastic buffers, such as felt, india-rubber, gutta-percha, &c., between the two. These have been found to answer fairly well in Beard's patent and other systems. But they are perishable, and when once saturated with water, the frost freezes them and so breaks the glass. Besides, one of the chief merits of dry glazing ought to be its greater durability, and so generally has this been recognised that not a few of the plans patented have claimed the name and the merit of indestructibility. Lord Kinnoul's plan is perhaps the nearest to this that has yet been invented—that is, were iron rafters used instead of wood, and there is no practical difficulty in substituting the former for the latter. Thus only iron, glass, and lead would be employed, and practically all these are well-nigh indestructible. Singularly enough, lead, probably the first metal used in glazing, may possibly also be the last. Its softness and flexibility render it a safe base for glass to rest upon, and enable it to fasten and hold it firmly in position with little risk of breakage. The framework of the roof is formed of wooden or iron rafters in the usual way, a yard or 3 feet 6 inches apart. Cross or glazing bars or purlines are then run across these at intervals of 2 feet or more. In the Dupplin houses they are 2 feet asunder and about 1½ inches square. On these thin strips of lead weighing 4 lbs. to the foot are fixed with copper nails. The lower edge of the lead is left in projecting scollops, which are bent up over the glass and holds it firmly in position. The square 2 feet long is then led up to the next cross-bar and rested on it, and so on with several squares until the space between the main rafters, or as long as the slips of lead are filled. Then another sheet of lead is nailed on the next glazing bar and brought down over the top of the first square of glass, thus fixing it immovably in its place, the projecting corners of the lead being bent back over the second, as over the first square, and so on till the top of the roof is finished. The glass used is 28 ounces to the foot; the squares are 24 inches long and 18 inches wide, the sides of the squares being butted against each other. By changing the line of the butted edges of the glass the houses are made more certainly waterproof, but with glass cut square it is found that butted edges keep out water even when the butting runs across the line of the water, and, as a rule, they are quite so when they run parallel with the fall of the roof. The houses at Dupplin are free from drip, and so strongly put together, that they have withstood some of the most severe storms that have ever visited this country. They are also extremely light and elegant, and might easily be made more so by the use of fewer and stronger rafters and glazing bars, heavier glass, and larger squares; but as they are, the new houses at Dupplin are at once strong, light, elegant, and sufficiently water and air-tight to be admirably adapted for horticultural purposes. They are, or might readily be made, as indestructible as any houses that claim that proud distinction, inasmuch as the purlines and rafters are protected at all points with glass and lead, and the whole outer surface is a continuous sheet of glass held in position by its own weight and a series of nails, which might be reduced in number without lessening the efficiency of the bent lead holdfasts.

D. T. FISH.

The weather in East Anglia.—In this part of the country we have had a week of severe weather. On Sunday and Monday, the 4th and 5th of the present month, the weather, although cold, was remarkably fine, but snow fell slightly during the night of the latter, and during each of the remaining days of the week snow has fallen more or less, and upwards of 6 inches of it now remains on the ground, while the minimum temperature has ranged between 14° and 17° below the freezing point, and while I write no indication of a change is apparent. The snow which covers the soil will, it is to be hoped, act as a protection to the young Wheat crop; and fruit trees in general are hardly in so forward a condition as to be seriously injured, unless it be in the case of Apricots, which, on some of the light soils in this neigh-

bourhood, influenced by the mild character of the preceding winter, were to some extent in bloom as early as the beginning of the month. This continuous and unusual depression of temperature occurring at so late a period will afford to cultivators of this fruit an opportunity of testing the merits of the various methods employed for protecting the blossoms and embryo fruit of these trees, and it is to be hoped that the results will be faithfully recorded. The snow which has fallen during the week amounts to, when melted, upwards of three-quarters of an inch, viz., '79 of an inch. —P. GRIEVE, *Bury St. Edmunds*.

TREES AND SHRUBS.

PICEA NOBILIS FROM GRAFTS AND SEED.

THIS fine Californian conifer in its native habitats is said to attain a height of from 150 feet to 200 feet, and a diameter of stem above the swell of the roots of from 3 feet to 4 feet. As it has proved to be quite hardy in this country, it is well worth planting extensively, not only as an ornamental tree, but also for the production of timber. Upwards of twenty years ago my practice was to fertilise the cones by means of a small brush loaded with pollen—cones at that time being worth a guinea each; but I found that as the trees advanced in age and size they generally produced abundance of beautiful crimson catkins loaded with pollen, which on being agitated by the wind shed it like a cloud of dust, fertilisation being thus effected without artificial aid. The cones are ready for collecting in harvest time, and care should be taken not to allow them to remain too long on the tree, or the seeds will be shed and lost. In spring the seeds should be sown broadcast on well-prepared light soil, in nursery beds about 1 foot wide, and as they are of large size, I have found it beneficial to pass a light roller over the bed after sowing, which has the effect of settling all down in a uniform manner. A little fine soil should then be evenly spread over the whole and the work is finished. When the young plants have attained a height of from 4 inches to 6 inches they should be planted out into nursery lines in the following manner: Stretch a garden line along the surface of the ground, and with a spade cut a notch on both sides of the line from one end to the other, thus leaving a small ridge below the line; then remove the line and set the plants along the ridge about a foot asunder, spreading the roots out both ways, and drawing the soil over them as the work proceeds. Under this mode of treatment they become furnished with fine roots round the whole base of the stem, and can collect food and support from all quarters, a matter of the utmost importance as regard their future well-being. When about a foot high they should be planted out where they are to remain, care being taken to spread the roots properly out at the time of planting. In this way I have raised and planted out with great success large numbers of this fine conifer, and although some of them are growing in exposed situations, I have never seen a single tree so treated upset by the wind. As regards

Soil, it makes rapid progress in all soils of ordinary texture, provided they are thoroughly drained. It, however, makes little progress in stiff argillaceous clay or rank peat bog, but in places where the latter is well decomposed, and a little soil mixed with it at the time of planting, it thrives admirably, often making growths fully 21 inches in length in one year. On the whole, I anticipate a great future for this tree, the only doubt being whether the leader will stand good when the tree reaches a medium size in exposed situations. A tree planted in 1845 lost its leader twice within a few years' time after it had attained a height of some 65 feet. I should add, however, that this tree was the produce of a graft placed on the common Silver Fir. Grafted trees of this conifer do not grow so freely in early life as trees upon their own roots. For example, the tree just referred to made no progress whatever in the way of growing, for some

years after it was planted being apparently quite dormant. At length some quadruped nibbled off the points of the side branches, but happily left the leader untouched, and this appeared to rouse the tree into fresh life, for it commenced to grow vigorously. Some thirty or forty years ago pruning conifers was greatly deprecated, and he would have been a bold man who dared to advocate such a practice. We, however, quietly took the hint clearly given by the tree in question, and have pruned in many cases with advantage. I have known other instances in which grafted trees of this species have lost their leaders after having attained a medium size, notably one fine tree on the Duke of Manchester's property at Tandragee Castle, Armagh. This tree lost its leader many years ago under similar circumstances. Trees which refuse to start into growth after grafting generally produce an unnatural swelling at the place where the stock and scion are united, and it is only by pinching and pruning the side branches that such trees are induced to make a start. I have never had an opportunity of testing the

Quality of the timber of this tree when cut up into boarding or scantling; young trees, however, which we have used as piling posts in the round state are very durable, although scarcely equal to Larch. As far as my experience goes, *Picea nobilis* has proved to be a grand conifer, and whether planted out as a specimen tree on well-chosen points of the lawn, or mixed up with others for the sake of contrast and variety, it has few equals, and certainly cannot be surpassed by any other species of conifer with which we are acquainted.

J. N. WEBSTER.

OSIERS AND OSIER BEDS.

It has been remarked that, "The many important uses of the different species of Willow and Osier serve to rank them among the first in our list of economical plants. The larger kinds which are, too, of the most rapid growth, yield timber, and exceed 60 feet in height; whilst the least of them (*Salix herbacea*), which grows on the summits of our Highland mountains, can scarcely be said to rise above the surface of the soil in which it vegetates. Many are in great request for baskets, hoops, and crates; their bark is used by the tanner, and that of one species (*S. fragilis* var. *Russelliana*) as a substitute for the true Peruvian bark. A correct knowledge of them, then, is of primary importance; yet there is not in the whole range of the vegetable creation a genus liable to more variation in properties, as well as in foliage and general appearance, at different periods of growth in different soils and situations, and under different circumstances; so that the accurate determination of its species, or even what constitutes a species, has baffled the researches of the ablest botanists." The following species are given as being cultivated in Osier beds: 1, *S. Forbyana* (fine basket Osier); 2, *S. rubra* (green-leaved Osier); 3, *S. triandra* (blunt-stipuled triandrous Willow); 4, *S. undulata* (sharp-stipuled triandrous Willow); 5, *S. fragilis* var. *Russelliana* (crack Willow); 6, *S. alba* (common white Willow); 7, *S. vitellina* (yellow Willow or golden Osier); 8, *S. viminalis* (common Osier); 9, *S. stipularis* (auriculed Osier); 10, *S. Smithiana* (silky-leaved Osier); 11, *S. nigricans* (dark-leaved Willow). This list gives eleven species that may be cultivated in Osier beds for commercial purposes, but the basketmakers have their own names for them, names which are almost unknown to other persons.

Forming an Osier bed.—The first operation will be to trench the ground to a depth of at least 18 inches, of course paying due attention to the quality of the subsoil. The ditches for drainage must be laid out with care and judgment. The sets should not be less than 2 feet long, and selected from strong shoots of the former year. The sorts should include as many of the different species as possible, but in this it must be observed not to mix them, or if mixed let it be alternating, so that if one sort fails the other may be safe, so as to cover the ground. But too much care cannot

be exercised in the selection of the sorts, as on this, more than on any other thing, will depend the success of the plantation. I know of a bed of some three acres which was formed with great care six years ago. It produced fine crops the first and second years; the third year it began to fail, as also the fourth year; the fifth year it was not considered worth cuttings and has not recovered itself this, the sixth year, a great many of the plants having died clean out. I have diligently inquired into the causes of this, and the owner, who is a practical basketmaker, is entirely at a loss for the cause, sometimes blaming one thing and sometimes another. The only feasible explanation seems to me to be that the sorts selected, of which there were two, were not suitable for the soil and situation, as one of the two sorts has suffered more than the other. Keeping this example in view, therefore, great attention will be required to select the sort most suitable for the soil and situation, although the sort selected may not be the most valuable in the market. After considering the whole matter, the only practical advice to be followed is to note accurately the description of soil, subsoil, and the situation of the ground to be planted, and then to find out an Osier bed flourishing under like circumstances, from which select your cuttings.

The sets are to be inserted into the ground, leaving 1 foot above it, in rows 3 feet apart, and 18 inches asunder in the rows; this to be done in the month of February. They must be thoroughly weeded, and the ground scuffled with Dutch hoes every year in dry weather (deep hoeing or cultivating is injurious), as the weeds make their appearance; otherwise they will destroy the plants. Shoots of one year's growth are the best for the basketmaker's use if they grow vigorously and produce clean, straight, and strong shoots; otherwise they should be cut but once in two years, or in three if not vigorous the second year. By intermitting a year or sometimes two, the roots will grow more strong, for the shoots will grow in strength proportionable to their roots, and cutting them every year should be done only when they have good roots, and the shoots grow long, clean, and healthy. Miller says in his "Dictionary of Planting:" "The willows are commonly planted in cuttings about 3 feet long, made from strong shoots of the former year; these are thrust down 2 feet into the ground. The cuttings should be placed about 3 feet apart row from row, and 18 inches apart in the rows. The best season for planting these cuttings in the Osier grounds is in February, for if they are planted sooner they are apt to peel if it proves hard frost, which greatly injures them." If the bed is kept clean there is no necessity to dig or break it up for twenty years, and the stools must not be cut over later February. The cost of digging or trenching the ground and planting an Osier bed, under ordinary circumstances, may be put at £12 per acre, and two hoeings at 10s. per acre.

The produce the second year should be eighty bolts or bundles, which should be 18 inches round at 14 inches from the butt. This, at 5s. per bolt, is £20; but whether this be too high an estimate of produce or not, of one thing there is little doubt—that a well-managed Osier bed is a profitable affair; and therefore no trouble should be spared to begin right, especially in the selection of the sorts. One other observation may be made, and it is that the ground need not necessarily be wet, for they will succeed well in a moderately damp soil. Indeed, the Willows are not all aquatic plants, some of the species being found naturally on dry banks, gravel, and even sand.—J. SMITH, in *Journal of Forestry*.

Magnolia conspicua.—I recollect that a specimen of this at Ganton about thirty years ago was always covered with bloom every year, except when there happened to be a smart frost in the latter part of February or beginning of March, which caused the flower-buds to drop off without expanding. It had a grand appearance on a sunny day in the latter part of March or the beginning of April. It may not be generally known that

the blossoms of this *Magnolia* are very useful in a cut state, as the buds expand beautifully in a warm room, and they travel well. It certainly is one of the best of spring-flowering trees. It requires, however, a sheltered situation if planted away from a wall. The plant at Gunton was planted against a south terrace wall. We pruned it always after it had done blooming, spurring it in like a Pear tree. It bore spurs from about 8 inches to 10 inches long.—E. SENDALL, *Thorpe Hamlet, Norwich*.

Hardiness of *Dracæna indivisa*.—Mr. Ramshaw (p. 170) should have given some

FLOWER GARDEN.

LARGE SULPHUR CORBULARIA.

NARCISSUS BULBOCODIUM CITRINUS is a great beauty from the shore at Biarritz, where it grows in copartnery with *Lithospermum fruticosum* and other of our garden flowers. Mr. J. D. Llewellyn found it there years ago, then Mr. Barr one day showed me very fine flowers, remarking that he believed it to be the *Corbularia gigas* of old Haworth. Bulbs of it came also, and Daffodil lovers were proud to add it to their collections. Then a woodcut sketch of a flower was given

Narcissus Bulbocodium var. citrinus (natural size).

clue to the locality in which he resides. I am now situated in the mildest part of Hampshire, in sight of the Isle of Wight, and here many greenhouse plants live out-of-doors all the winter. A fine variegated American *Aloe* which has stood out-of-doors in front of a villa here looks quite as healthy as those under glass, yet it would not be safe to say that this plant is hardy even in the same county, for some years ago when I resided in the central part of Hampshire I remember the thermometer falling below zero, and Laurels and similar evergreens being killed to the ground. It is, therefore, only by knowing the locality in which any plant proves hardy that we can tell whether it will prove suitable in our own case or not.—J. GROOM, *Seafield Nursery, Gosport*.

by me in the *Florist and Pomologist*, 1880, p. 67, where also will be found the original description of this variety by Mr. J. G. Baker, of Kew. The woodcut in the *Florist* is faithful, although evidently the sketch was made from a wind-tossed blossom growing in the open air. Now, Miss Jekyll has been so fortunate as to bloom it at Munstead in a greenhouse, and this figure is prepared from a tracing from a coloured sketch she made of it. It is a bold and shapely flower of a soft sulphur tint, "the colour having a luminous quality, the flower being like a little lamp of pale yellow light." A much smaller variety with pale yellow flowers was found in Spain by the Rev. H. H. Crewe. The larger kind is, however, most beautiful, and very, very rare. F. W. S.

FLORISTS' FLOWERS FIFTY YEARS AGO.

I HAVE recently become possessed of two beautifully illustrated volumes of great interest, and I believe of rarity also, as I cannot find that they are widely known—"The Florist's Guide and Cultivator's Directory," containing coloured figures of the choicest flowers cultivated by florists, including *Ranunculus*, *Carnations*, *Picotees*, *Pinks*, *Georginas*, *Polyanthus*, *Auriculas*, *Hyacinths*, and *Tulips*, with their descriptions and an account of the most approved methods of culture, by Robert Sweet, F.L.S., vol. i., 1827-1829; vol. ii., 1829-1832. The four volumes of Sweet's "British Flower Garden" are well known and frequently referred to. These are uniform in size, and are illustrated with coloured plates, evidently drawn and coloured with the greatest care by a true artist. The first impression which strikes one in looking over these volumes is a feeling of regret at the decadence of the florist's hobby. There are few, indeed, who would support the publication of such a superb book as this of Sweet's, devoted entirely to simple flowers. I suppose the development has reached forward, and that we must consider the Orchid grower, and the magnificent publications devoted to his plants, as the outcome of these smaller beginnings. However, the old florist's flowers and their cultivators still continue amongst us, and long may they do so. Commencing in alphabetical order with

The Auricula, here we have figured Booth's Freedom, one of the best green edges ever raised, and which there dates back to about 1827. It was then priced at 25s. in Hogg's catalogue. There are sixteen Auriculas figured in vol. i., of which Grimes's Privateer and Taylor's Glory are still amongst us. Vol. ii. contains ten portraits, amongst which are some great favourites, which thus date from about 1830. Lee's Colonel Taylor, one of our very best green edges, is beautifully figured, and the editor says: "It is considered by florists as the finest variety grown, and in Mr. Hogg's catalogue we see it priced at £3 each plant." Oliver's Lovely Ann is also there, and is still one of our very best green edges. The editor states that "It was raised by a person of the name of Oliver, who is now selling them at 20s. each. He grows them in a mixture of loam and decayed horse manure, in which they succeed very well." Another favourite—Wood's Delight, a good white edge; and the following interesting remark occurs in the editor's note: "It is a curious fact that those sorts which are naturally possessed of a fine green on the edge or margin of the flower are often known to lose that property when the stem proceeds from the very heart or centre of the plant; whereas those stems which proceed from the side produce larger pips, possessing their true natural colours in much greater perfection."

Of Polyanthuses there are but two figured in vol. i., and one in vol. ii., and of these the best is Burnard's Formosa, which is stated to have been raised by J. P. Burnard, Esq., of Formosa Cottage, Holloway. It is described as a bright velvety purple, but in the picture it is nearly black. Its flowers are very circular, the lacing good, and in all respects it is a first-rate Polyanthus. This variety is frequently exhibited, but I never saw it nearly so fine as is here shown. I have, however, been told that it frequently comes very good in the neighbourhood of Birmingham. The other two Polyanthuses are lost.

The Carnations and Picotees form a very numerous group, and show that the sorts grown fifty years ago included all the choicest now to be seen at our exhibitions, not excepting the yellow varieties, which Mr. Turner loves. Pinks also occupy a large space and appear to me to be finer than any we now see. It is to be hoped that Pink growers will be encouraged at our exhibitions. There are seventeen show varieties in these volumes; of *Ranunculuses* there are thirty-eight plates, and these are a most beautiful class, of which I fear scarcely any survive. Mr. Barlow was awarded a special prize at one of our Manchester shows last year for a collection of *Ranunculus* blooms, but I think they were from imported roots, and did not represent our old English

sorts. Perhaps he will give us some information on this subject. The Roses figured are very inferior to our present sorts, and contain no names now in commerce.

The Georginas, or Dahlias, are a very interesting lot. It appears the Georgina was then the general name for this plant. The editor says: "We have adopted Willdenow's name of Georgina in preference to Cavanille's Dahlia, there being a Cape genus named Dahlia before by Thunberg. All the Continental botanists have also adopted Georgina for the present genus." Georgina was a name given by Willdenow in compliment to J. G. Georgi, a Russian botanist, and Dahlia was named in compliment to Andrew Dahl, a Swedish botanist. It would be interesting to know how the name was subsequently changed again to Dahlia. One of the Georginas is a great beauty—the Painted Lady, or Anemone-flowered Georgina. It is described as belonging to a new type, the centre being composed of narrow radiated florets, like the small petals in the centre of a double Anemone. There is also a single scarlet and others like the sorts now in fashion. By far the largest space is occupied by

Tulips, sixty-one plates being devoted to this interesting class. It is to be feared that Tulip growing is a decaying art. There are two large collections which were left by enthusiastic growers (one of them poor Tom Mellor) which have failed to find purchasers, and which will probably follow the fate of the Ranunculuses and be lost, and yet there is no more delightful hobby than the Tulip fancier's, and none more easy to manage if leisure be at command. The old weaver who could leave his loom for an hour now and then was the best florist, as he had his hobby and his relaxation together, and he was able to watch the varying requirements of his pets and meet them as they arose. In these days of mills and workshops, the home hobbies get left aside, and are slowly passing from our midst. There are a few plates of Hyacinths, and this completes the recital. It is, however, worth adding, with reference to recent remarks upon shaded alpine Auriculas, that there is one figured—Howe's Venus—a fine shaded purple with yellow centre, reminding one of Gorton's Mauve Queen of fifty years ago. This carries the introduction of shaded alpine much further back than Mr. Douglas was aware of, as in 1829 the editor wrote, "The present variety belongs to the tribe called shaded alpine by the florists."

Brockhurst, Didsbury. WM. BROCKBANK.

FLORISTS' FLOWERS IN SPRING.

The Dahlia.—This showy autumn-blooming plant was greatly prized for exhibition purposes about twenty years ago, and it was certainly better adapted for this than for the flower garden; but the time is sure to come when the interest in any particular class of exhibitions cannot be maintained, and if flowers are grown more for the sake of winning prizes than for their intrinsic worth, or for the pleasure to be derived from seeing them in the flower garden, they are sure to decline in popular favour. About the time of which I speak what has been styled carpet bedding had begun to take hold of the gardening public, and this style became fashionable. The Dahlia could not be worked into beds planted and trimmed in that way. It was tried, I know, for I visited a garden in which Dahlias used to be well grown for exhibition. Instead of finding sturdy plants furnished with leaves to the base, I found them with lanky stems, from 3 feet to 4 feet in height, and on expressing astonishment at the change, the gardener vaguely hinted that they were grown so "for a purpose." Their long stems were to be pegged down in the expectation that they would break forth at the joints and form a dense bed a foot or so high in the flower garden; but the Dahlia could not be trained to make a satisfactory bed in that way. Its place was as a back row plant in the mixed border, where it made a goodly display. It will be a pleasure to many to know that the Dahlia is again to have a run of popular favour. "The

lumpish Dahlia," as it was styled by one of the leaders in horticulture, has to give place to the prim little bouquet or Pomponé; and the single forms which used to be unmercifully chopped up to swell the vegetable refuse heap have become a marketable commodity of great value, equally esteemed in the flower garden and in the boudoir. The spring treatment of them all is the same. They should now be put into a glass house where there is a little heat so that they may start into growth, and as soon as the growths are about 2 inches long they should be taken off and propagated in a hotbed or a forcing house where there is a little bottom heat. Each cutting should be carefully planted in a 2½-inch pot; the sort which the potters call long Tom is best. Very few of the cuttings will fail, and they do not take long to form roots. Some of them take longer than others, and those that are seen to have formed roots should be taken from amongst those that are not rooted. The young plants soon require repotting, and should be grown where they can get plenty of air and light. When danger from severe frosts is over the plants may be placed in cold frames, from which in fine weather the lights may be entirely removed.

The Phlox.—In spring, as early as we can obtain the cuttings, arrangements are made to propagate as many Phloxes as are required. Numerous shoots are thrown up by each established plant, and as soon as they are 1½ inches long they should be taken off and inserted singly in 2½-inch pots. If the pots can be plunged in a hotbed the cuttings very speedily form roots, and by repotting them into 4-inch or 5-inch pots strong flowering plants are produced the first year, which may either be grown and flowered in pots or be planted out in the beds or borders. The Phlox is an easily grown hardy plant, and will flower, even if neglected, year after year. The plants make a mass of roots, and soon exhaust the soil round them. One way of propagating them is to dig up an old stool and chop it into three or four pieces with a spade, replanting the divisions, but no really good spikes can be obtained in that way. Spring-struck cuttings always produce the best plants. Seedlings raised from seed sown now will also flower strongly and well, producing about 50 per cent. of the whole as good as the parents, but they vary very much. We saved a lot of seeds from some of the best dwarf pure white forms, but did not get a single white variety amongst them; and the rich dark coloured varieties did not give much better results. From amongst two or three hundreds of seedlings we did not get one that could be said to surpass the best of the named varieties. What we did obtain was plenty of spikes to cut long after all the named varieties were over. They flowered finely the second year, and after that they were destroyed. Those who have only seen this plant grown in the ordinary way in the herbaceous border have no idea of the great results that can be obtained from one-year-old plants put out 2 feet apart on deeply trenched and heavily manured soil. Three stems would be a sufficient number to each plant the second year.

Pentstemons.—These do not obtain so many admirers as the Phlox; nevertheless, they bloom very freely in the mixed border, and continue to do so well into the autumn, and they are not easily injured by wind or wet. The best way to obtain a stock of strong flowering Pentstemons is to take off cuttings in autumn about the same time that Calceolaria cuttings are put in, and they require much the same treatment in winter. They ought to be potted off from the cutting-boxes early in the year, and when well established, which will be by the end of March or early in April, they may be planted out. Like the Phlox, they prefer rich soil, and if in beds, should be planted 2 feet from each other. Old plants have passed through the winter in the borders this year without injury, and if cuttings were not put in in autumn, they may be inserted now, only instead of planting them under hand-glasses or frames it will be better to push them in a hotbed or propagating house, potting

them off or planting them in boxes, about 4 inches apart, until large enough to plant out.

Ranunculuses.—We have been anxious to plant out our stock of these, but have not been able to do so owing to the wet. They ought to be planted out about the first week in February, but they do not suffer much if the planting is delayed for a month. We like to get them out as early as we can, so that the bloom may be over early and the beds at liberty to be planted with Stocks, Asters, or some other autumn flowering plants. The ground is, however, so wet that it will be necessary to cover the entire surface of the beds with dry soil. If dry peat and loam in equal parts can be obtained, it is the best compost in which to plant them; the small tubers should be carefully placed in the ground, crowns up, and be covered to the depth of about 2 inches with fine soil. I place some fine sand over the roots before covering them with the mould. If Anemones have not been planted, they should be treated the same as the Ranunculi and be planted out at once. J. DOUGLAS.

THE TENBY DAFFODIL.

I AM afraid the name Tenby Daffodil is being applied to the wrong variety, viz. *Narcissus obvallaris*, "the short tubed spread crowned" variety of a deep yellow, almost self, and one of the earliest and most beautiful of all the Daffodils. I first became acquainted with this variety through Mr. Wolley Dod, who sent it to me as the Tenby Daffodil, and I have spoken and written of it as such until this day. To my surprise, however, I find that we have got the wrong Daffodil under this name, and that it has become current in the very best collections. On looking over Haworth's monograph of the *Narcissi* in Sweet's "British Flower Garden," 2nd series, vol. i., I find, under the Ajax II. section, No. 16, *Lobularis*: "Tenby six-lobed Daffodil." *Corollæ laciniis luteis tubo obconica exacte duplo longioribus; corona perulea patula sexlobata (lobis integris), laciniis tres lineas superante.*—Nob. in *Phil. Mag.*, May, 1830, p. 131. "This grows wild near Tenby, in Pembrokeshire, which, by mistake, was written Truby, in Derbyshire, in the place above cited. It is also interesting to note, in the discussions of the origin of single and double forms, the following record in Haworth under the same heading. Obs.: In Chelsea Garden a wild bulb from Devonshire, with double flowers, produced offsets bearing for the last three years permanently single ones."

Since writing the above, I notice that "Veronica" (p. 220) makes the very mistake I am now correcting. He says: "And the pretty Tenby Daffodil (*N. obvallaris*) is opening to-day, 26th ult." It will be a week or two before it blooms at Brockhurst. WM. BROCKBANK.

Brockhurst, Didsbury.

Helleborus maximus (p. 222).—Mr. Archer-Hind may be quite sure that this plant was in cultivation long before 1863, and neither originated in Miss Hope's garden nor in Aberdeenshire. I had it here many years before I had the pleasure of Miss Hope's acquaintance, but I have no record whence it came.—HENRY N. ELLACOMBE, *Bitton Vicarage*.

Double white Hepatica (p. 223).—Every spring there comes with the Hepaticas an inquiry for the old double white. I believe there is not and never has been a variety permanently bearing double white flowers. I do not say this because I have never seen it myself, but I say it on the authority of that good old gardener, Mr. Wheeler, of Warminster. He often told me that there was no such plant, but that the double pink or red sometimes produced autumnal flowers, and that these autumnal flowers were sometimes white. I always found his information thoroughly trustworthy, and I have no doubt this is the true account of the flower.—HENRY N. ELLACOMBE, *Bitton Vicarage*.

Iris reticulata.—As is recently stated in THE GARDEN, *I. reticulata* Krelagei is distinct from the

typical form. Its colour is a dull purple, but it is not generally known that the type *I. reticulata* also varies from bluish violet to a velvety blackish, but very bright, purple. I have for many years sowed this kind with the view of improving the strain, and I have already some success. I have seedlings in every shade of colour, whether produced from seed taken from a reddish or from a blue-flowered plant. *Iris Histrio* is a distinct and desirable kind, flowering fully four weeks earlier than *I. reticulata*. Its flowers are of a pale blue colour, blotched and margined with bright blue.—MAX LEICHTLIN, *Baden-Baden*.

Lilies.—In answer to "H. H." (p. 213), allow me to state that *L. Parthenion* is much like *L. Coridion*, and both may be but varieties of the same species. *L. Coridion* is a bright canary-yellow with numerous red tips on the lower part of the sepals. *L. Parthenion* is bright red splashed and streaked with yellow. I think that since Siebold brought it home it has not been re-introduced into Europe. *L. concolor* is a very different Chinese plant, akin to *L. sinicum*; the flower of the former is of a somewhat glaucous crimson-scarlet, rather thick in substance, and the latter is bright dazzling scarlet. A good sandy peat with a little loam added, and some half rotten manure laid around the stem, will suit the plant's requirements.—MAX LEICHTLIN, *Baden-Baden*.

Oenothera eximia (*alias* *O. marginata*?).—The plant described by Mr. E. H. Egles I saw in the herbaceous garden at Kew four years ago labelled *O. marginata*. On making inquiries from those who knew the genus, I was told that Mr. W. Thompson, of Ipswich, could supply me with seed of the true *O. marginata*, but that which I had seen was *O. eximia*. Mr. Thompson told me that after consulting various authorities he believed that the Kew plant was the true *O. marginata*. I obtained a plant the same year from Ireland by the name of *O. marginata*, and have grown it ever since. It is a troublesome plant. The flowers are larger than those of any other of the genus, and very sweet, but the straggling underground shoots must be collected every spring and put into fresh soil, or the plant dies out. It seems incapable of growing in the same spot for two years.—C. WOLLEY DOD.

ANEMONE FULGENS.

IN one of those bright flower notes signed "Veronica" (p. 220), after praising the Pau Anemone, the writer inquires what has become of Mr. Poë's fine fulgens from Mentone, and where is the giant form raised by the late Mr. Nelson. Both these treasures are safe and in great vigour in our garden. The former, kindly given by the collector, was till lately the finest I had seen, some of last year's blooms being 4½ inches in diameter, but everything is thrown in the shade by the great Aldborough variety—a flower simply astounding in all its qualities of size, substance, colour, and strong leathery foliage. The petals are a full inch across. "Six-foot run" of this grand flower is a possession not lightly to be esteemed, to say nothing of a bed of seedlings of the same, with the great interest in store of seeing how they turn out. The main stock of this fine plant is quite safe and in the best hands. Some have also the buff ring, but the most striking are the deep strong scarlet with black centres; the rich velvety texture seems to intensify the colour, till, as George Herbert says, its "hue, angry and brave, bids the rash gazer wipe his eye!" Those from the Mentone district are a splendid clear scarlet, but not so deep and intense as the Aldborough kind; some collected by another friend are mostly double, and the Mentone doubles are apt to be spoilt by being too full—unpleasantly congested-looking and mixed with green. These go to the rubbish-heap in company with the green-flowered double Daffodils that err in like manner from excess of zeal. I should like to know how long dry roots of *Anemone fulgens* will retain vitality. Some years ago some were collected for me near Cannes; they came home

packed with some old majolica, and were inadvertently put away in a piece of the pottery, and only found fifteen months later. They were at once planted, though with little hope of their recovery, but they started at once, and are now a fine stroug lot.

The Pyrenean variety is a most useful flower, having been in bloom since the middle of February. It may be that its early blooming is in consequence of the roots being newly imported, and therefore well ripened; it was planted as soon as received in the middle of last May. The colour is not the vivid scarlet of the Riviera kind. It has a quieter pinkish quality, like vermilion in powder; also, the petals are narrower and weaker, and the leaves have not the same bold, self-asserting character. Among my 200 roots from Pau are some very good doubles, the flowers well filled, but not over-crowded; the soft vermilion colour is very pleasing in the mass of petals. I have an old garden kind of double fulgens, or perhaps one ought to say double stellata, whose colour is yet softer and duller, though still of the pure vermilion character, very much like the one I have as the old single scarlet stellata. In comparing the varieties of this charming flower I suppose one would put this flower at the bottom of the scale, the great Aldborough fulgens being at the top. The intermediate variations seem endless. I hear there is a white fulgens, but have not yet been fortunate enough to see it. G. J.

Surrey.

NOTES AND READINGS.

VINES AND VINE CULTURE.—Mr. Barron's book on this subject will have the proverbial "wet sheet" effect on all previous works of the kind, but it is a pity such a good book, written "primarily for amateurs and young gardeners," should be so dear. The price is too high—disproportionally so—and will prevent numbers of those for whom it is written buying it. I see it stated in one of your contemporaries that the work is published "with the sanction and concurrence of the council" of the Royal Horticultural Society—although Mr. Barron does not say so—and that the public have a right in consequence to assume "that the book is a good one." We doubt very much if the public will attribute its excellence to this source, but, admitting some share of credit to the society for Mr. Barron's labours, the book is one of the best works it has ever promoted. The work is very appropriately dedicated to the President and Council of the Royal Horticultural Society, but the author's acknowledgments of assistance are tendered to outsiders.

THE BOOK is dry, but not discursive or exclusive, pithy, and practical, and the illustrations are all good and truthful, save one that is supposed to represent a properly thinned bunch which we are sure no good grower will copy. On the subject of borders the author is evidently familiar with the discussions that have taken place in reference to inside v. outside borders, and thinks outside borders are preferable for general culture; he points out how the roots prefer to go outside if they have the chance, and that inside borders favour Phylloxera. I think it is Mr. Baines who has attributed the departure of roots from inside borders to mismanagement on the part of the cultivator. Most cultivators will agree with Mr. Barron. Bottom heat, by means of pipes, &c., is dismissed in a few lines as being of little advantage as compared with its cost and other drawbacks.

PRUNING.—In such a correct work one regrets to see an old and palpable fallacy perpetuated. The author says we prune our Vines for various reasons, one of which is for the "purpose of attaining greater vigour in the plant." It will be readily admitted, as Mr. Barron states, that by cutting off a portion of a shoot or branch and concentrating the vigour to a lesser area ("the part that is left") we get a stronger growth,

but this does not prove in any way, as it is stated to prove, that we attain greater vigour in the plant thereby (pp. 76 and 77). Physiologists dare not now countenance this fallacy. Far more correct, if contradictory, is our author when he states that the extension system, which is inimical to pruning, induces increased vigour and fresh life and energy in the plant, and that it is assuredly favourable to longevity. Two directly opposite practices cannot surely produce the same effect; in fact, Mr. Barron says the "opposite treatment (restriction) more rapidly uses up the vital energies of the plant." Lindley said, and his words have never been controverted, that it was only "a supposition, or seemed to be, that when the branches of a transplanted tree are headed back the remaining buds will break with more force than if the pruning had not been performed." The great point to attain, he says, "is the renovation of the roots, and if the branches of the plant are removed by the pruning knife a great obstacle is opposed to this renovation." We know it is difficult to persuade gardeners that they cannot increase the vigour of a Vine, for example, by cutting it down, but if they reckon vigour by the production of leaves and wood they may easily discover by experiment that they cannot add one tittle to the strength of their plants by so doing. The cut-down plant makes a rebound merely and nothing more—not one extra leaf or a joint is added by the process of cutting back, but are, on the contrary, reduced.

Notwithstanding Mr. Barron's theory on the subject of pruning, however, it is gratifying to find him advocating in practice a great advance on the past plan of cutting young Vines down to or below the bottom wire at the end of the year. "A healthy plant may be allowed 4 feet or 5 feet of new stem, or even more," he states, which is almost as much as extensionists have contended for in general practice, and quite opposed to instructions in previous works on the Vine. As to

THE TEMPERATURE necessary for the setting of Grapes, we do not quite comprehend Mr. Barron. Discussing this subject specially under its own heading, at page 58, we are told that "the (night) heat should be raised gradually to 70° by the time Vines come into flower, and when the Grapes are fairly set a lower temperature may be maintained until after the stoning period;" and at page 86 occurs the following quite opposite advice: "Some cultivators consider it absolutely necessary to maintain continuously a very high temperature—from 65° to 70° by night—for the setting of their Grapes, but it is really not required for the mere 'setting' of the fruit. For example, in late houses and on open walls the Grapes set their fruit quite freely at a much lower temperature; we have frequently seen it below 45° at night, and yet the Grapes have set well. It is therefore fair to assume that a temperature ranging from 55° to 60° by night is quite high enough for the mere purpose of setting the fruit, provided there is the desired rise in the day temperature." Which system does the author of "Vines and Vine Culture" mean? There are several discrepancies of this kind between the beginning and end of the book, notwithstanding revision, that appear to indicate altered convictions on the part of the author.

THE GREAT VINERY at Chiswick is truly a noble structure and has placed valuable materials at Mr. Barron's hands. It surprises one to hear that it was predicted it would be found too large and light to grow Vines successfully, for large structures have long been favoured for Vine culture by cultivators, and the Chiswick vinery has apparently solved the problem that big houses require less ventilation proportionately than small houses. They are neither so soon heated nor so soon cooled as the latter.

THE FIGURED GRAPES.—These are probably the most valuable feature of Mr. Barron's book. With one exception, the varieties are truthfully rendered, and will enable anyone to understand

what they are like. The selection, too, is good. The exception alluded to is the Black Prince, which certainly does not pourtray the variety gardeners are familiar with under that name, nor the Grape Mr. Hill, of Keele Hall, used to show so frequently at Regent's Park. It has the most symmetrically tapering bunch known, and the berries are not so round as shown in the figure, which is more like a Black Hamburg than the variety it is intended for. It never shoulders, as shown, and it is so limp and supple in the stem that it always hangs as straight as a plummet, which Mr. Barron's bunch does not. There is something wrong here.

*

SCIENCE AND PRACTICE.—“A. D.” seems to represent science and practice as coming in conflict on the subject of “top-heating,” whereas the one is the father of the other. Science is practice. I admit that Mr. Cannell's flowers are fine, but do not acknowledge it is his top-heating that accounts for it, for equally good results have been and are obtained under less favourable circumstances than Mr. Cannell has to contend with in Kent. Besides, it is reported that Mr. Cannell is not extending the system. Placing hot-water pipes close to the glass roof is something like putting a warming-pan outside the sheets or trying to boil the kettle from the top. “A. D.” knows, too, that the “shapeless body” of air in a house corresponds exactly to “a column” of air, as mentioned by me, if the pipes are rightly placed. “A. D.” says “it was held to be a profound scientific fact that given top ventilation and the heated air would escape through the apertures,” but that practical experience has set our “preconceived notions” on this subject at defiance. Well, we plead guilty to having held the scientific notion that smoke did go up the chimney and out at the “aperture” at the top, and out at the top ventilators of a hothouse as well, but it is admitted that a good deal depends upon the balance of the currents. Too much top air is given as a rule and too little at the front.

*

SUBSTITUTES FOR PEAT.—From peat to Cocoa fibre for Orchid culture is certainly a curious transition, and one would imagine that peat, as regards supply, would hold its own the longer of the two. We have a conviction that there are thousands of acres of Orchid peat in existence yet. The objection to Cocoa-nut refuse of any kind is its liability to generate fungi, like most decaying vegetable substances. It does not matter so much about peat, however, because the roots of Orchids always appear to work least amongst it. Take *Odontoglossums*, for example. They produce just a skin of roots among the surfacing of living and dead Sphagnum, and penetrate the drainage below the peat, which they shun. The grosser-growing and feeding *Dendrobiums* and the like grasp the peat as they do any other light fibry substance of wholesome texture, but the more delicate subjects avoid it. Sphagnum is the only material that keeps clean and grows in the pot, and it would be a misfortune if it was to fail, for, although other hardy Mosses grow in our hothouses, they are not so suitable for the purpose as Sphagnum, which is becoming more popular every year for Orchid composts.

*

LONGEVITY OF ODONTOGLOSSUMS.—Can any of your readers tell us the age of some of the oldest *bonâ-fide* cultivated single plants of *Odontoglossum Alexandræ* or *O. vexillarium*? There are thousands of small recently established plants in collections, but few old ones, and I have a suspicion, from what we have seen and heard of the history of some stocks of plants, that the mortality among this section is rather serious, the stock being kept up by fresh importations. *O. vexillarium* appears to be the more certain grower and the more vigorous of the two. Bulbs the size of those large and plump fellows one sees in imported masses are not common in cultivated specimens of *Alexandræ*.
P. EREGINE.

GARDEN FLORA.

PLATE CCLXXX.

SHRUBBY SPIRÆAS.

(With a coloured figure of *S. Douglasi*.)

IF we except the herbaceous section, most of the Spiræas are free flowering shrubs, ranging in height from the diminutive *S. bullata* to 8-feet, 10-feet, or 12-feet bushes of *S. ariaefolia* and *opulifolia*. Some of them, too, are amongst the earliest of flowering shrubs, while others come in in succession till the end of the summer; some species continue indeed in flower during the greater part of that time. They are all of easy culture, preferring a good free soil in a somewhat moist position rather than where it is hot and sandy; in the latter case the growth is generally stunted, and though the plants will live, their blossoms are not nearly so effective as those produced on vigorous shoots, on which they are more abundant. As regards pruning, all that is necessary is at times to cut out the old exhausted shoots for the purpose of encouraging new growth of more vigorous ones, as if this is not occasionally done, the plants become masses of small twiggy branches, their floriferousness being thereby much impaired. The position which they occupy will, of course, depend upon their habit, for while a few of the smaller kinds are well adapted for rockwork, most of the others show themselves off to the greatest advantage when planted in the form of large clumps or masses. Thus treated, the graceful form of *S. hypericifolia*, known as *flagelliformis*, and lately figured in THE GARDEN; the erect-growing *S. Douglasi* here represented; or the pinnate-leaved *S. Lindleyana* are each in their way very beautiful. Owing to the quantities of suckers produced, all the Spiræas are easily propagated in that way, except the singular *S. lævigata*, which it is necessary to increase by layers. Seed is also freely produced, and from the readiness with which seedlings may be raised doubtless arises the confusion which now unfortunately exists concerning the correct nomenclature of these plants. Another reason probably being that some of the species are of very wide geographical distribution, and vary more or less in different localities. Be that as it may, it is often scarcely possible to assign some of the varieties to any particular species. Spiræas are generally divided into groups according to the way in which their flowers are arranged, *i.e.*, whether in loose panicles, in corymbs, or in dense upright racemes or spikes.

Flowers in upright spikes.

S. Douglasi.—A free-growing, erect-habited shrub, attaining a height of 5 feet or 6 feet, both young shoots and leaves being entirely pubescent, but mature leaves only on the underside. The inflorescence of this fine species is well shown in the annexed illustration; a large clump of it, composed of densely packed shoots, each terminated by such flower-spikes as that here represented, is, as may be imagined, very effective. This species is a native of North-west America, and is often met with under the names of *tomentosa*, *Nobleana*, and *Menziesi*, in addition to

* Drawn from a plant in Mr. Joseph Stevens' garden, Grassmere, Byfleet, in July last.

Growers or introducers of new plants will oblige us much by early intimation of the flowering of new or rare species, with a view to their representation in our “Garden Flora,” the aim of which is the illustration in colour, and in all cases where possible life size, of distinct plants of high value for our gardens.

that of *Douglasi*. Professor Maximowicz, in his monograph of the genus, gives *Nobleana* and *Menziesi* as synonyms of *S. Douglasi*. All of them are natives of the north-western coast of America. *S. tomentosa* from Eastern North America he considers to be a distinct species. Plants of it which have come under my observation differ but little from *Douglasi*, except in their larger amount of tomentum, and that character varies greatly in individuals, so that little trust can be placed in it. The kind generally recognised as

S. Nobleana is a stout, erect-growing shrub, the branches of which are downy when young, but smooth when in a matured state. The leaves are large, quite smooth on the upper surface, but greyish beneath. The flowers are disposed in an opener and more branching panicle than those of *S. Douglasi*, and the leaves are also somewhat larger. There exists a good deal of confusion regarding the origin of *S. Nobleana*. It was first brought into notice about 1854, and was at that time said to be a hybrid raised between *S. Douglasi* and *S. callosa*, but wild specimens sent home by Lobb agreed with it in all respects, and it seems probable, judging by the many slight variations amongst them, that the whole of the Spiræas just named may be reduced to one species. Planters should look out for the sturdy-growing, deep-coloured form, under whatever name it may be found. The undersides of the leaves of this are generally white.

S. salicifolia.—This and its varieties are widely distributed throughout Europe, Asia, and North America. Like the preceding, it is a dense, erect growing shrub, but with both the leaves and young shoots glabrous instead of pubescent. It reaches a height of from 4 feet to 5 feet, and blooms during July and August. The flowers are arranged in blunt, dense, erect racemes, and are pale red or deep rose in colour, but in the varieties all shades occur, from pale red to white. One of the North American forms (*S. salicifolia paniculata*) has flowers arranged in large branching panicles, pure white in colour, and very showy. This variety is of vigorous growth, and, besides the flowers, differs from the ordinary form of *S. salicifolia* in the young bark being red. It is also known as *Spiræa alba* and *S. canadensis*. Other varieties are *alpestris* and *latifolia*, the first small in stature, and the second, as its name implies, broad-leaved. Numbers of other forms may also be met with.

Flowers in loose, open panicles.

S. ariaefolia.—This is one of the largest of the genus, reaching a height of 8 feet or 10 feet and forming an erect, but branching shrub. The flowers are white and are borne in open plume-like panicles, which from their abundance render this species one of the showiest of summer flowering shrubs. Well known though be it, when in a somewhat moist and holding soil it grows so rapidly and forms so striking an object when in flower, as to commend itself to everyone. It is a native of North America, and is occasionally met with in nurseries under the name of *Spiræa discolor*.

S. lævigata.—This is very distinct from any of the others; indeed at first sight it would not be taken for a Spiræa at all, unless the flowers were present. It forms a stout, somewhat spreading shrub, from which but few suckers are produced. The leaves are oblong in shape, smooth, somewhat glaucous, and of much firmer texture than in the other kinds. The flowers, which are

SPICEA FLOWERS

white, tinted with pink, are not so showy as those of many of the other species. Although not so effective as some, this *Spiræa* is well worth a place in gardens on account of its distinct appearance. It is a native of Siberia, and flowers about May.

Flowers in umbels, corymbs, or cymes.

This class includes the greater part of the *Spiræas*, most of them being of a medium or low habit of growth.

S. alpina.—This is a slender, erect growing shrub, 3 feet to 4 feet high, with narrow lanceolate leaves and white flowers produced in terminal corymbs. It is a native of Siberia and Mongolia.

S. bella.—A loose growing shrub much in the way of the now better-known *S. callosa*, but slighter in habit than that kind and earlier flowering, its season being May or June, while *callosa* does not flower till July or August. The flowers, which are deep rose in colour, are disposed in large open terminal corymbs. It is a native of Nepaul.

S. bullata.—For rockwork this miniature species is quite a gem; it only reaches a height of 3 inches or 4 inches, and forms a little dense mass, which towards the end of the summer becomes thickly studded with tiny heads of bright

doubtless one of the prettiest miniature shrubs that we possess, and one at present but little known.

S. callosa.—This is a free-growing kind, bearing large corymbs of deep rose-coloured flowers. The young shoots and leaves are of a bright red hue and very effective, owing to their brilliancy. It does not usually come into flower till the bulk of the early ones is past, but when once the blossoms open a succession is kept up for some time. It is a native of Japan, and is sometimes called *S. Fortunei*, while *S. japonica* is but a deep tinted form of it. The remarks made in reference to *S. Douglasi* are equally applicable here; that is, to choose the brightest coloured forms when planting, as some individual plants are much superior to others in that respect.

S. callosa alba.—This is a dense bush about 2 feet high at the most, and bearing white flowers.

S. cana.—A small partially decumbent shrub, from 1 foot to 2 feet high, with white flowers borne in sparsely-flowered corymbs, and produced in June and July. From its decumbent habit it is well adapted for planting on rockwork. It is a native of the mountainous parts of Croatia.

S. chamædrifolia.—A very variable kind, and one concerning which a good deal of confu-

from 2 feet to 3 feet in height, bearing flowers in hemispherical corymbs during June and July. In colour they are white, and borne on long, slender stalks; the leaves are rather small, sharp pointed, and pale green in colour. It is said to be distributed through Eastern Europe, the northern and central parts of Asia, and even to North America. The most distinct varieties of it are *ulmifolia* and

Spiræa lanceolata.

flexuosa, the latter being taller and opener in growth than the species.

S. cuneata.—This is a free-growing kind, reaching a height of 5 feet or 6 feet; the tips of the principal branches arch over gracefully, and the minor ones do so in a still greater degree. The leaves are wedge-shaped at the base, and the flowers are arranged in close, corymbose panicles on the ends of the principal shoots and on the short lateral branches towards the upper part of the plant. Their colour is generally white, but occasionally they are slightly tinted. It is a native of Nepaul, and is also known under the names of *S. cuneifolia*, *S. canescens*, and *S. nutans*.

S. lanceolata.—A neat little shrub, not more than 3 feet high, with small lanceolate leaves and white flowers. *S. decumbens*, a trailing kind, is well adapted for rockwork or sloping banks—positions in which it flowers freely. It is a native of the Tyrol, and is also known as *S. nana*.

S. flexuosa.—A slender-growing shrub, about 6 feet high, with long flexuose shoots. The leaves are small and lanceolate, and the large, open corymbs of flowers, produced in June and July, are pure white. Sometimes the leaves are toothed, and at others deeply cut. This latter form is often known under the names of *S. incisa* and *S. laciniata*. It is a native of Japan.

S. hypericifolia.—This is a slender, twiggy shrub, the flowers of which are produced on shoots of the preceding year. They are white in colour, and arranged in small corymbs disposed thickly on short laterals throughout a great part of the branch. So thickly are the flowers arranged, and along such a length of shoot, that they form beautiful floral wreaths. It flowers in May and June. As regards native country, different opinions exist. Maximowicz gives it as a native of Asia Minor and Persia to Eastern Siberia. This *Spiræa* is found under an almost endless list of names, and its varieties are in a state of great confusion. *S. crenata*, *Plunkenstiana*, *acutifolia*, *oblongifolia*, and *flabellata* all belong to this species. The

Spiræa callosa paniculata (a hybrid variety).

rose-coloured flowers. It is stated by M. Maximowicz to be found in Japanese gardens, therefore presumably not wild in that country. It is un-

sion exists, some classing many varieties under this head, while others regard them as distinct species. The ordinary form is a twiggy shrub

variety figured in THE GARDEN as *S. flagelliformis* is a magnificent kind, and regarding the whole class no better advice can be given to the buyer than that which accompanied the figure just alluded to, viz., see the plants in flower, and select them then, as individuals vary so much. A variety of *S. hypericifolia*, known as *thalictroides*, is very distinct from the rest as far as the shape of the leaves is concerned. They are small in size and slightly three-lobed. This is altogether a dwarfier growing plant than the others, reaching only a height of 2 feet to 3 feet.

***S. prunifolia* fl. pl.**—This is a slender twiggy shrub 5 feet or 6 feet high, the shoots of which are long, and clothed for the greater part of their length with flowers. The blossoms are pure white, very double, and thickly produced in small lateral corymbs. It is a native of China and Japan, and is one of the first to open in spring, being often in flower early in April.

***S. Reevesiana*.**—A twiggy sub-evergreen shrub 3 feet or 4 feet high, with lanceolate leaves and terminal corymbs of pure white flowers. It blossoms about July, and seems to be the same as *S. cantonensis*. There is also a double-flowered variety of it.

***S. Thunbergi*.**—In general appearance this is like a small single-flowered form of *S. prunifolia*, the plant being dwarf in stature, open and twiggy in growth, and the flowers disposed in little clusters along the shoots. The leaves are very small and lanceolate, and make their appearance early in the season. It flowers in April and May, and is one of the easiest of plants to force into bloom early in the year, a few days in the forcing house being sufficient to induce its blossoms to expand.

Flowers in corymbs with inflated carpels.

***S. opulifolia*.**—This is one of the largest belonging to this class, reaching a height of 10 feet or 12 feet; the branches, too, are much stouter than those of any of the others. The leaves bear a great resemblance to those of the Guelder Rose (*Viburnum Opulus*), and the flowers are arranged much after the same manner as those of the sterile form of that shrub, although in not quite such globular clusters. In colour they are white, produced in June and July, and succeeded by inflated seed-pods of a reddish tint. This *Spiraea* is widely distributed in North America. There is a variety smaller in all its parts in which the young leaves are of a bright golden colour, and very showy in spring when they first unfold, but as the season advances the foliage becomes quite green.

With pinnate leaves.

***S. sorbifolia*.**—This is a stiff branched spreading shrub from 5 feet to 6 feet high, with large pinnate bright green leaves, and small white flowers borne in large terminal panicles. It is a very distinct and handsome kind, both in foliage and flowers, which latter expand in July, August, or even later. It is a native of Siberia, and prefers a cool, moist holding soil, in which it throws suckers freely and forms a large mass. There is a variety less in stature, but with larger flowers, known as *alpina*, *Pallasi*, or *grandiflora* which by Maximowicz is regarded as a species and named *grandiflora*.

***S. Lindleyana*.**—A stout, vigorous bush, reaching a height of 7 feet or 8 feet, and bearing very large pinnate leaves, much larger than those of *S. sorbifolia*, and without the twisted, irregular appearance often seen in the foliage of that kind.

S. Lindleyana is a free growing species, and in congenial soil soon forms a large, imposing clump, extremely handsome towards the end of summer, when the mass of foliage is crowned by feathery panicles of white flowers. It is a native of the western Himalayas, and is quite hardy in the neighbourhood of London, except in the case of exceptionally severe winters.

Besides the above a great number of names occur in catalogues in many cases mere synonyms, but several other presumably distinct kinds are given by Maximowicz in his monograph,

them as a separate genus under the name of *Sobraria*, and *S. opulifolia* is styled *Physocarpus opulifolius*. ALPHA.

SEASONABLE WORK.

FLOWER GARDEN.

Transplanting shrubs.—That flower beds may be afforded the necessary cultivation preparatory to the summer planting, it is now time that the shrubs and other hardy plants with which they have been filled in winter should be

Spiraea Lindleyana.

chief among which are — *S. caespitosa*, from North-west America; *S. parvifolia*, Mexico; *S. crenifolia*, one of the *hypericifolia* section; *S. prostrata*, Western China; *S. media* or *confusa*, Eastern Europe and Asia; *S. dasycantha* or *nervosa*, China and Japan; *S. Blumei*, Japan; *S. arcuata*, Sikkim Himalayas; *S. gracilis*, Himalayas; *S. micrantha*, Temperate Eastern Himalayas; *S. longigemma*, North-west China. Nearly allied to the *Spiraeas*, and by some botanists included with them, are the species of *Neillia*, Himalayan shrubs, *Chamaebatia foliolosa*, a curious pinnate-leaved little bush, and that beautiful white spring flowering shrub, *Exochorda grandiflora*. Maximowicz still adds to the list, as he divides the pinnate-leaved species from the rest and regards

transferred to their summer quarters. If planted later than this the probability is they might suffer from drought ere the plants had got established in the soil, but to guard against the possibility of such a check, it is our invariable practice to mulch with Bracken as soon as they are in their places, and for neatness sake the mulching is removed after there has been a long spell of showery weather to start the roots into active growth. Small plants of some few kinds of shrubs we use in summer as "dot" plants in foliage beds, and these, as a matter of course, when they can be made to fit in with the summer arrangements, are not transplanted at all. In order to better illustrate what we mean, we may say that we have here a border consisting of oblong panels and circles alternately. In winter the oblong panels have had as a centre small bushy plants of *Retinospora pisifera aurea*, and

the circles, small plants of *Cupressus Lawsoniana erecta viridis*. The winter groundwork of the oblongs was Heather, and that of the circles *Sedum glaucum*. All these shrubs will remain for the summer; the groundwork for the *Retinosporas* will either be *Alternantheras* or *Ajuga reptans purpurea*, and that for circles, *Mesembryanthemum cordifolium variegatum*. By thus endeavouring to retain all the plants possible that have done duty during winter, not only is the work lessened both as to labour of planting and propagation, but an effective and uncommon summer bedding arrangement is ensured. Beds that are vacant should be deeply dug, and manured or not according to the requirements of the plants to be used; all fine-foliated plants require abundance of manure, but the ordinary kinds of bedding plants need but little. When the beds are on Grass, the best arrangement, the soil should stand well above the turf and be edged with some kind of dwarf, close-growing, hardy plant. The best for this purpose that has yet come under my notice is *Herniaria glabra*; all our beds are edged with it, and they always look neat, and give but little trouble to keep them in order. About thrice during the summer they need trimming with sheep-shears. Box does not look half so neat, and certainly needs more keeping in order.

Herbaceous plants.—Borders of these are already beginning to look gay with *Crocuses*, *Hepaticas*, *Scillas*, and *Primroses*. All the kinds are now above ground, and gaps can therefore be perceived and be filled up either by dividing some of the old stools or by fresh importations, or indeed by sowing patches of hardy annuals. Trim off all decayed stems, clear away mulchings, and where it is not practicable from fear of injury to the plants to dig in well decayed stable manure, give a dressing of guano or of soot and wood ashes, and then surface fork the entire border. Fresh labels should be substituted for all that are becoming illegible, and especially should they be fixed to the less known kinds of plants, in order that all who are interested in them may the more readily become conversant with their names.

Indoor work.—In the houses and plantations there is now much requiring to be done. All kinds of roots and tubers ought to be started into growth. *Caunas* are quickly increased by cutting up the roots into single eyes, and starting them in small pots in warmth. Part the roots of herbaceous *Lobelias*, and plant them out in frames having a temperature of 50°. *Dablias* may be planted in the same way, but require greater heat if intended to produce cuttings. Those started a month ago will now afford cuttings, which strike quickly in a bottom-heat of 75°. The stronger the cuttings the longer are they in forming roots, and as they make no better plants than smaller ones, it is not therefore necessary to delay propagation in order to get strong shoots. Tuberous *Begonias* are gradually growing in favour for summer bedding; we tried a few last year, and they withstood the rain far better than *Pelargoniums*. Any tubers that are to be used for planting out should now be potted, and be allowed to start into growth slowly. A temperature of 45° or 50° is ample. *Begonia castanefolia*, a first-rate summer bedder, must be increased by means of cuttings. *Begonia Weltoniensis* also makes a fine bed, and this variety is most expeditiously propagated by division of the roots. Seedling sub-tropicals should be potted off before the roots get matted together in the seed-pans, and seeds of the quick growing kinds, such as *Tobacco*, *Castor-oil*, *Sunflower*, *Hemp*, *Maize*, and *Chilian Beet*, should now be sown. In order to make room for slow growing and less hardy kinds, *Lobelias*, *Verbenas*, *Ageratums*, and *Mesembryanthemums* may now be planted out in cold frames. The soil should consist of loam and leaf-mould in equal proportions. They will then lift with plenty of roots at bedding-out time. *Alternantheras* may now be planted out in manure frames, and a fortnight hence cuttings in abundance may be had, which, if inserted after the manner of the old plants in frames, will give but little trouble, except as to airing, till they are required for the beds. Fine-foliated *Pelargoniums*

must still be kept in warmth, but the common and hardier varieties may be transferred to cold pits. Cuttings of the same struck during the winter will now be ready for potting off, and till re-established in the pots should be kept close and warm.

ORCHIDS.

East India house.—As the sun comes out now with considerable force, we have found it necessary to put up the shadings so as to have them ready for any emergency. All our plants having been surface-dressed, repotted, and placed in new baskets where these have been required, there has been no other attention required for some time except to see to their daily wants; some species require more water than others, and when they are making their growth they require more than they do at other times. The *Angræcums* are now being grown in nearly all collections, and from the tiny *A. hyaloides*, a species at present thickly studded with pure white flowers on small spikes, to the large *A. sesquipedale* with its wonderful waxy white blossoms with tails 18 inches long, all are well worth attention. *A. citratum*, one of the most useful of the genus, is now flowering freely in most collections. It ought to be well known that most of them require plenty of water and sufficient atmospheric moisture. *Thrips* have been very troublesome, and we have had to go over all plants likely to be attacked once every three or four weeks, either washing or dipping them in diluted tobacco water, in which some soft soap has been dissolved, in most cases washing the leaves afterwards with clear rain water. Indeed, for all purposes, either for washing or watering *Orchids*, rain water ought, if possible, to be used. The various species and varieties of the genus *Phalenopsis* are making a very beautiful display at present. They succeed best suspended from the glass roof in baskets or pans, and they dislike being disturbed; rather than move them, we would pick the decayed material carefully from amongst the roots and substitute fresh stuff, continuing to do this annually until the teak decays. The new *P. Stuartiana* requires the same treatment as the others. This is a very distinct and beautiful *Orchid* furnished with long, many-flowered, branched spikes like *P. Schilleriana*. It ought not to be placed near the glass on the sunny side of the house; rather choose a partially shaded position for it.

Cattleya house.—Blinds must now also be put up here, but early in the year it is best not to shade more than is absolutely necessary. The varieties of *Cattleya Trianae*, introduced during the last few years, are remarkably beautiful, and at this season of the year last long in perfection. In Messrs. Veitch's nursery during unfavourable weather a variety of this species had flowers which remained in good condition for five weeks. Considerable quantities of it have been imported recently, and those who have plants of it should plant them in clean potsherds, merely keeping these moist until roots are formed; then remove an inch or two of the crocks from the surface, and substitute the usual potting material, taking care not to injure the roots. *Cattleya citrina*, also recently imported, requires different treatment; it seems to do best attached to a block or bit of Tree Fern suspended near the roof. Although this is the usual method, we have found it to do well potted in shallow pans in the ordinary way. The *Masdevallias* of the *M. Chimæra* and *M. bella* type should be placed near the glass in a shady part of this house; the *bella* form does best in baskets, as then the flowers either hang over the sides or push out through openings therein. The *Chimæra* form, if true, produces its flowers on an upright stem. *Masdevallias*, now growing freely, require a good supply of water. If plants of *Odontoglossum citrosimum* have not yet been repotted there is yet time to do so, but it ought to be done at once, as the plants will now be making fresh roots. *Anguloas* of all the different species ought to be potted when the young growths are seen to be starting from the base of the old bulbs. This they are now doing, and no time should be lost

in attending to them. If the potting material is not in good condition it ought all to be shaken from the roots. We have frequently recommended plants of *Dendrobium Jamesianum* and *D. infundibulum* to be grown exclusively in the cool house, where they do well all the year round, but we do not think we ever saw more healthy plants of these than we did the other day in Sir T. Lawrence's collection at Burford Lodge and in that of Mr. Lee at Downside. In both cases they were grown in the cool end of the *Cattleya* house. Some of the plants were attached to blocks; others were potted in the usual way. *Odontoglossum Londesboroughianum* succeeds best in the warmest end of the *Cattleya* house. This is not often seen in collections, but when well grown it is an excellent plant, the long, drooping, branched spikes continuing to produce flowers for months together. It is well grown at Burford Lodge, attached to a semi-circular framework of teak rods, through which the roots run into a compost of turfy peat and *Sphagnum*. It also likes a light position.

Cool house.—Repotting and surface dressing being completed, it now remains to carefully attend to the growing and flowering of the plants, and it should be understood that the conditions most conducive to healthy leaf and bulb development are not those under which the flowers remain longest in beauty. A damp, cool atmosphere, with little artificial heat, causes the flowers to spot, and for this reason it is desirable when the collection is a large one to be able to remove the flowering plants into a house by themselves, where they can have the advantage of a warmer and drier atmosphere. They usually rest a little before they start into growth after flowering. It will also be found that although they were free from slugs and snails before they were potted some have been introduced with the fresh *Sphagnum*. As the weather gets warmer the temperature will increase. If 50° has been the minimum hitherto it will gradually rise above this in mild weather, although it may still fall below it on cold nights. Newly-imported plants of *Odontoglossums* need not be potted at once. If there is no room for them they may be laid on a surface of dry Moss or some similar material, and be shaded from the sun. As soon as new roots form they may be potted. Among the newer *Odontoglossums* adapted for cool house culture *O. Edwardsi* is proving itself to be a really distinct and desirable species. It is now throwing up strong spikes, each containing more than 100 blooms of a distinct violet-purple tint quite new, and about three-quarters of an inch across. It has blossomed in Mr. Walter Cobb's collection at Sydenham. We have noticed sometimes in looking over collections that the small-growing species of *Odontoglossums*, such as *O. Rossi*, of which there are now so many fine forms, a charming species; *O. roseum* and *O. Cervantesi* are placed where they are overshadowed by larger plants. It is better to place the pots containing these in baskets, and suspend them near the roof; or if the collection is large, they may be placed in a part of the house by themselves. These small growing *Orchids* also succeed if placed in shallow pans. It is well to be careful in watering such plants, as if they are hung up out of the reach of the eye they are apt sometimes to be neglected.

PROPAGATING.

No more suitable time could be chosen for cutting back and striking *Crotons* than the present. When the cuttings are taken off insert them as quickly as possible, removing no more leaves than is absolutely necessary; take some clean 2½-inch pots, put a few crocks in the bottom, and fill up moderately firm with soil consisting of loam, peat, and sand in equal parts. After insertion give them a good watering and keep them close, when they will soon root. *Nepenthes* may also be struck without difficulty, especially in spring, and by this means short, sturdy, fully developed plants may be secured. The soil in which they root best is fibrous peat and *Sphagnum*, cut up moderately fine with a liberal admixture

of sand. Take the cuttings, not necessarily at a joint, and insert them in small well-drained pots in the compost just named; after this water them, and then place them in a close case or under a hand-light in the stove, if possible, where there is some bottom-heat. Take care to keep them close and shaded from bright sunshine till rooted, and on no account allow them to become dry, as a moist, steamy atmosphere hastens the formation of roots.

Tree Carnations that have been flowering during the winter will, from the warmth received during that time, have made good young growth suitable for cuttings, and if put in now will make fine flowering plants by winter. A suitable soil for them is equal parts loam and leaf mould, with a good sprinkling of sand, the whole being well mixed together and sifted moderately fine. Let the cuttings be of as recent growth as possible. Remove the two bottom leaves, and shorten the others if they are of an unwieldy length, then insert them four or five around the edges of a 4-inch pot, and place them in a gentle hotbed. In this way they will soon root, when they must be hardened off and potted singly in small pots.

Cyperus alternifolius is frequently increased by division and treated as a stove plant, while if raised from seed now and grown on in a cool temperature till autumn the produce would be stout healthy plants, well calculated to resist the various changes of temperature, to which, when used for indoor decoration, it is exposed. In order to obtain seed two or three old plants should be potted in large pots and allowed to flower, when seed in abundance will be the result. It should be sown as soon as possible after it is gathered, for if kept long, it germinates much more slowly and irregularly. Before sowing give the pots intended to receive it a good watering, then sow on the surface, and afterwards sprinkle a little dry sand over the seeds. Place a pane of glass over the pot, and set it in the stove till germination takes place, which will not be long if the seed is fresh, and when that takes place remove the glass at once. The variegated form can only be increased by division, for which the present is a suitable time. In preparing pots for all kinds of soft-wooded cuttings do not press the soil too firmly, as that retards rooting. This remark only applies to soft-wooded subjects such as Fuchsias, Heliotropes, Verbenas, &c. All firm-wooded plants, such as Heaths, Camellias, Rhododendrons, and Conifers, require the soil be made as firm as possible.

FRUIT.

Early orchard houses.—One of the most important operations in this department at the present time may be said to be the thinning of the fruit, else Nature may assert her right to relieve herself by casting the whole of the crop. It will not be wise to thin Peaches and Nectarines down to the exact number of fruits each tree is considered capable of carrying, but under well directed management a small percentage will suffice for the final thinning after the stoning process is complete. If thinning has been carried on simultaneously with disbudding, and all the drooping fruits have been removed, those which are placed near home should be selected for the crop, as the wood near the base is generally well ripened and swells off the largest fruit, while the cultivator insures to himself the option of disbudding and shortening back his trees where they show a tendency to become loose and unshapely in their growth. As the days increase in length and the sun gains power the trees will take liberal supplies of stimulating liquid a few degrees warmer than the mean of the house, and good syringing with clean soft water at a temperature of 70° twice a day when fine will keep them clear of spider and facilitate the rapid development of the fruit. If Strawberry plants occupy the shelves, keep them thoroughly syringed backwards and forwards until they begin to change for ripening, and then if possible move them to quarters where spider can do no harm, and thoroughly cleanse

the shelves they have occupied. Give timely attention to ventilation on bright mornings by opening the lights: when the temperature touches 65° run up to 75°, with a free circulation; reduce gradually and syringe about 3 p.m. The minimum heat should not exceed 55° on mild nights until the fruit is stoned, and 50° will be sufficient in severe weather.

Late houses.—Owing to the absence of sun, trees in late houses and others which have been wintered in the open air are all in an equally forward and promising condition. If the latter were well washed before they were taken into the house nothing more will be needed until the blossoms begin to show signs of opening, when a good fumigating will keep them free from aphids until after the fruit is set. In the arrangement of the trees it must be borne in mind that Figs, Peaches, and Nectarines will stand the most heat; then follow Apricots, Plums, Cherries, and Pears. Of the latter the best dessert kinds only should be grown, and in the event of the space being limited they may be plunged in a warm, sheltered place in the open air, when all danger of spring frosts is over. Ventilate to the full extent, and dispense with fire-heat until the blossoms begin to open, when a little warmth will do good service in damp or frosty weather.

Peaches and Nectarines.—We must again direct attention to the important operation of disbudding and pinching in early houses. Weak trees to which we lately alluded, as well as late kinds grown at the coldest end for succession, will now require manipulation upon the same principle as they break into free growth, the best of all proofs to the practised eye that root action is going on, and daily pinching will not produce a check. Many people make a point of leaving a great number of these pinched shoots to form spurs and sometimes in early houses they do very well, but to us spur fruit never appears so fine as that borne by a good shoot of 1 foot in length, and the system is a failure in late houses. When all the base shoots have been neatly tied down to the current year's fruiting wood, a free and easy growth may be encouraged quite up to the stoning period, gross shoots and leaders only being tied in to check an uneven distribution of the sap, or to form shade to large bare branches in the centres of the trees. With a large area of foliage exposed under glass and all the roots inside, plentiful supplies of water will be needed, and syringing twice a day will play an important part in good culture. If forcing is not being carried on against time a low night temperature of 56° to 60° is strongly recommended until after the stoning is complete. The heat by day may range 10° to 15° higher, with plenty of air, provided it can be given without causing a draught or sudden depression in catching weather, when early closing of the valves and moderate ventilation will answer best. A sharp watch must be kept for green, brown, or black fly. The first, if taken in time, succumbs to a moderate smoking; the last two are more tenacious of life, and being generally found on the points of gross, crude shoots, dipping in a strong insecticide may precede the smoking. Spider sometimes puts in an early appearance, but unless Strawberries have been occupants of the shelves, no excuse can be found for the person who syringes the trees.

Succession houses.—Persevere in the regular syringing of trees in succession houses until the flowers are ready to open, and fumigate before they expand. This important, simple, and inexpensive operation should never be neglected, as many houses are spoiled for the season by allowing fly to get into the blossoms. See that the borders are well watered, and old or weak trees mulched before they begin to feel the strain of a crop of fruit. Ventilate freely, and lay up strength and vigour by keeping the houses cool at night. The buds on wall trees and in late houses are still coming on together, and it is a question if the walls will not be in advance at flowering time. Be this as it may, follow up liberal ventilation until the flowers are fertilised, and if extreme lateness be an object, only use fire-heat when there is danger of the flowers being injured by damp or very severe

frost. Of the latter, Peach blossoms under glass will stand several degrees, provided they are kept dry and free from draughts.

Cherries.—Where the roots are confined to the interior of the house an examination of the borders should be made as soon as the fruit is set, and in the event of water being required it should be supplied at the mean temperature of the house, which may range from 40° at night to 56° by day. If late kinds are still in flower let them be carefully fertilised, and defer general syringing until they are safe and the petals of the flowers begin to fall. When trees which have covered the trellis have made five or six leaves, all side shoots not likely to be wanted may be pinched to form spurs, and leaders may be tied down to the wires. When syringing is resumed use tepid water twice a day. Give air at 50°, open the front lights at 58°, and run up a few degrees under sun-heat with a free circulation, always bearing in mind that the Cherry is the most impatient tree we have to deal with under glass, and it is always best to err on the side of low temperatures with plenty of air when cutting draughts can be avoided. When this stage has been reached, the usual enemies, black or brown aphids and the small grub, may be expected to appear. The first may be destroyed by timely and repeated fumigation, but the latter can only be extirpated by careful hand-picking.

Melons.—The first batch of pot plants plunged in bottom-heat from fermenting leaves placed over hot-water pipes will now be making good progress, and the daily routine will consist in careful watering, syringing, and ventilation wherever a chink of air can be admitted through the early part of the day. It was stated lately that confinement of the roots by means of pot culture causes some varieties to throw out side shoots and produce plenty of female blossoms before the leaders reach the top of the trellis. Where this is the case and very early fruit is wanted, the points must be pinched out to throw strength into the side shoots when the blossoms begin to open; the atmosphere of the pit must then be kept drier by means of increased fire-heat to admit of a gentle circulation of air, and syringing may be discontinued for a few days until the fruit is set and begins to swell. When grown under the restrictive or pot system it rarely happens that the most wilful rambler is not brought into bearing at an early age; and when a "set" of fruit has been secured, the plants may be well rammed and top-dressed with stiff loam, bone dust, and dry cow manure, into which a complete mat of hungry feeders will soon find their way. These must be well supplied with good liquid, a few degrees warmer than the house, which must now range from 70° at night to 80° by day, and 85°, or even 90° after closing, with solar heat and moisture. In pot culture the preservation of all the stem leaves is an important matter, and some of the succulent, hairy-stemmed varieties, which are subject to scalding, should never be syringed on bright mornings, as they hold the water and suffer when air is admitted, but this danger disappears after the house is closed for the day, when overhead syringing will do no harm.

Cucumbers.—To maintain the supply through March and April, old plants which have been in bearing all the winter will take liberal supplies of warm liquid to keep them going, for if once allowed to receive a check, early spring-sown plants will commence fruiting before they can recover and be of further use. By this time the plants will have replaced the old foliage with young growths, which must be neatly tied down and stopped at the first joint beyond the fruit when it becomes evident that the foundation of a complete covering has been laid. If spider has gained a lodgment, this cold weather will favour its destruction by the use of insecticides or regular syringing with clean, soft water, light cropping, and high feeding with good liquid from the tank and guano water alternately. Sprinkle all available surfaces with the same, top-dress the roots with pure loam and old lime rubble in preference to manure, which encourages worms and leads to ultimate failure. Aim at a steady bottom-

heat of 85° from pipes and fermenting material combined. Let 70° be the standard at night, and 85° by day. Give air at 78°, and close early with atmospheric moisture, but avoid wetting the pipes when they are hot enough to generate scalding steam.

Spring plants.—These are now making good progress, and their clean, healthy growth is always pleasant to look upon. If planted upon hills, avoid producing a too vigorous flush of Vine by feeding or the use of manure, as the time is at hand when stimulants will be needed. Train regularly without crowding, and defer stopping until quite two-thirds of the allotted space is covered. Keep the glass well washed inside and out. Let the night heat stand at about 68°, give air at 76°, and close with plenty of solar heat in preference to having recourse to sharp firing. Earth up plants in frames, renovate the linings back and front alternately, to prevent checks, and aim at the heat recommended for spring plants in houses. Always keep a supply of warm, dry compost and plenty of fermenting material on hand. Cover at night with dry mats and give a little air to prevent the accumulation of injurious gases.

KITCHEN GARDEN.

THE main crop of Brussels Sprouts, Snow's Broccoli, and Red Cabbage, the latter for cutting late, should now be sown on a slight hotbed under glass; also Veitch's Autumn and Self-protecting Broccoli, with a pinch of Paris Cos Lettuce. Still we always find in spring-sown Lettuce the few seeds sprinkled on the top of the Onion quarter the earliest. Onions and Carrots had better wait for some days; when sown early the sharp spring winds turn them yellow, and we have had on two occasions to re-sow Onions. Parsnips may now be sown with advantage. We are busily employed turning up every inch of ground which we possess, thus bringing all under crop at the proper season. Now is a good time to make plantations of Globe Artichokes. On taking up the old stools we possess, in one case many dead or crippled; we pulled away the young suckers and planted them in burnt refuse, a capital thing for many purposes; whenever we sow small seeds, outside or in, we always cover them with this material. Early frame Potatoes, Radishes, Carrots and young plants generally should be duly aired. When the weather has become warm and genial, all the lights should be drawn off, so that full advantage of the opportunity may be taken by all inmates of pits and frames to get fresh air. Prick off early Celery in small boxes for early work, and get manure well worked to make the bed which the main crop of Celery will occupy. We sow about this time. Tomatoes may soon be sown; grow them on until they worthily occupy 6-inch pots when they will be 3 feet high in May, and begin to flower and fruit at once. Little plants put out in May grow up to September before setting or ripening their fruit. French Beans must be attended to in accordance with the demand (as a market crop they are ruinous). This fine dry weather gives us an opportunity of getting all walks free from weeds, thus making all clean and tidy.

MARKET FRUIT GARDENS.

OWING to the favourableness of the season, work is generally in a forward state. Planting may now be considered to be finished. Stocks intended for grafting are headed down in readiness for that operation, and younger stock is planted out in nursery lines. Grafts, if not already secured, should be cut immediately, as the sap will now be moving in nearly all kinds, and they are best cut in as dormant a condition as possible. Young bush fruits, such as Gooseberries, Currants, and Nuts, not required for forming new plantations should be lifted and cut in quite close and replanted about 1½ feet apart, so as to make useful little bushes for another season. Cuttings collected and laid in by the heels during the pruning season must now be prepared and planted in lines. Suckers of the Farleigh Prolific Damson,

a kind that reproduces itself true in that manner, are collected and planted in rows to gain strength for forming standard or half-standard trees, the latter being preferred, except in positions where cattle would destroy the branches; for, if required, a half-standard can be readily converted into a full standard by cutting away the lowest tiers of branches by degrees; the stem, too, needs less supporting by means of stakes than that of standards, and it increases in diameter much more rapidly when the lower branches are left on for a few years than when they are trimmed at once. If not already done, all freshly planted trees should have a covering of partially rotted manure spread over their roots before drying spring winds affect them.

The pruning of Nuts of all kinds may now be completed, for the catkins are fully in flower, and the abundance of little red-tipped female blossoms give promise of a good crop. All useless wood is cut away and only fruitful spray reserved. The Nut crop is so valuable that special care is taken not only in forming the bushes by careful pruning, but also in manuring them—a favourite application being the refuse from skin and hair factories, such as the dressings from hare and rabbit skins, old rags, &c. This is lightly forked in around the bushes, which, being surface-rooters, are found to depend more for fruitfulness on their active roots close to the surface than those that penetrate deeper. This is a good time to give both trees and bushes a good dusting of freshly-slaked lime, which answers the double purpose of killing Moss and Lichen and making the buds distasteful to birds; when washed off, too, it acts as a stimulant to the surface roots. It should be put on in damp, still weather, so that it may stick to the trees and get dried on before heavy rains occur.

The protection of fruit in the way usually practised in gardens is not possible on a large scale in market grounds; nevertheless, owners of such grounds are fully alive to the importance of shelter, and we find many are now planting rows of Poplars and other quick, erect-growing trees quite thickly, so that they may run up and form a barrier to break cold currents from exposed quarters. Thorn or Quick hedges may also be allowed to run up, keeping them cut in narrow both at base and top, as it is surprising the amount of shelter which a hedge will afford. Preparation must also be made for the coming fruit season by looking over the stock of baskets, ladders, &c., and replacing any deficiency before the busy season arrives. A good supply of packing wood must be cut and stored in some dry place. Long rods of Ash, Hazel, or Chestnut are generally used; they are prepared in wet weather by cutting them in lengths to suit sieves or half sieves, and split up to the size required. If kept dry until a few days before they are wanted and then soaked in water, they will be found to be as tough as wire, and will withstand the rough usage to which the baskets are subjected in travelling to market, while green wood would fail.

Cost of plant carriage.—In answer to the question of "March" (p. 235), allow me to say that I have had many parcels sent to England by the Continental Parcels Post. Those from Germany reach England rapidly, and a parcel weighing 7 pounds or 8 pounds costs about four shillings; but on reaching England, instead of being forwarded by railway, as I have always requested they may be, they are consigned to a private firm of carriers, who, it seems, has the monopoly of these German postal parcels in England. This firm has agents in the large towns of the kingdom, to whom the parcel is then sent. A letter is sent by post to your address as represented on the parcel, and you are informed that a parcel has arrived for you, which you must send for, and can then have on payment of whatever the carriage may cost. The nearest agent to me is nine miles off, and if I happen to be from home when the parcel arrives at the agent's, it is probably a week before it is forwarded. As at present managed, therefore, the Continental Parcels

Post is by no means a desirable form of conveyance from Germany for those who live in the country.—C. WOLLEY DOD, *Edge Hall*.

FRUIT GARDEN.

TRAINING VINES.

"PEREGRINE," in his remarks on the latest author but one on Vines, condemns in a sweeping manner the somewhat modern, yet none the less sound, method of training Vines 3 feet or 4 feet from the glass. In the bygone days of half opaque roofs there were good reasons for training the Vine as close to the glass as possible, but that necessity no longer exists since we now obtain far more luminous rays at the base of the house than we did formerly immediately under the glass. Not only do the Vines now receive sufficient light at this distance, but one of the greatest evils in Vine culture under glass, contact with leaves and glass, is thereby averted, and that without hourly attention in the growing season. No sealing of leaves to the glass by condensed moisture to be converted into tinder by the sun's rays by this method, but a clear space, allowing a free and uninterrupted circulation of air between roof and foliage. It is useless to say that less than 3 feet allows ample space for this purpose, because the leaves themselves in this vinery to which he adverts are Rhubarb-like in dimensions. The argument that not one Grape grower in a hundred will be found to favour the idea is worthless, inasmuch as most probably not even that percentage of Grape growers have tested it; when they have done so, however, the comparison may be reversed. There is unquestionably some slight loss in length of rafter, but the loss on a trellis 3 feet from the glass as compared with one at the ordinary distance is so little, as not to be worth consideration when weighed against the advantages derived from the greater distance where ample space is afforded for the proper development of every necessary leaf without impinging against the glass. The high lantern roof to which "Peregrine" alludes is no doubt both unsightly and expensive, and to my mind worse than useless either in a vinery or plant house; but I feel assured that the author just referred to does not thus value it, and I must admit that I have never looked at the contents of that noble vinery without being both surprised and gratified. Whether it be from the peculiar construction of the house, the somewhat novel method of cultivation, or both, and all other details of management combined, and made to properly suit each other, that these satisfactory results have been obtained, I know not, but true it is that at the present time it is perhaps one of the most wonderful vineries in the kingdom.

W. C. T.

TOP-ROOTED VINES.

PERMIT me to assure "Peregrine" that I do not feel at all aggrieved at having been anticipated in the discovery of the readiness with which Vines take root at either end by the writer to whom he alludes. Why should I? seeing that the writer in question says, "be it remembered I have not tried the plant, and it only occurs to me just at this moment" (which moment was some time last year), whereas I practically tested the plan at least seven years ago, and I myself had been anticipated, years before that, by the late Mr. Rochford, of Page Green, Tottenham, a fact that makes it the more surprising that the author in question had never heard of the plan till it dawned on him last year in the form of an "original idea" when writing a chapter on pruning the Vine. All of us might expect to be similarly left in the rear if, like him, "we never had read an essay on Vine culture," or if, "when one was placed in our hands," and its contents were found not to agree with our pre-conceived notions, "we at once closed the book." Such a proceeding would certainly soon make all of us his brethren in misfortune. In answer to "Peregrine's" query as to what I think

of this plan of rooting the tops, I have to say that the Vines have done better ever since. They are not double, but treble rooters, a double rod having been run up from each Vine, and each of the rods being layered in a border as soon as they reached the opposite side of the house, thus giving to each Vine three distinct sets of roots. Before this was done they had always borne prodigiously and finished well, but both bunch and berry beginning to deteriorate, and there being no means of extending the original border to keep the Vines up to their original state of excellence, I determined on making a new border for the tops, and, this being done, they were layered in it to a length of from 1 foot to 5 feet, according as the wood of each top was considered sufficiently well ripened. The result exceeded my most sanguine expectations; the Vines the first season finished a much heavier crop and just as finely as they did when but four years old. In 1881 there were again signs of deterioration of bunch, and as I was anxious to test the experiment still further, I, in January of last year, cut off a few of the Vines at the apex of the roof, and pulled out the halves on which were the original roots; the parts left, the tops, looked comical enough, certainly, with their thickest end uppermost, and I was half afraid that I had been too daring, but as it happened all turned out well, for those standing on their heads showed and finished their fruit just as well, of course in lessened proportion, as did the treble rooters at the other end of the house; a new border was made in the part from whence the original roots were taken and new Vines planted, and as soon as these are sufficiently strong to have their tops layered as the others were, the remaining halves of the Vines will be pulled out.

Heekfield.

W. WILDSMITH.

ALICANTE GRAPE.

I WAS glad to read in the notice of Mr. Barron's new work on the Vine that he had the courage to speak out in reference to the quality of this Grape, which he considers to be third-rate, and that in my opinion is what it is. It has been overpraised for years. When fairly well cultivated, however, it is the most showy and taking in appearance of all black Grapes, and, if we except the Hamburgh, it is the easiest of all black Grapes to grow. It is, in fact, an accommodating variety; as Mr. Barron says in his cultural notes, it sets well and colours magnificently. To this I would add that it grows vigorously, and will bear a little rough treatment without resentment. A half-hour's neglect in giving air on a bright June morning will nearly spoil the foliage of Gros Colmar and scald a score or more berries in the bunches of Lady Downes, but it will have no effect on Alicante. Therefore for amateurs and others who cannot for various reasons give so much attention to their vinerias as is absolutely necessary when more tender kinds are grown, a better variety than this could not be selected for use from December to the end of January. It will therefore be understood that I do not wholly condemn it. There are "Grapes and Grapes"; the Alicante in my opinion occupies a useful place, but those who would wish to grow Grapes of the best quality should avoid it.

As a late keeper it has not many rivals, but, according to my experience, if required to be kept until February and the early part of March, it will keep better if not hurried too much in the early part of the season, and, what is equally important, if the Vines are allowed to develop their bunches as much as possible in a natural temperature. Under such circumstances they will be more regularly formed, their shoulders will be more prominent, and there will be a greater number of bunches than when the Vines are forced to start into growth by artificial heat. I have always found when the crop was ripened in rather a high temperature in September and in the first half of October that the flavour has been much superior to that of those finished off in a cooler house. There are several varieties of Grapes that require a long season of growth in order to ripen their fruit properly, but there cannot be two opinions about the Alicante

not being adapted for starting early. If it is allowed to start without the aid of artificial heat it always breaks more regularly and produces better formed bunches, and all it wants in order to secure it in its best condition as to flavour is to give it a high temperature to finish with. Any outlay upon it at the end of the season will give much better results than the same expenditure would do if devoted to it earlier.

The best examples of this Grape which I have seen were in a small house devoted exclusively to it. It was a lean-to with a long rafter, and the roots had the advantage of a wide space extending a good way across one of the quarters of the kitchen garden. The rods were therefore of a substantial character, and the crops which they bore were simply magnificent, because all the conditions for promoting vigorous growth were eminently favourable. Each rod had a clear space of 5 feet; therefore there was plenty of room for lateral growth. These Vines were allowed to start into growth without artificial heat, but as soon as damp and dull weather set in after the middle of August, fire heat was applied for six or seven weeks to keep up the temperature to 75° during the day and 60° at night. Very frequently the day temperature by means of sun heat would range from 85° to 90° with a fair proportion of air. This treatment seemed to suit it exactly, for I have never before nor since tasted such well flavoured Alicantes as these Vines produced.

J. C. C.

DOMESTIC GARDENING.*

WE may well say of gardening, as a beginning, that it is "an art which does mend Nature—change it rather, for the art itself is Nature." We may define gardening as the art of providing suitable plants for certain conditions of soil and climate, or of providing suitable soils and climates for those plants we especially wish to cultivate. Vegetation is the earth's clothing, and was created before all animal life, because it is of all things most necessary to animal existence. Before man was created, as the Bible tells us, vegetation flourished. The animal and vegetable worlds are balanced so exactly that whatever is useless or superfluous to the one is taken hold of by the other, and so utilised that nothing is lost. Domestic gardening comprehends the culture of all plants, useful as well as beautiful, which may be grown in or about our homes. For children especially a garden in which they can dig and plant flowers of their "very own" is most important, so conducive is such employment to healthy development both of body and mind. I never was so surprised at the results which children can produce in plant growing as last year, when Dr. Nelligan asked me to award the prizes for plants, flowers, and vegetables as exhibited in his schoolroom at Leeson Park. Some few of the plants exhibited there, and which had been grown in windows, could not have been surpassed had their owners had the advantages of a greenhouse. One little child—a girl—obtained the first prize for Parsley by sending a cigar box full of earth, in which the most fresh and beautiful Parsley imaginable had been grown from seed. As I left the little exhibition I wished many more prizes had been available, so good and interesting of their kind were the exhibits. In any

Domestic gardening movement we must firstly and above above all things enlist ladies on our side. Women are by nature, if not actually gardeners, lovers of the beautiful, as it shows itself in blossoms and leafage, and upon ladies as a body all ideas of domestic gardening must mainly depend. Home, be it what it may, is emphatically woman's province. She spends a far larger proportion of her life and her labour within its walls than man can ever do. It is the place in which she rules by right as well as by custom, and she is wise to make it attractive. One

way to this end, after scrupulous cleanliness, is to have flowers about the house, plants in the cottage window, or, better still, a garden, be it ever so small, in which fragrant blossoms and fresh vegetables for culinary uses may be grown. The greatest men of our time, such as Longfellow, Cowper, Keats, Wordsworth, and Wendell Holmes, have written favourably of flowers and their culture. "In the culture of flowers," says Dickens, "there cannot, by their very nature, be anything solitary or exclusive. The wind that blows over the cottage porch sweeps over the grounds of the nobleman, and as the rain descends over the just and the unjust, so it communicates to all gardeners, both rich and poor, an interchange of pleasure and enjoyment, and the gardener of the rich man in developing or enhancing a fruitful flavour or a delightful scent is in some sort the gardener of everybody else." The more we see and know of flowers the more we learn to cherish them. We lay flowers, autumnal leaves, and fruits on the altars of our places of public worship at festival times. The Hindoo strews the gorgeous flowers of *Amherstia nobilis* or those of the Sacred Lotus in his stately temples, while the Mexicans gather the finest and rarest of Orchids from the Andes for their various religious rites and ceremonies.

Towngardening.—Everyone cannot possess the luxury of a garden in the widest sense of the word, but all may grow plants and flowers in and around their dwellings. Many who live in crowded courts and in lanes, and who unfortunately have no little garden wherein to grow a few sweet-scented flowers, yet manage to extemporise ways and means to gratify the love of nature which appears to be nearly universal. Window gardening in towns has indeed been practised for centuries under difficulties, and our garden poet Cowper thus alludes to the practice:—

The sashes fronted with a range
Of Myrtle or with fragrant weed,
There the pitcher stands,
A fragment, and the spoutless teapot there;
Sad witnesses how close-pent man regrets
The country; with what ardour he contrives
A peep at Nature when he can no more.

Nor is this love for cultivated plants and window gardens confined to our own country alone; for whoever visits Paris cannot fail to notice the rich profusion of Palms, Dracenas, Cyperuses, Ferns, and delicate Mosses with which the windows and apartments there are most tastefully decorated. In Germany, Russia, and also in America, the love for beautiful plants and fragrant window flowers is rapidly increasing; nor is this to be wondered at, since the great charm of window gardening consists in the immense variety of beautiful effects that may be obtained at a slight cost, even by the use of hardy plants alone. Ivy is common enough everywhere in hedges or on old walls and on the stems of trees; and when tastefully arranged in a basket or vase of wet Moss, it forms one of the most elegantly beautiful of all plants used for the winter decoration of apartments. Beginners in plant culture should commence with common hardy plants first.

One of the greatest mistakes in any branch of floriculture is to commence with rare and valuable species before the few simple rules necessary to insure successful treatment are understood. I say this because failure at the first is apt to disappoint beginners; not but that experience of this kind is very instructive, and often teaches us far more than can possibly be learned from written directions alone. Do not, however, let imaginary difficulties deter you from attempting their culture. Many an old countrywoman who cannot read or write can root cuttings under cracked tumblers, and can grow Musk, Mignonette, Calceolarias, Fuchsias, sweet-scented Verbenas, and Geraniums to a high state of perfection, and, with the aid of a few other common plants, can keep her cottage window gay with flowers all the year round. That many fail in window gardening is true, but really the whole affair is very simple where a real love for flowers exists. It is

* A lecture (abridged) by F. W. Burbidge, F.L.S., Curator of the Trinity College Botanic Gardens, Dublin, author of "Domestic Floriculture," &c., delivered by desire of the Rathmines Sanitary Association, in the Town Hall, Rathmines, Dublin, March 6, 1883.

not enough to buy a few plants from the market and place them in the window to droop and die. They must be carefully and regularly watered; and as the love for fresh, healthy plants increases, something like a succession must be kept up, so as to secure as much variety as possible. Indeed, the knowledge essential is so easily obtained by observation that we can only wonder why every window and balcony is not gay with ornamental plants and flowers for a considerable portion of the year. Lavender, Wallflowers, Thyme, Carnations, Rosemary, and Mignonette should be around every country house, and it is possible that in years to come some part of every dwelling will be constructed expressly for the culture of plants and flowers within it. A small conservatory, or at least window cases, as fixtures will be considered as essential as a good kitchen range or a bath room. At the present time we have a few roof conservatories and gardens, and doubtless in time these and other appliances will become universal, especially in towns where space is valuable.

Ill effects of gas on plants.—One of the most serious of all drawbacks to the successful culture of plants in rooms is the use of gas as a lighting agent. The slightest escape, either from the metre or pipes, is sufficient to cause the leaves to droop and fall off prematurely, besides otherwise injuring their appearance. In all cases where the use of gas cannot be dispensed with provision should be made for carrying off the fumes as speedily as possible by a thorough system of ventilation. This much is actually essential for our own comfort and convenience, and the evil of a gas-polluted and over-heated atmosphere ought to be more generally acknowledged and provided against than is at present the case. If much gas is used it is as well to content ourselves with a few interesting plants and Ferns, and to give these the protection of a close glass shade or Wardian case. Most plants grow very luxuriantly in these contrivances, defying both the destructive influence of the gas, aridity, and dust. Cold draughts, caused by opening doors and windows simultaneously, must also be avoided when possible, though our own personal comfort generally guides us correctly in this matter. It will be found an excellent plan to carry room plants outside once or twice a week during the summer months, and either syringe or sprinkle them with a watering-can thoroughly well, so as to remove all dust, insect pests, and other impurities from their foliage. Setting plants outside during warm, summer showers is an excellent plan, none the worse because old-fashioned. In

Selecting plants for the decoration of our dwellings we are too apt to commence with fully developed specimens, selected either from the greenhouse or plant stove of the nearest nursery garden, and as a rule such plants disappoint us by their gradual decline from health and beauty when brought into cooler and more exposed positions in the house. Plants always suffer more or less when brought suddenly from a high temperature into a comparatively cold and irregular one; hence, in selecting plants for the decoration of apartments or the sitting-room window we should prefer those that have been grown in pots out-of-doors, or in a temperature as cool as or even cooler than that of the room for which we require them. It is always best to commence with young plants, either seedlings or rooted cuttings, as these gradually become inured to the fresh conditions in which they are placed.

Artisans' greenhouses.—I think it is the poet Cowper who has said, "Who loves a garden loves a greenhouse too." Let me, therefore, just describe a greenhouse—a conservatory for green and healthy plants—which I should like to see in the garden or back yard of every artisan who is fond of flowers. A structure such as I propose is cheap and effective; indeed, anyone handy with a saw, a hammer, and nails may erect it for himself. It is simply a framework or skeleton erection of rough timber quartering put up in the form of a greenhouse, and covered with rough tiffany or hempen canvas instead of with glass. The idea is not my own; it is that of Mr. Matthew

Williams, as given in a lecture delivered before the Society of Arts in London: "When the Midland Institute commenced its existence in temporary buildings in Cannon Street, Birmingham, I was compelled to ventilate my class rooms by temporary devices, one of which was to throw open the existing windows, and protect the students from the heavy blast of entering air by straining it through a strong, gauze-like fabric (tammy) or canvas stretched over the opening. After a short time the tammy became useless for its intended purpose; its interstices were choked with a deposit of carbon. On examining this, I found that the black deposit was all on the outside, showing that a filtration of the air had occurred. The recollection of this experience suggested that if a cheap, strong, gauze-like fabric can be obtained, and a sort of greenhouse made with this in the place of glass, the problem of converting back yards into gardens might be solved. After some inquiries and failures in the trial of various cheap fabrics, I found one that is already to be had, and well adapted to the purpose. It is called 'wall canvas' or 'paperhanger's canvas'; is retailed at 3½d. per yard, and is one yard wide. If I am rightly informed, it may be bought in wholesale quantities at about 2½d. per square yard, i.e., one farthing per square foot. This fabric is made of coarse unbleached thread yarn, very strong and open in structure. The light passes so freely through it that when hung before a window the loss of light in the room is barely perceptible, and, stretched upon a frame, a printed placard, or even a newspaper, may be read through it. The yarn being loosely spun, fine fluffy filaments stand out and bar the interstices against the passage of even very minute carbonaceous particles. These filaments may be seen by holding it up to the light. The fabric being one yard wide, and of any length required, all that is needed for a roof or side walls is a skeleton made of lines or runs of quartering at 3 feet distance from each other. The cost of such quartering, made of pitch pine or Memel, the best material for outside work, is under 1d. per foot run; of common white deal, about ¾d. Thus the cost of material for a roof, say a lean-to from the wall top to the side of a house, which would be the most commonly demanded form, of 30 feet by 10 feet, i.e., 300 square feet, would be 110 feet of quartering (11 lengths), at 1d., 9s. 2d.; 300 square feet of canvas, at ¾d., 6s. 3d.; nails and tacks, say 1s.; total, 16s. 5d. The size of the quartering proposed is 2½ inches to 1½ inches, which, laid edgewise, would bear the weight of a man on a plank while nailing down the canvas. The canvas has a stout cord-like edge or selvedge, and holds the nails well. I find that what are called 'French tacks' are well suited for nailing it down, and if the nails are driven through gun wads or sections of a bottle cork, the strain is not so likely to tear the canvas. The construction of such a conservatory is so simple that any industrious artisan or clerk with any mechanical ingenuity could, with the aid of a boy, do it all himself. No special skill is required for any part of the work, and no other tools than a rule, a saw, and a hammer. Side posts and stronger end rails would in some cases be demanded."

Canvas screens.—There is another purpose to which this coarse canvas material might be applied. A week or two ago, Dr. Dickenson, in a singularly practical and able lecture entitled, "The Influence of Light on Life," told us that the light of windows in narrow thoroughfares might be much improved by stretching a piece of canvas in front of the window flush with the masonry of the house itself. For such a purpose this coarse canvas may well be employed, and in addition to an increased quantity of light, we obtain also an atmosphere filtered so that it is practically free from dust and sooty particles, and the window sashes may be freely opened to admit fresh air without any danger of cold draughts. Those also who remember what Huxley has taught us as to the subtle connections between dust and disease will here recognise a simple plan for purifying the atmosphere of town houses. I have used canvas screens over some of the doorways and ventilators of the glasshouses devoted to the culture of rare

tropical Orchids and other plants under my care in the Trinity College Botanic Gardens, and with the best possible results; and I have observed that mountain plants, from the pure air of high altitudes, have been especially benefited by the adoption of these simple canvas filters or screens. This being so in hothouses especially constructed for plant culture, I need scarcely say that plants grown in windows and in town apartments would be even further benefited by their adoption. Even if some little loss of light be in some cases the result of using the canvas, I feel sure the gain of a comparatively pure atmosphere and effective ventilation would more than compensate for any seeming loss of light.

Temperance and good gardening go hand in hand. In the discussion which followed Mr. Williams' lecture Mr. Liggins remarked that, although not a total abstainer himself, he had recently, when travelling in the United States, been struck by the difference in appearance presented by the houses in districts wherein the Maine Lignor Law was enforced, and soon learned to distinguish where it was adopted by the clean, cheerful look of the workmen's dwellings, the neatness of the gardens, and by the presence of beautiful trees and flowers which in other districts were wanting. Another speaker, a landed proprietor, said that his own experience in the building of cottages had proved to him that the addition of a piece of garden ground had a most beneficial influence on the social, moral, and religious life and welfare of the inmates. It kept the father from the public-house, and the boys, who had been brought up to hoe and weed these little home gardens, had turned out the most industrious and intelligent labourers upon his estate. This last remark reminds me of the fact that in those districts in England where what are called "allotment gardens" are most common, it is a popular remark that those men who make the best use of their little gardens are also the best workmen in their respective callings. So patent, indeed, is this, that some proprietors offer prizes and other inducements to their dependents, and in many villages the date of the rustic flower and vegetable show is looked forward to as the gala day of the year. The secret seems to be that gardening offers moderate exercise congenial to both body and mind, and the material results of earth culture are quite as remunerative, even if not more so, than any other kind of rural labour. Gardening teaches people to be observant, and in cultural matters attention to detail is everything. We must keep our eyes open. If I wanted to know what kinds of fruit trees or of flowers to plant in a garden in any particular district or locality, I should not look into trade lists or scientific books, but I should carefully observe what varieties were most fruitful in the neighbouring gardens. A friend of mine told me the other day that he had planted an orchard consisting of 300 fruit trees, Apples and Pears, only ten varieties or kinds being admitted; but, he added, those ten kinds as scattered here and there in our locality have never missed a crop for the past ten years. This I have called common sense, but it is really "applied science" of the most valuable kind. It would be very easy to give you the names of the plants which grow best in rooms and windows, but those really interested would learn this best by a walk around their own neighbourhood, carefully observing those plants which succeed best in other rooms and in other windows quite near to them, and so growing under the same advantages or disadvantages as the case may be.

School gardens.—In the case of our public schools I am convinced that elementary horticulture should be made use of as an educational subject of the highest possible value. In France, in Germany, and in Sweden this is done already with the best of results, and I trust the day is not far distant when it will also be so used nearer home. In the case of countries like France and Ireland, both alike mainly dependent on the results of agriculture for their revenue, it seems inexplicable that the rudiments at least of those laws which regulate successful earth culture are

not taught to children when at school. Just a word on

Plant propagation. This is very interesting work, and either seeds or cuttings of the plants required are the means most generally employed to this end. Nature's great plan of reproduction in the vegetable world is propagation by seeds; she sows most of her seeds as soon as they are ripe, at the same time giving them the protection of the falling leaves of autumn, which eventually act as manure to the seedling plants. Multiplication by seed is simple, and is generally adopted in the case of hardy herbaceous and border plants, and always in the case of annuals or such plants as spring from seed, grow, flower, and perfect seed in their turn within the same year. *Mignonette*, *Asters*, *French Marigolds*, *Balsams*, and many other beautiful plants belong to this class. The main point in seed sowing is to sow during dry, warm weather, and not to cover your seeds too deeply. The smaller the seed, the less earthy covering it requires; the finest of dust-like seeds should not be covered at all with earth, but sown in a well drained, and watered seed-pan, a pane of glass being laid on the top to augment the heat and prevent drought. A little frame for raising cuttings or seeds in the open air is a great advantage. Those who have tried town gardening will have had some difficulty in getting up seeds. A waggish friend once told me he had no difficulty at all—they came up quite quickly; and when I pressed for detail, he said, "The cats scratched them up at night, and the sparrows ate them up next morning." Now I think a simple frame or several of them even in large gardens will be useful. Some may make them for themselves of a brandy box, costing sixpence, two panes of glass and a dozen nails costing only a few pence more. Wherever nice little hardy plants are grown, such as *Pinks* and *Carnations*, these cutting or seed-protecting boxes will be found very useful, defying, as they assuredly will do, both the nocturnal industry of the cats and the self-help tendencies so characteristic of the town sparrow.

ORCHIDS.

A FEW USEFUL DENDROBES.

D. NOBILE is so well known as one of the most useful of this class of plants, that it is unnecessary to say anything about its culture. The possessor of a dozen specimens of it may have it in flower for at least six months in the year with very little attention indeed compared with what some plants require. *D. Wardianum*, now in many gardens, is a magnificent species, and one easily cultivated. It may be grown either in pots, pans, or baskets. The two latter I prefer, as the plants have the best effect when suspended from the roof, and the stems should be allowed to hang about in their own wild way. Its cultural requirements may be summed up in a few words: it has a season of growth and a season of rest. The resting period may be continued from the autumn when growth is completed until the flower-buds are far advanced in spring. During that period scarcely any water is required, and the plants do best in a warm greenhouse temperature while they are at rest. I like to expose them well to light, and in a part of the house where they are not in a direct current of air between the top and side lights. In order to obtain a succession of bloom the plants must be put into heat at intervals, but if the heat is too great early in the season many of the flower-buds will come blind: on the other hand, if the plants are gradually inured to the warmer temperature, they will not be so likely to come defective. Perhaps the best time to repot or rebasket is immediately after the flowering period is over; by that time the young growths will have advanced considerably, and young rootlets will just be starting from their base. The fresh compost gives new life and vigour to them, and if a moist temperature and warm atmosphere is maintained, they will make considerable progress in the course of three or four months.

D. crassinode is by some preferred to the more showy and richly marked *D. Wardianum*. It is a beautiful species, and quite as easily grown as that just named, requiring indeed the same treatment. When its thick pseudo-bulbs with their singularly swollen joints are about 2 feet long, and furnished nearly the whole length with beautiful white flowers blotched with yellow and purple tipped, few *Dendrobies* can excel in beauty this species. *D. Ainsworthi*, also in flower now, is a charming garden hybrid, but it is too expensive as yet to be universally cultivated. It requires the same treatment as the others. There are two forms of it—one with rose sepals and petals, the other with white. The variety *roseum* is most esteemed; it does not differ from the hybrid form *D. splendidissimum*.

I have drawn attention to the foregoing because they are *Dendrobies* that may be grown in every garden, whether there are houses specially devoted to Orchids or not; all that they want is sufficient heat during the growing period and a fair amount of light. The flowers are delicately beautiful, and yet of sufficient substance to stand well in vases or glasses when cut; and if the plants when the flowers first open are removed to a warm greenhouse they will last in beauty for

markings, and well merits culture in quantity for the sake of its grateful fragrance.—F. W. B.

ORCHIDS AT SUDBURY HOUSE.

DURING such wintry weather as that which we have had during the last week or so, such a paradise of flowers as that which exists at the present time in Mr. Peacock's garden at Sudbury House, Hammersmith, seems all the more enjoyable when compared with the dreary aspect of things outside. In this particular garden there is, however, not much room for comparison, for the whole place is almost one vast conservatory, thus defying the vagaries of our English climate. Since our last visit, at the close of last year, five more capacious glass houses have been completed, or nearly so, and these are to be filled entirely with Orchids. What more striking proof of the rapidly rising popularity of that class of plants? A few years ago such a vast Orchid collection as exists here at the present time could scarcely be found in the country, and if the larger collections increase in size, smaller ones also become proportionately larger. Mr. Peacock could scarcely have turned his attention to a more beautiful or more satisfactory class of plants, though his old love for Cacti is

Odontoglossum Rossi var. *Warneri*.

some six weeks. With the exception of *D. Ainsworthi*, plants of these can be obtained for a few shillings each, and the flowers which they will produce in a few years would repay the cost of plants ten times over. J. DOUGLAS.

Orchid perfumes—I remember a green sepalled *Pilumna* which once bloomed in the Orchid house at Kew had precisely the odour of the Poet's *Narcissus*, and the old *Epidendrum ciliare* smells like roasted Apples. *Coelogyne cristata* is often scentless, but when odorous it is not at all nice. All the *Angraecums* are mostly perfumed at night, nearly entirely losing their perfume during the daytime. On the other hand, *Zygopetalum Mackayi* and one or two other species are deliciously fragrant during the day, but lose their odour towards evening. The old *Dendrobium nobile* is very variable in odour, having a breath of Primrose in the morning, honey-like at noon, while its odour is Grass-like in the evening. *Brassavola nodosa* is scentless during daylight, but fragrant at night. *Anguloa Clowesi* has a strong odour of *Paeungræk*; *Dendrobium macrophyllum* like Turkey Rhubarb, although one form or variety of it is called *anosmum* because it is scentless. *Epidendrum radiatum* has the smell of parched corn, and *Stanhopeas* are suggestive of a chemist's shop. *Odontoglossum Warneri*, to which I alluded as having a Violet-like odour, well deserves more general culture. It differs from *O. Rossi majus* in having a halo round the dark chocolate spots on its petals, as also in habit and peculiar

still undiminished, and he justly prides himself in still possessing the richest private collection of succulent plants in existence. From now onwards till June the garden here will contain an unequalled display of orchidaceous plants, and nearly all the houses being arranged in continuous lines, the visitor passes literally through vistas of Orchid flowers in infinite variety and of every conceivable hue and form. At present it is difficult to say which section is the more beautiful, but the gayest are the housefuls of *Odontoglossums*, *Phalaenopsis*, and *Dendrobiums*.

The Phalaenopsis house is a lovely sight, there being hundreds of flower-spikes all in perfection, and none appear to have been affected by the foggy weather, which proved so disastrous to other London collections. Probably the reason of this is that the plants were later to flower, and the buds were not advanced enough. Since we saw the collection last the whole of the *Phalaenopsis* have been removed to a house to themselves specially prepared for their culture. It is a low, sharply pitched, span-roofed house, running east and west, and fully exposed. On either side of the central path is a raised bed, and above this is a raised trellised stage high enough to bring every plant within a foot or two of the roof, a condition, we are convinced, quite indispensable to successful *Phalaenopsis* culture. On this stage the plants are placed, and the majority of them being in square wood baskets, their roots are thrown out in all directions, and fasten themselves to the staging in eagerness, as it were, for the moisture which arises from the moist bed of Cocoa-nut fibre beneath.

This is, we consider, an excellent plan of growing Phalaenopsis, for, all the plants being get-at-able and under the eye, the individual wants of each can be attended to, and there is less chance of their delicate and brittle roots becoming bruised than if they were in suspended baskets. The main display of bloom is effected by *P. Schilleriana*, of which there are some admirable examples and some beautiful varieties, some with flowers $2\frac{1}{2}$ inches across, others with deeply-coloured blossoms, and some, again, with branching and numerous-flowered spikes. One, we observed, was copiously spotted with minute dots of deep purple on a rose-pink ground, similar to one we lately saw at Burford Lodge under the name of *delicatissima*. The still rare *P. Stuartiana* was in bloom, among which the variety *nobilis* could be at once singled out by its finer and more richly spotted flowers. It is found here to be a capital grower under the same treatment as *P. Schilleriana*. The rare little, but not very showy, *P. Manni* was in bloom, but the choicest of all were two fine specimens of *P. grandiflora aurea*, which is a great beauty, remarkable for the rich golden yellow markings on the labellum and by its larger and more rounded blossoms. It is an extremely fine Orchid, as beautiful as it is rare. It was originally received by Mr. Peacock direct from Borneo among an importation, and it is a pity that more of it could not be imported.

The *Dendrobium* house was a brilliant sight, for, being just the height of the *Dendrobium* flowering season, there were crowds of species and varieties in bloom. The greatest show was made by masses of such as *D. nobile*, *Wardianum*, *crassinode*, *Pierardi*, and other bright coloured kinds which might be counted by scores. It is only when seen in such quantities as this that the grand effects Orchids are capable of producing can be obtained, and it seems to be one of the first principles with Mr. Peacock to have the finest display possible of his particular favourites among Orchids. Where the species are represented so numerously as here there are of course many varieties among them, some exceptionally fine. Here we saw the finest variety of *D. crassinode* we have yet seen, the flowers being more richly coloured than those even of the splendid variety *Barberianum*. A plant of this fine form, in a small basket, had a growth about a foot in length literally covered with blossoms. The type and numerous other forms were similarly represented. We should think that all the known varieties of *D. nobile* may be found here from large to small flowered, and from almost white to the deepest tinted forms. Some of the growths of *D. Wardianum* are a yard or more in length, and furnished for fully one-half with blossoms, which is the best forms are quite 4 inches across and most beautifully tipped. The plan here is to grow this *Dendrobium* in pots, which, compared with the size of the plants, are small, and the bulbs are tied erect. The home-grown bulbs are in many cases larger than those imported, which in itself is a proof that they receive skilful treatment. Another *Dendrobium* grown here uncommonly well is the old, but pretty, *D. Pierardi*; against a wall are suspended some dozens of plants attached to blocks, and from these depend long slender bulbs often 4 feet in length, wreathed with delicate mauve-tinted blossoms. The wall being covered with greenery sets off the flowers to perfection, and the moisture therefrom no doubt conduces to the well-being of the plants. We observed a variety of *D. Pierardi* with a decidedly yellow cast on the blossoms, rendering it very distinct, quite unlike the ordinary form. The following other *Dendrobiums* worthy of special note were *D. Freemani* in the way of *D. nobile*, but with more deeply tinted blossoms, a useful kind and one that every Orchid lover ought to possess. *D. luteolum*, with primrose-yellow blossoms, is quite different from the ordinary run of *Dendrobiums*, and, moreover, with a perfume akin to Primroses, and being evergreen the flowers look well among the green foliage. *D. crepidatum* is a pretty species not much known, but worthy of consideration. It has flowers the size of those of *D. crystallinum*, but with bluish tinted segments and a rich yellow

blotched lip. The rarely seen *D. hedyosmum* was just in perfection, and perfumed the house with its delicious odour like a mixture of Violets and Cowslips. The flowers, white and green, are not showy, but the scent amply compensates for this. *D. primulinum*, *fimbriatum*, *Paxtoni*, *barbatulum*, and a host of others were in flower, besides *D. Findleyanum*, which we consider one of the prettiest of *Dendrobiums* when seen in such a finely grown condition as here. It is of dwarf growth, and has singularly knotted bulbs, which are thick and of a pale green. The flowers, about 2 inches across, have rosy pink sepals, and the broad shallow lip has a large blotch of rich yellow; a fine plant of it here with a dozen or more bulbs was quite a picture in itself. It does not seem to be much known, but it is undoubtedly a valuable kind, and distinct from any other. Passing from the *Dendrobium* house, we come to the

Odontoglossum houses, in which hundreds and we might say thousands of flower-spikes were either carrying expanded flowers or incipient buds. The most numerous species is *O. crispum* (Alexandria), which is evidently the greatest favourite with Mr. Peacock, for he grows it by the thousand, and, as may be imagined, their effect when in full bloom, as at the present time, is indescribably beautiful, for each houseful of them fairly bristles with spikes. Some excellent varieties were in bloom at the time of our visit, chiefly of the Blunt type, which Mr. Vicary, the gardener here, distinguishes from *O. Alexandria* by the flowers not having broad segments spotted and usually suffused with a purplish tinge.

Against a wall (facing north) are hung hundreds of plants on oblong trellises of *O. Rossi majus*, the greater portion of which bearing flowers, and among them may be singled out some exceptionally beautiful varieties, remarkable both for large size and rich colouring. This is no doubt one of the best ways to grow this Orchid, for it seems to like the subdued light, and the roots cling to the damp wall with great tenacity. Among rarer kinds we noted *O. Wilckeanum*, of which there were two distinct forms, one with flowers of a brighter shade than the other, and which Mr. Peacock originally bought from Mr. Norman. Both are superb varieties, with flowers 3 inches or 4 inches across, richly coloured with chestnut brown on a yellow ground. Another variety was *O. Ruckerianum*, and we thought it the finest form of it we had seen. It may be best described as having the flowers of *O. Andersonianum*, but flushed with purple, and in the plant here the colouring is much deeper than usual, rendering the flowers exceedingly attractive.

The new *O. Sanderianum* is not such a great rarity here as in other collections seemingly, for we observed several flowering specimens of it, and one was a particularly fine variety. This novelty is in the way of *O. gloriosum* as regards habit of growth, size, and shape of the flower, but its chief character is the pure white labellum, which, combined with the yellow, chocolate blotched petals and sepals, makes a handsome flower. *O. triumphans*, *bictonense*, *cordatum*, *maculatum*, *pulchellum*, *Halli*, *nebulosum*, *gloriosum*, *odoratum*, the rare and beautiful *O. Edwardi* with branching spikes of purple blossoms were among other kinds in bloom, and shortly there will be a grand display of bloom of the beautiful *O. cirrhosum*, judging by the number of spikes which are produced.

Cymbidium eburneum forms in itself a beautiful floral sight, there being not far short of a hundred plants in one group massed at the end of a span-roofed house. Each plant was carrying one or more spikes of its large ivory white blossoms amidst the elegant grassy foliage. We had never previously seen such an assemblage of this Orchid before, and rarely have we seen it grown so well. It is grown by Mr. Vicary, not in ordinary Orchid soil, but in a compost of loamy soil. He has treated the plants thus for a long time, and they seem to luxuriate under the conditions. A few years ago this species was a great rarity, and no one then supposed that it would in so short a time be seen grown in such numbers in one garden as

here. There are one or two distinct forms of it having flowers copiously spotted with purple on the labellum. The flowers are deliciously scented, and, being of easy culture, it should be a favourite with everybody.

Among other Orchids of note in flower were *Cœlogyne ocellata maxima*, with flowers larger and more richly spotted than in the type; *Miltonia cuneata*, remarkable for the snowy-whiteness of the lips of the flowers, produced on tall erect spikes; *Cyrtorchilus Karwinski*, a handsome and uncommon species, with the sepals and petals mottled with brown and olive-green, and with a white labellum; *Oncidium Rogersi*, the loveliest perhaps of the genus, having long hairy branches of blossoms some 2 inches across and of a clear chrome yellow; *Lælia harpophylla*, the beautiful species alluded to in *THE GARDEN* several times lately, was still in charming bloom; as was likewise *L. anceps Barkeri*, there being numerous spikes in excellent condition, though so late; *Ada aurantiaca* lighted up one of the houses with its long spikes of orange-scarlet blossoms, as did likewise the sweetly pretty *Angraecum citratum*. The *Cattleya* houses were enlivened, as might be expected, with *Cattleya Trianae* in its endless varieties. Among the curiosities might be mentioned *Epidendrum criniferum*, with singular triangular blossoms, and one, we believe, is very rare. Every portion of this extensive collection bears evidence of the skilful treatment it receives, though of course there are the inevitable failings as in every large collection, but lessons are derived from these for future guidance.

Cattleya Trianae Bonnyana.—A variety so named we saw the other day in Messrs. Veitch's nursery, Chelsea, and is, we consider, one of the finest forms of *C. Trianae* yet introduced. The flower is of the largest size, with petals $2\frac{1}{2}$ inches broad, and these, as well as the sepals, are of a soft lilac-mauve tint. The labellum measures 2 inches each way, and the edges of it are beautifully frilled. Its colour is pale mauve in the throat dashed with yellow, the rest a brilliant carmine-magenta, while the margin is of a pale tint. The plant is a large one fixed to a suspended flat trellis, and the flowers, three in number, are borne from one sheath. Ordinary forms of *C. Trianae* have a poor appearance compared with this superb variety. It was named after Mr. Bonny, of Hackney, with whom it originated.

Phalaenopsis Sanderiana.—This new Orchid was exhibited for the first time at South Kensington, on Tuesday last, by Mr. Hill, gardener to Sir Nathaniel Rothschild, Tring Park. The flowers strongly resemble those of *P. amabilis*, but are larger than even the finest forms of that species; the petals are almost round, and, with the sepals, are of a snowy whiteness flushed with a faint purple tinge. It differs from *P. amabilis* most in the structure of the labellum. The leaves are said to be mottled like those of *P. Schilleriana*, and not plain, as in *P. amabilis*, hence it must be a very distinct plant. The spike shown bore three flowers, each over 3 inches in diameter.

SHORT NOTES.—ORCHIDS.

Cocoa-nut fibre for Orchids.—My experience agrees exactly with that of Mr. Baines (p. 215) respecting the use of this fibre for Orchid growing. I have always found that after twelve months the fibre began to rot and get white with fungi that killed the roots. Fresh-made roots that came in contact with it turned black and stopped growing. The consequence was, I had to shake the plants out, wash them clean, and put them in fresh compost.—G.

Books on Brazilian Orchids.—"Walper's *Annales*," vol. vi., price 25s., is a more modern work than Lindley's "Genera and Species of Orchidaceous Plants" and contains descriptions of many Brazilian Orchids. So also the parts of De Candolle's "Prodromus," art. Orchids. A flora of Brazil is now being published in volumes, one or more of which will no doubt include the Orchids of that region. At Kew, in the herbarium, our correspondent could see many Orchid books and obtain much information re Brazilian Orchids unobtainable elsewhere.—R.

Odontoglossum nevadense.—Of this handsome and distinct species Sir Trevor Lawrence exhibited on Tuesday last three unusually fine spikes cut from the plant to which the name was originally applied. The spikes are more slender than those of similar species, and one of those shown bore eight expanded flowers. The flowers are about the size of those of *O. luteo-purpureum*; the sepals and petals are chocolate brown, edged and tipped with a yellowish tint; while in contrast to the dark colour is the pure white labellum which bears a prominently ridged crest. It is a rare species and grown to perfection in the Burford Lodge collection.

GARDEN DESTROYERS.

APHIDES IN ADVANCE OF THEIR FOOD.

UNDER this heading Mr. D. T. Fish makes some remarks on the early appearance of aphides, a circumstance doubtless owing to the mildness of the winter. Having had a few sunny days, they hatch and show themselves round the fast-budding shoots or young blossoms, and are often a great source of trouble when they get into the latter, especially in the case of Peaches and Nectarines, which they spoil. The best way to prevent this is to do as Mr. Fish says—fumigate the house before the buds open, as then the trees will be free from insects till the blooms set, when it will be necessary to repeat the fumigation, but this should always be done with care, and only when the tender foliage is dry. Instead of a heavy fumigation, it is always safest to give several whiffs following each other night and morning till the aphides are destroyed, which they will be after two or three turns if the tobacco paper is good. The latter varies so much in quality, that it is always advisable to procure the best, as much harm is often done by using inferior kinds. However good the paper or cloth may be, I always like to have some real tobacco with it; and though it is now high in price, I am not sure that it is not the cheapest in the end. Proper fumigators should be employed, so as not to require anyone to remain in the house. There is much economy in this as well as safety, for with a good fumigator the tobacco only smoulders and gives off much smoke, and may be left to burn itself out if only a limited quantity is put on at first. With an open pot or any makeshift of that kind, it would be highly dangerous to do that, as the paper would be almost sure to flame, and send up hot blasts of air that would ruin the foliage. To start the tobacco, and keep it burning, a few pieces of lighted charcoal are best, as they hold the fire a long time, and are not liable to become extinguished by the ashes in the way hot cinders do.

S. D.

Woodlice in Mushroom houses.—If your correspondent (p. 126) damps the edge of the Mushroom beds and the floor about three o'clock with a very fine rose, so as not to make the floor too wet, and then go into the house at night with a light, he will find that all the young ones have come out after the moisture—small red creatures—they can then be killed with ease by merely smearing his fingers over them. It must, however, be done very carefully, or they will run back again into their holes. This must be repeated night after night till he finds that none are left. This is how I cleared our fernery, which, when I came here, was smothered with them.—J. H., Bedford.

Onion and Carrot grubs (T.).—Your Onions and Carrots, as you imagine, are attacked by different grubs. The former by the grubs of the Onion fly (*Anthomyia ceparum*); the latter by those of the Carrot or negro fly (*Psila rosea*). The same remedies are useful in both cases. Take up carefully any roots which are attacked, and be sure not to leave any of the grubs behind in the earth, and after the crop is removed trench the ground deeply. Gas-lime or a quart of paraffin oil mixed with a barrowful of sand or ashes strewn over the bed is very useful in keeping

the flies away. Sow as far as possible from ground which has borne an infested crop; keep the ground round Carrots as firm and compact as possible to prevent the flies from getting to the roots.—G. S. S.

ROOF HEATING.

ADVERTING to our system of roof heating, allow me to say that it has been greatly misrepresented. Many who have seen it, and to whom we have pointed out all particulars, have afterwards described it so reverse to the actual facts, that we hardly care to say anything further about it. As "W. C. T.," however, seems to imply that we are not sincere as regards the system first adopted by us at least twelve years ago, allow us to state that our houses and even pits, without a single exception, are all heated with pipes running along the rafters 3 inches or 4 inches from the glass, and about 10 inches from the wall plates or sill. It must, however, be understood (strange as it may appear) that all our water is made to circulate in a way exactly contrary to that usually adopted—that is to say, it flows along the pathway, turning up towards the roof at the far end, and running, as before described, just beneath the rafters to the end of the house, where it first entered in the pathway, having a gentle rise all the way, and where the pipes pitch down (being the highest point) into the main return pipe the air tap is inserted. With us nothing can be more satisfactory than this plan, and it is very evident plants like growing towards the heat as well as towards the light. Hitherto the notion has been to apply the heat somewhere under the roots. We have no bottom heat whatever of any description, and it is our belief that having the heat applied at bottom has done more to injure horticulture than all other erroneous notions put together. The flow and return pipes from and to the boiler are not in any way different from ordinary pipes. Any kind of boiler will answer for this method of top heating just as well as our own.

H. CANNELL, JUN.

Swanley.

QUESTIONS.

Charcoal in Vine borders.—I am going to make a new Vine border, and as I have some charcoal, would some of your readers kindly let me know if it would be a good thing to mix with the soil, and, if so, in what quantity?—CONSTANT READER.

Mushrooms in caves.—Would some of your readers state how Mushrooms are grown in the caves of Paris, and what is the temperature of those caves? Here, at Sandwich, in Kent, we have large caves in the solid chalk, and the temperature of them is always 52°. How are Mushrooms to be grown in them?—W. V. L.

Pruning Rhododendrons.—Will some of the readers of THE GARDEN kindly reply to the following question? We have a large bed of Rhododendrons, some of which are in flower now, and others will come in succession for the next three months. They are overgrowing their limits, and getting hollow in the centre. I want to know the proper time for pruning them, and if there are any special rules to be observed.—LOCKHART.

Beds in a span-roofed house.—Will some of the readers of THE GARDEN kindly give me their advice as to which is the best mode of constructing beds in a span-roofed house, 12 feet wide, with 3-feet path up the centre, leaving the remainder for beds on each side? The house is wanted for growing stove plants, propagating cuttings, and raising seedlings for bedding, &c. Two ways have been recommended, viz., 1st, filling in from the bottom pipes with coarse gravel; 2nd, covering with slate slabs. Which of the two is best? or if there is a better way still I should be glad to know it. We are in a district where thin stone slabs can be procured cheaper than slate. Would they answer the same purpose?—W. K.

Our readers will greatly oblige by replying, so far as their knowledge and observation permit, to these questions. The title of each query answered should be prefixed to each answer, and replies will be printed in the department of the paper under which the subject falls. The questions that arise and must be solved are so many in these days, that it is only by a general interchange of ideas and experiences among practical men that we can hope to answer them satisfactorily.

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 13.

OWING to the cold weather which we have had, and still are having, there was on this occasion almost an entire absence of plants of a very tender character; but, on the other hand, there was a goodly display of greenhouse and hardy plants, chiefly Abutilons, Primulas, Cinerarias, Fuchsias, and Amaryllises.

First class certificates were awarded to the following:—

AMARYLLIS DR. HOGG.—A fine variety, having flowers 7 inches across, with broad overlapping divisions of a deep rich crimson, and with a band of white running up to the middle of each segment. Shown by Messrs. Veitch.

DENDROBIUM WARDIANUM VAR. WADDELIANUM.—A variety differing from the type in having smaller flowers and without colour, except deep yellow and maroon blotches in the interior of the labellum. It is identical with the variety album. Exhibited by Mr. Ward, gardener to Mr. G. Waddell, Stony Stratford.

AMARYLLIS GEORGE GORDON.—A handsome flower 6½ inches in diameter, with broad reflexing segments, making a finely shaped flower. The colour is a bright scarlet, and with a band of white running along the centre of each division. Messrs. Veitch.

AZALEA DEUTSCHE PEARLE.—A variety of the Indian or greenhouse Azalea, with large, perfectly double flowers 3 inches across, of snowy whiteness, and abundantly produced on small plants, one of the best double white Azaleas known. Shown by Mr. C. Turner, Royal Nurseries, Slough.

AMARYLLIS A. F. BARRON.—A fine flower 7½ inches across, but not so perfect in form as the smaller varieties. The colour is a splendid rich crimson, and there being four fully developed flowers on the plant it was remarkably attractive. Messrs. Veitch.

DENDROBIUM NOBILE NOBILIUS.—The finest coloured variety of the old *D. nobile* known. Its flowers are 3½ inches across; the petals are 1½ inches long by 1 inch broad, and are of a resplendent purple colour, while the lip has a dark blotch on it like that of the type, in contrast with a zone of white edged with purple. Shown by Mr. Salter, gardener to Mr. Southgate, Selborne, Streatham.

ZYGOPETALUM CRINTUM ROSEUM GIGANTEUM.—A fine variety of an old Orchid. The flowers are larger than those of the type, and the markings on the labellum are decidedly of a rosy hue. The plant shown bore four spikes, each about a foot high, and was a fine specimen of good culture. Shown by Mr. Wilson, gardener to Mr. H. M. Pollett, Fernside, Bickley.

PESCATOREA LEHMANNI.—A flower of this Orchid was shown also by Mr. Pollett. It was 4 inches across; the petals and sepals were a deep plum colour copiously lined with white; the labellum was singularly studded with white hairs on a purple ground. A very handsome and rare Orchid.

CINERARIAS COLONEL CLARKE AND CAPTAIN EDWARDS.—Two very fine varieties, perfect as regards size, shape, colour, and habit. The first has flowers just upon 3 inches across, with broad overlapping florets and of a deep velvety magenta. The other has similar flowers and of a brilliant magenta, set off by a ring of white in the centre. Exhibited by the raiser, Mr. James, florist, Farnham Royal, Slough.

FUCHSIA MRS. RUNDLE.—A remarkably fine hybrid variety in the way of Lord Beaconsfield, with flowers 2½ inches long and with the spreading sepals 4½ inches across. The sepals are flesh colour, while the corolla is an orange-scarlet. It is a wonderfully free flowering variety; the plants, about a score in number, though in 3-inch pots, were 1½ feet high, and completely hung with blossoms on their upper parts. Shown by Messrs. Cannell, Swanley.

CINERARIA A. F. BARRON.—A double flowered variety, with large, globose, full flowers 2 inches across, and of a bright magenta. It is of a dwarf, compact growth and floriferous. Messrs. Cannell, Swanley.

A very pretty group of forced shrubs was shown by Messrs. G. Paul & Sons, Cheshunt. It consisted of about a dozen standard bushes of Pacquerette Rose, a variety of *Rosa polyantha hybrida*, an extremely pretty plant, with clusters of small, pure white double flowers. Some excellent examples of Lilac Charles X., and white Clematises, Vesta, Edith Jackman, and Miss Bateman, all beautiful varieties, and some superbly flowered plants of *Staphylea colchica* completed this choice group, for which the exhibitors were awarded a bronze medal.

Messrs. Cannell brought from Swanley a fine display of Cinerarias, Fuchsias, and Primulas. The Primulas consisted chiefly of the old double white, which was remarkably well grown, being fully 1½ feet across, and profusely flowered, though the plants were only in 4½-inch pots. The Cinerarias were single and double varieties. The doubles included some very fine sorts, notably Sir T. Clarke, with large violet flowers, good in form, and Professor Henslow, with bright violet large flowers. The best of the single varieties were G. F. Wilson, with tricolorous flowers with maroon margin and white zones; R. Dean, bright magenta, with central ring; Dr. Masters, similar, but smaller, but, like the last, perfect in form; S. Hibberd, G. Bryceson, W. Robinson, W. E. Gladstone, J. Moore, and J. Douglas were likewise among the best of this choice selection, all of which were far in advance of the ordinary strains. These were all admirably grown, and a bronze medal was awarded to the exhibitors.

A group of about three score of seedling Abutilons was exhibited by Mr. George, Putney Heath. These embraced a great variety of colours, and the majority were remarkable for large size and fine form of the flowers and distinct colouring. A selection of the finest included Brilliant, reddish scarlet; Lustrous, rich scarlet; Striata splendida, orange-scarlet, much striped; Purpurea, dull reddish purple; Cloth of Gold, one of the best of the yellows; Silver Bell, pinkish, veined with red; Orange Gem, very large, shallow flowers, orange-red; and The Bride, pink, veined with red. The above are a few of the best of larger-growing varieties. Another and very distinct type was shown under the name of Compactum, the members of which were very bushy in growth and not more than a foot or so high. The varieties Little Beauty, Vivid, Roseum, Pink Gem, Aureum, and Scarlet Gem were the best in this group, which is one that ought to be encouraged. A bronze medal was deservedly awarded to Mr. George for his extensive collection.

Chinese Primulas in variety and admirably cultivated were shown by Mr. Child, gardener to Mr. W. G. Bell, Garbrand Hall, Ewell. The most remarkable of these was that named Alba gigantea, having large trusses of white flowers 1½ inches across and beautifully fringed. It is vigorous in growth and a profuse flowerer. Other kinds were Rubra superba, good in colour and habit; Laingi Improved, an excellent white; and the now well known Chiswick Red.

Two new seedling Roses were shown by the raiser, Mr. Bennett, Shepperton. These were named Mrs. George Dixon, a large flower with massive petals of a deep rose-pink. This was a Hybrid Perpetual. The other was a seedling Tea variety named William Francis Bennett. This was exhibited in the bud state, shown as a button-hole bouquet flower. The colour is a deep crimson, and very pretty in a bud state.

Azaleas Duke and Duchess of Albany, new seedling greenhouse varieties, were shown by Mr. Todman, gardener to Mr. G. Connell, Bushy Down, Tooting Common. Both are small flowered, the first a kind of Indian red, the other pure white. Both are extremely floriferous and very useful sorts for forcing into flower early.

A fine Chinese Primrose in the way of Alba magnifica was shown by Mr. Burgess, florist, h iple, Bradford. The plant is vigorous in

growth and very floriferous. The trusses were large and the flowers, 2 inches across, pure white and beautifully fringed.

A double Cineraria named Vortigern was sent by Mr. Vertegans, Chad Valley, Birmingham. It is a pretty sort with full globose flowers of a bright magenta. A very elegant foliage plant, *Sisymbrium millefolium* was also sent by Mr. Vertegans. It is an erect herbaceous species with long ferny foliage of a bright green. It is nearly hardy and particularly suitable for growing in pots for decorative purposes.

A very fine group of coloured Primroses and Polyanthes in pots, about 150 in number, came from Mr. A. Waterer, Knap Hill Nursery, Woking, which made a bright display, and the same exhibitor showed a fine plant of *Andromeda japonica*, an extremely elegant hardy shrub. The plant was bushy and clothed with thick evergreen foliage, and nearly every branch was terminated by drooping clusters of small waxy flowers of transparent whiteness. Such a beautiful shrub as this is well worthy of pot culture for conservatory decoration in spring. A silver medal was awarded.

Primulas were likewise shown by Mr. Eckford, gardener to Dr. Sankey, Boreatton Park, Shrewsbury. Among these were Crimson Gem and Duchess of Albany, both of a brilliant crimson; Emperor and Empress, rich purple; and Perfection, of a pale pinkish purple. A well-flowered plant of *Dendrobium Wardianum* was exhibited by Mr. Ward, gardener to Mr. J. Waddell, Stony Stratford. The variety was one of the best, the blooms being 3 inches across and tipped with deep purple-magenta.

Cut spring flowers, including Primroses, Narcissi, Scillas, and Iris reticulata, were shown by Mr. G. F. Wilson, from his garden at Oakwood, Wisley, to show how well the flowers had withstood the effects of high winds and severe frosts. A charming basketful of Primroses came from Mr. R. Dean's seed grounds, Ealing. These included three superb sorts—Bluebell, with pretty purple-blue flowers, yellow eyes, and striped petals; Virginia, almost a pure white, with orange centre; and Sulphur Queen, yellow, with deep yellow centre. Another called Bedford Beauty, with flowers as large as a crown, and of a rich crimson-maroon.

From Chiswick Mr. Barron sent a fine painful of plants of the beautiful orange coloured *Lachenalia Nelsoni*, admirably grown; also two fine specimens of *Imantophyllum miniatum*, one named superbum being remarkable for its intensely rich orange-scarlet flowers.

Fruit.—The principal exhibit was a dish of a new seedling Apple, called Warner's Seedling, exhibited by Mr. E. Warner, Broomfield, Chelmsford. It is of large size, evenly round in shape, and with the skin of a pale yellowish green. It is said to be of good flavour. It was in excellent preservation, thus showing what a good late variety it is. A first-class certificate was awarded. A large dish of forced Vicomtesse Héricart de Thury Strawberry was sent by Mr. Allan, gardener to Lord Suffield, Gunton Park, Norfolk. The fruits were of fair size and good colour, and a cultural commendation was accorded to the exhibitor. Fruits of *Carica cundinamaricensis* were exhibited by Mr. Green, gardener to Sir George Macleay, Pendell Court, Bletchingley. They were egg-shaped, about 2 inches long, and of a reddish orange colour.

The committees included the following members—Fruit: Mr. H. Veitch (chairman), Messrs. P. Crowley, S. Lyon, J. Willard, F. Burnett, J. Roberts, W. Denning, W. Paul, A. Sutton, C. Silverlock, J. Lee, G. Paul, R. D. Blackmore. Floral: Mr. G. F. Wilson (chairman), Messrs. J. Llewellyn, W. Bealby, N. Ridley, T. Moore, H. Bennett, G. Duffield, H. Eckford, H. Turner, T. James, H. Ballantine, C. Green, J. Wills, H. Cannell, W. B. Kellock, J. Hudson, J. Doyle, H. Ebbage.

Scientific committee.—Sir J. D. Hooker in the chair.

Tulipa Chisiana.—Dr. M. Foster made some remarks on the eastward extension of this species,

stating that it had been found in South Persia, further east than had been previously recorded.

Lachenalia Nelsoni.—He also exhibited flowering spikes of a *Lachenalia* named by Messrs. Barr aurea × rosea, which appeared to be the same as *L. Nelsoni*. It had a red rim to the edges of the petals, and some features resembling *L. tricolor*. What rosea referred to appeared doubtful.

Frost at Lamorran.—The Hon. and Rev. Mr. Boscawen stated that the frost last Friday was 12° Fahr. in a valley, the thermometer being on the ground and fully exposed. It was 10° of frost less on the higher and more open country. Mr. Loder said he had recorded 3° Fahr. on the same night at Weedon at an altitude of 300 feet above the sea.

Potato disease.—Dr. Masters read a portion of a paper on this subject forwarded to him by Mr. A. Stephen Wilson, and having special reference to the Sclerotia, which Mr. Wilson had discovered in nearly all the organs of the adult plant as well as in the seedlings and tubers. The Sclerotia are supposed to germinate and lie in a state of incubation in the haulm. Ultimately they give rise to the conidial threads. The conidia form, according to circumstances, either (1) zoospores, (2) plasm granules, or (3) secondary conidia. These are succeeded by oospores and a non-parasitic mycelium, from which latter, as it creeps through the soil, are thrown out "floats" and specks of the seminal plasm. The seed tuber comes in contact with the plasm in the soil, it is absorbed, and becomes developed in the shape of Sclerotia, and thus the life cycle is completed. From the tuber or seed to the conidia is the parasitic arc. From the conidia to the tuber is the non-parasitic arc. The author illustrates his position by what happens in the case of cereals, wherein the plasm, say, of smut or rust is absorbed by the cells of the scutellum or cotyledon, passes through a period of gestation, and then germinates. Mr. G. Murray observed that a microscopical examination of certain specimens did not clearly reveal any organic connection between the sclerotia and the Peronospora mycelium, and thought that possibly they might prove to be glandular bodies of some kind belonging to the Potato itself. Moreover, they could not be true Sclerotia in the fungoid sense, as the latter are a compact mycelium.

Plants exhibited.—*Hybrid between Carica cundinamaricensis and Carica erythrocarpa.*—Mr. Green sent leaves and fruit. He observed that the fruit of this plant is borne all the way down the stem like that of *C. cauliflora*, whereas the flowers of *C. papaya*, the Papaw tree, are in a terminal cluster. The fruit was devoid of seeds, though the plant which bore them was originally raised from seed.

Retinospora pisifera and R. plumosa.—Mr. Noble contributed a specimen showing the foliage of these two supposed species on one branch. Dr. Masters remarked that the spinescent foliage of the latter is characteristic of a young state, but the adpressed form of the latter is adult. There are correspondingly microscopic differences in that the latter has more stomata than the former, possibly correlated to its more vigorous growth when young.

Juniperus chinensis.—Mr. Noble also sent a male spray, taken from a female tree, growing from an altitude of 14 feet from the base of the tree of the latter kind, the sexes in this species being usually quite distinct.

Garrya elliptica grafted on Aucuba japonica.—He also sent a young plant showing the two growing together. Mr. Henslow remarked how this was an instance where physiological affinity corroborated the morphological in that while Endlicher placed *Garrya* between the Hop and Plane, Sir J. D. Hooker assigned its position next to *Aucuba*, but the discovery of its power of grafting on *Aucuba* was a purely accidental discovery in Messrs. Veitch's establishment.

Primula.—A variety called Miss Eckford, shown by the gardener to Dr. Sankey, of Shrewsbury, was a curious instance of an attempt at "dialysis" of the petals, which were very deeply cleft, somewhat in imitation of the Ragged Robin (*Lychnis Flos-cuculi*).

Primula sinensis (hybrid ?).—A supposed seedling hybrid between an *Auricula* and *P. sinensis* was sent by Mr. Roberts, of Rose Hill, Ipswich. The pedicels and calyx were of a pinkish hue, the corollas white, but with no trace of the meanness characteristic of some *Auriculas*.

Primula denticulata.—Six very fine varieties of this species from Nepal was sent by Mr. J. D. Llewellyn. It was first introduced by Mr. Veitch in 1842, and figured in the *Botanical Magazine*, No. 3959.

Phajus maculatus.—Mr. Boscawen exhibited a fine spike of this Orchid, which he described as being nearly hardy.

Lecture.—Mr. Henslow first called attention to a fine collection of *Primulas* of the *Polyanthus* type exhibited by Mr. Waterer, as well as to a collection of finely flowering double white ones by Mr. Cannell, and a series of six varieties of the Nepal *Primrose* by Mr. Llewellyn. It was at one time thought that the common *Primrose*, which has given rise to so many excellent types under cultivation, was the same species as the *Cowslip*, the probable origin of all our older *Polyanthuses*, and that the *Oxlip* is a hybrid between them; but Mr. Darwin was inclined to think them distinct, as their habit of growth and time of flowering do not agree, as well as that they differ in the details of the flowers. The fine *Polyanthus* forms exhibited by Messrs. Waterer, Dean, and others are the results of various crossings of *Primrose*, the usual flowers of which, though apparently growing singly from the rootstock, really rise from an abbreviated peduncle which elongates under cultivation. Mr. Henslow alluded to the other *Primroses* described in the report of the Scientific Committee. *Sisymbrium millefolium*, a European species, with finely divided leaves, suggested remarks upon an allied species, *S. Irio*, the London Rocket, which appeared suddenly after the burning of London, and also in the Oxford Botanic Gardens after the burning of weeds, &c. It was suggested by Dr. Masters that the sudden appearance might be specially due to the increase of the quantity of potash and other salts which stimulate the dormant seeds into life. Similar results arise after burning forests in America. Mr. Henslow alluded to the practice of forcing coloured lilac in the dark to develop white-flowered sprays, and remarked on M. Bert's experiments with plants grown in high latitudes, and which bore more brilliantly coloured flowers than those grown in the neighbourhood of Paris. The colours do not depend directly on light, but on the supply of nutriment supplied by means of the foliage, which is finer under the more continuous supply of sunlight in high regions. Hence *Hyacinths* will bear blossoms of their normal colour in the dark, but the *Lilac*, though coloured under sunlight, is colourless in the dark, presumably because it has no or insufficient food in reserve.

Sisyrinchium grandiflorum.—This deserves a better generic name than it has got. *Rush Lily* is indeed a good name in every way for this charming plant. I have grown it for six years, and we have always spoken of it as the *Satin-flower*, a name by which it is known at its wild home, and used by the trade in North America. "W. G." (p. 199) speaks of this plant as of doubtful hardiness. It has, however, survived with me the recent severe winters; and in the autumn of 1881 I put a plant of it in the coldest part of my garden which is not without clay, and it has grown strongly, having made an extra crown, and will probably be in flower in some two days' time if the weather be sunny. During the past week we have had 8 inches of snow, and since most of it melted we have had 23° of frost during one night (March 9 and 10), which has cut off nearly all the *Helibore* bloom stems and many other things; the *Satin-flower*, however, is all right, though the friendly snow scarcely covered it at that time. I therefore think it perfectly hardy, and, moreover, fond of moisture, but not in the least of that of a stagnant character. Such has been my experience of this plant for six years.—J. Wood, *Kirkstall, Yorks.*

AMERICAN NOTES.

Manures for bulbs.—An ounce of nitrate of soda dissolved in four gallons of water is said to be a quick and good stimulant for bulbs to be applied twice a week after the pots are filled with roots and the flower-spikes are fairly visible. A large handful of soot, or about a pint, tied up in a piece of old canvas and immersed in the same quantity of water for a day or two, will furnish a safe and excellent stimulant; also good and safe is a quarter of a pound of cow manure mixed in a large garden pot of water and used as required. Any of these stimulants will do good, or the whole of them applied alternately will benefit bulbs that need more sustenance than the soil affords.—*Scientific American*.

Coal ashes as a fertiliser.—These are said to contain very little enriching material, a statement with which I agree, but they derive some value from the ashes of wood used in lighting the fire. We used anthracite in the kitchen as well as parlour some years ago. When the grates required clearing we removed ashes, slag, &c., that would not sift through the bars. Pine was mostly used to rekindle, some few Beech or Maple chips being employed with it. A liberal estimate of wood ashes, hard and soft, would be one-half bushel to each two-horse load of twenty bushels of coal ashes. The ashes were run through a sieve, and early the following spring drawn and spread on three acres of lawn, not expecting to derive any benefit, but as a convenient method of getting rid of them. Where the ashes were spread there was a noticeable increase in thrifty growth of red Clover where little was to be seen before. The result would have been as beneficial had a less quantity been applied and the surface harrowed, the sod being thin and "hide-bound." From the above experience I am satisfied that coal ashes are a fertiliser of the nature of gypsum, although they will not show as good results as the latter in equal weights.—I. S. MASTERS.

Dried fruit.—These, being reduced in weight to one-fifth, are easily moved from place to place; 200,000 baskets of Peaches canned in San Francisco making 250 car-loads, would be reduced to 42 car-loads if evaporated. The sale of dried fruits in California already amounts to over £400,000. The raisin crop in 1882 amounted to nearly 200,000 boxes, worth £100,000. The recommendation was strongly urged "to put up nothing to sell not first-class." It may be proper here to remark that the improved facilities for drying Grapes to raisins in trays, and turning by inverting a loaded tray while drying into an empty one by placing their faces together, are a simple and great improvement.—*Country Gentleman*.

Sex of the Ailantus.—A note in the *American Agriculturist*, probably from the pen of Professor Thurber, than whom there can be no better authority, calls attention to the fact that there are three kinds of *Ailantus*—the male, which is fetid for the few days it is in flower, the female, which is inodorous, and the hermaphrodite, which, though perfecting seeds as the female does, has also disagreeable flowers. The purely female is the form which those should raise from root cuttings who find fault with the odour of the others.

A new Catalpa.—Dr. Warder says that Mr. H. H. Hunnewell, of Boston, has contracted with Messrs. Douglas & Sons, of Waukegan, the well-known nurserymen, for the planting of several hundred acres with the hardy Western *Catalpa*, the soil being first broken up and planted with grain for one year or more before setting out the *Catalpas*. They are placed 1 foot apart, requiring nearly 3000 for an acre, and Messrs. Douglas agree to furnish the trees, plant and tend them until old enough to take care of themselves, at the rate of 3 cents each. This would be 80 dollars an acre, probably one of the most profitable investments on the part of the land owner that can be made.—*Gardeners' Monthly*.

Canning Oranges.—By a process similar to that used for preserving other fruits, Oranges have recently been successfully canned and shipped. The fruit is peeled and broken into its natural sections before canning, and when taken out is just ready for use. This is likely to become an important industry in the Orange growing districts of California and Florida.—*American Garden*.

Trees in May.—The month of May is a critical time in northern tree growth. The stem is surcharged with crude sap which soon decomposes as the weather becomes warm if the leaves do not unfold and use it. Hence rapid decay of wood cut then, and fatal effects from pruning at that time. But a week may make a great difference, especially if the weather is very wet or very warm, or both or neither, and one tree may be in the critical stage of growth, while another adjoining may have passed it.—*Rural New Yorker*.

OBITUARY.

We learn from a Colombian paper of the death of Mr. J. H. CHESTERTON, the well-known botanical collector, which took place at Puerto Berrio on January 26 last. He has for many years followed his precarious calling, collecting chiefly in South America, and he is said to have crossed the Atlantic 48 times. His name is associated with several new plants, which among others he discovered and sent home. Among them are *Odontoglossum Chestertonii*, one of the finest varieties of *O. crispum*, and *Oncidium cucullatum Chestertonii*, also a very handsome variety. His last trip was taken, we believe, for Mr. James O'Brien, who instructed him to confine his attention to collecting Orchids.

Cinerarias.—(G. A. F.).—Good, but much inferior to the best strains.

Fruits (*Pomologie, A.*).—"Dictionnaire de Pomologie," by Andre Leroy, Paris.

Chinese Primulas (*T. Eush*).—The flowers you send represent a fine strain, being of large size, brilliant in colour, and, as you observe, good in substance.

Primula and Cineraria (*D. D.*).—The flowers you send represent beautiful strains. The *Primula* seems to be identical with that known as Chiswick Red.

Cinerarias.—A boxful of blooms sent to us by Mr. Bull, Chelsea, are remarkable for large size (some nearly 3 inches across), good in form, brilliant and varied in colouring.

Kew Gardens (*J. T. H.*).—A two years' stay at Kew would be of much service to you, provided you fully availed yourself of the advantages there offered for study. Young gardeners on leaving Kew do not receive any of the Government grant.

The weather in Yorkshire.—I do not remember such severe weather at this time of the year as we have lately had. Roses and Gooseberries which were green in leaf on the 1st inst. are now hanging black and dead. Wall trees have not suffered so much; they are not quite in flower yet; but the change from the fine weather we have lately had is terrible. Snow 4 inches deep fell on the 8th.—B. WADDS, *Birdsall, York*.

Names of plants.—A. S. Smith.—*Physalis edulis* (Cape Gooseberry).—A. C.—*Dendrobium crassinode*. Fern is too much withered to recognise; send latter in season when fronds are much more matured.—M. Lockwood.—A species of *Tillandsia*. Grow it on a block as you suggest.—D. D.—*Dendrobium Freemanii* (good variety).—*Raby*.—*Dendrobium fimbriatum oculatum*, *Dorypteria nobilis* (Fern).—Ferns.—*Young Botanist*.—1, *Blechnum occidentale*; 2, *Polystichum angulare proliferum*; 3, *Goniophlebium subpetiolatum*; 4, *Polystichum capense* syn. flexum; 5, *Cyrtomium anomophyllum*.—Jan.—Fern is *Lastrea Filix mas cristata*.—Constant Reader.—Apparently *Acacia pulchella*; Australia (try layering).

"This is an Art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

FRUIT GARDEN.

VARIABILITY OF GRAPE SEEDLINGS AND CROSS-FERTILISATION.

It has been a matter of surprise to me, and no doubt to many others of your readers, that in the various notices of Mr. Barron's book on the Vine his statements relative to the subjects which head this paper have received so little attention. His opinions on the fertilisation of the Grape and Grape seedlings are, I believe, hardly shared by any other authority. It is a great pity Mr. Barron has not been more explicit on this subject, and stated when and where and by whom his somewhat dogmatic assertions on these matters have been verified. I do not remember ever to have read or been told before that "the varieties of Grapes usually reproduce themselves from seed—that is to say, if the seed of a certain variety be sown, that same variety will most likely be raised from it. *They do not sport or vary*, or but to a very limited extent, excepting they are artificially impregnated. . . . Excepting great care has been taken to properly cross or fertilise the flowers the chances are a hundred to one that nothing ever will be raised." I have reproduced Mr. Barron's full statement on this head from p. 25 of "Vines and Vine Culture." "This accounts," Mr. Barron continues, "for the many varieties of Grapes sent out as distinct, which ultimately prove to be nothing but old sorts." With the exception of Venn's Muscat and Bowood Muscat, we have not heard of any authenticated seedling Grapes reverting to the original type. No white berried seedlings have turned black that we know of in the course of time. The white Lady Downes Grape, for example, is a seedling from the black variety of that name "not crossed with pollen from any other variety" (Burbidge's "Cultivated Plants," p. 575), and there are many other seedlings in cultivation. Mrs. Pince and others have as yet shown no disposition to change. In the work just quoted (Burbidge) it is also stated that "Vines raised from seed are nearly as variable as Apples, Plums, Pears, or other cultivated fruits," and I believe this is the generally accepted opinion, if not the correct one, so that the discovery to the contrary must be Mr. Barron's own, and ought to be authenticated. The writer of this paper has probably seen as many seedlings raised and proved as most growers, but he cannot remember any variety reproducing itself except the Black Hamburgh. In fact, it is doubtful, according to Mr. Barron's showing, if any of the so-called crosses in existence are anything else than seedling sports from self-fertilised seeds, for I believe I am quite within the mark in stating that in few instances were the flowers fertilised in the careful manner Mr. Barron says they require to be. He states that cross-fertilisation "is a ticklish operation, requiring the greatest care and patience, and one of the most trying garden operations." If in the bunch of flowers to be cross-fertilised "a single flower be allowed to expand naturally, it may ruin the whole experiment. . . . the chances are a hundred to one nothing new will be obtained," &c. The flowers are to be manipulated by a pair of scissors "in advance of the natural development," every single flower is to be carefully operated upon, not a grain of the natural pollen is to escape, and the bunches under operation are to be enclosed in muslin bags. Is Mr. Barron aware that many of the most remarkable of reputed cross-bred Grapes were from bunches of which no such care was taken, a bunch of another variety having been only shaken or suspended over the bunch to be fertilised? And yet the progeny

from such Vines warrant the opinion that they had been cross-fertilised. If they had not been, it is almost certain that Mr. Barron's assertion that "Vines do not sport or vary" unless cross-fertilised must be erroneous, for not one of the seedlings so treated came like its parent. Raisers of seedling Vines will, I believe, corroborate this view. If cross-fertilisation be as difficult a matter as Mr. Barron represents, what comes of the reputed cases of the setting of such varieties as the Alnwick Seedling, for example, which, it has been confidently stated, has been set by simply sprinkling foreign pollen over the bunch? In fact, Mr. Barron recommends that plan himself in his book, although the Vine produces plenty of pollen of its own, which, according to Mr. Barron, it is a hundred to one will effect the fertilisation if but one flower be allowed to expand naturally. Are we to understand that the Alnwick Seedling and other shy setters are an exception to Mr. Barron's rule in regard to self-fertilisation? Such an admission would be fatal to his case; but it is for Mr. Barron to explain the inconsistency of his theory and practice.

In Burbidge's "Cultivated Plants," in a well-authenticated chapter on Vines, I find a long list of the best new Grapes given as examples both of "cross-breeding and seminal variation." Whoever is right, it is certain that one has only to sow seed of Grapes to get new varieties, for the most part worthless, perhaps, but still different from the parents. Mr. Barron's idea, too, that self-fertilisation is the rule in Grapes is opposed to Mr. Darwin's views, which have been verified by others. "Nature abhors self-fertilisation," he has stated. GROWER.

DOUBLE-ROOTED VINES.

It would appear from "Peregrine's" note (p. 209) that information respecting double rooted Vines would be acceptable. Having a wish to test the plan, I began seven years ago to prepare for doing so. I had a house of Vines, 30 feet long, with all the roots inside; the Vines, three in number, were planted at one end and trained horizontally under the roof. They had been planted about eight years and had already reached the other end of the house; I therefore selected one of them and trained down the wall the leading rod, which reached the border in one season. Early next spring I pegged this rod down on the border and left about 1 foot in length beyond the point where it was pressed on to the soil. This was necessary in order to insure growth being made beyond the point, which touched the soil, and to encourage the formation of roots. With this in view I encouraged one bud to grow and extend a few feet in length. In a few weeks roots began to form rapidly, and in one season there were sufficient roots to thoroughly establish that end of the Vine. At pruning time the branch that extended beyond the roots being no longer necessary was cut off, and at the present time this Vine remains rooted at both ends, the whole length of the rod being as near as possible 50 feet, 30 feet being bearing rod, the other 20 feet divided between each end. The house being a high one, the rod has therefore to make a growth of nearly 10 feet before it reaches the wires on which the lateral growths are trained. This Vine has now existed, with roots at each end, for five years, and if I were asked if I thought it had in any way been benefited by the additional roots, I should, without hesitation, answer "No." Up to the present time I do not consider I have obtained one ounce in weight of Grapes more than I did when it existed on one set of roots. The only benefit I have received from this experiment was the year that I was training the leading rod down the opposite wall. I had that season the best Grapes on that Vine that I have had since or before, a circumstance which, to my mind, conclusively proves that the extension system of Vine growing has much to recommend it. Nevertheless, the experiment proves, as it has done in other instances, that the Vine is an accommodating plant. I may even go further and say that its amount of capacity to enable the cultivator to

step out of the beaten track is not yet fully comprehended. People interested in this subject may fully satisfy themselves as to the

Flow of the sap.—Get a strong pot Vine, place it in a warm house, get another pot of the same size filled with good soil, and then peg down that end of the Vine on the top of the soil, leaving two or three eyes beyond the point from which the roots are expected to obtrude. Encourage one of these buds to grow for a time, and rub off all the rest but one on the other side of the pot as they break forth. The growth of the buds on each side will be about equal for a time, but the one at the extreme end will take the lead if not checked to the injury of the others. As soon as roots begin to form, the end growth must be gradually shortened back until only a leaf or two is left; this will throw all the strength of the roots into the growth on the other side. In order to secure a cane strong enough for fruiting the next year, it should not be detached from the parent Vine until the leaves fall off in the autumn. Of course the young rod will want some support in the way of a neat stick, or else be so placed as to be trained on wires; but for all practical purposes a rod 4 feet long and well ripened will be of sufficient length to test the principles of growing Grapes with the sap flowing backwards, because it must be clearly understood that no roots are attached to that bud from which the young rod is grown. The sap must therefore, as ordinarily understood, flow backwards.

A pot Vine which I had obtained in the way just described grew and fruited as freely as if it had been raised in the ordinary way; but I attach no importance to either of these experiments in a useful sense beyond demonstrating the erroneous impressions entertained that it is not possible for a plant to exist under the circumstances just described. In my own case the experiment was not made with a view to obtain definite information. The idea was merely fanciful, and worked out without there being any particular object in view. J. C. C.

Unpruned Pear trees.—Were I in your correspondent's place (p. 235) I should refrain from pruning the Pear trees in question at all beyond taking out any weak shoots that seemed to be useless for any good purpose. Having terminal bloom buds is a good sign, as that is evident that growth from the points will be checked, and that the vigour of the trees will largely flow into the side buds, causing them to plump and possibly form fruit buds for next year's cropping. Were these long shoots shortened back materially, as possibly some might recommend, the result would be that the buds left would burst into strong growth all over the trees, and a setting of fruit buds would be as far removed as ever. If some of the shoots seem of ungainly length, they may be drawn in in a drooping form and tied to the stem of the tree by means of stout twine, and in a year or two this pendent form will become set.—A. D.

Vines away from the glass.—"W. C. T.," in THE GARDEN (p. 251), upholds the method of training Vines 3 feet or 4 feet from the glass. Perhaps it may interest some to know that "W. C. T." is not alone in thinking that Grapes may be well grown trained 3 feet from the glass. Last year I was about to cut out three young rods I had trained up the previous year from the base of two Black Hamburgs and one Muscat of Alexandria, but the thought occurred to me that I might try and fruit them tied to a wire strained under the other Vines. I accordingly strained three wires 42 inches from the glass, and on these wires under the other Vines these rods fruited, and finished their crop as well as those did above them on the permanent Vines. It seems to me from this experiment that Vines do not require so much light as is generally supposed. I may add that the Grapes were not highly finished in this house, but I do not attribute that deficiency to the manner of growing them, but to over-cropping

as they were allowed to carry far too heavy a crop. I mean to repeat the experiment this year with one or two Vines, and if they do well I do not see why one should not have a double crop under one roof. The only trouble would be thinning that next the glass.—G. A. PASSINGHAM, *Milton, Cambs.*

ORCHIDS.

NOTES ON ORCHIDS IN FLOWER.

THE Orchid houses in Mr. Ball's nursery, Chelsea, are now gay and spring-like, and among the crowds of species and varieties are some worthy of special note either on account of their rarity or beauty.

Masdevallias alone make a beautiful show—the whole collection fairly bristling with flower, spikes. The chief display is made by the charming *M. ignea*, indisputably the finest *Masdevallia* for winter and early spring—its chief flowering season. Its colour, a bright orange-scarlet, is very telling, and the flowers are produced in profusion even on small plants. On one plant in a 4½-inch pot we counted a score of flowers nearly all expanded. Some dozens of this species in a mass at one end of the house formed one of the brightest sights we have seen among Orchids this season. Too much cannot be said in praise of *M. ignea*, and it is particularly a suitable plant for small and select collections. Similar to this species is *M. militaris*, as yet a very scarce plant. It differs in its brighter colour and larger and thicker texture of the flowers. This is likewise in bloom. *M. triangularis* to us is a singularly interesting species, though not a showy one. The flowers are triangular, and the tails of the sepals much attenuated, and their bronzy colour is very pleasing. Like *M. ignea*, it is extremely floriferous; on a small plant have we counted no fewer than thirty-two blossoms. Other noteworthy species in bloom were *M. Shuttleworthi*, probably the most perpetual flowering of all, and very pretty; *M. xanthina* in the way of *M. Wageri*, but the paler flowers produced much earlier; *M. Estradæ* delicate, a new and rare variety, differing from this type in its lighter coloured flowers. All the three preceding are among the gems of the genus. In a short time, judging by the number of spikes that have been developed, there will be a fine display of the *M. Harryana*, *Veitchi*, and *Lindeni* groups. Already there are some in bloom, and among them we noted a very fine variety of *M. Harryana* called *vivicans*, which has large rounded flowers of such a brilliant carmine-magenta as no colour on the artist's palette could reproduce. The rare Humming-bird Orchid, *M. trochilus*, was just expanding its large grotesque-looking flowers.

The white Cœlogyne is just now a lovely sight. Numbers of plants of it placed in one mass are full of bloom of snowy whiteness. Nothing could well surpass the chaste purity of the flowers of this Orchid, in which there is not the slightest trace of colour so often found in the majority of so-called white Orchids. There is no question that this white Cœlogyne is one of the most valuable additions to Orchids of recent years, but it will be a long time before it will come into general cultivation. It is apparently as easily cultivated as the ordinary *C. cristata*, and flowers quite as freely, but in the form of the flowers there is a marked difference, so much so that some believe it to be a distinct species. Prof. Reichenbach calls it *C. cristata hololeuca*, but it is generally called simply *C. cristata alba*—certainly the more expressive name. In company with this was a huge specimen plant a yard through of a major form of *C. cristata*, usually known as the Chatsworth variety. In this the flowers are not only considerably larger than those of the type, but as many as seven, eight, and nine are borne on each spike. It surpasses the type in every respect. It flowers later, and so prolongs the flowering season of *C. cristata*, which is, perhaps, its greatest merit.

Among the *Odontoglossums* were superb varieties of *O. crispum*, as fine both as regards size and form as could be wished for; so

also of *O. Pescatorei*, of which we saw a variety that has not previously come under our notice. Its point of distinction is the crest of the labellum, which, instead of being pale yellow, is of a deep, rich apricot, at once rendering it distinct from all the rest of the varieties. If it should prove to be constant, it will be a beautiful addition. The charming little *O. blandum*, one of the neatest and prettiest of all *Odontoglossums*, was conspicuous among all the rest. From its allied species it may be at a glance distinguished by the small, much spotted flowers gathering into a congested spike, and by the broad white labellum. Such a refined little Orchid only needs to be seen to be appreciated. The full beauty of *O. Rossi majus* can only be enjoyed when seen in considerable numbers, and this is the case here. In a large group, all in flower, may be seen every imaginable gradation in size and colour from what is generally thought to be the type to these varieties, having flowers 3 inches across and superbly coloured. One called *mosaica* with tessellated markings on the sepals and petals is most distinct. *O. Rossi* is grown in a cool, moist house in company with *Sarracénias* and similar plants, and under such conditions it thrives admirably. Among other varieties in bloom were *O. Wilckeanum pallens*, with flowers paler than those of the type; *O. cristatellum*, with handsomely marked blossoms; and a beautiful *O. baphicanthum*, with narrow sepalled flowers of a soft lemon yellow sparsely spotted with chocolate brown. A variety of *O. Halli*, called *leucoglossum*, on account of the lip being white instead of yellow, is an extremely handsome plant, so likewise is *O. facetum*, a great rarity of the *Luteo-purpureum* stamp. It has flowers some 2½ inches across, with light yellow sepals marked with cinnamon-coloured blotches and with tooth-edged petals of the same colour, except that the spots are smaller and more numerous. The lip is adorned with a fine yellow-fringed margin, and is also heavily blotched with chestnut brown; it is as handsome as it is rare. *O. nebulosum pardinum*, a finely spotted variety, is very pretty, as was also a fine variety of *O. cirrhosum*, a species which will take a prominent part in the display presently.

Dendrobium Johannis semifuscum.—This is a new variety of a distinct Australian species, itself by no means common in cultivation. In habit of growth it resembles *D. superbiens*, and every pseudo-bulb bears from near its apex an erect spike of flowers about 1½ inches across, having singularly twisted sepals and petals of light green flushed with a bronzy hue. It is not a showy Orchid, but from the profusion of its blossoms and their uncommon colour, combined with their delicious perfume, it is a kind sure to be in request. Among the numerous other *Dendrobes* in bloom we singled out from among the plants of *D. Wardianum* a very fine variety called *superbum*, remarkable for the large size (4½ inches) of the blossoms and the deep, rich markings of the sepals and petals. *D. macrophyllum giganteum* was worthy of note, being one of the handsomest of *Dendrobes* notwithstanding its strong Rhubarb-like perfume. The flowers are 5 inches across and of a plum-purple colour.

Other flowering Orchids of note were *Cœlogyne ocellata maxima*, with blossoms nearly twice the size of those of the type, and an extremely beautiful plant; *Phalenopsis Stuartiana*, a superb variety form of this choice species; *Aerides Licanum* with a much deeper crimson labellum than ordinary, thereby rendering the raceme of flowers more attractive. *Trichopilia suavis superba* is a truly superb variety of a lovely plant. The labellum of the flower is much larger than usual, and is white copiously blotched with rose-pink. The perfume of this Orchid is in itself a recommendation to grow it.

Cymbidium Devonianum is a singularly handsome Orchid, and though introduced nearly fifty years ago, seems to be scarce at the present time. It is distinct in habit of growth from most other species, having rather broad leathery foliage produced from small bulbs; from the base of these the long pendulous flower-spikes proceed,

and often attain as much as 18 inches in length. The flowers, over an inch across, have olive-green sepals and petals, with veinings of purple, while the labellum, the most conspicuous part, is a deep, rich crimson, inclined to claret. When the blossoms first expand the colour of the lip is strikingly bright and attractive, but at length it becomes duller. It is now in flower in Mr. Peacock's collection at Sudbury House, Hammer-smith. It is an Indian plant, inhabiting the Khoosea Hills, in India, whence it was sent home in 1837 to the Duke of Devonshire, by Mr. Gibson, then collecting plants for the gardens at Chatsworth.

THE SPECTRAL MASDEVALLIA.

(M. CHIMÆRA.)

OF all Orchids no genus we can just now call to mind is more distinct or is composed of species more widely divergent in size, form, structure, and colour than is this one of *Masdevallia*. It was founded well-nigh a century ago by Ruiz and Pavon on a species from Mexico, *M. uniflora*, which, so far as I know, is nearly if not quite unknown to present day cultivators. When Lindley wrote his "Genera and Species" in 1836 three species of *Masdevallias* only were known to botanists, but twenty-five years later, when he prepared his "Folio Orchidaceæ," nearly forty species were known in herbaria, and to-day perhaps fully a hundred kinds are grown in our gardens, while travellers tell us of all the gorgeous beauties which are known to exist high up on the cloud-swept sides of the Andes and Cordilleras of the New World. *En passant* it is a little interesting to note that while species of *Cypripedium* exist in Europe, Asia, and America in both the east and west, the *Masdevallia* is confined to the western hemisphere alone, and as in bird and animal distribution, so in the case of many Orchids we find that when any genus is confined to one hemisphere, those who look for another representative genus in the other are rarely disappointed. Thus horobills in the east are represented by toucans in the west, and the humming bird of the west by the sunbird of the east, and so also in the Malayan Archipelago. Notably in Borneo we find *Bolbophylls* without pseudo-bulbs and with solitary or few flowered scapes and other traits singularly suggestive at first sight of the western *Masdevallia*. Thus some *Bolbophyll*, for example, have caudal appendages to their sepals, as in *Masdevallias*, and on the other hand some *Masdevallias* have their labellums hinged and oscillatory, which is so commonly the case as to be almost "characteristic" in the genus *Bolbophyllum* or *Sarcopodium*. Speaking generally, *Masdevallias*, coming as most of them do from high altitudes, lend themselves to what is now well known as "cool treatment," and cultivators find it equally necessary to offer them moisture in abundance both at the root and in the atmosphere, also seeing that when at home in cloud-land they are often and well-nigh continually drenched by heavy dews and copious showers. Although collectors tell us of their epiphytal habits at home, they succeed so far as we at present know when treated as terrestrial Orchids, and potted in small well-drained pots of peat fibre and Sphagnum Moss. Now and then, as at Burford Lodge or at Chelsea, we find a special structure entirely devoted to this genus; but, as a rule, they succeed well in company with the *Odontoglossums* and *Disas*. When we come to consider the

Species best worth notice in a short paper of this kind, the difficulty is where to begin. Those fond of small things will see infinite beauty in *M. triaristella*, a fine plant of which might be packed into a match box, flowers and all, and yet its dwarf Agave hystrix-like habit of growth and tiny speckled flowers are, of their kind, most attractive. *M. Wageri* is another little beauty of the spatulate-leaved race, having stiff tails to its lower sepals, so that its little blossoms rest on the moss on these and the slender scape in a way which reminds one of a three-legged stool or easel. *M. melanopus*, with

MASDEVALLIA CHIMERA (natural size).

two or three flowers on a scape white spotted with purple, with short yellow tails, is another beauty of the pigmy group, and the densely speckled

M. polysticta is most floriferous; also *M. Shuttleworthi* is very distinct—indeed its markings are unique, and its beauty is such that no collection of rare Orchids is complete without it. It is a long time since its discoverer showed me dried flowers in a sun and rain-stained pocket-book at a time when one or two plants only were alive in Europe, but it is now more abundant and a general favourite to boot. When may we hope to see *M. racemosa*, which Bateman says “has scapes a foot long, flowers larger than any Burlingtonia, and of the most vivid scarlet?” Now and then we come across species of melancholy interest apart altogether from their beauty. For example, take those species discovered by poor Franz Klaboch, also *M. lata*, with flowers of metallic brilliance, which reminds one of poor Zahn, who, with his horse or mule, was drowned while crossing a stream in Central America. Then there is *M. Bruchmulleri* (poor Bruchmuller!) and that dainty little *M. nidifica*, which Lehmann found growing out on the twigs of dead trees in Ecuador, making the gaunt white branchlets lovely in February during the heavy rainy season there. There are, in fact, species of equal and differential styles of loveliness by the dozen equally deserving of our notice had we space to comment on their beauty and singularity. When we come to the showy everyday kinds what glowing colours do we not find. What in floral colouring surpasses the subtle variations observable in different individuals of *M. Veitchi*, varying from yellow to scarlet shot with purple? *M. Harryana* and its forms, *M. Denisoniana*, *M. coerulescens*, *lata*, “Bull’s Blood,” *M. Whitechurchiana*, and *M. Lindenii* (André), again, are most beautiful in their variety, and so of *M. ignea*, which exhibits somewhat of the glowing brilliancy of a red-hot iron in the type, but becoming nearly yellow in the distinct variety called *M. Marshalliana*. Then of all forms of *M. ignea*, that known as Dr. Paterson’s variety is one of the largest and finest in blossom, although dwarf withal. As an example of snowflake-like purity of whiteness, perhaps no other flower can equal *M. tovarensis* (*M. candida*), each of its triangular scapes bearing from two to four flowers. Just as I write I come across a note of Baron Rothschild’s plant of this species in the Ferrières collection, which in 1878 bore no fewer than 137 flowers on forty-five spikes, and I remember a pan in what some of us call “Seden’s department” at Chelsea a year or two ago bearing about a hundred blossoms. *M. amabilis*, *M. Davisii* (golden), *M. ephippium*, *M. Colibri* (Linden and André), *M. Estradae*, *M. coriacea*, *M. civilis*, *M. fenestrata*, *M. Wallisi*, *M. Bruchmulleri*, and others, if less showy than some of the foregoing, are yet to be included among the most interesting of all cultivated Orchids. Of all the cultivated *Masdevallias*, however, none are so weirdly strange and fascinating, as is the species *M. Chimæra*, which is so well illustrated in the accompanying engraving. This singular plant was discovered by Benedict Roetzl, and about 1872 or 1873 I remember *M. Lucien Linden* calling upon me one day and among other rarities showing me a dried flower of this species. I remember I took up a pen and rapidly made a sketch of the flower, which soon after appeared (1873, p. 3) in the *Florist*, and was perhaps the first published figure of the plant. It was named by Professor Reichenbach, who could find for it no better name than that of the mythical monster Chimæra, than which, as an old historiæ tells us, no stranger bogie ever came out of the earth’s inside. Our engraving shows the plant about natural size, and indicates the form and local colouring pretty accurately. The ground colour is yellowish, blotched with lurid brownish crimson, the long pendent tails being blood colour, and the interior of the sepals are almost shaggy. The spectral appearance of the flower is considerably heightened by the smooth, white, slipper-like lip, which contrasts so forcibly in colour and texture with the lurid shagginess around it. Sir J. D. Hooker in describing this species in

the *Botanical Magazine*, t. 6152, says that the aspect of the curved scape as it bears aloft its buds and hairy flowers is very suggestive of the head and body of a viper about to strike. Dr. Haughton, F.R.S., told me long ago that *Darlingtonia californica* always reminds him of a cobra when raised and puffed out in a rage, and certainly the likeness is a close one. To return, however, we have several of these

Chimæroid Masdevallias in cultivation, and *M. Nycterinia* so closely resembles the true plant, that it is even yet grown and mistaken for it in some gardens, as also is *M. Wallisi*. Then there is *M. Backhousiana*, near to but much superior in size and colour to the last named. A plant of this variety, which flowered at York in 1879, bore great blotched flowers, the extended tails of which measured 16 inches from tip to tip. Another of this strange group is the *M. troglodytes*, figured in the *Belgique Horticole*, 1877, t. 5, although the flowers are rather small. *M. radiosa*, found by Wallis at an altitude of 8000 feet, near Frontino, is at first sight in habit and general appearance so near *M. Wallisi*, that even that keen-sighted collector himself for some time confounded them. Grown in shallow Teak wood baskets, suspended near the roof in a partially shaded structure, all the Chimæroid section of *Masdevallia* succeed even better than when grown in pots or pans, as they have a Stanhopea-like habit of pushing out their flowers at all sorts of deflected angles. A close glance at the engraving will show that for convenience sake the artist has propped up the flower with a stick, this much arrangement being a necessity so as to enable the tails to lie diagonally across the picture. From tip to tip the flower represented is 9 inches, or not so much by 7 inches as the flower measured in Messrs. Backhouse’s nursery at York. Those who wish

Further information on this genus may refer to THE GARDEN, Vol. X., pp. 240-245, where are descriptions and references to figures of some of the more showy of cultivated species, and a charming group of *Masdevallia* flowers was painted by Mrs. Duffield for THE GARDEN, Vol. XIII., p. 102. The plate referred to is a good example of successful colour printing, and the portrait of *M. Veitchi* more especially therein given is perhaps the most faithful and characteristic ever produced. Of all Orchids none are more singularly weird and uncanny in their general aspects than are these *Masdevallias* (named after Dr. Masdevall, a Spanish botanist, &c.) of the Chimæroid or slipper-lipped (*Saccolabiate*) group. F. W. BUREIDGE.

Vanda Parishii Marriottiana.—Judging by some flowers of this very rare variety sent us by Sir W. Marriott, The Down House, Blandford, with whom it originated, it is a splendid Orchid, the flowers, over an inch across, having thick wax-like segments of a rich amethyst purple, flushed at the tips with a brownish hue. The type is a handsome plant, but this surpasses it much in richness of colour.

A gigantic flowered Dendrobium nobile has been sent to us by Sir William Marriott. Each of the three flowers sent measured fully 4½ inches across the outspread petals, which are an inch broad. The colour, too, is rich and deep, each tip of the petals and sepals being stained with violet-purple, while the huge lip has an intensely deep blotch of maroon-purple. This variety is far beyond all others in point of size that we have seen, and we imagine that it is unique, at least in this country.

Epidendrum Wallisi.—A flower of this rare Orchid, sent by Sir William Marriott, shows well what a handsome species it is. It is one of the tall-growing kinds, with slender reed-like stems, at the top of which the flowers are produced in clusters. The flower is about 1½ inches across and of very thick waxy texture; the sepals and petals are a clear yellow spotted with dark purple. The broad wedge-shaped labellum is white and veined with purple, altogether a singular and rare combination of colours. It flowers

continuously for several weeks in the early part of the year, and is exceedingly attractive when well grown and flowered. It is a native of New Granada, and has been introduced about eight years.

Cymbidium Lowianum.—An extremely fine spike of this Orchid comes to us from Dr. Paterson, Fernfield, Bridge of Allan. It is nearly a yard in length, and carries about a score of blossoms. These are some 4 inches across, and of thick fleshy texture. The colour of the petals and sepals is a mistletoe green, while that of the labellum is a deep crimson—a strange association of colour, yet a remarkably striking one, and seen in no other Orchid. It is evident that Dr. Paterson knows the requirements of this plant. With this comes the deepest coloured variety of *Odonoglossum cordatum* we have seen, the colour being a rich reddish brown, set off by the transverse bars of white on the petals and the almost wholly white heart-shaped labellum. There is a richness of colour about these flowers that make them singularly attractive, and the spike bears a dozen of such blossoms.

Dendrobium Ainsworthii roseum.—Mr Douglas in his interesting remarks on useful Dendrobes (p. 254) says, in reference to this hybrid that “it does not differ from the hybrid form, *D. splendissimum*.” I do not know if Messrs. Veitch grow the rosy-tipped variety of *Dendrobium Ainsworthii*, but if they do so, perhaps they could best tell us if there is any difference between them. I am the more interested as I have quite recently been making a special study of all these *D. nobile* × *heterocarpum* hybrids for a purpose which I need not now name, and any opinions *bona-fide* growers may have formed of them would just now be very welcome. It is most desirable that any opinions offered are the results of actual comparison from plants growing side by side, as memories of the best are treacherous in these matters.—F. W. B.

Dendrobium Dalhousianum.—A remarkably fine flower-spike of this species, one of the finest of all Dendrobes, has been sent to us by Mr. Field, from Stanley Hall gardens, Bridgenorth. It bears 15 flowers, all expanded at once, and each over 4 inches across. The sepals and petals are of wax-like texture, creamy white, but so thickly veined with pink as to give the flower quite a salmon bluish tint. The large shallow labellum has two heavy blotches of deep maroon-crimson which make the flower so attractive. Though this is such a handsome Orchid, good specimens of it are scarce, owing to its being a somewhat difficult plant to grow well. Respecting his plant, Mr. Field writes that “it is bearing three spikes, this being the third year in succession in which the same growth has borne flower-spikes, some of them even finer than the one sent.” It is evergreen, and, as a rule, flowers on the old growths, which attain as much as 8 feet in height.

Dendrobium nobile var. nobiliss.—This without question is by far the finest of the varieties of this popular Dendrobe, and we have never seen it in greater perfection than in Mr. Southgate’s collection at Selborne, Streatham, where there is a plant of it bearing now nearly thirty flowers and buds. Each flower measures quite 3 inches across; the sepals and petals are deep violet-purple, while the labellum has a dark blotch of maroon edged with creamy white. This superb variety originated in Mr. James’ nursery, at Lower Norwood, a few years ago, being part of an importation bought at Stevens’ rooms. This plant was afterwards sold to Messrs. Rollisson, who exhibited it at the great Ghent International Exhibition in 1877. Mr. James subsequently re-bought the plant which forms the subject of the present note, and a few other plants of it have been propagated and sold at high prices. It is still extremely rare, and is much sought after by lovers of Orchids. Mr. Southgate’s plant is a large one, having been admirably grown by Mr. Salter, who grows Dendrobes uncommonly well; indeed, at the present time the Dendrobe house at Selborne contains some remarkable examples of skilful culture; among them the most remarkable is *D. Wardianum*,

of which numerous fine specimens are grown in 6-inch pots (small for the size of the plants); the bulbs are not drooping, but tied to erect sticks, as is usually done with *D. nobile* and others. Some of the growths have as many as thirty flowers on a space of about a foot. The home-made bulbs are quite as large, and in some cases larger, than the imported ones. Another extremely fine plant is the still rare hybrid *D. Ainsworthi*; a specimen of it in a suspended basket about a foot square is bearing about six dozen blossoms. Both the type and the roseum variety are represented here. *D. crassinode* is also very fine, as are likewise numbers of *D. nobile* representing several varieties including that known as Rucker's, a pale flower, and one with quite a yellow suffusion in the blossoms.

Substitute for Orchid peat.—Dr. Paterson's intended experiment with the outer shell of the Cocoa-nut as a substitute for Orchid peat will not be a new one. When visiting the Orchid houses of the New Plant and Bulb Company, Colchester, last year I saw *Cattleya Trianae* planted in this material, and was very sceptical as to its being successfully utilised. Another visit after showed me it could be so. The pots were filled with vigorous roots, and the plants appeared in robust health. I do not know whether Mr. Horsman, the manager of the Company, uses the material for other Orchids besides *Cattleyas*, but no doubt he would furnish information if they were desired.—W. MORGAN JONES, *Rectory, Mark's Tey.*

Orchids from Perth.—Judging by some very fine specimens sent to us by Mr. Macdonald, Woodlands House, Perth, Orchids are grown to perfection in the north by a few cultivators. The gathering includes some remarkable examples of *Odontoglossum*. *O. Pescatorei* is represented by a glorious four-branched spike carrying nearly a score of spotless white blossoms—in itself a sufficient indication of skilful culture. *Of *O. cordatum* there is one of the finest varieties we have seen. The long attenuated sepals measure nearly 4 inches across, and, like the petals, are of a clear reddish brown, transversely barred and spotted with yellowish green; the heart-shaped lip is of a warmer brown and blotched with white. When represented by such a fine variety, this species is really a handsome and desirable Orchid, and, moreover, one of easy culture. The spike sent bore ten flowers; a similarly fine spike, bearing seven flowers, of *O. triumphans* represented a superb variety, the flowers measuring 4 inches across, with the sepals and petals of a pale yellow, heavily blotched and spotted with coffee-brown. This is one of the best varieties we have seen of this species. Two *Masdevallias* were also sent—*M. Shuttleworthi* and the rare *M. trochilus*, the Humming Bird Orchid. The first is now tolerably well known, but it is not often represented by such a fine variety as Mr. Macdonald possesses, the colour of which is much brighter than usual, though perhaps the Scotch air has something to do with its richness. *M. trochilus* is a very singular species, having baggy sepals of a reddish brown furnished with long slender yellow tails between 4 inches and 5 inches in length. This, Mr. Macdonald considers to be the most perpetual flowering of all the *Masdevallias*, as he has had it in flower for ten months, and he has now small plants "bristling with blossoms."

Edgings.—After trying various materials for these I have proved black vitrified stable bricks, though perhaps a little more expensive than some other articles, the cheapest and most satisfactory in the end. They afford no harbour for vermin, and no foothold for mosses or fungi, and are practically indestructible. They are set on edge with the face side towards the path, and may be either sunk level with the soil or raised a little above it. I use the kind with a channel across the centre to match with the joined ends, which if they are properly laid are scarcely visible. If by the action of frost on the soil or from other causes, any become out of line, a blow with the foot sets it right again. They cost, at the nearest railway

station to me, about 14s. a hundred, but probably near the kilns they could be got for considerably less.—J. M., *Charmouth, Dorset.*

TREES AND SHRUBS.

HEDGES AND SCREENS.

NEXT to walls hedges are the most important fences around a garden; indeed, in many new places they are made to take the place of walls, as, now that glass is so cheap, houses may be put up at moderate cost, and Peaches and Nectarines grown therein with the certainty of obtaining a crop; whereas on walls these and other tender fruits have been almost a failure for several years past, and from present appearances are likely to be so again. To be of real service hedges should be dense and close, both for the purpose of keeping out intruders and warding off wind, for which purpose there is nothing like

Yew or Holly, the last named being preferable where it will succeed. The soil that suits Holly best is that which is light and sandy, and in districts where it can be so accommodated this fine evergreen flourishes amazingly, and always has deep green healthy foliage quite cheering to look on. Like building a house or other structure, the great point towards success in raising a Holly hedge is to start with a good foundation, the first thing to be thought of being the preparation of the ground, as on this much depends as regards the growth of the plants, for to stick them in without digging or trenching is to lose time and not give them a fair chance at the start, as it is impossible for their roots to ramify in land that is bound together and nearly as hard as a floor. Not only is it necessary to dig or trench in preparing to plant a hedge, but it is also important that the soil be enriched by giving a dressing of rotten manure, which, however, should not be strong and rank, but of a mild nature, as then the young plants can feed on it at once, and get the rich diet they want. In places naturally wet it is better to have a shallow ditch for draining them, and the earth thrown out in cutting it may with great advantage be used to raise a sort of embankment, which should be wide and flat, so that the Hollies can have the full benefit of rain during the summer, instead of its running away and being lost, as would be the case were the ridge narrow and sharp at the top. Where lands are naturally dry, it is better to plant without raising the surface, but before doing this the ground should be broken up at least 2 feet deep and 1 yard wide; and when this operation is being carried on the manure can be well worked in and thoroughly mixed up with the soil. All will then be ready for planting, which can best be done by taking out a trench a foot or so wide and 8 inches or 9 inches deep, according to the size of the plants to be planted. Some go in for those that are large; but size is not always desirable, as it often happens that large plants suffer more than small ones from removal. The most preferable for making hedge-rows are those from 1 foot to 2 feet high that have been frequently transplanted, as then they have an abundance of fibrous roots that take to the soil at once, and the young Hollies are therefore able to start off and grow without feeling a check through the lifting. In planting, the roots should be spread out in the trench, and after being just covered with soil, heavily watered, by doing which, the earth will be carried thoroughly in amongst them, and if then allowed to settle, the final filling up can be done a day or two after. The next thing to be thought of is a mulching, which is a great protection, as it not only keeps the moisture in by preventing evaporation, but, by shading the ground, fosters and encourages root action, and greatly expedites the growth of the plants. The best time for planting Hollies is the first week in April, as then they are just on the move, and the genial showers and refreshing night dews we generally get at that season keep the bark plump and enable the buds to break quickly and strongly. Planted in the autumn

or winter, they have searching winds and hard frosts to contend with, and the two combined take the sap out of them and wither the leaves and rind to such an extent that often many die, and those that live are left crippled and are long in recovering. The next best plant to the Holly for forming a hedgerow or screen is the

Common Yew, which will thrive in cold, heavy land, and grow where the Holly will not. At Campsey Ash, near Wickham Market, in this county, there are some remarkable specimens of Yew hedges, which are, or were, some 15 feet to 20 feet high, and so thick and dense as to look like solid green walls. There are also some equally good in this latter respect at Culford, near Bury St. Edmunds, which are used to shut out the vegetable quarters, and right well they answer the purpose, besides forming shelter-screens, which Yew hedges do in a most effectual manner, as they sift and break up the wind, which seems to bury itself in them, and is lost. Desirable, however, as the Yew is for screens and hedges, it should be widely known that its leaves and branches are poisonous to cattle, and therefore it ought not to be planted anywhere within their reach; it is necessary, too, to exercise great care in disposing of the clippings, which should be burned at once on being cut off. The Yew is so hardy and always so well rooted that it may be planted at any time from September to the end of April or later if the soil is washed in about the roots to give the plants a start. To have thoroughly good hedges, whether of Yew or Holly, or any other shrub, they must be kept wedge-shaped, or wide at the bottom and narrow at the top, as it is only by letting plenty of light on the base and forcing out the growth there that hedges of any discription can be kept well furnished below. At first commencement, and while in full vigour, it may be necessary to clip twice during the season, but after a time once clipping at or about midsummer will generally keep them in order.

For simple screens that can be got up quickly, Laurel answers admirably, but it does not bear clipping, or rather soon looks slabby afterwards, and to have a nice face the shoots must be taken out with a knife, as then the leaves are not severed. The *Arbor-vitæ* is also a capital screen plant, and one that stands the shears better than most others, and becomes very dense and close after being subjected to a few years' trimming. Box, too, of the large-leaved, upright-growing sort is also excellent for hedges and blinds, and is a plant that may easily be kept in good order, the only thing against it being that it will not get very high and is rather slow growing. For quickness in getting up, the Privet is one of the best, and with tall iron hurdles to thread the shoots through between the bars to support them, it may soon be run to a height of 10 feet or more, and by careful clipping made to look well. As an ornamental hedge there is nothing to equal *Berberis Darwini*, which is not only a beautiful evergreen, having small handsome shining foliage, but bears masses of rich, warm-looking, orange-coloured flowers, that are succeeded by a wealth of bluish-black berries. This *Berberis*, like most of the others, is a ticklish one to deal with in transplanting; it should not be moved till April, and then it is necessary to exercise great care in taking the plants up and getting them into the ground again before the roots dry. For an outer boundary fence, a mixture of Beech and Quickthorn forms one of the best, as the former draws the latter up, and they interlace their branches in such a way as to be impenetrable by any large animal if the plants are planted thickly and are well furnished below. Quickthorn and Holly are also good, although they do not agree so well as the first named mixture, as the Holly, being evergreen and thick, has a tendency to choke the Quick by robbing it of light and air when making its growth. Privet and Thorn get on well together and make a capital hedge, as the Thorn, being stiff, supports the Privet, and the latter, having small leaves, does not unduly encroach on and overshadow the Thorn.

J. SHEPPARD.

BIRDS' NESTS IN WELLINGTONIAS.

WE have a great many Wellingtonia trees here of goodly size, but only once have I found a nest in one. That was about twelve years ago. The bird was a small one, and I regret I did not note at the time what the bird was. The branches of these trees are not naturally well adapted for nest-building; both they and the branchlets feather downwards and do not present an inviting place in which to tempt a bird to build its nest. Most of our common birds try to select a position where the branchlets form a forklet in which the nest can be built and there maintained steady during windy weather, a condition which cannot very safely be calculated upon in the Wellingtonia. Since the query respecting nest-building in the Wellingtonia appeared in THE GARDEN I have sent my boys—now well versed in the smaller British birds and their eggs—round all our Wellingtonias to try and find even an old nest, but none was found.

The *Araucaria imbricata* is a tree one would think presented but little temptation for a bird to build a nest in, particularly where there is abundance of other trees, but I remember a few years ago finding a hawkfinch's nest in one of these Chili Pines, *i.e.*, if nest it could be called, for it consisted only of about a dozen small sticks without lining of any kind, and so loosely put together that one of the eggs dropped down into the miserable wattle and so escaped hatching. This egg I kept for years as a specimen, unblown, when one winter night, having a good fire in my office, it burst with a loud report. In these trees we have also found the nest of the missel thrush, chaffinch, and fly-catcher. Why they should select a prickly tree of this kind to build in is difficult from our point of view to account for. It is said that monkeys find it difficult to climb these *Araucarias*, and so in this country small birds in choosing them may, from some natural instinct, hope to escape the ravages of the claws and teeth of the prowling house cat.

All birds, however, do not confine themselves to forklets in trees or bushes in which to build their tiny nests. For instance, the reed warbler (*Salicaria arundinacea*), a small migratory bird, all the way from Morocco, will lay hold of three or four more reeds by the side of or over a stream, and with dry Grass and Moss weave together in a most extraordinary manner a little nest which in its way is nothing more or less than a very interesting natural curiosity. When these birds are with us the reeds are quite alive with their noise. They are very intent on minding their own business, and when disturbed their flight is short, soon turning in and dropping out of sight among the reeds. How this small bird, which is little larger than a jenny wren, and having so short a flight, can find its way to this country over both land and sea, all the way from Morocco, is a problem in natural history difficult to solve. The land rail, though of course much larger, is also a bird of short flight, and the wonder, too, is how it maintains its flight over that narrow streak of sea which only one human being has been known to cross aided only by his own natural limbs and arms.

Once I was much amused by the performance of a nest of house sparrows and a pair of martins. The sparrows had got possession of a hole in a wall over a door prior to the arrival of the martins. On the arrival of the latter they chose a spot on which to build their nest immediately below the hole in which the sparrows entered theirs. The martins soon had their nest constructed, and the sparrows were in danger of being shnt in or out, for, judging from the contour of the martins' nest, it was evident that unless some arrangements were come to between the two families, the sparrows would lose possession of the entrance to their home. An arrangement, however, was made, for there was left on the top of the martins' nest a small depression which allowed ample ingress and egress for the sparrows. The year after the house was repaired; the hole in which the sparrows domiciled was filled up with cement; they lost their home, in short, and I the opportunity of observing

how friendly the two small families lived in such close proximity.

During the last days of February of this year we had occasion to remove a quantity of decayed leaves which left a rather overhanging face of about 5 feet high. Scarcely had we got away when a wren took possession, and snugly, in the face of the decayed leaves, built the usual comfortable little home. Wrens, it is said, build seven nests before they select one in which to breed; whether, therefore, the one got together so early in the season is to be the chosen one remains to be seen.

From the mild weather we have lately been having we have now a return to very cold east wind, with snow showers, which may, perhaps, put a temporary stop to such precocious early nesting of, it may be after all, only young birds.

Combe Abbey Gardens.

WM. MILLER.

THE AUCUBA AS A POT PLANT.

If the late Mr. Fortune had done nothing more in the interest of horticulture than introduce the male variety of this shrub he would have merited the grateful thanks of all lovers of ornamental plants. In the open-air of this country, however, owing to the uncertain character of our climate, the flowers of the female variety do not always get sufficiently fertilised to induce them to carry a crop of berries. The protection of a glass roof is necessary to secure an effective display, and the conservatory and greenhouse during winter and spring can contain few more attractive objects than fine healthy plants of the Japanese *Aucuba* densely furnished with rich scarlet fruit. The foliage of the plant, whether under glass or in the open air, is very ornamental, and when such plants are raised from seed there is considerable diversity both in the way of foliage and habit of growth, some of the seedlings having the leaves green, while in others they are more or less blotched or variegated. Until, however, the plants show indications of flowering their sex cannot with certainty be ascertained; and as the female or berry-bearing plants are the most ornamental, it will seldom be necessary or desirable to have more than one or two male plants in a structure, as pollen is generally produced in great abundance; so much so, that artificial fertilisation is hardly necessary. Plants of any desired dimensions may be used for greenhouse decoration, as even when of small size they produce their small and very inconspicuous flowers in abundance. As in the case of the Hazel, the pollen generally appears to be ripe long before the female blooms are expanded, but if the weather prove at all favourable, fertilisation, nevertheless, to some extent generally takes place, effected either by insect agency, or possibly by atmospheric action alone. Not the least attractive objects in a large garden establishment near where I write are two large seedling plants of the Japanese *Aucuba* growing in tubs placed inside a large span-roofed unheated orchard house—one on each side of the doorway. One is of the male variety, and has very prettily marked foliage, while the other, or match plant, is a female, with bright green foliage and literally covered with bright red oval-shaped fruit. Both plants are handsome pyramidal-formed bushes in an exceedingly healthy condition.

Bury St. Edmunds.

P. G.

Abutilon vitifolium.—I think there must be more than one variety of this fine shrub. The plant figured in the *Botanical Register* is very different from Mr. Gumbleton's plant figured and described the other day in THE GARDEN, and my own plant differs from both. Mine came from South Devon, where it grows and flowers well, but both leaves and stems have a greyish tint, and the flowers are large and more purple than those of the *Botanical Register* and THE GARDEN. Moreover, I gather from Mr. Gumbleton's description that his plant is deciduous, but in mine the leaves remain all the winter. It is hardy, but in most places requires the protection of a wall. It is increased easily by cuttings, and so ought to be

more common than it is.—HENRY N. ELLACOMBE, *Bitton Vicarage*.

—*Abutilon vitifolium* is a beautiful plant in some parts of Devon and Cornwall, where it comes up from self-sown seeds. In the isles of Scilly it is also a fine plant, and there I have seen a white variety. At Cambridge it does not flourish; in the open it has been killed, but on a wall in a warm corner I have had a plant for nearly three years. It is now about 6 feet high, and has not yet flowered, though it will flower this summer probably.—R. IRWIN LYNCH, *Botanic Garden, Cambridge*.

HARDY TREES AT HERRENHAUSEN.

LAST autumn, when travelling from Hamburg to Vienna, I visited the Botanic Garden at Herrenhausen, and found there, besides the far-famed collection of Palms in the great Palm house, an equally interesting collection of trees in the grounds. In the quiet part of the garden, surrounding the mausoleum, I was much delighted with the fine groups of trees abounding thereabout. Amongst American Oaks I noticed *Quercus palustris*, *coccinea*, *rubra*, *falcata*, *heterophylla*, *imbricaria*, *tinctoria*, *nigra*, *oliveformis*, *macrocarpa*, *phellos*, *castanea*, *ilicifolia*; of others *Q. Egilops*, *Cerris*, *lacinata*, *pedunculata*, *pendula*, *Concordia*, &c. Equally interesting was an old specimen of *Robinia Pseudacacia* covered with Ivy. Others consisted of *R. Pseudacacia crispa*, *R. amorphæfolia*, *Carya amara*, *Betula nigra*, *B. papyracea*, *Celtis occidentalis*, *Gymnocladus canadensis*, *Virgilia lutea*, *Liquidambar styraciflua*, *Sophora japonica*, *Nyssa aquatica*, *N. biflora*, *Acer heterophyllum*, *A. platanoides* var. *Leopoldi*, *Tilia grandifolia*, *argentea*, *mandschurica*, *Catalpa Bungiana*, *Liriodendron Tulipifera*, &c. Of conifers there are fine specimens of *Pinus Strobus* and several noteworthy examples of *Taxodium distichum*; smaller in size, but equally good, were also *Cupressus Lawsoniana*, *C. nutkaensis*, *Pinus excelsa*, *P. Cembra*, *Abies canadensis*, *A. Nordmanniana*, *A. cephalonica*. In the central part of the garden, sheltered by hedges of Thuja, is a small dale planted with peat-loving plants, such as *Magnolias*, *Rhododendrons*, American *Azaleas*, *Andromedas*, *Kalmias*, *Hydrangeas*, and *Heaths*. On the borders of the shrubberies were patches of Lilies and hardy Ferns, all in luxuriant health. LOUIS KROPATSCH.

Laxenburg.

Striking Japanese Privet and Garrya elliptica.—Both of these plants may be readily increased by means of layers or cuttings. *Garrya elliptica*, however, succeeds best from layers, although cuttings placed in sharp sandy soil under a hand-light in a shady position root freely. Layering should not be practised in the case of Privet unless as a means of extending game covers, as cuttings strike readily and produce the best specimen plants. The end of August is the proper time to insert cuttings, the temperature of both earth and air being then about equal.—A. D. WEBSTER.

Hardiness of Erica codonodes.—I was surprised to read in THE GARDEN recently that this Heath was hardy so near London as Coombe Wood, because here in Somerset I have had great difficulty in keeping it alive through a severe winter. As a matter of fact we lost two large plants of it in the hard winters of 1879 and 1880; the first terribly crippled them and the last killed them outright. Before these dates we had a run of mild winters, and I had begun to look upon this plant as being quite hardy, and found it of great value for cutting from during mild weather in January and February. Its small white flowers, so thickly studded on the branches, and its stiff erect growth make it peculiarly valuable in a cut state, and the fact that it flowers in the depth of winter makes it still more welcome. As regards its hardiness, it is only right to say that our plants were growing in a very exposed position. The soil is a silky loam in which *Rhododendrons* and other similarly rooted plants thrive so well with us, and I am inclined to believe that although the plants grow in the most vigorous manner and never failed

to flower, that both soil and climate were too damp for them. As a consequence the wood did not get sufficiently ripened to endure nearly 30° of frost, which we had here in the last named winter. The best plants of this Heath I ever saw grew some years ago in the nurseries of Messrs. Wood & Son, at Marefield, near Uckfield. They were 4 feet high and broad in proportion, but there the soil is light and friable and well drained. If I had a good peaty, well drained soil and the position well sheltered from cold cutting winds, I should not hesitate to grow this Heath again. From my experience of it I should say it is rather inclined to get lanky. It appears to have a disposition to start away with three or four main shoots, and then the plants have not a very pleasing appearance. To secure well formed specimens they should stand at least 4 feet apart.—J. C. C.

NETTED RAFFIA BALLS.

MR. G. F. WILSON, Heatherbank, Weybridge, has directed our attention to what we consider a capital plan for keeping raffia fibre for tying plants neat and tidy. The strings of raffia are

Netted Raffia ball.

tied end to end and worked into a compact egg-shaped ball, about 6 inches long by 3 inches in diameter, on much the same principle as balls of twine are wound. Over this ball is a netting of twine, and this keeps the whole intact, and as the raffia is used by drawing it out from the bottom of the ball the net may be tightened; a loop at the smaller end serves to hang the ball up by, or suspend it to a button while in use. For amateurs especially these little balls will be found useful, and they do away with the untidiness of the bundles of matting or raffia as used in the ordinary way. These balls, we understand from Mr. Wilson, are made by Miss Campbell, a lady eighty-one years of age, who sells them for a shilling apiece, and gives the proceeds of her industry to a charity. The annexed illustration is a miniature representation of the raffia ball, and, as may be seen, it is a neat contrivance and one that would find a ready sale provided there was an ample supply.

SMOKELESS FUEL.

I AM happy to welcome the adhesion of so reliable an authority as Sir John Hawkshaw in a matter which has been repeatedly advocated with more earnestness than visible effect. Sir John writes to the *Times* to urge, after the example set by New York, the use of anthracite, or smokeless coal as the real preventive of black fog. It may be in the recollection of some people that the outcome of some very careful remarks on the Smoke Prevention Exhibition at South Kensington in THE GARDEN pointed steadily in this direction. In the present state of science the only mode of preventing smoke, at all events from domestic fires, is to burn smokeless fuel. Hitherto it has proved impossible to consume smoke liberated by the combustion of ordinary fuel for household purposes. Of smokeless fuels there are two descriptions, viz., solid and gaseous; or, in other words, anthracite coal and gas. As to the latter, the chief drawback in its use is its cost. A ton of coal will yield only from 9000 cubic feet to 10,000 cubic feet of gas, that is to say, 333 lbs. of fuel, or less than 15 per cent. of the weight of coal. And although the value of the other 1907 lbs., or, at all events, of a large proportion of them, is enough to pay for the cost of distillation, we are still in face of a price which checks the use of clear, smokeless, and ever-ready fuel.

It may seem almost paradoxical, but our opinion is that it is the use of gas for lighting purposes that has been the main obstacle to its general utilisation as a fuel. For the production of light the richer the gas is in carbon the higher is its illuminating power. On the other hand, for heating purposes, the larger the amount of hydrogen the better. All our efforts, however, have hitherto been chiefly directed to the improvement of the luminiferous quality of gas. Whether in the selection or treatment of coal, this object is continually kept in view. The increase of the heating power has been attempted by the Bunsen burner and some other expedients. But we are yet at some distance from the time when we may expect to see a double gas main, one set of pipes being intended for the conveyance of luminiferous and one for that of calorific fuel, laid on to our houses. Unless, then, some revolution in this respect takes place we must look forward for some time to come to the production of gas as rich as may be in carbon, and thus to the neglect of a cheaper and more calorific gas for the purpose of fuel. Under these circumstances the only alternative—if we would diminish the terrible evil of fog, distressing as it is to every one, and often fatal to the aged and the delicate—is to burn anthracite. I call attention to Sir John Hawkshaw's testimony, accordant as it is with long personal experience of the combustion of the coal in South Wales. Nor must I fail to repeat the recommendation that was before given of the

Pembrokeshire "ball fire," the balls being composed of culm, or anthracite dust mixed with clay, as at the same time the cheapest, and, taking it for all in all, the best of kitchen fires. This admirable fire, which never goes out, and on the grates containing which reliance may be placed for a supply of hot water at all times, had no advocate in the smoke abatement exhibition, for the simple reason that it was only the users, and not the recommenders, of the method who would derive advantage from its adoption. Of course London servants or Yorkshire servants, or any but the active, sprightly maidens who hail from the anthracite districts, would rebel against the ball-fire. But in any case of improvement that kind of opposition—and I would be the last to deny its formidable nature—has to be reckoned with. It is, I think, however, rather the negative than the positive aspect of the case which is most hostile. When the coal merchant's bill is set against the ill-will of the cook there is a very powerful influence at work; and where a great economy is actually ascertained it will in many instances turn the scale. But against the other difficulty, the doubts—Who ever used a ball-fire? Who ever saw one? Who ever heard of one? the remedy is less obvious. And

the fact that it is nobody's interest to introduce the best fire (unless he can get something out of it) is the real dead weight in the matter. So simple is the ball fire that it can be burned in the rudest form of grate. Therefore no ironmonger has any lively interest that it should be burned, and it is not a great leap to say, therefore, that it is not burned anywhere, except on the very verge of the culm districts, where it has been burned from time immemorial. As to the introduction of anthracite coal, clear and bright as it is, into the dining room, there are certain objections to be weighed against the advantage of its smokeless combustion; but as to the use of ball-fire in the kitchen, we know of no serious drawback to set against its smokelessness, its great heat, and its large economy. In these days of frugality this, it may be mentioned, is a subject of great importance to the gardener, and one to which he must, in order to keep down the expenses of the garden, give his careful attention. In the past age of

Heating by flues, when the price of fuel was comparatively low, when the coal cart was from necessity nearly always kept on the move, and when the coal bill was generally passed over as a matter of course, the first lesson the young gardener then had to learn was not how to stoke a fire in the most scientific and economical manner, but rather how to perform the herculean task of shovelling on tons of coal to a score of fires in the most dexterous manner and in the quickest possible time. Thanks to our scientific friends in the hot-water line, this state of things fortunately exists no longer, although they do sometimes, like the wonders of Aladdin's lamp, enchant and bewilder us with their multifarious and marvellous productions; still we willingly admit that they have to a great extent provided us with the means and the power to economise considerably in this department of the garden. Although, however, they appear to have taxed their inventive powers to the utmost in discovering and manufacturing the most economical and efficient fuel consumers, they have done comparatively little in testing and deciding which are the cheapest and most effective kinds of fuel for horticultural use. With some truth it may be said that this is a matter which concerns the gardener more than the hot-water apparatus manufacturer, also that the real value of fuel is uncertain and depends to a great extent on the ease and facility with which a special kind of fuel can be obtained in a given locality. This uncertainty and doubt seem to point to the very reason why it is essential that the scientific hot-water apparatus engineer should aid the gardener in choosing the most effective and economical fuel to be obtained in the district in which he may be located; and, what is equally important, that he should be in a position after making careful experiments to be able to recommend to the gardener not only the best form of boiler, but also to construct the furnace in such a manner as to be most suitable for the special kind of fuel it is intended to burn. At the exhibition held at South Kensington last year of the appliances for the abatement of the smoke nuisance, some of the exhibitors set an example in this respect which might perhaps be copied with advantage by hot-water apparatus manufacturers. There might be seen

Special grates for gas, coke, anthracite, and other kinds of fuel. A good many years ago I saw a large and very excellent hot-water apparatus arranged. When finished the question was asked the engineer, "What kind of fuel would you recommend?" His reply was "coke," as it is the least injurious to the boiler, and also the most economical. Coke was, therefore, used for several years, but the expense was found to be very great, and as clay was plentiful in the locality it was decided to re-set the boiler so as to make it available for "ball-fire" fuel, which was then tried with the result that the fuel bill was reduced to two-thirds of its former amount, although the cost of the anthracite, with which it was mixed, was necessarily high in consequence of the great distance of

the place from whence it was obtained. Again, in another locality I have seen a mixture of culm and chalk used with equally satisfactory results, and I doubt not but that in the peat districts an equal if not a more economical fuel still might be readily manufactured. To be successful, however, a suitably arranged boiler and furnace for these special kinds of fuel should be first supplied, and no attempt made, if I may use the simile, "to place the saddle on the wrong horse." If inventors would only turn their attention to this question, I venture to think something tangible might be effected towards lessening one of the greatest items of expense in garden management.

Having such an authority as Sir John Hawkshaw advocating the freer use of anthracite, and also as it has proved to be so superior to other kinds for the manufacture of compound fuels, it does appear strange that no greater advance has been made in this direction by horticulturists giving, as it does, a steady, lasting, clean, and a thoroughly economical and smokeless fire.

W. C. T.

INDOOR GARDEN.

BEGONIA WELTONIENSIS.

THIS Begonia is so free flowering and so easily cultivated that time and space could hardly be devoted to a better plant. It is not difficult to grow into an exhibition specimen, and it is equally useful for flowering in 6-inch pots. Young tops of it taken off now and inserted in sandy soil on bottom heat either in a propagating pit or Cucumber frame will root freely in three or four weeks. They should then be potted singly in 4-inch pots; the best soil for them is equal parts loam and leaf mould with a sprinkling of sand. After being potted they will be benefited by being again placed in heat. A temperature by fire heat of 60° will be ample for them. At the same time it may be well to state that artificial heat is not absolutely necessary, as this Begonia may be successfully grown all the year round in a greenhouse. The advantage of a warm temperature is that young plants grow faster into large ones than where there is less heat. After the middle of June any warm greenhouse will suit them admirably, and as they fill their pots with roots they must be shifted into larger ones. If then placed in 6-inch pots they will not require any more shifting the first year. We find that when the cuttings are struck early in spring and grown on in a suitable temperature, that plants in this sized pot become valuable for dinner table and other household decoration. The habit of the plant also renders it suitable for this purpose, as the bunches of flowers droop gracefully, and being of a delicate pink colour they contrast admirably with the surrounding greenery. To make

Specimen plants requires time; no doubt when pushed on in a high temperature it may be possible in one season, with an early start, to convert a small cutting into a large plant, but there is not always the convenience of doing this, and for my own part I should prefer for exhibition purposes plants with more stamina in them than there can be in those obtained by means of undue excitement. I should prefer an intermediate temperature, and for this purpose should insert half-a-dozen cuttings round the side of a 6-inch pot, and shift them on without disturbing them. A large amount of pot room is not necessary for this plant, for although the roots are numerous, they are not so strong as those which some plants possess. With careful watering with manure water, a strong plant may be kept growing vigorously after the pot has become full of roots, and when well-flowered examples are required it is better to resort to manure water than to give more pot room. This is supposing always that there is not more than six or eight weeks before the plant is wanted to be in flower. Should there be a longer interval between the time the plant has filled the pot with roots and its being wanted for a special purpose it will be wise to give a

small shift. This Begonia is not very particular as to

Soil so long as it is moderately light and rich. We grow our plants of it in a mixture of loam and leaf mould, equal parts, and a rather liberal supply of coarse sand. If required to furnish flowers during the later part of the autumn, they must have a light position in some structure in which the temperature is maintained at about 10° warmer than that of an ordinary greenhouse. In order to prolong the flowering season the plants seem to want a warm, dry air and plenty of light, and then they furnish flowers that are valuable for any purpose. In dealing with old plants in spring they should first have some of the long weak growths shortened back; then they should be taken out of their pots, and two-thirds of the old soil shaken away from the roots, when they may be put back into the same pots again. I find it to be best to place them in rather large pots at once, as in the case of large plants there is some risk of injuring the roots in shifting them. A few neat sticks are necessary in order to get large plants into proper form, and these should be used early in the season. In the matter of watering a moderate degree of care is necessary, as too much moisture at the roots causes the bottom leaves to turn yellow. When the pots get full of roots more water may of course be given, except during the dull winter months when the plants are at rest, and then the soil must be kept rather dry than wet.

J. C. C.

PROPAGATING PINGUICULA CAUDATA.

IN a note of mine published some time ago in THE GARDEN I mentioned this plant among others on which I had successfully experimented with a view to increasing it by means of leaf propagation; and as it does not appear that this ready means of raising a stock of this beautiful Butterwort is generally known, perhaps a word on the subject may prove serviceable. On the 13th of December, 1881 (I always put the date on which cuttings or seeds are put in on the label), I took off several of the largest of the leaves of *Pinguicula caudata* close to the stem, and after cutting these across the middle of the midrib, they were placed on a pan of very sandy peat and held down by means of pieces of crock. A pane of glass was placed over the pan and the soil was kept moist. The pan was placed on a shelf in the propagating house. In about a month afterwards roots were emitted both from the base and the transverse cut, little bulbs were formed, and in less than a month afterwards the plantlets were separated, with a portion of the parent leaf attached to each, and potted in small pots. We nursed them on in the propagating house until midsummer, and then placed them in a cool house near the glass, still keeping the small pots plunged in moss in a pan with the pane of glass over them. Either fourteen or sixteen plants were thus raised, and these, with the exception of three which are now bearing flowers, were distributed. I think cool treatment is better for this *Pinguicula* than that of an intermediate house, as suggested by "Veronica." Peat and loam are what we pot these plants in, and of course plenty of water is given all the year round.

I have thus given the details of our treatment as complete as I can, because I believe others have tried to increase this plant by means of leaf cuttings, and have failed. Ever since the summer of 1881, when our plant commenced to flower, it has continued to bloom without ceasing, and at the present moment it has open on it one fine flower and two other buds are pushing up. I know of no plant which for its size and nature can vie with this either in the production of flowers or in beauty. It has won the admiration of many, and there is a future of great popularity in store for this the finest of all cultivated Butterworts. Last year we saved seeds, which germinated freely, but the seedlings are still small and very delicate. Can "Veronica" spare a plant of *P. alpina*? Our collection of these plants wants only this amongst the cultivated species, and it seems rare. We grow *P. grandiflora*, *P. lusitanica*, *P. vulgaris*, and *P. caudata*. Large pans, 1 foot in diameter, of these

little plants have a very pretty effect; we grow them in the house in which *P. caudata* is grown, though of course during the resting period we place them in a cool frame. Frost does not injure these plants, even after they have been kept in a warm house through the summer. *P. grandiflora* is the most difficult to keep, the bulbils rotting round the base, and for no apparent reason so far as regards treatment. B.

CAMELLIAS AT WANDSWORTH.

AS a select and admirably grown private collection of Camellias we have not seen an equal to that which is now the chief attraction of Mr. Hermann Rucker's garden at West Hill, Wandsworth, and, considering that it is only just outside the four mile radius from Charing Cross, the cultural success is the more remarkable. It was in this garden that the once celebrated collection of Orchids existed belonging to the late Mr. Sigismund Rucker, under the care of Mr. Pilcher, who still superintends the garden, but this has gone, and now the Camellia seems to be one of the main objects of culture. There are three or four capacious houses devoted almost exclusively to Camellias, but the finest display is that in what is called the promenade, a large structure with its lofty roof hung with red and white *Lapagerias* and other climbers. On either side of the central pathway is a wide border in which are plunged the pots containing the Camellias—large bushes, some of which are 10 feet in height and nearly as much through. Every one of the plants are in pots, and this arrangement admits of their being readily removed or taken out for cleaning. Standing at one end of this house these two fine lines of luxuriant bushes profusely laden with blossoms are a grand sight, and show well what a beautiful shrub the Camellia is in the hands of a good cultivator, like Mr. Pilcher, and what a valuable aid it is in making gay cool conservatories in early spring which otherwise would be flowerless.

The most effective bushes in this house were Marchioness of Exeter, one of the finest of all the rose-pink sorts, the flowers being large, well shaped, and abundantly produced. This specimen was a sight in itself, being laden from top to base with blossoms. An equally fine example was Countess of Orkney, a lovely variety with large white flowers, with closely imbricated petals prettily striped pink. This also is an excellent cropper and a luxuriant grower. Of the old Double White (*Alba Plena*) there was a fine bush, but as the main crop was past there was but a few stray blooms. Madame Strekaloff, with large, finely shaped blossoms of a delicate peach colour, is one of the finest in its colour, and here it was represented by a splendid specimen. The old Matthotiana, with its huge, lurid crimson blossoms, was as effective as any, and must be named among the finest. Of *Reine des Fleurs* there was a splendid bush literally covered with medium sized, but exquisitely shaped blossoms of a rich crimson. *Lavinia Maggi*, a very fine white flaked like *Carnation* with pink, was just in perfection. *Beauty Supreme*, with lovely peach-coloured blossoms of moderate size; *Story*, another fine deep pink variety; *Verschaffelt*, rose-coloured, very large; *Chandleri*, a profuse flowerer, with large crimson blossoms; and *Centifolia alba*, a good white form. The above is a dozen of the finest in flower in this fine collection, and all of which may without hesitation be recommended to those who require a small, but choice collection.

Another capacious house contained the collection of smaller specimens, all in pots except those trained against the back wall of the house. These comprised a magnificent plant of the old Camellia *reticulata*, loaded on every part with huge blossoms some 6 inches across, semi-double, and of a soft rose-pink. This was a beautiful sight. Other wall plants were *Gaele*, with small, but neat and compact flowers of a deep crimson, particularly suitable for cutting for bouquets. From the pot plants in this house we singled out the following as being worthy of notice: Mrs. Anne Maria

Hovey, an American raised variety, varying from pure white to deep crimson, but pretty in all its phases; *Triomphe de Liège*, with rich rose-coloured high-centred flowers freely produced on fine-habited plants; *Clementina Magnani*, pink edged with white; *Napoleon*, deep rose banded with white—a beautiful variety; *C. H. Hovey*, dark velvety crimson, large, and perfect in form; and *C. M. Hovey*, similarly fine, but scarlet-crimson in colour. These two last are both the newest of American raised varieties in English gardens, and very beautiful they both are; in fact, indispensable to a choice collection of *Camefias*. W. G.

SINGLE CHINESE PRIMROSES.

THE season for these beautiful winter flowers is now practically over, although some few late plants will continue to yield blooms till the end of April. Really the season of the Chinese Primroses is from the beginning of November to the end of February, and from that latter period onward they begin to exhibit evidence of deterioration, in so far as quality of bloom is concerned, though March is perhaps the best month for floral fertilisation and the setting of the seed organs. In one respect not a few of our newer varieties of the Chinese Primrose entirely fail as the truss expands to sustain the promise of a well-rounded or full head of bloom, and so far scarcely one out of the many new kinds can compete with, much less excel, the old market white and red forms. The very best heads of bloom yet seen on any apparently new sort were on *Princess of Wales*, a charming bluish-tinted variety, evidently from the old alba strain, and shown in lovely condition by Mr. Cannell. This, as grown in 4½-inch pots at Swanley, seemed to be the very acme of a market Chinese Primrose. The cause of the failure just alluded to on the part of newer kinds lies chiefly in the undue length of the single flower-stalk and its lack of stoutness, a defect which growers will do well to work by fertilisation to rectify. It is obvious that even the finest flowered kind we have may yet be far behind commoner kinds in decorative value if defective in habit.

Some new distinctive kinds are being added yearly to our stock of sorts, but the distinctions are necessarily minute. Of the red, or so-called purple-flowered, section, however, none exhibit more entire distinctness than a variety shown the other day at South Kensington by Mr. Eckford, and which he has named *Perfection*. The colour of the flower is a soft peach, not shaded, as most of the flowers of the red section are, but a pure self. The blooms are large, very stout, perfectly flat, and the eye a clear lemon, admirably defined. It is hoped that this variety may be seen in better form next winter. Mr. Child, of Garbrand Hall, at the same time, put up a very fine form of *fimbriata alba*. If it is, as he claims it to be, perfectly distinctive, it is a very fine strain. If it be not distinct from the old white, under Mr. Child's culture the strain had developed marvellously fine blooms. It is of the true old white hue, and in no sense is it flushed as so many whites so-called are. Tomkins' *White Queen* is a huge flower, and is borne on plants so stout and robust, though of compact habit, that, as far as the latter is concerned, the ideal of a Chinese Primrose seems to have been realised. Yet the blooms are ragged and irregular, and so flushed with colour, that the merit of the kind for decorative purposes is much detracted from. One great fault of these exceedingly large flowered kinds is that when two or three blooms drop a space is left on the truss that does not fill up again. White kinds, so called, that come tinted always fail in producing good effects. This feature is particularly apparent in *alba magnifica*, a kind that blooms profusely and has elegant foliage, and yet always fails to produce an effective head of bloom. A very prettily shaded white named *Mont Blanc* is a product of the old white crossed with *Holborn Gem*, and the latter has impressed upon the white some of its blue tint, so that we get nearly a mauve flower. However, as in most other flowers, so in the Chinese Primrose, the

more colour is intensified so much the more are the kinds appreciated. It therefore happens that whilst *Holborn Gem* is better than a mauve, so will that kind be all the more acceptable when its blue tint is deepened. In the same way, because *Princess of Wales* is a deep pink flushed flower, so does it, next to the pure whites, command most admiration. Nearly all the old carmine and red-flaked flowers have gone out of cultivation. They are seldom seen, and probably have been little cared for, because not effective. On the other hand, all the madder-coloured sections have grown into greater favour the more the colour has been deepened, because a bright vermilion-madder is so very striking, and specially so under artificial light. Carmine of pleasing hues have been with us for a long time, and producing plenty of flowers as fine as we see now.

The *Chiswick red strain*, however, showed a marked advance in colour, though it is to be regretted for the sake of the colour that there are strains in which the blooms are thin and poor, and besides really good rich coloured fringed flowers look very inferior. We see in such developments from *Chiswick Red* as *Swanley Red*, *Meteor*, and *Vermilion Queen* really superb flowers, the richer forms laying on colour so dense as to be quite blood-red. Then the purple or magenta-flowered section have given some advanced hues of great beauty. *Rosy Morn* and *Magenta Queen* are both flowers of good size and quality, with colour somewhat deeper than is found in the market reds or purples. Perhaps the designation of magenta hardly does justice to the deepened hue of the latter kind. *Swanley Purple*, too, is a rich, deep coloured variety of the same section, and in the dull sunlight some of the colouring is truly brilliant. The kind certificated some time since as *rubro-violacea* is of the same strain, though hardly so robust in habit. One or two striking flowers have been shown from *Chiswick*, one especially, an unnamed seedling having flowers of fine form, pale purple in colour, and charmingly fringed. Another one, named *Chiswick Rose*, was a beautiful rosy carmine, the foliage being of an intermediate tint, neither red nor pale green. There are some charming flowers of the *punctata*, a speckled strain, carmine blood-red, and magenta. One of the most pleasing was seen at *Chiswick*, a deep red flower, literally covered with minute white specks. These are but a few of many kinds, or perhaps the so-called kinds, for as every raiser or hybridist works very much on the same lines, very much the same results follow in each case. About a dozen really distinct kinds make up a pleasing and truly representative collection, and those who may be fortunate to secure such a collection have no reason for complaint. No doubt the present prices of many of the kinds are almost prohibitory, for 5s. for a tiny packet of seed, with considerable risk attached, is not encouraging. A good packet of all the best kinds in equal mixture for 5s. that would produce 100 plants would not be dear, and if such mixtures were obtained from three or four growers, probably all the best kinds in commerce would then be secured. It is not at all difficult once good Chinese Primroses are obtained to keep up a good stock by seeding; given a small camel's-hair brush, a fairly dry atmosphere, and plenty of light, and flowers may be fertilised and made seed-producing easily enough. The practice of pulling up the anthers set down in the tube of the flowers to fertilise the pistil is not a scientific if a simple one, but cross fertilised blooms give the best results. A dozen good kinds are the *Old Alba* or *Market White*, the *Waltham* or *Swanley White*, which has dark red foliage; *Princess of Wales*, bluish pink; *Carnation Flaked*, white, with carmine or red stripes; *Old Carmine*, the foliage reddish; the *Rosy Carmine*, the leaf-stalks reddish green; *Marginata*, lavender, edged with white; *Holborn Gem*, blue; *Rosy Morn*, rosy purple; and *Magenta Queen* or *Swanley Purple*, both deep magenta; *Swanley Red* or *Vermilion Queen*, madder-red, and the deep coloured *punctata*, make up a good selection of a beautiful class of greenhouse winter plants. A. D.

CHRYSANTHEMUM ROOTS V. CUTTINGS.

I WAS pleased to read the very sensible article of Mr. Harding on Chrysanthemums and his mode of propagating his plants by the roots instead of by cuttings. I referred to this plan in your pages a year or two back, and once you adverted in complimentary terms to a bundle of shoots loaded with flowers which I sent you, and which, if I remember correctly, were from plants raised from the old roots. There can be no doubt that if we want large bushy plants and hundreds of flowers, the way to secure both quickly and easily is to grow on the roots of the previous year. This will look like absolute heresy to "professional" growers, but, with due deference to their opinions, I may state that they have not yet proved that either better specimens or better flowers can be procured from cuttings than from roots, while there is no comparison as regards time and trouble in the two cases, for a root, if potted in April, will beat a cutting struck in January or sooner, as regards size and earliness, and equal it, I have no doubt, in vigour. I have often grown our plants, or a portion of them, in this way, and many gardeners who have seen them have taken them for cutting plants. One gardener who takes an interest in their cultivation for exhibition purposes called here in June one year, and was much puzzled at the size and vigour of our plants, until I told him they were all old plants potted in spring. He acknowledged they were "the best plants he had seen for the time." According to the instructions laid down by professional Chrysanthemum growers, their plan is something as follows: Their aim being to secure good sized and early specimens, strong shoots and good flowers, they begin to strike cuttings any time between September and January, potting on, pinching, and training well on till midsummer, when the plants are allowed to grow on till budding time, by which time they are nearly a year old. When propagated by division of the root, or by repotting the roots whole, the plants are cut down after they have done flowering and set away in a cold frame till March or April, when they are shaken out, potted, and allowed to grow into bushes at once, as they need no pinching nor pegging out to increase their size, and the result is the plants are every way as good as those raised from cuttings. The shoots are equally strong and tall, and equally floriferous, and in the hands of good growers could no doubt be made to produce as fine flowers as plants from cuttings; hence I take it the extra four or five months devoted to the rearing and nursing of the latter is labour lost.

The notion is held by growers, I suppose, that a plant propagated from a cutting possesses more vigour than one propagated from the root, but one cannot see how this can be under equal conditions. Herbaceous plants of the same nature as the Chrysanthemum succeed best by division as a rule, and the Chrysanthemum is probably no exception. There is more in this than some may think at first in the case of a plant grown so extensively as the Chrysanthemum. If it can be grown equally well by simpler, cheaper, and easier means, and just as successfully as it can by the plan usually practised, I daresay no gardener would care to waste his time or resources on the latter. It must be obvious to the simplest comprehension that what vigour a Chrysanthemum cutting possesses must be derived from the root from which it sprung, and the question is, Is additional vigour infused into the plant by being detached and rooted on its own account? In other words, Is a herbaceous plant cutting stronger than the root, and why? We know that seedlings are more vigorous than cuttings, but between a cutting and a root there is not the same difference. By cutting is simply another way of propagation by division. These are questions for Chrysanthemum growers to answer who tell us to devote nearly a whole year to the culture of plants which can, some think, be grown equally well in half the time.

In propagating a Chrysanthemum by the root it might be necessary and better to divide the latter. Old and broad stools have not the same chance of

making vigorous and new roots as smaller pieces have; hence it would no doubt be better to split the stools up, so as to allow all the roots proceeding from the various shoots ready access to the compost. J. S. W.

PAPWORTH HALL, HUNTS.

THIS, the residence of E. Cheere, Esq., stands on a gentle eminence in the midst of a pleasantly undulated well-timbered park and grounds. It was built in the early part of the present century, and is a massive square Grecian structure, eminently suggestive of comfort. The entrance is beneath a portico of noble proportions, which adds greatly to the appearance and character of the building. The chief approach from the public road, which winds along the valley below, passes through an avenue of young Limes. On the southern side of the hall is a wide, open stretch of green lawn, which, starting close up to the windows, trends away up the rising ground till it becomes merged in a series of glades or avenues, with wide belts of trees and shrubs intervening. Apple trees being in some instances planted amid the other trees with good effect. The view from the windows is very pretty, almost unique in character. Several of the vistas or glades lead the eye into the open country beyond, but in most of them the terminating object is a gnarled old Oak or other forest giant, the growth of centuries. At the end of one of these broad avenues is a pretty circular flower garden surrounded by a moat, the latter being enclosed by a miniature forest of Filbert bushes. To the north-east the ground falls away till the fields are reached in the distance, though it does not lose its park-like character, in consequence of the number of trees which are scattered about in a picturesque manner. Amid the undulations of the lawn on this side is a small lake connected by a channel with the moat round the flower garden. The conservatory, a long narrow span-roofed structure on the eastern side of the mansion, is now gay with forced bulbs, Primulas, Spireas, zonal Pelargoniums, Roses, Bouvardias, &c. The back wall is covered with various kinds of creepers, and the bed in the centre contains several handsome Tree Ferns.

The kitchen garden lies on the south side of the mansion and grounds, and is hid from view by plantations. It is in two divisions, and contains about 3 acres. The soil, a heavy adhesive loam, produces excellent crops, Strawberries especially doing well in it. The pyramid Pears which line the central walk and the trees on the walls showed signs of vigorous health and fertility, and the espalier Apples had abundance of blossom-buds on them in embryo. The glass erections are in two places, and comprise a useful lot of smallish houses, including two vineries with the buds just starting, an early Peach house, in which the trees were in blossom, the Royal George Peach and Elruge Nectarine still being reckoned among the reliable early forcing varieties. Mr. Smith, the gardener, has been for some years past a successful exhibitor at the local horticultural shows, and neat specimens of the usual kind of exhibition plants are scattered about freely in all the houses. Bougainvillea glabra, Polygala Dalmaisiana, Rhynchospermum jasmoides, Statice Holfordii and profusa, with some good specimen Roses were in the vineries. In another house were a few hard-wooded plants in very good condition, including Hedera tulipiferum, Aphelexis macrantha purpurea, Boronia alata, Lapageria rosea, and a nice little flowering specimen of the white variety. In the Pelargonium house besides the Pelargoniums was a collection of double Primulas very well grown. The varieties included Gilbert's sorts, but the colours of these were hardly so distinct as when first sent out. It appears as if the striped varieties had a tendency to hark back. In this house were some well grown pots of Miles' Spiral Mignonette. In the stove I noticed several nicely coloured Crotons, including Queen Victoria, Weismanni, and majesticum. Allamandas and Dipladenias were represented by nice

little specimens, and I noticed also a good plant of the useful old *Rondeletia speciosa* and one of the finest specimens of *Eucharis amazonica* I have ever seen. The pot, a No. 1 size, was literally crammed full of strong bulbs, which might be made to flower any time by the proper resting treatment. There was also a fine potful of the beautiful *Pancratium fragrans*. In one of the warm houses were a number of trained specimen Ivy-leaf Pelargoniums, Mr. Smith having obtained the collection figured in THE GARDEN some time ago, and had brought his cultural skill to bear upon them with satisfactory results. One especially, a double pink flowered variety, named Annie Pfitzer, Mr. Smith recommended as a winter bloomer. The plant had several handsome trusses on it at the time of my visit, about a fortnight ago, and more buds were showing. In a light glazed frame was a named collection of Carnations and Picotees in pots, and in another part of the garden was a range of low span-roofed houses and a range of forcing pits in front. In the former was a healthy

Collection of Orchids. Though the plants are small for the most part as yet, they are in all respects in excellent condition, and most of the best families are well represented. I am pleased to find that in many out-of-the-way country gardens small, but thriving, collections of Orchids are being established. There is no class of plants more beautiful, or I might add more useful, where a supply of the choicest flowers is required in winter, and most of the best families for this purpose can be grown in a moderate temperature. The kitchen gardens are well protected by sheltering woods from cold winds. There being a difficulty in obtaining gravel on the estate, the kitchen garden paths are made of asphalt with such materials as can be obtained, including a proportion of ashes and gravel mixed with gas tar. They wear well and look clean. There are some thriving young specimens of Conifers about the grounds, including *Picea Pinsapo*, *Cedrus atlantica*, *C. Deodara*, *Wellingtonia gigantea*, *Thujaopsis dolabrata*, &c. From the high ground to the west of the hall, the church of Papworth, St. Everard, forms a pretty and interesting feature among the trees in the distant landscape. E. HOBDAY.

Polyanthus Narcissi.—These are excellent for pot culture and early blooming at this season. When in London last autumn I procured a number of varieties, and for the past month they have outvalled my Hyacinths, at least in their holding their blooms longer, if not in sweetness. *Gloriosa* was the first to open in the last days of February. It was potted in October in a 6-inch pot and put in a cold frame. It has twelve expanded blooms now on it with two to open, each two-thirds of an inch across—a very fine truss. Equally fine is *Her Majesty*, and *Gloriosa* and *Bathurst* splendid too. Dwarfier are *nobilissimum* and *Etoile d'Or*. I would never force them by heat at all.—W. J. M., *Clonmel*.

Polyanthuses and Primroses from seed.—These beautiful spring flowers should be raised from seed annually, but not treated as annuals beyond the annual sowing of seed. There is absolutely no difficulty about the matter, because the *Polyanthus* always seeds pretty freely, and the *Primroses* will do so from the later blooms in the case of strong plants. By sowing seed as soon as it can be well ripened, and pricking out the seedlings in frames shaded from hot suns, so that they may be strong for planting out into beds in the autumn, I get a good bloom from nearly all the plants the first spring, and a truly grand bloom the second year, when the plants seem to have reached their best; and from that time, whether lifted, divided, and replanted, or left untouched, they almost always begin to decay. Very much depends upon the summer. If hot and parching, then the leaves are eaten up by thrips, and the crowns rarely recover; but if cool, the plants may stand fairly well. More plants, when they get a few years old die, however, from root rot than from any other cause; and it is not possible to

counteract this decay except by lifting the clumps entire, pulling off each crown singly, clean from the old root, and then dibbling these out into fresh soil, where they may get a new lease of life. Still, the plan of raising a fresh batch from seed is simplest and best. My batch of *Primroses* of the second year's blooming were, just prior to the recent sharp frosts, beautiful indeed, flowering marvellously, and giving scores of diverse hues and markings. Not a few have the long-looked-for blue tint in a far more marked degree than I have seen previously, and I do not despair of getting ere long a *Primrose* as blue as a *blue Pansy*. It is unfortunate, however, that this coveted colour is the first to suffer under white frosts.—A. D.

GARDEN FLORA.

PLATE CCCLXXXI.

CATHERINE NERMET TEA ROSE.

THIS is at once one of the most chaste, beautiful, and useful of all the Teas. At first blush it somewhat suggests a likeness to *La France*, so recently illustrated and described in THE GARDEN. It has, however, a deeper tinge of flesh colour in its rich and delicate petals than that variety, and there is a dash of green in the shading of its petals in the place of the pale lilac, almost running into French white, that adds so much to the softness and refinement of *La France*. Both *Roses* are globular in form, as may be seen from the illustrations, but *Catherine Nermet* is less pointed in the centre, hardly so high, more round and open, with the petals more imbricated than *La France*. *Catherine Nermet* is light rose or delicate flesh-coloured, large, perfect in form, globular, with centre open (I do not mean by that showing the eye, but full and imbricated). It is a free rather than a vigorous grower, though several *Rose* authorities call it vigorous, the wood and leaves in a young state being highly coloured—nearly purple, the spines strong, hooking downwards, large, and very sharp. It blooms freely, and the bloom is one of the most beautiful in all stages, from the opening bud of deep rose colour, just peeping forth from its large, enfolding, green calyx, to the last. Having plenty of material and good form, this is one of the *Roses* not by any means too numerous of good staying properties, thus proving as useful and reliable for exhibition as for general purposes. The fulness of *Roses* as a means of adding to the durability of single blooms is one of those qualities that has not yet received the measure of attention it deserves. The *Roses*, as a matter of course, soon expand all their petals, and so reveal their poverty by opening wide their eyes; whereas full *Roses* of the type of *La France* and *Catherine Nermet* have such a prodigal profusion of petals, that they seldom or ever unfold more than a moiety of them. This is a point well worth the attention of our hybridists and raisers of new Teas and other *Roses*; even the *Devoniensis*, matchless, as it may well be called in fragrance and form in budhood and early youth, cuts but a sorry figure as it expands its whole force of petals into the full-blown impotency of old age. It would be a feat worth living for to pack it doubly full of its inimitably soft and delicate compound of white, pink, and yellow petals, though for myself I never could detect any yellow in it

Growers or introducers of new plants will oblige us much by early intimation of the flowering of new or rare species, with a view to their representation in our "Garden Flora," the aim of which is the illustration in colour, and in all cases where possible life size, of distinct plants of high value for our gardens.

ROSE CATHERINE MERMET

unless in the sere and yellow leaf of old age already adverted to, and I love *Devoniensis* too well ever to permit it to reach that state within reach of my knife or fingers. M. J. B. Guillot, the younger, the raiser of *La France*, has also the high honour of raising this *Rose*; the former was raised in 1867, and Catherine Mermet in 1869. Had there been a longer interval between them, one might have supposed they might have been partly cause and effect. But that is impossible, and it is more probable that both were prizes from some happy and successful endeavour to unite some of our older Teas or Chinas with our best Perpetual or other *Roses*. Few things could prove of more absorbing interest to rosarians than a chapter from this most successful raiser of *Roses* on the affinities and parentages of his large family of beautiful and indispensably useful children.

This *Rose*, like *La France*, has a great future before it. Such cruel weather as we have just had, and terrible slaughter as I now find the last fortnight's winds and frosts have inflicted on Tea and other *Roses* in the open, will but render such valuable sorts as Catherine Mermet more valuable than ever under glass. If my memory and note-book serve me aright, this was one of the best varieties among that charming collection of Tea *Roses* in pots, exhibited by Mr. George Paul at the great show at Manchester last year, that created so much interest and had such a stimulating effect in inducing many to grow Tea *Roses* in 8-inch or 10-inch pots. The splendid examples, several yards high and through, exhibited by Messrs. Veitch, Turner, and others, were simply magnificent. But their very grandeur discouraged general imitation while most useful in revealing the full power and capacity of the *Rose* as a pot plant. But when the public saw a large collection of most of the best Tea *Roses*, such as Catherine Mermet, in flower in 8-inch or 10-inch pots, in robust health and with foliage to the rim, and a capital head of buds and flowers for the third time within the year, the sight brought *Rose* growing in pots within reach of many possessors of a pit or frame. The tiniest greenhouse or window garden should have all these positions, and for forming beds and masses in the garden, on the lawn, and in sheltered, warm nooks and corners in woods, I prophecy a great future for this delicately soft and rich *Rose*, Catherine Mermet. Should these cruel, heart-breaking, *Rose*-slaying Marches repeat themselves, we must also have heated walls covered and uncovered with glass for these and other *Roses*, for our present modes of covering too often lead to failure, inasmuch as although it is easy enough to cover when we will and to any extent as we list, we are totally unable to so ascertain the coming weather as to know when and how to uncover with any degree of safety to our *Roses*.

D. T. FISH.

Fortune's yellow *Rose*.—Allow me to tell you in answer to your request (p. 236) how I treat *Fortune's yellow*, commonly called the *Flame Rose*. We have it planted in a span-roofed greenhouse that stands east and west. We have also *Maréchal Niel* planted in the same house, the two covering the north side, 29 feet long; they are worked on Brier stocks 3 feet high. The best results are to be had by pruning back annually to the top of the side lights as soon as the last bloom is cut, leading strong young growths away traioed to the wires as before. Thus managed, strong young canes are made for the ensuing spring. Every care is taken to tie in the young growths and keep them clean from green fly, red

spider, and mildew. In the autumn I shorten and thin out where the wood is too thick. *Maréchal Niel* is just beginning to bloom.—T. McCURE, *Hartley Grange, Winchfield*.

ROSES AFTER THE FROST.

POSSIBLY as yet even it is too early to write after the frost, for though it has been thawing, it has also been snowing throughout the greater part of the day, but the wind has mellowed round to the west, and the snow on the ground has been in process of rapid dissolution. As the thaw progresses the effects of the cold become more vividly as well as painfully apparent. The results may be summed up in a single sentence thus—every forward bud wrecked and ruined, the *Rose* season pushed back a month, and the majority of Tea and tender *Roses* crippled or killed. Doubtless there may be exceptions to this state of things; but, as a rule, I fear this will prove an under rather than over-statement of the cruel results of this abnormally cold twelve days' frost from the 5th to the 17th of March. While the cold continued the frozen shoots looked far less severely injured than they were. The frost held them together, and preserved to a great extent alike their form and colour. But now they are black, drooping, or wholly withered up, and as every bud that had moved seems more or less severely injured, fresh breaks will have to be made before any prospect of bloom can be had. How long it will take the plants to break afresh will much depend on two points—the state of the weather and the degree of injury the plants have sustained. In the case of dwarfs that have escaped with their lives the loss of time may probably prove the greatest. They possess a sure source of recuperative power in their root-stocks or underground stems, and sooner or later this reserve of vital energy will be expended in fresh shoots. But with standards it is widely different. During such storms as we have just passed through the whole of the *Rose* is set in the teeth of the harsh, keen wind with the hard-biting jaws of the frost set at a penetrating power of 20° or more. Under such unfair conditions it is indeed but little surprising that the *Roses* have perished. We had

Planted several hundred standards in October. They were mostly our best varieties. Nothing could have taken better nor rooted more profusely. The top buds had also mostly broken or swollen to bursting point, and now the buds are either black or brown, and on many of them the wood, right up to the Brier, is of that sickly yellow hue that foretells death from jaundice, lack of circulating power, severe shock or check, or by exhaustion. The very tissues of the more succulent wood have been frozen into a decomposed mass, and have lost alike the structure and form of healthy *Rose* wood. Dormant buds in many cases now threaten to continue dormant evermore. A few more such frosts in March are likely to do more to bring *Roses* back to earth on their own roots than all the shafts of ridicule or forces of reason that have been brought to bear on standard *Roses*. My own standpoint still is that they are useful in elevating and undulating the sky-line of our *Roses* as well as in yielding some of the finest of our show flowers. But dwarfs have their own special merits, and among the latter this must be reckoned as one of the most valuable that when killed to the ground line by stress of weather they live again. More, the very slaying of the *Roses* not seldom renews their youth as well as their strength and their beauty. Assuredly the killing severities of this March will afford abundant opportunities for dwarf *Roses* to exhibit their rejuvenating powers during the coming summer. Observations might also be made to test the

Hardiness of Briers when placed in the open with little or no head but a dormant bud or a small *Rose* top. The Brier or Dog *Rose* in its natural hedgerow or ditch bank is practically frost-proof; but it is widely different in the open, bare ground, as the bitter experience of 1880–81 proved. The results then were not only thousands of *Roses*,

but tens of thousands of Briers killed outright. In many cases the Briers died before the *Roses* and it was one of the most painful as well as the most common incident of that terrible winter of the slaughter of *Roses* and other innocents to see the *Rose* buds and branches struggling for dear life on dead Briers. It is to be hoped that this feature may not be so prominent this year. This the *Roses* had to contend with first and several degrees to boot. But that was in mid-winter, when all Nature was in a partially dormant condition. And it is more than probable that 20° this March may work as dire destruction among *Roses* as, say in round numbers, 35° that December. Never could *Roses* have been taken at a more serious and fatal disadvantage than this year. Full of sap as well as life, the frost and wind cut up through them without baulk or barrier, and the results are such as may well make rosarians weep without just cause of effeminacy, and it needs almost superhuman courage not to bate a jot of heart or hope under such depressing circumstances, but still push right onward in our favourite pursuit. No doubt this

Terrible slaughter of our *Roses* will give even greater force and urgency to the cry for more glass for our Teas. It is astonishing what glass alone will do for some of these. Since these frosts I have seen two fine *Maréchal Niel* *Roses* on the back wall of a coolinery that had had no fire. Not a bit of the wood nor a started bud were injured. This, I confess, surprised me. Neither would I cite it as a case to be imitated. The frost had been so severe as to almost pull the pipes asunder at the joints formed of india-rubber rings, and so saved them from bursting. It would have been every way better to have put a little heat on as well for the safety of the pipes as the *Roses*. But this was not done; the grand plants of *Maréchal Niel* were nevertheless safe and sound from lowermost base to the topmost extremity, and not one broken shoot nor embryo bud were injured.

WINTER AMONG THE ROSES.

SINCE my remarks were made on protecting and pruning Teas we have had a week of most wintery weather, beginning on the evening of the 5th of March, and still continuing on this, the 20th. The frost has ranged from 6° to 8°, and never did the north wind seem more stern and harsh as it dashed snow, hail, and sleet in the teeth of the tender *Roses* than during these few days. It seems marvelous that any of the young growths should have lived through this severe and long-continued storm—or rather incessant succession of storms—for no sooner has the sun infused a little more geniality into the air than clouds of snow, hail, and fresh hurricanes of wind have again arisen.

But, nevertheless, some of the young shoots of the Hybrid Perpetuals, and also those of *Gloire de Dijon*, have passed so far through the December-like weather unkilld. But many of the Teas, still under slight protection, are a sorrowful sight. The young leaves and shootlets look as if they had passed through fire. It seems less the severity of the frost, intense though that has been, than the harsh buffetings of the wind that have blasted the tender shootlets. *Maréchal Niel* on walls seems to have suffered most severely, and it is to be feared that standards in the open in exposed places may have perished. Such mild Februaries as we have had this year prove dangerous temptations to rosarians. The air seemed so soft and balmy, the birds began to sing and to build their nests, and the *Roses* grew so fast and furious, that I confess I was led into pruning Teas earlier than usual. We had almost finished by March 5, and now I wish our *Roses* had not yet been touched by the pruning knife, and that their winter protection had remained intact. One of the most curious phenomena of this abnormally wet and mild winter is the backwardness of fruit trees on walls and the forwardness of *Roses*. Neither Peaches nor Apricots show bloom on our warmest walls; whereas the *Roses* in the open have made several inches of growth,

A curious fact in reference to the effects of these cutting frosts has been noted. After the first frost and piercing wind on the 6th the Rose shoots drooped considerably, but did not seem permanently injured. During a lull and a more genial hour or so on the 7th they recovered and stood up. This process of drooping and reviving was repeated several times. But as the cold continued and became even more intense, the shoots lost their recuperative power, and now the majority of all the forwardest seem crippled for good or destroyed. All this is very trying, for never were the rosarian's prospects brighter probably than up to March 5 this year. The constant rains seemed to have done the Roses no harm, but rather good. They had washed the plants clear of dust and dirt, and of insects there were no trace. The buds were breaking with abnormal strength and regularity, the leaflets were most verdant, and the early ones unfolded were of good size, and had the robust character of health and vigour. The roots were also active, those of autumnal planted Roses being specially so and rising near to the surface.

And now—well, at the very best all growth of root and top has been roughly and rudely arrested and nothing is so fertile of attacks of mildew and other fungoid and other pests as these violent arrestments of growth. The effects will not be, all at once apparent. Not a few of the Roses may manage to even develop their flowers, though the latter are likely to be inferior through the effects of the storm. It is also well-nigh certain that not a few plants will die outright during the summer as the direct result of their severe freezing through this March. What the frosts have crippled the fire of June sunshine is likely to kill. Hence no means should be left untried, late though it be, to propagate more Tea and other Roses by budding, grafting, or cuttings where suitable material and means can be procured. Tea Roses may also be purchased and planted out in April or May. Those who have lost their plants may thus still have Roses during the summer.

Bury St. Edmunds.

SEASONABLE WORK.

FLORAL DECORATIONS.

WITH a favourable change in the weather we shall doubtless soon again have an abundance of hardy flowers that will prove of great service for decorative purposes. Primroses and Violets associate well together, and for these any shallow, flat receptacle can be turned to good account, using either sand or water, but in either case some fresh green Moss will be useful; so also would a few small pieces of the finer-leaved kinds of Ivies. A few patches of Violets, taken up when in full flower, will keep for some time in a soup plate if a little soil can be got with them. In this way Violets look very well—better than in bunches, and they do not fade so soon. Wallflowers may now be had in abundance; they like plenty of water, and will keep in good condition longer if the ends of the stems be cut off once or twice. We shall shortly be cutting blooms of *Magnolia conspicua* from a large specimen. These will look exceedingly well arranged in a pale blue vase for side-board decoration. We find them to invariably open well when cut just as they are about to expand their ivory-white blossoms. Their fragrance is also agreeable, but perhaps rather too strong for a somewhat small room. Daffodils may now be had in profusion. A few flowers of one or more kinds of these look well arranged with their own foliage something like the way in which they grow, and not bunched up in huge masses, as is oftentimes done. Of forced flowers, neat sprays of *Deutzia gracilis*, somewhat drooping in habit, are very serviceable as a fringe to a trumpet vase, the centre of which would look well filled up with a few pieces of *Hoteia japonica* and *Dielytra spectabilis* or *Chionodoxa Luciliae*. Clumps of the Lily of the Valley will be valuable now in vases, and

will be found more durable for this purpose than single crowns. Different coloured varieties of *Azalea mollis* look well together with a few pieces of their own foliage. From want of something better, a finger glass will suit very well in which to arrange them. Avoid placing vases of exotic or forced flowers or plants too close to an open window, the draught from which would soon spoil their beauty. When it is desired to prolong the perfection of choicer cut flowers as much as possible, it is an excellent plan to arrange them in a receptacle that can be placed under a bell-glass. In the case of scentless flowers this method is worthy of consideration.

FLOWER GARDEN

Cannas.—For outdoor summer decoration these cannot well be overrated; they are of easy culture, quickly increased, and wonderfully effective, both before and when they are in flower, and the variety and colour of both foliage and flowers are very great; though some are better than others, all the varieties grow and flower freely in the open air from June to October. They produce the best effects when planted in masses, the taller ones in the centre, and those that are dwarfer outside. They also look well alternated at wide distances apart with large plants of variegated *Abutilons* or *Acacia lophantha*. They attain the greatest perfection in deep, light, rich soil (a peaty loam with plenty of stable manure in it is best); they also do moderately well in stiffer soil provided the drainage is good. To get up a stock quickly the best way is to raise them from seeds, which, if sown in bottom-heat at once, will make useful plants for putting out in June next. Seedlings do not always come true; therefore when it is desired to retain any given variety, recourse must be had to division, an operation which may be performed any time before the roots start into growth; the portions separated should be potted in small pots and started into growth in heat. In dry soils in the south of England the roots winter safely in the beds if the surface be mulched with Bracken or Cocoa-nut fibre; but in less favoured districts and soils they should be lifted after the first severe frost occurs in autumn, and packed in dry soil in frost-proof sheds or cellars. The following are a few of the best varieties, viz., *aurantiaca*, *magnifica*, *peruviana*, *gigantea* major, *nigricans*, *Premices de Nice*, *iridiflora*, and *Warszewiczii*.

Hardy Ferns and rockery.—Most kinds of Ferns are now throwing up new fronds, and before they get so much advanced as to be injured by working amongst them, all old fronds, weeds, and new plantings, or rearrangements should be completed as early as possible. Remove the mulchings and give fresh soil to any plants needing that attention. This is the best season to plant out Ferns; therefore, any new additions to this department should be furnished forthwith. Plant carefully, well firming the soil about their roots with the hand; after that give them a good watering to further consolidate the soil, and unless the weather proves exceptionally dry, no further artificial watering will be necessary. An immediate furnished effect may be had by intermixing with the Ferns a few compact growing shrubs, such as *Thujas*, *Retinosporas*, and Irish Junipers. A free use of mossy Saxifrages and Sedums as a carpeting for Ferns is both appropriate and desirable, as they furnish the ground until the Fern fronds have become fully developed. The rockery is now beginning to look gay; *Aubrietia Campbellsii*, *Phlox verna*, and *Lithospermum fruticosum* are one mass of blossoms, and others are fast unfolding. In the presence of so much beauty, weeds, decayed stems, or, indeed, anything of an untidy character, should have no place. Many kinds may still be planted, and if when the stock of plants has become exhausted there are still vacancies, these may be filled in by sowing *Mignonette*, *Silenes*, *Virginian Stocks*, or, in fact, any of the dwarfer spreading annuals.

General work.—Mowing must now begin in earnest. We began with the lawn mower a

month ago, for the Grass has grown the whole of the winter. Negligence as to mowing early in the season results in coarse Grasses and a sickly coloured sward throughout the summer. Plenty of rolling, a dressing of soot or wood ashes, and early mowing ensure a fine velvety turf at all times. It is high time that lawn Grass seeds were sown; level and rake the surface fine, sow on a still day, rake the seeds well in, and roll frequently, but particularly after a frost, which upheaves the ground. Edgings of turf not yet trimmed should be so without delay, as they will soon be too dry to be operated on neatly. Walks, too, should ere this have had all necessary repairs done, and have received surfacings of fresh gravel, and rolling should be repeated after each heavy rainfall till they are hard and firm to the tread. Walks under trees are apt to get Moss-grown and discoloured; in all such spots apply a sprinkling of salt; this will remove the discolouration, and add brightness to the gravel. Laurel and other shrub pruning should be completed forthwith, as should also any planting that yet remains to be done. Vacant beds and borders should be dug or trenched, and with the view of lessening the pressure of work at the general planting-out time all kinds of plants that can now be put out with safety should be planted.

INDOOR PLANTS.

Achimenes and Gloxinias.—As soon as *Achimenes* started early have made an inch or two of growth they should be placed in their blooming pots or baskets, whichever are used. A few more ought now to be started, reserving a portion to be brought on later, for if it is deemed desirable to have them in bloom for a lengthened period they must be started at different times. Some of the old bulbs of *Gloxinias* should now be potted and placed in a brisk heat, but as soon as the tops begin to move they must be put as near the glass as possible. Few things are so much influenced by the treatment they receive in this respect as *Gloxinias*, which, if grown in a way that causes them to be at all drawn up, are rendered almost useless. If not already sown, a little seed should be put in. Few plants have been so much improved in recent times as these. If a good strain of seeds is obtained they will yield flowers equal to the best named kinds.

Eucharis.—Now that the season is coming on when the sun may be expected to have a good deal of power, see that these plants are not too much under its direct influence. Easy as *Eucharises* are to manage, many fail with them through an inability to keep their leaves in a healthy state. The most frequent cause of this is allowing them to be exposed to the sun to which, unlike almost all other cultivated bulbs, they have the greatest dislike unless far from the roof. Plenty of pot room is essential to quick growth and free flowering, and if small specimens are deemed the most desirable they should be divided, and the bulbs placed three or four together instead of letting them remain crowded. If by any chance the plants are strong and do not flower so freely as they ought to do, the shaking out and separation needful for their being put in small pots is almost sure to have the effect of throwing them into bloom. See that they are free from worms, as where bottom-heat is used the soil is often liable to contain them, and their presence for any length of time generally results in the plants getting into bad condition. Soot water made moderately strong will usually free the soil from worms. If the plants are at all affected with scale or mealy bug the sponge ought to be well used before the higher temperature, consequent on warmer weather, causes them to increase faster than they otherwise would do.

Shrubby Calceolarias.—Comparatively few soft-wooded subjects are more useful or effective for conservatory or greenhouse decoration in spring than these, and, considering the small amount of trouble they give to have them in good condition, it seems strange that they are so little grown. By cutting them back each summer when

the flowering is over, like Pelargoniums, but not shortening the shoots so close as in their case, they will last for a number of years, attaining a large size and blooming so profusely as to all but hide the leaves. Old examples fairly well wintered if given a shift now into rich soil and kept in a temperature of from 40° to 45° in the night, and quite free from aphides, will form strong bushes full of flower by the beginning of May. Amongst yellows the old bedding variety aureo-floribunda is one of the best; the darker coloured kinds succeed equally well. Young plants now in their blooming pots should be kept a little warmer than ordinary cool greenhouse stock if they are wanted in bloom early.

Hydrangeas and Neriums.—Where Hydrangeas are grown in small pots from cuttings struck annually they force well, and where the pots are full of roots they must be treated to manure water every week, as on this depends the size and strength of the flowers. If a portion of the stock is kept cool a succession of bloom can be maintained for several months. Small plants of Neriums are most useful; where well ripened by full exposure to the sun in the open air during the latter part of summer they rarely fail to flower. Care must be taken that they are plentifully supplied with water, for although the plants will bear drought without injury in the autumn and winter, yet as soon as the bloom buds begin to move if too dry they will most likely fall off. An intermediate temperature is sufficient for such as are to be forced, as if subjected to too much heat they do not generally flower well.

Humea elegans.—This old-fashioned plant deserves a place wherever room can be found for it. It is not only elegant in growth, but it has the additional merit of being at its best at a time in summer when there is usually a scarcity of conservatory stock. To have plants of it in good condition they must now be moved into large pots, as if cramped for root space they will be deficient in size and the lower leaves will not keep fresh, after the loss of which half their beauty is destroyed. They are subject to aphides, which must be regularly sought for, as they lie concealed at the under side of the leaves, and if allowed to remain they soon do irreparable harm.

Lilium giganteum.—Although this stately plant will succeed out-of-doors over a good part of the kingdom, still it will flower in a pot, if well managed, much more profusely than in the open ground. Examples that have been wintered singly in 8-inch or 9-inch pots should at once be moved to others 16 inches or 18 inches in diameter, giving them good turfy loam, enriched with manure, pressing it moderately solid in the pots. As soon as the roots have got well hold of the new material, manure water will help them, but, like almost all other quick-growing subjects, if stimulants of this nature are to have their full effect, they must be applied at the time the plants are gathering strength to form their flowers.

Fuchsias and Cinerarias.—See that everything needful is done to keep last summer's struck Fuchsias moving freely, as any check as regards want of pot room, or keeping them too cold, will throw them into a premature flowering state, after which little progress in size is possible. Where Cinerarias are wanted in bloom by the end of the year, a bit of seed ought shortly to be sown.

FRUIT.

Pines.—Examine the first batch of suckers which were potted early in February and plunged in a strong bottom-heat of 90°; and if it is found that the young fleshy roots are beginning to coil round the outsides of the balls, give sufficient tepid water to keep them in a nice growing state. Ventilate more freely and dew them over with the syringe after closing with solar heat. If the young plants are kept close to the glass and have plenty of room, the top-heat may now range from 65° at night to 75° by day; and to prevent the

newly formed roots from receiving injury, the heat about the pots may be allowed to descend to 80°, at which it must remain until they are potted. Where very strong suckers are obtained to start with, and the one-shift system is to be followed, make the usual preparations for carrying out the work with dispatch when the plants are in a fit state and the weather is favourable. Let the beds be made up of tan or leaves some time beforehand to ensure a steady bottom-heat of 85° to 90°, as getting into a newly-plunged bed to rock and lift the plants is very objectionable. Err on the side of small pots—say 10 inches to 12 inches for Queens, and 12 inches to 14 inches for Cayennes; use pure, rough, fibry loam—bone dust and charcoal if inclined to become adhesive—ram very firm to prevent all possibility of water being held in suspension, and while maintaining a moist, growing atmosphere by a judicious use of the syringe, carefully avoid saturating the soil until the roots begin to work freely through the new compost. Keep a close watch upon newly-potted plants, and place some very light shading over the glass for an hour or two on bright days. Let the heat in fruiting pits range from 70° at night to 80° by day; close with sun-heat at 85° and run up a few degrees with atmospheric moisture well charged with ammonia. See that plants in flower have a brisk circulation of heated air to insure perfect fertilisation, and to prevent the crowns from becoming too large, as is often the case in close, dank, ill-ventilated pits.

Vines.—Disbud, tie down, and stop succession houses as the Vines advance, and remove all surplus bunches from free setting kinds as soon as the most promising for the crop can be decided upon. Early Muscats having plenty of fresh, active roots working in inside borders may also be divested of ill-formed bunches, provided a fair percentage of the best are left to choose from after the Grapes are set. Draw the points of the bunches up to the light when in flower, fertilise with Ham-burgh pollen, and let the heat range from 70° at night to 85° by day, and 90° when solar heat is available. Grapes now swelling must have a liberal supply of moisture charged with ammonia, and as keen easterly winds with bright sunshine frequently prevail in March, guard against checks from draught by shutting off fire-heat early on fine mornings, by timely ventilation, and by early closing with sun-heat at a temperature of 85° to 90°. As the stoning process approaches, allow a free and easy growth of laterals, stimulate the roots with warm diluted liquid, and aim at a steady night temperature of 65° to 68° with a little air. When this strain upon the Vines is over, sharper forcing may be indulged in if it is really necessary, but the figures I have just named are quite high enough for all Grapes which do not come under Muscat treatment.

Late houses.—Endeavour to give the Vines as long a growing season as possible by shutting up with strong sun heat; syringe the rods several times a day, and maintain a moist atmosphere by damping the mulching material every evening. Vigorous young rods which have never borne fruit will require dexterous handling to get them to break evenly, particularly where the young beginner has been led or misled into leaving his canes long enough to carry a crop which his Vines cannot finish; but much may be done by tying down the points and elevating the dormant buds over heaps of fermenting material placed on the borders.

Hardy fruit.—All arrears of winter work, if any, must now be gathered up, as spring operations will now require attention. As many of the recently planted fruit trees have not received a thorough soaking of rain water since the roots were disturbed, see that all mulching is well done before they suffer from the effects of drying winds and bright sunshine. Tread the soil firmly now it is dry before the manure is put on, and give all doubtful trees a moderate watering to keep them going until the sap finds its way back into the usual channel. Young stone fruit trees intended for training as supernumeraries must be treated as the above, and if

cutting back is still a portion of the grower's creed, all buds must be pretty well advanced, or, better still, the work may be delayed for a year before they are subjected to a second shock. Where, in low damp gardens the topping of Raspberries is put off till spring, cutting back may be performed in March, and if well mulched early in the autumn a hand-weeding of the stools will complete this part of the garden for a long time, as digging amongst the roots is simply barbarous. Look over Strawberry beds, remove all weeds, spread down the mulching and rake off before the crowns become too prominent. On our cold damp soil we make it a rule to lay the autumn mulching in ridges between the rows, and after dressing the beds with soot, the manure is levelled down early in the spring—the advantages being freedom from slugs, more complete rest to the crowns, and a later and better bloom in the spring. With the exception of Pears, which bore heavily last year, fruit trees of all kinds in this locality are laden with blossoms, which promise to be bold, vigorous, and perfect, and so far the season is highly favourable, provided the advice to protect, which teems in every journal, is not carried to excess. It is of course well to be prepared for an emergency, but covering which excludes light and air checks and weakens the vital energy of the trees, and does more harm than well coped, but otherwise exposed, trees would receive from several degrees of dry frost.

KITCHEN GARDEN.

POTATOES should now be planted. Our sets have been kept on shelves in a well-aired room and are in fine condition, having small, but stout sprouts. The varieties are Early Frame, Early Hammersmith, and Empress Eugénie, but the bulk consists of Myatt's and Old Ashtop. We merely draw the drills and lay in the sets, but leave a slight ridge above each row. Other operations consist in filling up blanks in Cabbage and Lettuce quarters, and keeping the soil well cultivated between the rows, which is the very life of vegetation, and which should receive attention on all favourable opportunities. Now is about the very best time to make a selection of Broccoli for seed; take only one, but let it be the king among them. When in flower sulphur it to keep off insects. We have been busy cutting up all old stumps of Brussels Sprouts, Savoys, &c. What a useful vegetable sprouting Broccoli is! Some few years back Mr. Dancer supplied us with a stock of it, and capital it is. We also grow the white variety. Our opinion is that it is not so sweet in flavour as the purple. Our early spring Cabbages will be in time to succeed the above; therefore, no blanks, but all prizes, are the order of the day. French Beans are the only vegetables which occupy much space under glass just now; they are very unprofitable, but cannot be dispensed with; therefore, keep up a stock of them in accordance with the demand. Early Peas in boxes in cool houses are just now little pets, Laxton's Minimum being dwarf, prolific, and good in flavour. When the flowering period is over mulch the boxes with rotten manure and give plenty of water, attentions which the Peas fully repay. Early Potatoes in boxes now in the Peach house should be kept short of water; only just enough should be given to keep them from flagging. We sowed our main crop of Celery to-day, the varieties being Major Clarke's, Sandringham White, and Carter's Incomparable Crimson.

Late-flowering Chrysanthemums.—Although some varieties flower much earlier in the season than others, even under the same conditions, yet the great point in obtaining late blooms is to treat the plants according to the time they are required to flower. That a great deal depends on their mode of treatment is shown by blooms of Elaine and M. Lemoine being even yet in good condition, though neither of them would be selected for late flowering, the first being one of the earliest Japanese, and the latter comes in with the bulk of Chrysanthemums. The flowers

in question came from side shoots developed after the removal of the terminal flower or flowers, as the case may be. A great deal may be done by late striking of the cuttings; but, at the same time, the latest flowered kinds should be selected. A Japanese variety called splendens I find to be one of the latest of the whole. It does not grow so tall as many of the Japanese kinds, but is quite a medium height. The flowers are of a deep yellow colour, and composed of broad strap-like petals, the inner ones of which are partially incurved. This variety should certainly be noted for its late-blooming qualities.—H. P.

NOTES.

Little bits of "true blue" are but rarely represented amongst spring blossoms. We are always very pleased to see *Scilla bifolia* pushing up the dry clods towards the end of February, that is supposing that February is dry and east-windy, as it was this year, and not the "fill-dyke" month of rain which our forefathers made it out to be. As I said, we welcome the two-leaved Squill and fondly imagine it to be blue until *S. sibirica* makes its appearance a little later, and then we find that it is almost purple by comparison (I mean modern purple, not the ancient purple, which was nigh on scarlet). This reminds me that comparisons by memory and comparisons in fact (as when two plants supposed to be the same are seen side by side) often give very, very different results. Another bit of "true blue" is *Omphalodes verna*, a Forget-me-not of the earliest, and surpassed by no other hardy flower, except perhaps some *Gentian* and *Eutoca viscida*.

Anemone apennina is of all seasonable flowers one of the most exquisitely beautiful. To enjoy its freshness of colour it must be plucked in the bud stage and opened indoors or they may be pricked into a saucer of wet Hyphnum Moss. If you want to emphasise the colour, arrange a few flowers of *Narcissus* with it, say *N. odorus*, or, failing that, *N. minor*, one of the earliest of our outdoor kinds. We have had a clump of *A. apennina* here for some time from which roots are dug every season for exchange or for dibbling into the sparse grassy spaces under trees, and yet, like the widow's cruse of oil, that clump seems inexhaustible, and every year they come up seemingly as thick as ever. This is one of the good points in many species of *Anemone*, they are so easily increased by breaking up the roots either intentionally or otherwise. In the case of *A. apennina* this is especially the case. We have a few other plants which seem to increase the faster for having bits stolen away from them. *Anemone japonica* and its white variety do this, and so also the Caucasian Comfrey (*Symphytum caucasicum*), which now bears its blue bells dangling among its hoary leaves and is a perfect weed with us.

Primula rosea and seedlings of *P. cashmeriana* are now flowering quite freely outside, the first-named pushing its vivid rosy buds and blossoms up through the thick coat of leaf mould, with which we always like to protect its netted mat of surface roots during the frosts of winter. Of all modern introductions from Northern India, *P. rosea* is one of the best in the Primrose way; but I must remember Dr. Watt's illustrated paper in a recent number of the Linnean Society's *Journal*, and not be too proud of my favourite lest one or more of these new beauties should surpass her and take up the pride of place before what I now call the rosy queen of all the Primroses. Here having many forms from seed we find *P. rosea* very variable, some deep rose, like the first glint of the Almond buds as they push through their hoary bracts, others as pale as the palest Almond or Peach blossom can well be; but all are beautiful, and I think the shades of colouring more satisfactory than if all were exactly alike, as is the case when division of old clumps is trusted to as the only means of increase.

Garrya elliptica fecmina.—In reply to my allusion to this rare shrub, a friend writes to say that a specimen of the female *Garrya* has existed in a garden near Bristol for the last twenty or more years, and has fruited every year since 1867. For all this information I am most grateful, but I could have found it for myself in *THE GARDEN*, Vol. X., p. 254. What I particularly wished to know was, not where the plant existed, but from whence, by purchase or otherwise, it might be procured. Now that we have a "general index" to the first twenty vols. of *THE GARDEN*, I imagine but few of us need other references than that affords. Nevertheless, original information is ever more welcome than references to the pages of a paper we know pretty well already. Again, I repeat my question: where may a plant of *arrya elliptica fecmina* be obtained? for "*Veronica*" much and truly desireth to have the same.

A good hardy foliage plant is *Ileuchera americana*, or what I have named as such, with leaves like a zonal Pelargonium in size, but of a silky texture, and a bronze or brownish red tint. They are very fresh and clean all winter time, defying both frost, snow, and biting east winds, and as seen under artificial light no tropical leaves could well be more attractive. As seen on the dinner table, people wonder what lovely leaves they are; indeed they have done so when we employed the red autumnal leaves of the common *Mabonia*, so nigh akin are they in real beauty to tropical kinds. This *Heuchera* would be most useful to all who have to furnish dinner-table decorations in great variety. If pale green plants of the same form are desired, the old *Tellima grandiflora* will afford them in any quantity. A very pretty arrangement just now for a hall table is Ivy leaves, green and golden, in an old brown jug, among which are placed long twigs of "pussy" Willows and sprays of the young leaves, and magenta blossoms of the flowering Raspberry, *Rubus spectabilis*. Another arrangement of Wallflowers and Daffodils in the same brown jug is always admired.

Golden Daffodils and Pæony leaves form just now a very pretty combination on our borders here, and I never see a large bed of herbaceous Pæonies about a place without longing to drop a few hundred roots of the common double Daffodil in amongst them. Just when the Daffodils flower the Pæony leaves and stems are of a rich glossy purple, a colour which contrasts most effectively with that of the nodding Daffodils.

Dendrochilum glumaceum is one of the most elegant of all Orchids now blooming. We are not as yet able to cut over a hundred of its elegant spikes in one day, as Mr. Thomson now and then does at Drumlanrig, but its drooping Rye Grass-like spikes are here with us very much admired, and this as much for their Meadow Sweet-like fragrance as for their beauty. Suspended in shallow pans of peat and Sphagnum quite near the roof of a warm stove, this Orchid grows and flowers quite freely, and is to us quite as welcome as are the more showy blossoms of its associates, the Cattleyas and Vandas.

Among the Dendrobates now in bloom shall I give first place to the dainty wreaths of *D. Devonianum*, with its ethereal magenta-tipped petals and the pure orange blotches on the lip, which remind me of blotches on the wings of a little native butterfly, which I remember quite well as a child, although I now forget its name (a friend tells me that this butterfly is the "orange tip" or "wood lady," *Euchloe cardamines*). One visitor who breathed its peculiar fragrance for the first time here always calls it the "spring morning Orchid"—so rich and fresh and full of sweetness is its odour in the early sunshine. *D. Wardianum* is ever lovely and wax-like; so also *D. crassinode* and "old nobile" comes as an old and well-tried friend. *D. Ainsworthii* is also very pure and distinct, but one of the gems of our tiny collection is

a remarkably fine variety of Freeman's collecting (I think in Assam) of the now rarely seen *D. lituiflorum*, so named because its labellum reminds one of the long curved horns or clarions used in ancient times for signalling purposes. Nearly all *Dendrobates* are beautiful when well grown, but of all the above *D. Devonianum* is and has ever been a great favourite with me, so delicate and fairy-like is its floral texture and sweetness.

The old Red-stalked Rhubarb.—Of all the varieties of Rhubarb grown in our gardens for culinary uses, how rarely do we meet with a dwarf and early kind which I remember grew in our home garden when I was quite young. Is it the kind now called Early Crimson? The petioles of the small rhomboidal leaves were only 10 inches or 12 inches in length and not thicker than one's finger, and yet for tarts it was a great favourite on account of its fine colour, and also for its early growth. If I remember aright, the stems were red throughout and not greenish when peeled, as are those of most other varieties, especially the giant seedling kinds now so much grown.

Good King Henry as a substitute for Spinach is not so generally grown as I think it ought to be. In the farmhouse gardens of Lincolnshire it is quite common as a successional crop to their winter Sprouts and Kales of various kinds. Really, it is a native plant—*Chenopodium Bonus Henrius*—and so is, of course, quite hardy in all soils and localities; it is now throwing up its succulent leafy shoots from among a rather liberal top-dressing of rough leaf mould, with which we protect it during winter. Its flavour is quite distinct from that of any other vegetable, and so it deserves culture on its own merits; although we think it very good, yet we long for the fresh inviting flavour of Asparagus which it suggests.

The song birds are already nesting with us, and I yesterday found a thrush's nest with eggs in a Holly bush quite near to my door. It is a little too late now, perhaps, to give advice, but here we take every care of our birds, *i.e.*, those which naturally make our old garden their home for breeding. During the winter we find old meat bones especially acceptable to the worm or grub-hunting kinds, while bread-crumbs and fat suit others better. We find that during hard frosts they often suffer for want of water, and so break holes in the pond for them, to which they at once repair in flocks, and almost fight for a drink, so eager are they for moisture. Having but little fruit here, I am sure we are amply repaid for caring for the wants of the birds during winter-time. We generally have a meat bone hung up in a tree near the window for the blue-tits, who delight to creep around it; and so while feeding they afford us endless amusement, so quaint are their antics. I remember once calling upon Sir Joseph Hooker at Kew, when he showed me two or three blue-tits clambering and twittering on a nuttun bone on his verandah, and I was so pleased at the sight that I have ever since offered these sprightly little birds a similar attraction, I presume, much to their benefit, but, I am at any rate sure, much to my own amusement.

In protecting the birds, which we here find quite as necessary as the feeding of them, we find that the hawks, magpies, and prowling cats do more damage even than boys' bird's nesting, which is absolutely forbidden. The dogs keep the cats at bay pretty well during the daytime, but during the night and early morning the cats do some little damage. Hawks and magpies are simply shot or shot at whenever they appear, and one result is that our old garden, although near the town, is quite a refuge for song birds of all kinds, and during early morning and in the evenings the trees and shrubberies are alive with them, and the air full of bird music. As I have said, we grow but little fruit, and that little is so easily netted that we favour the birds; even the bud-picking bullfinch is not forbidden, and we have some rather rare visitors,

to wit, a gold-crested wren generally builds with us, as also goldfinches in our Apple trees. Last year a blackbird built her nest and reared her young safely in a large New Holland shrub in our greenhouse. A robin always selects the Orchid house for its nest, and a little wren built herself a pretty nest in an Orchid basket, and did not mind us at work or walking about underneath.

Euonymus albiatus, a Japanese species, is rather uncommon, albeit it is an effective and cheerful evergreen shrub when in fruit. The leaves are glossy, broadly lance-shaped, finely serrated, and 3 inches to 5 inches in length. Fruits

Euonymus albiatus. Japan.

in lax axillary clusters of a pale pea-green tint, but showing bright scarlet-coated seeds as they attain maturity, and burst open, as is the fashion in this genus. Our engraving shows leaves and fruits natural size. It is hardy in Ireland, and makes a good pot plant in a cold house.

Double Daffodils of the common kind are now very gay in clumps and masses, and but few kinds, if any, are so hardy or so satisfactory for distant effects on the Grass. Of the rarer kinds, one of the most distinct is *N. eystettensis* (*N. capax* fl.-pl.), of which the perianth segments only are duplicated, and superposed as those in a Lady Hume's Blush Camellia apparently are. It is a slender-growing plant, bearing delicate straw or sulphur-coloured flowers on stalks 9 inches in height. The dwarf *N. Tradescanti*, or "*Tradescant's double Daffodil*," is also in bloom, with the true double English kind said to be wild in the Isle of Wight, but very rare in gardens. It is much smaller and paler in colour than the common double. One of the finest and certainly one of the most distinct of all double kinds now flowering is one sent me some years ago from Haarlem by Messrs. Barnart & Sons. It is like what a double bicolor might be expected to be, the perianth segments being whitish and the coronal segments

golden. It is figured in Hale's (Hill's) "*Eden*" a century or more ago, and is therein described as the "*silver and gold*" Daffodil with double flowers. The two distinct shades in the flower render it unique among double Daffodils, and it is a pity such a beautiful variety is at present so rare.

Irises on the Grass.—How comes it, among all the bulbs and flowers hitherto recommended and planted on lawns here and there, that we so seldom see the many varieties of German or Flag Iris so used? We find them most successful so planted; indeed as our soil is deep, light, and sandy, it follows that while almost all Nymphs or bulbous Irises succeed well, the Flag Irises, if they do not actually fail, do not luxuriate so well as they do on stronger soils. Seeing this, we made a trial of planting them here and there on the turf, and the result surpasses our expectations, and we anticipate some pretty effects in this way. Being evergreen, they are not likely to be so unsightly as deciduous plants on Grass must sometimes prove, and it is quite easy to mow round good bold clumps and masses of these Irises (as of other plants) when it is not so easy when things are dribbled in in a scattered way. The common purple Iris germanica, as seen on a grassy lawn, is a noble object, but there are twenty varieties of it at least, some as fine as Brazilian Cattleyas in colour and as hardy as the Grass itself, and the effects to be obtained by the artistic grouping of these on sheltered, but sunny bits of lawn, are among things "not generally known." VERONICA.

KITCHEN GARDEN.

TWO METHODS OF PEA CULTURE.

THAT Peas are both a source of worry and pleasure to many gardeners as well as amateurs not a few of your readers will readily admit. All must have them, but all are not equally well experienced in their culture, and others have exceptional difficulties to encounter as regards their growth. One thing is certain, and that is that Peas of our own growing are the most delicious; at any rate it is rare that we can procure any from the markets or shops to equal those fresh picked from our own rows. Probably in the case of some it may be cheaper to buy what green Peas may be required than to grow them, as where space is limited or manure and stakes have to be bought the crop proves expensive. At the same time I hope to convince many who at present grow few or no Peas that they are not altogether wise in the matter. Peas are really easily grown, and stakes though preferable, are not absolutely necessary. Witness the enormous quantities annually sent to the London markets. Few if any of these are grown other than in the open fields and

Without stakes. It is true the conditions under which they are grown are different from those belonging to garden culture, but they may be imitated, as I have proved, in private gardens, and with most satisfactory results. The market crops are grown on land into which a fairly good dressing of good stable or London manure, as the case may be, has been ploughed, and this land soon becomes comparatively firm. This induces the growth of a sturdy short haulm, which, as a rule, is literally crowded with pods. It is therefore evident a deeply dug and heavily manured yet loose soil is not suitable for unstaked Peas, and I am of opinion that a loose soil is not the best root-run for those to be staked. Prior to sowing, the ground should be heavily trodden, and single drills about 30 inches or 3 feet apart and 2 inches deep may be drawn and the seed sown thinly. When about 4 inches high the plants should be moulded up and care taken to destroy all weeds between the rows before the haulm covers the ground, as this will be a difficult matter afterwards. Early varieties can be cleared off in time to admit of the ground being planted with such crops as Broccoli, Savoys, or greens, while in the case of the later sorts the haulm may be carefully laid along the rows, and this will admit of the

spaces between being filled with more of the same kinds of plants. Here, then, is a good bit of double cropping, and the extra firmness created for and further increased by the Peas renders the ground more suitable for the Broccoli and other winter material, as these grow more sturdily, and, as a consequence, are much more hardy than if grown on loose, rich land. Much, however, depends upon having

Suitab'e varieties. Some of those preferred by the growers for market are scarcely good enough in quality to suit the private grower. Round-seeded sorts only can be relied upon for the earliest sowings, as the wrinkled Marrows, unless the season is exceptionally favourable, are apt to rot in the ground. Sangster's Improved No. 1 still finds many admirers among both market and private growers, but I am inclined to think cheapness of the seed unduly influences the choice, as there are more superior early sorts. Caractacus, of a similar type, is decidedly preferable, while Kentish Invicta and William I. are much better in every respect, and will invariably command higher prices in the markets; in fact, I have seen good samples of these find buyers at a fair price when wretched, yet average, samples of Sangster's had to be nearly given away. Taber's Perfection, again, is not worth growing. Day's Sunrise, being a wrinkle-seeded variety, and as such comparatively early, is deserving of and doubtless will be extensively grown in the future. It is well adapted for small gardens, whether stakes are available or not. Laxton's Supreme is still a popular second early market variety, but, although it produces an abundance of long, well-filled pods, the quality is somewhat poor, and the earlier Sunrise should supersede it. Dr. McLean has no equal, whether for small gardens or the fields, unless the soil happens to be extremely cold and heavy. Last season, although unfavourable to the Pea crops, we inspected several acres of this variety, and the crop for weight, size of well-filled pods, and quality was by far the best I have yet seen of any sort. The soil in this case was a deep and somewhat strong loam, and had received a liberal dressing of fish manure; and this powerful and lasting fertiliser I should strongly recommend to the notice of farmers within easy distance of London. Unfortunately it is too highly perfumed for private gardens, and would, if used, be at once voted a nuisance. For the main crop Yorkshire Hero, or, as it is now generally termed, Veitch's Perfection, is the best yet grown in the fields, and either this, Omega, or the good old Hair's Dwarf Mammoth may well be grown in private gardens for both main and late crops. I do not greatly value the much lauded Stratagem and Pride of the Market Peas, and am of the opinion that neither will ever be extensively grown for market purposes, nor will be found particularly profitable in private gardens. Both these and the taller growing, but in other respects very similar, varieties, Telegraph and Telephone, are very robust and good second earlies, but in the markets thick fleshy pods, however well filled, do not long find favour, simply because they do not yield a proportionate quantity of Peas. This I have proved even in a country town where buyers are seldom so cute as your thoroughbred cockney. In the case of the more

General methods of growing Peas, we find a great diversity of opinion. As regards time of sowing, suitable positions, soil, and manure, but more especially as to the merits of certain varieties, much depends upon the locality, nature of soil and subsoil, the amount of labour at command, and last, but not least, upon the tastes of those most concerned. In warm soils, these being necessarily of a light texture, it may be a good plan to sow seeds during November for the earliest crops the following year. For my part I have long since become disgusted with this practice, or at all events with the results of my efforts in that way, and now invariably sow seeds about the middle of February in ordinary Pelargonium boxes filled with light mould. This sowing usually consists of two round-seeded varieties, with, perhaps, a third added by way of experiment, and an early dwarf wrinkled sort. Wil-

liam I., Laxton's First Early, and Veitch's Extra Early are grown this season, the latter only for the first time, and the American Wonder is the dwarf variety. They were started into growth on a light hotbed, given air freely when weather permitted, and eventually transferred to a cool Peach house to harden off, care being taken to prevent them becoming drawn and weakly. Weather and state of ground permitting, these will be planted out about the middle of March, the American Wonder at the base of a warm garden wall, and the taller sorts on a sheltered border and in lines 3 feet apart. When planting a deep drill is cut out with a spade, the Peas are shaken clear of the soil, and bunches of about four plants are put in at a time, the tops touching each other, and the roots, going down to their full length, are covered with some good light soil. More of the ordinary soil is drawn up to the rows; next small branches of Spruce Fir are disposed on each side of them, so as to afford protection and support. This being completed, the soil is loosened between the rows with a fork, and a row of Spinach sown between each. In this manner we have at once good even rows of Peas, which will not even flag in ordinary bright weather, but will quickly become established, and will generally yield good crops available by the end of May. Pots, turves, and troughs have all been tried for raising Peas, but I much prefer the boxes. I ought to state that a layer of crocks is placed in the bottom of each box in order to prevent the roots clinging to the wood, and we always use sifted soil composed largely of leaf-mould, our aim being to preserve intact the long tap roots bristling with fibres, otherwise the Peas must experience a check. It is by this method they most quickly root into the surrounding soil after planting. To succeed those transplanted it is advisable to sow late in February, or as early in March as weather permits, one or more long rows, according to the demand, of first early varieties, and in the case of cold soils, as with us, to make yet another sowing. This time we give the preference to a good wrinkled variety, such as Telephone, and, as with the earlier sorts, sowing rather thickly, and about two-thirds of the quantity of seed as would have been required for a row or rows if sown in the open ground. More of this second early variety and also Criterion and Huntingdonian are sown on the first favourable opportunity in March. Should there be any gaps in the rows of these, caused either by the seed rotting—a by no means unfrequent occurrence with us—or injury by mice, birds, or slugs, as soon as this is discovered sufficient seed to make good the rows is sown at once in boxes and placed in gentle heat, the plants thus obtained being hardened off and planted where necessary. In this way good rows are insured and the supply maintained. The ground being very wet and cold this season, many seeds may fail to germinate, and my practice of sowing in boxes or a somewhat similar one should be adopted if creditable rows of Peas are desired, and it is also necessary in the case of

Growers for exhibition who may wish to have large podded sorts of the Telegraph type early in the season, say about the middle of June. That immense podded variety, Culverwell's Giant Marrow, again will in all probability be in great request this season for exhibition purposes, and sowing the seed under glass, though not necessarily in heat, will be found both economical (the seed being scarce) and advantageous as the variety is extremely vigorous and branching, and transplanting thinly tends to make it more prolific as well as earlier. The inexperienced are frequently at a loss to know exactly when to make different sowings so as to maintain a succession and avoid gluts; but if they adopt the simple plan of waiting till one sowing is pushing through the ground before the next is made, taking care, however, not to defer it any longer, other conditions being favourable, no break will occur. If several varieties are grown, two or three, according to the extent of the demand and space available, may be sown each time. For instance, to succeed our planted

out Telephone, as before stated, we, early in March, sow a row each of Telephone, Huntingdonian, an early and improved form of Champion of England, and Criterion, this being an early and most excellent form of Ne Plus Ultra. When these, which will be fit for use in the order named, are through the ground, we sow the two latter varieties, and with these a planted-out row of Culverwell's Giant Marrow will be in full bearing say about the end of June or early in July. Our next sowing will consist of Duchess of Edinburgh, Reading Giant, and Ne Plus Ultra, and the following a repetition of these varieties, while to succeed this sowing the two last named and King of the Marrows will be selected. The next will consist of Ne Plus Ultra, King of the Marrows, and Sutton's Latest of All, and as this will bring us to near the end of May, the final sowing in all probability will consist of Latest of All and three rows of Ne Plus Ultra. Well manured and deeply dug ground is particularly necessary for the latest crops, and the highest point in the garden, especially if the garden be situated near water, should be selected. In this manner we gathered Peas last season up to the middle of November, but all the rows in the middle and lowest part of the garden had long previously been destroyed by frost. By the foregoing it will be seen I depend almost exclusively upon tall-growing varieties, the exceptions being the early sorts and Latest of All. These tall varieties, according to my experience, are, provided stakes are to be had and there is sufficient room, the most profitable, as they are of better constitution and therefore not so liable to be injured by excessive rains or drought. At the same time I am well aware the majority of growers have to rely principally upon medium height varieties on account of a difficulty in procuring suitable stakes or other causes. With many there is no choice in the matter, simply because they grow such sorts as are supplied in collections of vegetable seeds. For their benefit I may state that I have found Stratagem and Pride of the Market good dwarf substitutes for Telephone and Telegraph, and Advancer a good second early. Dr. McLean and Sharpe's Invincible good for successional crops. The latter, Challenger, Veitch's Perfection, and G. F. Wilson good for the main crops and for later sowings. I can recommend Veitch's Perfection, Omega, and Hair's Dwarf Mammoth. When

Preparing the ground, if we could rely upon having certain weather, we might shape our course accordingly, but unfortunately we have or ought to be careful to avoid the risk of preparing for a dry season only, and thereby be unprepared for a very wet one. If we were in a position to double-dig much of our garden, we would annually devote a quarter thus dug to a Potato crop, well knowing what splendid crops of the "noble tuber" are produced on deeply dug land. The next season this quarter would be selected for Peas, as it would afford the desirable deep root run without being unduly loose and maybe prejudicially saturated with wet. I do not believe in sowing Peas directly over the old Celery trenches, as I consider the Celery completely exhausts the ground. Our practice is to mark out the ground in widths of 6 feet, alternated with 3-foot widths; the former being lightly manured and dug, while the latter are more heavily manured, giving the preference to semi-rotten farmyard manure and double digging. This is managed by first wheeling about two barrowloads of the top spit of soil from the commencement to the end of the intended trench. The manure is then spread over the second spit and dug in, on this being disposed the next width of surface soil, and so on to the end of the trench, the bottom or sub-soil still remaining at the bottom, but well mixed with the manure. The trenches or widths prepared for the latest sowings have the top spit distributed on each side, the manure being then dug in and part of the top soil returned. Later on the remainder is banked up to the stakes, and this forms a trench which facilitates waterings. This trenching is particularly necessary in the case of shallow, gravelly, or sandy soils,

and cow-yard or pig's manure should, where available, be freely employed. Narrow trenches as we frequently see formed for Peas are unsatisfactory, especially in somewhat heavy soils, as in this case the soil in the trench is apt to shrink from the sides, and the ill effects attending either drought or excessive wet are liable to be aggravated rather than mitigated. Our wider trenches are much less liable to be injuriously affected, and by disposing the rows 9 feet apart we greatly improve the cropping capabilities of the Peas. Between the rows there is ample room for two rows either of early Potatoes or Broccoli, and Coleworts can take the place of the Peas as these are cleared off. If liquid manure is employed with us, it is immediately after rain or after administering a good soaking of pond water. Absence of lime in the soil is most detrimental, and where this is thought necessary, a good dressing of it should be slaked and forked into the surface. Blood obtained from the butcher's, and spread thinly on the surface and washed in either by rains or by softened water, is very stimulating to the crop, and much may also be done by surface dressings with guano or artificial manures. We tread the ground firmly prior to sowing; a single wide drill about 2 inches deep is then drawn and the seed sown evenly and thinly. If mice are troublesome, the seed is steeped in paraffin for a short time, and they do not then interfere with it. Ducks, soot, and lime are employed to check the slugs, and the two last and a cat or two are the best remedies against birds' attacks. Peas intended to be staked are not allowed to fall about, but are supported with spray as well as stakes. Hazel stakes are the most common, but the best we have yet employed was the undergrowth or branches of large Spruce Firs. The stakes should not be disposed very widely at the bottom and run in too sharply at the top, or they fail to support the haulm in the earlier stages, and do not confine it sufficiently near the top. All main and late crops should be mulched with rough manure, or failing this with Grass from the mowing machine. Driblets of water are quite thrown away on Peas; if watering is commenced, liberal quantities should be given and be repeated at short intervals according to the weather experienced. In conclusion, let me advise all those who are in the habit of or intend disposing the rows somewhat thickly with perhaps a row of Spinach between to at least have the rows as far apart as the varieties usually attain in height. Better a few good rows than many crowded and poor ones.—*Grower and Exhibitor.*

SAGE CULTURE.

It may, I think, almost be stated as a fact that in nine gardens out of ten Sage is grown and treated as a perennial (which it is) and propagated by cuttings, *i.e.*, when a fresh stock of young plants is wanted; in addition to this, it is no uncommon thing to see it growing in some out-of-the-way place, and the year's requirements depending entirely on a few old scraggy plants of it may be half a dozen or a dozen years old. Instead of this old practice and rough-and-ready system of growing Sage I would recommend those who are desirous of obtaining the best results to treat it henceforth as an annual, and thereby ensure success as a certainty. Sow seed at once in pans filled with a compost consisting of finely sifted soil, leaf-mould, and sand, place them in a brisk heat, and when the young plants are large enough to handle prick them out in shallow boxes or in frames 2 inches or 3 inches apart each way. There they may remain till the end of April, and after being duly hardened off, planted out in the open ground in rows a foot apart, and the same distance plant from plant in the rows. Previous to planting, the ground should be dug and well manured with newly-collected horse droppings, and be raked over afterwards with a fine-toothed rake. Should the weather prove dry at the time of planting, give a good soaking of water through a rosed watering-pot, and at intervals subsequently till the young plants get established.

Nothing further is required except an occasional hoeing to keep down weeds. Towards the end of August, when the plants have attained their full size, the crop should be harvested, and may be cut either by scythe, sickle, or knife. After being thoroughly dried in the sun, tie the whole up in bunches and store them in some dry place. By adopting this mode of culture and growing sufficient plants to fill a bed from 12 yards to 20 yards long and 4 feet wide, a supply of Sage for nearly every day in the year may be had for a very large establishment. H.

Early Peas.—If the nomenclature of early kinds of Peas goes on in its present form, we shall soon be landed in inextricable perplexity. We have now First and Best, Earliest of the Early, Earliest of All, and Earlier than the Earliest, and we have but to wait a season or two and then there will be announced Earlier Still, Even Earlier, the Very Earliest, and so on *ad infinitum*, making confusion in Pea names worse confounded. Perhaps a protest against this sort of thing may prevent raisers from perpetrating further absurdities in this direction. "W. J. M." asks what is the best test of what constitutes an early Pea? The best answer is, "Grow the various kinds yourself under exactly similar conditions, and the earliest will soon be apparent." The exhibition of dishes of pods of various kinds at shows is entirely misleading when the dishes are grown in diverse localities and under diverse conditions, some, perhaps, being raised and fruited in pots, others in frames, others again raised in turf or in pots, and turned out to fruit on a warm border, and yet others sown on a warm border and needing no transplanting. The finest pods, or rather those best filled, would doubtless gain prizes, and yet may not be of such early sorts as others grown out in the open ground from the first. No fair test of the relative earliness of kinds of Peas can be had if sown too early, because some may suffer more or less from frost, or winds, or vermin. If sown now the surest test will be obtained. A good trial of Peas will again take place at Chiswick this year, when some definite information as regards earliness may be obtained.—A. D.

Live edgings best.—Where dead edgings are employed, both for wear and appearance I have found nothing better than the Staffordshire tiles, with a plain rolled top. They are hard, and therefore not liable to become broken by frost or a knock in digging or kicking against them, and they are not so conspicuous as the notched patterns, which will not bear rough usage. There is, however, to my mind, something objectionable in all dead edgings, and I should, therefore, advise all who use tiles to make the earth well up at the back, and plant there either Thrift, Gentians, Sedums, Sempervivums, Cerastium tomentosum, Violets, or other suitable plants that will partly or entirely hide them, and make long lines of beauty. Gentiana acaulis is lovely at this season, and there is no place where it looks more at home than by the side of garden walks; and a dead edging forms a capital support for it, as it likes moisture, and can drive its roots down the side of the tiles and find what it wants. Large pebble stones, however, or flints do nearly as well as the tiles, and in many places may be got for next to nothing; the former are found in gravelly soil, and the latter in chalk. The ground that suits Gentians best is that which is somewhat stiff and close, in which they flourish and flower in the greatest profusion. If old plants can be got, now is the time to set to work with them, as at this season they are just starting into growth, and may be divided by being pulled apart, and so increased to almost any extent. The quickest and best way of planting is to dibble the pieces in, and when doing so, the soil should be pressed close, and a good watering given immediately afterwards, so as to settle the soil about the roots, in order that they may get hold at once and have a fair start. If Violets are made use of, the Czar is the most suitable kind; it is a strong grower, carries plenty of foliage, and is one of the freest of bloomers.

Runners, dibbled in now, will soon make fine plants that will get together during the summer, and become crowded with flowers next spring. Thrift prefers light land; it is a native of the sea shore, where it is found growing freely in sand; *Armeria grandiflora*, a seedling from *A. maritima*, is the finest, but as yet plants of it are not over plentiful. *A. maritima* may be had cheap, and if the tufts are pulled apart, many pieces may be made and long rows formed in very quick time. Daisies also make pretty edgings, especially when the red and white are mixed, a blending of colours both chaste and effective.—S. D.

TOP HEATING.

SOME of your correspondents appear to be unable to realise the advantages derivable from the employment of hot-water pipes fixed near the roof in plant structures, but as more than one of our leading plant growers either have or intend to adopt this method of heating, we may feel assured that it has some advantages. I feel convinced that "roof pipes" are a step onwards, and that as time wears on they will be more or less generally adopted throughout this country. There is one point in connection with this system of warming plant houses which does not appear to have presented itself to those who have written against it, but which constitutes one of if not its greatest advantage. When, as must be the case in the ordinary way of heating, some of the pipes are taken round the house, and either lie upon the bed of soil which forms the stages, or, where these latter are built of open woodwork, are underneath them, a great portion of the plants are either in close proximity to them, or are so directly within the influence of the arid air engendered thereby, as to be banefully affected during periods of frosty weather when high pressure has to be resorted to. Mr. Warhurst, who is, however, careful to state that he is not a grower, evidently considers the open woodwork stage with the pipes under it all that can be desired, but I would direct his attention to the fact that whilst we often find it needful to dry the atmosphere, and consequently the foliage and flowers of plants in glasshouses, we do not wish to unnecessarily dry the roots, watering during the winter time being a necessary evil, and to be avoided as much as possible.

The woodwork stages once, indeed even now, so much in vogue are a hindrance to good culture and a snare for the inexperienced. What with the current of air under them by day and the heated air arising through them when the house is warmed, the soil in the pots dries so rapidly as to increase the labour of watering to an unnecessary extent, and it often happens that when fire is applied in the morning to dry up damp, the greater portion of the plants require to be watered in the course of the day, thus creating the very evil it is desired to prevent. Very often, too, when the firing is gently done the lowermost roots are quite dry whilst the surface soil is yet damp, and many plants are ruined from this cause alone. I remember, in earlier days, having the charge of watering a large house of *Pelargoniums* of the show type. Along the front of the house ran a wooden stage, and I was often puzzled to know which to water in winter when the flue was heated daily. I have often turned a plant out of the pot, and found the bottom roots far too dry when the surface soil gave no signs of there being any lack of moisture. In Mr. Cannell's houses this danger is cleverly avoided, as two 4-inch flows run up the house on each side of the path, and 1-inch or 2-inch returns fixed near the roof complete the arrangement. The plants stand on a cool ash or earth bed, and it is easy to see that the house may be quickly and efficiently heated, and yet not a single pot is brought into proximity with the pipes, which, moreover, do not in any way take up space which might be better occupied. For such plants as are to be in fine bloom in the darkest and dampest days of the year, the value of this system of heating must be great, as the warmth from the roof pipes quickly dissi-

pates condensed moisture, dries and warms the cold, damp air entering by the laps, and, radiating downwards, clears off stagnant moisture from flowers and foliage, creating a buoyant atmosphere around the plants, the roots the while remaining moist and cool. Surely this is the more natural way of heating plant houses, and one cannot but feel astonished when a correspondent writes that the placing of all the pipes at the bottom of the house is an imitation of Nature's method of creating warmth. Perhaps in the case of

Frames one can better appreciate the value of roof pipes, and "W. C. T.," who insinuates that Mr. Cannell preaches one thing and practises another, would find himself undeceived by a visit to Swanley, for there may be seen range after range of frames all heated by roof pipes alone, which in practice are found all sufficient to drive out damp and keep out frost, a fact which is fatal to Mr. Warhurst's theory that top heat alone will not suffice to create a buoyant atmosphere. Mr. Cannell's theory is—keep frost and damp out; do not allow the enemy to gain foothold. The fact is, one may just as well doubt the power of the sun to render our atmosphere light and wholesome as to suppose that pipes at the bottom of a glass structure are indispensable to effect a similar purpose. Facts are stubborn things, and they are here arranged in a fashion which must dispel many old ideas about heating and ventilating. With much of what Mr. Warhurst has to say upon this subject I agree, but I cannot follow him when he asserts that the roof pipes cannot be termed returns because they are fixed so high up in the house. Theoretically they may be regarded as an elongation of the flow, but practically they conduct the water back to the boiler, and are, therefore, to all intents and purposes return pipes. Mr. W. endeavours to clinch his argument by adding that the roof pipes must be hotter than those which lie at the bottom of the house, which is the same as saying that the point of a flow pipe farthest removed from the boiler is the hottest, a fact which, if true, is new to me, and which does not in the least accord with my experience. I fancy that Mr. Cannell's plant growers would tell us that the coolest portion of the piping was that part of the roof pipes nearest the boiler; but here I am open to conviction, and shall be pleased to hear all that may be said upon the subject. We have run so long in the old grooves in the matter of heating and ventilating, that with many it costs a pang to take a new departure; and although a vast amount of progress has been made in the last twenty years, a very great deal remains to be done, and I am pleased to see our horticultural builders and engineers discussing such matters in gardening papers, and in due time it may have for results that the badly heated, wrongly constructed, and unnecessarily expensive glasshouses which are so often seen in private gardens, and which are a sharp thorn in the gardener's side, will be things of the past. We have cheap glass and wood; all that we need now is that the heating and building shall be done in such a manner as to facilitate the labour of the grower.

J. CORNHILL.

WEATHER TRIALS AND TROUBLES.

WEATHER, the common subject of casual remark amongst all classes, relating as it does to personal comfort, health, and convenience, is to the gardener with a varied and extensive charge a consideration of almost vital importance in connection with the many delicate and dependent objects gathered from every country under the sun, and its severity and fluctuations a source of great anxiety and a tax on his skill and resources. The inopportune arrival of weather of unexampled severity early in March has, amongst other evil consequences, exposed shrubs prone to early excitement and plants employed in spring gardening to an amount of injury which will blight the promise of a display from some of the very early and interesting plants and shrubs which are of so much value in early spring decoration. The record of disaster often conveys a lesson and explains consequences that may accrue ultimately in garden affairs, and

therefore is worth making. Frosty weather commenced on the 4th, and on this and the following morning 5° of frost were registered. The wind N.W. and N. at these dates; on the 6th a bitterly cold and violent gale swept over the country, bringing showers of snow. The gale abated somewhat on the 7th, but was still severe with snow-storms. Frost was keen on the same night and 8° were registered; snow 3 inches in depth. On the morning of the 9th there were 12° of frost, on the 10th 22° or 9° Fahr., on the 11th 12°, 12th and 13th 7°, and the 14th 3° of frost. This is really a very painful story of the weather, and as far as my recollection extends perfectly unexampled in the month of March. Snow still lingers on the ground, and scarcely a day has passed without driving showers of sleet or snow, and it is not until this time of trial is over that we shall be able to recount all the evil effects of its severity. The early Rhododendrons (*dahuricum*, *præcox*, *superbiens*, *Nobleanum*) have had their blossoms entirely destroyed. The exposed blossoms of *Saxifraga ligulata* have been killed. *Forsythia suspensa* has had its beauty marred, and the beautiful *Myosotis dissitiflora*, fully in bloom in sheltered spots, shows only brown, drooping, and decaying heads of what were blossoms of brightest blue on the first three days of March. *Iris reticulata*, hardy as it is, has drooped its lovely heads of bloom, and the bright coloured Primroses have suffered a degree of cold beyond their power to bear. The lovely, but not less beautiful, flowers, *Saxifraga oppositifolia*, *Anemone blanda*, *Scilla sibirica*, and *Chionodoxa Lucillæ*, have successfully braved the blast, and *Erica carnea* appears uninjured. The full list of the maimed in this elemental battle has yet to be told; it is premature to speak with any degree of confidence, as the frost still holds the ground and snow covers the hills.

FLOWER GARDEN.

ST. BRIGID'S CHRISTMAS ROSE. (*HELLEBORUS NIGER ANGUSTIFOLIUS*.)

THE varieties of that old favourite in all good gardens, the Christmas Rose, are just a little perplexing. So far as we at present know their history seems unwritten, and traditional lore but too often lands us far out into the misty and chartless obscurity of times past. We may never know how or by whom all the many beautiful old Daffodils, Primroses, Pæonies, or Christmas Roses were originated, but one thing is left to us; we at any rate take the opportunity of collecting them together, and of watching their distinctive traits of habit and blossoming in our gardens of to-day. In this comparative observation among garden plants good work has already been done by Mr. Elwes and Mr. Baker, who both "considered the Lilies," and by Mr. Geo. Maw, whose "labour of love" among the Croci we are glad to know approaches completion. Then Mr. Peter Barr did much in clearing up the garden history of Daffodils, Irises; and last, but by no means least, I have with Mr. Moore devoted some thought to the species and varieties of *Helleborus*. We must remember, however, that the perplexities and interruptions of business too often interfere with thoughtful plant study, and so we must hope for Mr. Archer-Hind, the Rev. Mr. Wolley Dod, Mr. Brockbank, or other amateurs who love and cultivate all the known forms to give us a monograph on this interesting family. In speaking of the known forms or varieties of *H. niger*, Mr. Barr uses the following list of them as a synopsis or standard. I had written to Mr. Barr, sending him specimens of leafage and blossoms of a large pure white variety grown in a neighbouring garden, and which I have always spoken of as *H. niger angustifolius*, and the following is his reply. "I suppose your plant is *H. niger angustifolius* of Miss Hope and *H. niger intermedius* of the Aberdeen people, but I offer you my standard and you can judge which member of the family you possess: *H. niger*, well known; *H. n. minor*, dwarf, and pure white; *H. n. de Graaff*, pure white when first open, then a

pale primrose after; *H. n. intermedius*, flowers full face, not campanulate like the other members of the family, pure white; *H. n. maximus*, dull green, large foliage, dark, almost black, marbled stem, flowers large, and pinkish when fully exposed; *H. n. major*, a doubtful variety; *niger* with variegated foliage. I have all the foregoing except *de Graaff* var. I returned my specimen to the raiser, he having lost his stock." As this practical synopsis is likely to be of real service to many other growers besides myself, I am sure Mr. Barr will forgive my publishing it in THE GARDEN.

The idiosyncrasies of *Helleborus niger* are very perplexing. Here in our garden it rarely seeds

flowers and buds within an encircling whorl of its stout thick leaves. The present plant is quite different, and mainly (as has before been pointed out by "Veronica") in having no trace of red colouring either in stems, leaves, or flowers. I have a theory, founded on some years of close observation, that varieties of a species having a modicum of red colouring among their chlorophyll granules are hardier and more robust than those which are merely green. If this theory be a true one, red Celery and red-stalked Chinese Primroses ought to be stronger in habit, and so hardier than the pale-stalked varieties. On this principle *H. niger maximus* ought to be the most robust

Helleborus niger angustifolius.

naturally, and I never could find out the cause of its not doing so, for if we fertilise artificially by shaking a handful of cut flowers (just as the pollen bursts from the anthers) over the clumps in bloom, seed is produced in plenty. I believe in Miss Hope's garden (and am I not right in saying at Bitton also?) many kinds of *Helleborus* seeds grow up spontaneously, but I know for a certainty that in many other gardens seemingly as favourable they absolutely refuse to do so. It is the same with Daffodils, Snowdrops, Crocus, and Iris to my own knowledge, and doubtless with many other cultivated plants also. But to our present plant, I know how lovely *H. niger maximus* (*H. altifolius*) can be, having recently seen a plant at Straffan nigh upon a yard in diameter, and bearing fully two hundred open

and hardy of all Hellebores of the *H. niger* race, and this may account for its succeeding in some gardens better than our present plants and some other green-stalked kinds. I think I shall give in to Mr. Archer-Hind that *H. niger maximus* (or as some ever prefer to call it *H. altifolius*) is really and truly "king of all the Hellebores," but if this is true, I may, I think, fairly claim that St. Bridgid's variety is the queen of Christmas Roses. Mr. Brockbank told a friend of mine that it grew abundantly with him in the cold, wet Lancashire climate, and I understood him to say that Mr. Brockbank considered it if not the best at least one of the very finest of all the Christmas Roses he had seen or grown. Mr. Archer-Hind did not appear to know this variety until "Veronica's" notes called his attention to it, but if it

succeeds in South Devon as well as it does on the wind-swept hill of Howth, near Dublin, all I can say is that he will soon succumb to its snowdrift-like whiteness of blossom and its noble habit of leafage. The leaves of this variety are 5-9 lobed, and now quite fresh and dark green in colour, being borne on erect stalks. Here with me *H. niger maximus* has the leaf-stalks deflected near the ground level, and the leaves themselves are turning yellowish, as is their wont soon after the blossoms fade.

The annexed engraving gives a good idea of the flowers of the plant now under notice, although rather below the average natural size. As I first saw this variety in an Irish garden, and at once recognised it as a little known form by its noble port and leafage alone, and as I am now penning this account of it on this 17th day of March, the feast of St. Patrick, I have ventured (seeing that its real name in Latin is a matter of some doubt) to call it St. Bridgid's Christmas Rose (a name as pretty, I feel quite sure, and as accurate for its purpose as is that of St. Bruno's Lily) in memory of a remarkable woman of early times who did much to carry forward the good work St. Patrick himself had begun.

I may mention that the plant here has been seen by many cultivators of hardy plants, and I have sent flowers and leaves to friends and others interested, all of whom will, I am quite sure, be glad of a good popular name for this the queen of Christmas Roses. F. W. B.

THE TENBY DAFFODIL.

MR. BROCKBANK thinks I have sent him the wrong Daffodil as the Tenby Daffodil. Mr. Peter Barr, whom I consider the best living authority in the world on the varieties of Daffodil, is responsible for giving it the name of *obvallaris*, a name with which I know he is not quite satisfied, but I am responsible for the name "Tenby," by which I always call it and distribute it. The whole stock, now very large, in my garden has been obtained from three bulbs sent when in flower to me by post from Tenby by my sister about twenty years ago. She dug them up herself, and told me that there were three meadows full of them, and that she thought they seemed different from the common wild Daffodil. In the old series of Curtis's *Botanical Magazine* are several coloured drawings of *Narcissus*, made between seventy and ninety years ago. The characters and colouring are admirable, and the plants can all be identified at a glance. I know no representations equal to them, and it is much to be regretted that the author did not give us more of them. In Sowerby's "English Botany" it is described under the name of *N. Bromfieldi*, and it is said there that the same variety is found in the Isle of Wight, but I have never been able to trace it to or obtain bulbs from this habitat, and I should be grateful to any one who would help me to do so. The writer in Sowerby seems to think it identical with the *N. lobularis* of Haworth, but Mr. Peter Barr assigns this name to a variety of *N. minor*, with the mouth of the trumpet deeply cut into six prominent lobes, a variety which seems to correspond much better to the name. "Tenby" is marked by characters as distinct as any Daffodil I know, and I could easily pick out all the Tenbies from a thousand flowers of single yellow Daffodil.

Mr. Barr told me that until recently, when he introduced it, the variety was quite unknown in Dutch bulb gardens. I think Mr. Brockbank places too much faith in the older writers on Daffodils; but if he compares the names and descriptions of the single varieties, as given by Parkinson, Haworth, and Herbert, and adopted from them by other writers who took little or no trouble to verify them, he will find inconsistencies and variations which cannot be reconciled. What Parkinson says in his introduction to his Daffodils is true in these days. It is to the effect that "one catalogue calleth a species by one name, another by another, so that you may never know what they mean." Mr. Peter Barr has done more than anyone else to reduce these names to order; he found them in such hopeless confusion, as to present truly a *nodus deo*

vindice dignus, and he is quite aware that he has not entirely succeeded in clearing away the difficulties, which are greatly increased by the large number of garden hybrids and varieties yearly appearing. The whole subject wants handling by some central committee whose authority would be recognised. I enclose flowers of Tenby from my garden at Edge, where it came out by the dozen last week in spite of frost and snow.—C. WOLLEY DOD, *Llandudno*.

—Mr. Brockbank has opened up an interesting question, and one not at all likely to be settled in a satisfactory way unless some kind friend sends us veritable specimens from the Tenby district, where it seems to be abundantly naturalised. If we can obtain fresh flowers of the Tenby Daffodil direct from the Welsh locality, we can then soon decide as to whether it is *N. obvallaris* or not. I may as well point out that one observer ("W. D. F.," Isle of Wight) on the spot thought at the time that the Tenby Daffodil was *N. major*, and he writes as follows concerning it in the *Gardeners' Chronicle* for the year 1875, p. 471. This account is so full of interest, that I venture to quote it in full:—

"As you have of late been writing on the Daffodil, I enclose specimens of *Narcissus major*, which is commonly called 'the Daffodil' near Tenby. I do not think it is generally known that this species is abundant within a radius of some miles round Tenby, South Wales. Some years since I happened to be in that neighbourhood just as the plants were going out of flower, and was much struck by the metamorphosis of *Narcissus Pseudo-Narcissus* there. I brought some bulbs away, and was much pleased to find in the following spring that they were *Narcissus major*, a native of Spain, and a very great addition to my spring garden. They grow very luxuriantly on the road from Tenby to Penally in several places, and also beyond Penally on the Pembroke road, and (as I was informed by the late Archdeacon Clark) in several other distant localities, from which he kindly sent me specimens. As I was collecting bulbs from the first place and wondering in my mind how a Spanish plant got there, I caught sight of a very fine ruined round-tower chimney, peculiar to the neighbourhood of Tenby, and which are said to have been built by the Flemings, of whom a large colony lived formerly in and round Tenby, driven from their homes by the persecution of their Spanish masters on account of their religion. This seemed at once to account for these beds of *Narcissus major*. Flanders had so much intercourse with Spain, that nothing would be more natural than for this showy *Narcissus* to be a favourite with the Flemings; and it is equally natural that they should bring some of these easily carried bulbs with their penates to South Wales when they migrated. Probably I am telling an old story, well known to many, but I do so because I have never met with any who did so, and because all whom I met at Tenby thought that their plant was the *Narcissus Pseudo-Narcissus*, which I did not see there. The *Narcissus major* is a great addition to the spring flower garden, its golden flowers coming out very early and with great luxuriance. Everyone admires my Tenby clumps. It also lasts a long while; it has now been in beauty all this month, and will go on some weeks yet. I cannot understand the various opinions about *Narcissus Pseudo-Narcissus* becoming so frequently double; it has been a favourite in my garden for forty years, and I never saw the slightest tendency to its becoming so. We have acres of it in great beauty in many localities in this island, but the late Dr. Bromfield, who knew almost each individual plant in this island, says of this *Narcissus*, 'One solitary clump in St. Urian's Copse among thousands of the single kind, unquestionably wild, and perfectly similar to the double garden Daffodil.' 'Also a very double, but certainly wild specimen on a bank at Yaverland.' One would not have supposed that this pale flower would have produced a double one of the bright golden tint of our garden Daffodil. I have always supposed that the *Narcissus major* was the original of the garden Daffodil, and

I see Dr. Bromfield says further on, 'I cannot distinguish the wild double variety from the common great yellow Daffodil of the gardens, though that is supposed to be a different species—the *N. major* of *Botanical Magazine*, and a native of Spain.' My *Narcissus major* bulbs have a tendency to become double, and are of a very beautiful golden yellow, as one would suppose from the single one. I have never seen a locality for the common Daffodil that did not make one doubt its being brought there, and the same with *Narcissus biflorus* and poeticus. They all seem to grow round old abbeys, or where cottages have been. In this island our largest bed is St. Urian's Copse (now written in all our maps "Centurion's Copse"), where a church or chapel once stood, of which St. Urian was the head. All our other stations of it are suspicious, as I have observed, in all other parts of England where any of the three species of *Narcissus* grow."—F. W. B.

NARCISSUS TORTUOSUS.

THIS appears to be a rare Daffodil, as it is not offered either in Barr & Son's, or Ware's, or Backhouse's catalogues for 1882. I have fortunately met with a plentiful supply of it from an old garden where it has grown from the commencement of the present century. The descriptions in the handbooks of gardening fail to give a correct idea of the flower, leading one to expect it of a bicolor variety, whereas it comes of a pure greenish white, without a shade of difference between crown and perianth divisions. When grown under glass its flowers are of exquisite purity. I used a good many last week in a bride's bouquet with excellent effect associated with *Eucharis*, *Azaleas*, and other usual flowers of pure white, and of all these the white Daffodils were most admired. A single bulb produces two or three flowers, a pot of four having ten forming a most lovely table plant. The tube, or crown, is about one-third longer than the outer divisions of the perianth, and these are twisted, giving the flower a very jaunty appearance. The flower is carried firmly, without the excessively drooping habit which so spoils the other white Daffodils—*cernuus* and *moschatus*. Haworth's description is by far the best, and, freely translated, it is as follows:—"N. tortuosus, the great tortuous white Daffodil.—The divisions of the corolla twisted, sulphur white, much shorter than the crown, which is crenated and of citron colour, merging into white." In "Hardy Flowers" it is described as "crown lemon colour fading into sulphur-white, and that in other respects it does not differ much from *N. bicolor*," which is certainly an error. Burbidge only mentions it casually in his monograph of the *Narcissi* in the following paragraph: "Some forms introduced from Spain, about 1600, are nearly all white, or white with lemon or sulphur coloured cups. Haworth speaks of four kinds *N. cernuus*, *N. moschatus*, *N. tortuosus*, and *N. albicans*. They are, however, but slightly dissimilar, being simply pale flowered Continental forms of the common Daffodil." This might hold good of the other three, but it certainly does not fittingly describe *N. tortuosus*, which differs from all other Daffodils with which I am acquainted. It holds the same place in the whites which *N. obvallaris* holds in the golden section, coming earliest, and having the same shortened corolla, and sturdy habit, and in its own prettier way of equal beauty and value. When it becomes better known *N. tortuosus* will be one of the most popular of all the Daffodils.

Brockhurst, Didsbury. WM. BROCKBANK.

Gerarde and Parkinson (p. 222).—If Colonel Lockwood will refer to the volume on whose authority he questions the accuracy of Mr. Wolley Dod's assertion, that Gerarde's work preceded that of Parkinson, he will find that he has quoted not from Gerarde, but from Johnson: Chapter 86, comprehending the three species of Hoop Petticoat *Narcissus*, was written by Johnson, not by Gerarde, whose work does not contain any of them. As a matter of fact, Gerarde had been in his grave twenty-two years before the issue of

Parkinson's "Paradisus," and twenty-six years before Johnson's book was written. The date of Gerard's "Herbal" is 1597; of Parkinson's "Paradisus," 1629; of Thomas Johnson's "Gerarde," with additions of his own, 1633.—T. H. ARCHER-HIND, *South Devon*.

PLANTS IN FLOWER.

LACHENALIA NELSONI.—A spike of this extremely beautiful new hybrid variety raised by the late Mr. Nelson, of Aldborough, comes from Sir William Marriott, Down House, Blandford. The flowers differ from those of all other *Lachenalias* by their rich, warm yellow tint. They are about an inch long, and densely arranged on a spike about 5 inches or 6 inches in length, the whole flower-stem being about 9 inches high. When so well grown as this specimen is, this *Lachenalia* is as pretty a plant as one could wish for at this season of the year.

BIGNONIA UNGUIS, now profusely laden with blossom in the Palm house at Kew, is a beautiful and most desirable stove climbing plant, but not half known enough. It has tubular open-mouthed flowers, some $2\frac{1}{2}$ inches long, of a pale mauve, prettily veined and netted with purple. These are borne in clusters, and as they hang gracefully on the long slender shoots have a pretty effect. It is a rampant grower under ordinary stove treatment, and never fails to produce a good crop of bloom during early spring. It is also named at Kew *B. speciosa*.

BEGONIA VALIDA.—This, in Mr. Bull's nursery, Chelsea, is the prettiest of all the kinds now in flower, yet it does not seem to be much known. It is of dwarf growth, and has ample leaves deeply cleft into lobes. The flowers are a clear rosy pink, and though small are produced abundantly even on small plants, rendering them extremely attractive. It is of easy culture in a warm greenhouse, and may be always depended upon for producing a good supply of bloom at this season.

CLIANthus PUNICEUS.—Under the name of *C. magnificus* some uncommonly fine clusters of flowers have reached us from Mr. Wadds, Bird-sall Gardens, York. As a showy greenhouse climber for early spring it has but few equals, particularly when flowered so profusely as the plant is from which the specimens sent have been cut. The flowers in shape are somewhat like the claws of a lobster. They are bright crimson, and are produced in clusters from the lips of the branches. The pinnate foliage is elegant, and gives the plant a light, graceful appearance. It is a New Zealand plant, and though almost hardy against an open wall, it does not flower satisfactorily except in an airy greenhouse.

A GATHERING OF NARCISSI from Mr. Burbidge, of the Trinity College Botanic Garden, shows the richness of the collection there, and also the earliness of the Dublin climate compared with that of London. Amongst the kinds sent are some worthy of special note. The finest is *maximus*, the largest of all Daffodils. It is indeed a noble flower; its stem is upwards of 2 feet high and stout in proportion. The blossom itself does not differ materially from that of the major variety, figured so long ago as 1790, but perhaps it is a little larger. The divisions are broad and as long as the crown, the rim of which spreads widely, and is deeply lobed and crenulated. The colour of the crown is a rich warm yellow, and that of the divisions a shade or so brighter. What makes the flower so beautiful is the absence of any stiffness of any part thereof, a fault belonging to some of the finer Daffodils. With this noble variety alone one could have a fine bit of colour in the spring garden by growing a good clump of it as Mr. Burbidge does. It is a plant practically unknown in gardens generally, but after seeing it once who would not desire to possess it. The stiff-twisted glaucous foliage, as tall as the flower-stems, is a well-marked character of this variety. The Tenby Daffodil (*N. obvallaris*) is also sent in fine condition; likewise a handsome one which we consider to be the *Telemonius* variety, the single

form of the common double Daffodil in gardens. A smaller flower than this agrees with Haworth's *cambricus*, a superior form to our common *N. Pseudo-narcissus* both in size and colour. Mr. Burbidge has sent, we imagine, his first bloom of *N. Horsfieldi*, the handsome relative of *The Empress*, with white divisions and a rich golden crown. About London the flower-buds of this are as yet scarcely showing. We are surprised, too, to see *N. biflorus*, which is a late kind, but probably it comes from a warm corner. The flowers are good, being as fine as those of a Grand Monarque Polyanthus Narciss, but not so the varieties of *N. Tazetta* sent, which look as if they opened too early, and so caught the brunt of the late storm. The singular *N. eystettensis*, with its primrose-yellow rosettes and petals arranged one above the other so as to form a five-pointed star, is also in this collection.

STAUNTONIA LATIFOLIA.—Of this handsome greenhouse evergreen climber, some very fine flowering sprays have been sent to us by Mr. B. Wadds, Bird-sall Gardens, York, who grows it in a cool house trained to a pillar. The powerful and sweet odour of the flowers, which are borne in loose clusters from the leaf axils, amply compensates for their dull, livid purple tint. Even for its handsome evergreen foliage it is worth growing, and it is of easy culture if planted out in a bed of free soil in a greenhouse and kept clean. In some parts of the country it is almost hardy. Mr. Wadds adds that the flowers are much prized for vases, wreaths, &c., their sweet scent pervading the whole room in which they are placed.

HENFREYA SCANDENS.—This is one of those beautiful tropical plants that one seldom sees or hears of outside a botanical collection, though it possesses merit enough to rank as a beautiful stove plant for general culture. We have seen it in flower in one of the stoves at Kew for the past six weeks, a proof of its continuous flowering tendency. It is naturally of a climbing habit of growth, as its name implies, but it is grown admirably at Kew as dwarf bushes in pots to adorn the plant stages, and even when so small it bears a quantity of flowers. The large plant of it trained to a rafter is now bearing clusters of its pure white blossoms, which are 2 inches long and trumpet-shaped like those of a *Bignonia*. It is, in short, a desirable plant, and one that people ought to be able to obtain readily from nurseries. Being a native of Sierra Leone, it thrives best in a warm, moist stove. The species is the only one in the genus which commemorates the name of the late Professor Henfrey.

OPEN-AIR FLOWERS.—After such a stormy fortnight we scarcely expected such a boxful of flowers as that Mr. Burbidge sends us from the College Botanic Garden, Dublin. It contains amongst other things such little gems as *Iris reticulata*, *Sisyrinchium grandiflorum album*, *Chionodoxa Lucilia*, *Anemone apennina*, and the Chilean *Triteleia uniflora*, none of which look the worse for the taste of wintry weather to which they have been subjected. The garden *Anemones* are uncommonly fine, as are also *Primroses*, *Polyanthuses*, *Wallflowers*, *Hellebores*, and yellow and striped Dutch *Crocuses*. Among shrubs the bright little *Erica carnea* predominates, and the old double *Kerria japonica* has already begun to flower at Dublin as well as *Cydonia japonica*. A bright crimson Himalayan *Rhododendron* has seemingly done its best to flower, but its half-opened buds have been overtaken by frost. The finest contents of Mr. Burbidge's box, however, were the *Narcissi*, which he grows so well, and which are deserving of a separate note.

SPRING FLOWERS FROM GOREY.—A charming gathering of spring flowers from Miss Owen's richly stocked garden at Gorey are the freshest and finest we have yet received this season, and shows how favourable the east coast of Ireland is for open-air flowers. The list sent is a long one, but some of the most conspicuous are Dog's-tooth Violets, including the pale pink or nearly white variety, *Adonis vernalis*, *Anemone coronaria*, fulgens, the yellow *ranunculoides*, *apennina*, and *memorosa*, the latter with a stalk a foot or more

long. Among *Primulas* are the sweetly pretty *P. rosea*, with its bright carmine flowers; *P. denticulata*, *Polyanthuses*, and the double white and purple *Primroses*, both beautiful sorts. Among *Narcissi* are *N. moschatum*, minor, and the golden Tenby Daffodil (*N. obvallaris*), *Myosotis dissitiflora*, single and double *Periwinkles*, *Hellebores*, blue and white *Grape Hyacinths*, *Siberian Squill*, *Sisyrinchium grandiflorum*, *Erica carnea*, *Pulmonaria angustifolia*, *Chionodoxa Lucilia*, *Aubrietias* in variety, double white and crimson *Daisies*, double and single *Hepaticas*, and Dutch spring *Crocuses*. The handsome foliage of *Arum italicum*, the claret-purple leaves of *Anemones*, the young shoots of a large variegated leaved *Sedum* were also sent along with the flowers.

QUESTIONS.

Bleeding Walnut trees.—Can anyone tell me what will stop Walnut trees from bleeding?—G. C.

Rootery.—I have a number of old roots of trees, with which I should like to form a rootery. Will some of your readers kindly give me a few hints as to how to make it, and what plants to put on it?—BAGATELLE.

Time water.—Our main supply of water for the garden is drawn from a spring well, which has a large percentage of lime in it. Will some of your readers kindly say if it is fit for horticultural purposes? and, if not, how can it be made so?—MAC.

Shrubs for undergrowth.—Will some of your correspondents kindly give a list of shrubs for growing under trees in a peat soil which has too much lime in it to suit the common kinds of *Rhododendron*? and also the names of a few herbaceous plants suited to a lime and peat soil?—C. M. O.

Grass-destroying grubs.—I should feel much obliged if any of your readers could tell me the best way to get rid of a brown worm, or rather grub, that is eating away the roots of the Grass on a lawn. On turning up the soil the grubs are found at the roots of the Grass in great numbers. The soil is sandy, but the Grass is, as a rule, very green and good during the summer months. Any information as to how to get rid of the troublesome intruders will greatly oblige.—R.

Pruning Banksian Roses.—I find it difficult to prune a yellow Banksian Rose growing in a greenhouse, so as to ensure flowering. Can anyone give me a hint on the subject? Should it be left unpruned, or the weak shoots cleared out? Mine flowers well some seasons and not at all in others. If correspondents would only add to their often useful information in names and lists of plants the height above the sea or the climate in which the things mentioned grow it would indeed be a boon to those living in Scotland and cold parts of the east coast.—B.

Chrysanthemums out of doors.—Will any of your contributors kindly give those who have neither glass houses nor conservatories to help them a few hints as to the cultivation and management of *Chrysanthemums* out of doors in sheltered borders, and not in pots? For instance, what is the best soil? the names of some of the hardest sorts? whether one or all the shoots should be allowed to grow up? when and how to stop them, and at what height from the ground? whether the plants should be moved annually and divided, or allowed to grow on undisturbed for a season or two? with any other hints as to outdoor cultivation and propagation.—PRO BONO PUBLICO.

Room plants.—Will any readers of THE GARDEN who have had experience of what evergreen plants will thrive and grow all the year round in a drawing-room kindly give me a list of various sorts suitable for forming groups? I have had *Chamaecyparis humilis* for three years in one room where it has grown immensely, but the atmosphere is not moist enough for Ferns; and the winter before last, when fires were needed to keep the frost out at night, I lost all my Ferns. Will *Bambusa Metake* and *Aradia Sieboldi* flourish perpetually indoors? I should be very grateful for names of any tropical-looking plants that would be suitable.—WEST HIGHLANDS.

* * Our readers will greatly oblige by replying, so far as their knowledge and observation permit, to these questions. The title of each query answered should be prefixed to each answer, and replies will be printed in the department of the paper under which the subject falls. The questions that arise and must be solved are so many in these days, that it is only by a general interchange of ideas and experiences among practical men that we can hope to answer them satisfactorily.

FERNS.

ASPLENIUMS.

(Continued from p. 219.)

A. hemipterum.—A very elegant small growing evergreen species from Tropical America, and very well adapted for small hanging baskets. The fronds are produced in great abundance from a short, thin, erect stem. They are of almost horizontal growth, about 10 inches to 12 inches long, pinnate with pinnae deeply cut on the superior edge, whereas the inferior edge is quite smooth, as in *Lindsaya Lowi*, or in *Hymenophyllum pectinatum* and *Pteris semipinnata*. This peculiar form of the pinnae gives the plant a very striking appearance. It is of a pleasing light green, and its graceful fronds are prolific at their extremity, where they root freely. Stove.

A. laxum pumilum.—Although of unknown origin, this is most likely one of the many forms of the New Zealand *A. laxum*, which under cultivation varies very much. The present form, however, is one of the most handsome of the variations, inasmuch as the fronds, which are produced from a thick fleshy rhizome, are plentiful, and of a dark shining green colour; they are tripinnatifid, with pinnae as finely cut as in *A. fabianum*, but the most distinct character is the closeness of the crown, which is always well filled up with fronds falling outwardly and yet forming a most compact and symmetrical plant. Greenhouse.

A. longissimum.—This noble-growing pendulous species from Penang is the best adapted of all the Aspleniums for growing in a basket of large dimensions. Its beautiful pinnate fronds of a dark glossy green reach from 6 feet to 7 feet in length, and are produced in great abundance from a thick and slightly creeping rhizome, so that, being an evergreen species, the plant is well furnished at all seasons. The pinnae, which are sessile and alternate, deeply serrate and acuminate, are of a more leathery texture than those of most basket Ferns, and thus the duration of the fronds is greatly prolonged. Stove.

A. lucidum.—A fine, large free growing New Zealand species, whose fronds, of a very graceful habit and of a beautiful shining green colour, are produced in great quantities from a creeping scaly rhizome; they are pinnate, and, according to the treatment received and the allowance of room, vary from 2 feet to 4 feet in length, with pinnae large, oblong, and coriaceous. It is a most distinct species, which ought to be found in every collection if only on account of its special appearance when seen among other Ferns. Although doing very well in the mixture recommended for Aspleniums in general, it will be found of a brighter colour, and the fronds will also be more pendulous if potted or planted in a mixture of peat and sand only. Greenhouse.

A. monanthemum.—This, one of the prettiest of the small-growing evergreen Ferns, is found in great abundance in Madeira, South Africa, and even in temperate parts of America. The fronds, of a lively green colour, are erect, and borne on slender black, shining stalks; they grow to about a foot long and about an inch wide; they are pinnate, with pinnae so closely set as to be in some cases almost overlapping, and instead of being prolific at their extremity, as most Aspleniums are, they possess the peculiarity of producing young bulbils at the axils of the basal pair of pinnae only, being in that respect different from any other kind of Asplenium in cultivation. Greenhouse.

A. myriophyllum.—This very elegant Fern from Mexico might be described as a most gracefully cut form of *A. cicutarium*, which it resembles as to its mode of growth; but its fronds, of a darker green colour, are much more feathery and more graceful in outline, although produced in the same way from an upright, short stem. They are from 12 inches to 18 inches long, tripinnate, lanceolate, and prolific at their extremity; the numerous pinnules are very minute and closely set. This handsome plant can

hardly be described so as to do justice to its exquisite beauty. Stove.

A. Nidus (*Thamnopteris Nidus*, *Neottopteris Nidus*).—This East Indian interesting species, which is popularly known as the Bird's-nest Fern, from the remarkably peculiar manner of its growth, produces entire fronds about 30 inches in length and 4 inches in breadth, which rise up from the crown, leaving quite a hollow centre at their base, formed by the fronds of equal breadth throughout growing horizontally at first before taking up their upright course, thus leaving a large, open centre. This plant dislikes loam. Rough fibrous peat with chopped Sphagnum Moss suits it best, as it requires but very little soil, most of its nourishment being derived from aerial roots, which are produced freely on the surface if the atmosphere is kept in proper condition. Stove.

A. Nidus var. australasicum.—Although a native of New South Wales, this fine evergreen plant may possibly be only a variety of the preceding species, from which it differs greatly by its fronds being of larger dimensions altogether and of an elliptic lanceolate shape, instead of being of a uniform breadth. Besides the above characters there is one point essentially distinct; the fronds, instead of growing horizontally at first, are produced all round the rhizome and take an upright direction at the first start, so as to leave the crown elevated and exposed, thus making the hollow centre more funnel-shaped. Both this plant and the above species are wonderfully well adapted for vases, in which they make splendid objects. To do well this plant requires a mixture of fibrous peat and chopped Sphagnum only, like the preceding species and for the same reasons. Although requiring stove heat to grow and develop properly in during the best part of the year, *A. Nidus australasicum* will stand very well outdoors in the summer time if not exposed to the full sun. Great care should be taken to keep away slugs and woodlice, which are exceedingly fond of the young fronds; the best way to prevent these pests getting at the plants is by placing the latter over a pan of water on three inverted pots so as to prevent the bottom of the pot touching the water, but at the same time leaving a liquid barrier of 2 inches all round to keep off all intruders.

A. nobile.—A very handsome and most elegant species from New Guinea, with beautiful plumose fronds of a bright shining green, produced from a thick fleshy rhizome. They are quadri-pinnate, with pinnae narrow, but very symmetrically set along the rachis; they are when fully grown beautifully arched and attain a length of 16 inches, and their feathery appearance is rendered still more striking by the quantity of young plants which literally cover the upper surface of the mature fronds. As the first fronds of these young plants are very broad indeed, one may almost say the entire, the contrast is very effective. It is a very easy plant to grow. Stove.

A. Novæ-Caledoniæ.—As its name indicates, this evergreen species comes from New Caledonia, and is one of the most striking possessing as it does well marked characters. The fronds, produced from a thick, stout, fleshy rhizome, are remarkable for the leathery texture of their long narrow divisions, which are not much wider than the rachis to which they are attached. They are of a dark shining green and triangular in shape, sometimes reaching 15 inches in length; they are tripinnate with rigid segments of about half an inch long or more, distant from each other, and as the pinnules are also distant from the main rachis, the centre of the frond appears peculiarly open, while the long interlacing segments of the adjacent pinnae give quite a crowded appearance to the circumference. It requires a moist heat. Stove.

A. obtusatum.—A free growing New Zealand Fern perfectly evergreen. Its fronds, which are thick and fleshy, are produced from a creeping rhizome, and average about 10 inches in height; they are pinnately divided; pinnae obtuse, the surface of which is ornamented with bold and conspicuous sori. Although not altogether a deco-

rative plant when grown in pots, it is of a very distinct character, and as such is very valuable for planting in the rockery. Greenhouse.

A. palmatum (*A. Hemionitis*).—This very handsome and distinct evergreen dwarf-growing Fern, from Madeira and Teneriffe, must not be taken for the West Indian *Hemionitis palmata*, for although there is a great similarity in names, and a certain amount of confusion in regard to them, there does not exist the slightest analogy between the two subjects. The true *Asplenium palmatum* has fronds very distinct in shape and of a coriaceous texture; they rise from a creeping rhizome, and are from 5 inches to 8 inches high, of a light green colour, palmate in form, and cordate at the base. There is also a garden variety, named *A. palmatum cristatum*, in every respect resembling the former species with the addition of a large crest at the extremity of the frond. Greenhouse.

A. præmorsum.—This very remarkable Fern seems to be very widely distributed, as it has been found in the Mauritius, in Tropical Asia, and also in Madeira. From its good constitution, as well as on account of its general appearance, it is a general favourite, and well deserves the care bestowed upon it; its beautifully arching fronds, sometimes 3 feet long, are among the most decorative of those of all Aspleniums; they are produced from a slightly creeping rhizome, bipinnate in shape, with long erose pinnae, in some varieties much broader than others. The stalks and rachis are very scaly; besides being gracefully pendulous the fronds are of a rich dark green. Greenhouse.

A. rhizophorum.—A highly decorative pendulous species from Jamaica, remarkably well adapted for suspending from the roof in a basket of good dimensions. It is an evergreen species, with fronds light green in colour, almost triangular in shape, and whose extremity is lengthened out into a tail bearing a young plant on the end, which roots very freely when brought in contact with either the soil or the Moss of the basket; they are bipinnatifid, and of about 18 inches in length, exclusive of the tail-like process. Stove.

A. Sandersoni.—A charming dwarf-growing tufted evergreen species from Natal and of comparatively recent introduction. The fronds, which are prolific at their extremity, and bear a solitary prolific bud on each of the small peculiarly formed pinnae, are from 8 inches to 10 inches long, narrow linear in form, pinnate, with the rachis slightly winged; pinnae about half an inch long, shortly stalked, the posterior side straight or entire, curved backwards, the anterior side divided into a few blunt rounded teeth; they are also set obliquely and somewhat deflexed. The small size and well-marked forms of the pinnae give this Fern a very elegant aspect, and make it a very useful plant for baskets of small size. Stove.

A. Serra.—A very fine evergreen Brazilian Fern, undoubtedly the noblest growing species of this group. The fronds, which grow upwards of 2 feet in length, rise from a stout, creeping rhizome; they are dark green in colour, pinnate in form, and beautifully arched; pinnae large and deeply serrated on the margins; the sori linear, lying at an acute angle with the mid-rib. It is a highly ornamental Fern either for pot culture or for planting in the rock fernery. Stove.

A. viviparum.—This very distinct, well known, and elegant species is a native of the Mauritius. It is greatly admired on account of its fronds, which grow to about a foot in length, being very finely cut and of a beautiful dark glossy green colour; they are tripinnate, and their upper surface is densely covered with young plants, which should be pegged down up on the soil, where they will root very freely. It is one of the few Aspleniums which do best in a mixture of peat and sand without any addition of loam. Stove. PELLEA.

Oenothera eximia.—The Rev. Mr. Nelson, of Aldborough, gave me a few pieces of this Evening Primrose several years ago. They were planted in a light, loamy soil in a rather damp situation.

They grew and flowered most beautifully for two or three years, when they began to die away. I removed part of them to a very dry situation where the soil was light loam; here they also grew most beautifully. Some were planted in a damp situation in a mixed soil, in which they grew well for a year or two, but these last wet seasons have killed them completely in the last-named situation. My experience is that this Evening Primrose likes a dry situation with a sandy or chalky subsoil and light loam to grow in, and to be fresh planted at least every year or two. I consider it to be quite distinct from *taraxacifolia* and much more handsome. The flowers are longer and very sweet scented, their perfume in a summer evening being delightful.—E. SENDALL, *Thorpe Hamlet, Norwich*.

NOTES OF THE WEEK.

APPOINTMENTS FOR THE WEEK.

March 27.—South Kensington.—Committee Meetings and Spring Show of Royal Horticultural Society.

23.—Regent's Park.—Spring Show of Royal Botanic Society.

INTERNATIONAL EXHIBITION AT MARSEILLES.—We learn from the Science and Art Department that an international horticultural exhibition will take place at Marseilles on the 19th of May next.

GARDEN CHANGES.—We regret to hear that Mr. David Wilson, of Castle Hill, the noted Pine and fruit grower generally, is obliged to leave Devonshire and his much-esteemed employer on account of his wife's health. We feel sure such a good gardener will not be long out of a suitable situation.

—An address, writing cabinet, and a purse containing £10 were given by way of a testimonial to Mr. H. A. Mann on his removal from St. Vincent's, Grantham, to take charge of the gardens at Denton Hall, Grantham.

THE THAMES EMBANKMENT.—The Metropolitan Board of Works has deposited a petition in the Private Bill Office of the House of Commons, praying that the standing orders of the House may be dispensed with in order that a bill may be introduced for the repeal of the clauses under which the Metropolitan District Railway are empowered to erect ventilators on the Thames Embankment and other public thoroughfares.

A NEW ROSE AND PANSY society has this season been started at Hawick, at the first show of which numerous prizes, though small, are offered in both departments. It is to be held on July 12. Amongst the rules, we observe, it is stated that "All Pansy blooms must be shown upon green painted stands without paper. Any stand containing show Pansies under 1½ inches diameter or fancy blooms under 1½ inches diameter will be disqualified." Prize lists may be had of Mr. Turnbull, 51, High Street, Hawick.

PERNETTYA MUCRONATA.—A huge branch of this evergreen shrub literally smothered with purplish red berries about the size of Peas comes from Mr. Rawson's garden at Windermere, where evidently the *Pernettya* thrives to perfection, for we have seldom seen such a finely berried bush. We have frequently written in praise of this neat little shrub which ought to be in every country garden, for there is nothing among shrubs so ornamental when in berry during winter and spring. We should like to know on what soil the bush is growing from which Mr. Rawson's specimen was cut.

THE FUTURE OF ALEXANDRA PARK.—A notice was published the other day asking the people of Hornsey, Highgate, Finchley, Wood Green, and Tottenham to meet in conference to discuss the best means to adopt to preserve Alexandra Park from the invasion of the speculative builder. The agitation is being commenced owing to a bill that is being presented in Parliament by the London Financial Association for power to sell portions of the park for building purposes. The inhabitants complain that there is no public recreation ground

in the northern suburbs, and it is suggested whether the Government ought not to be appealed to to secure the Alexandra Park as a recreation ground for the people. The subject has occupied the attention of the Hornsey Local Board, but only a portion of the park is within their jurisdiction, and whilst they recognise the desirability of obtaining the beautiful grounds for a public park, they feel as a public body they cannot petition Parliament to throw out the bill.

SADLER TESTIMONIAL.—Some of the friends of the late Mr. John Sadler, curator, Botanic Garden, Edinburgh, have opened a subscription list with the view of providing some memorial to show the regard and esteem in which he was held. It has been resolved that this should take the form of a fund applicable to the maintenance of Mr. Sadler's widow and family of seven children who, in consequence of his sadly premature decease (at the age of forty-five), are left altogether inadequately provided for. Already nearly £200 have been subscribed, but further donations are greatly wanted. Post-office orders should be made payable to the treasurer, Dr. William Craig, 7, Lothian Road, Edinburgh.

THE LATE STORM.—The area over which the late snowstorm extended must have been very wide. The Riviera in parts seems to have suffered severely, and several gardens, as Cauneo, to be severely injured. In a letter from Algiers of March 13 the writer says: "Yesterday there was a fall of snow, and it was quite curious to see Palms and Bananas bending under the weight of it. Surprising to say, it has done no harm except to some *Geraniums*, which are broken. But the effect was very singular—a bright blue sky, a brilliant sun, snow on the ground, with *Maréchal Niel*, delicate *Roses*, and red *Geraniums* in full bloom." One thing is clear, not only are English gardens liable to the effect of sudden and unusual winter, but even those nestled on the shores of the Mediterranean or bathed in the sun of Africa.—BRINSLEY MARLAY.

SLAG SAND AND ITS USES.

THIS, for some purposes, I believe to be invaluable. Its colour is difficult to describe; perhaps I may call it a dirty grey. The granules have very sharp, irregular edges, are about the size of split Peas, and porous. This sand is light in weight. I induced a friend of mine to make an analysis of it, which is as follows: Silica, 31.00; alumina, 19.00; lime, 42.00; magnesia, protoxide of iron, and phosphoric acid a trace; sulphide of calcium, 3.00. We should say it consists chiefly of a double silicate of lime and alumina. I need not describe it further than to say that it is one of the products of the iron blast furnaces. Its cost is nominal. Obviously there is some nutrition in it for some plants, but whether or not in a very acceptable form I leave others to judge. A capital crop of Clover was produced last year in a yellow clay lightened with this sand. Neither grit nor sand approach it in keeping soils open. It disintegrates more quickly than Derbyshire spar, an advantage in more ways than one. We all vainly try to keep

Slugs at bay. Well, here is the antidote. I do not say it is slug-proof, but nearly so. As a fact, exposure breaks down the very sharp edges, but it is easy enough to give a fresh sprinkling once or twice during the slug season to the surface around the plants on which they feed. When a slug has been placed on the sand and begins to move, the slime acts as an adhesive in attracting the sand to its body. Moreover, sharp, gritty surfaces are inimicable to slugs. Last season not a plant on my rockery which had an environment of slag sand was molested by them. Worms are a desperate trouble among tiny plants, but they are few and far between in a mixture of soil and this sand. We rarely see them in soils charged with granite grit. Many alpine, North American, Himalayan, and other plants require protection from excessive evaporation during the summer months; for such, I think, this material is more suitable than pebbles, broken freestone, &c., but

I would prefer Fir leaves if I could get them. Rockery men quarrel about what is best for

Plunging purposes in the open and in frames. I am sorely against river sand, which becomes very sodden. Coal-ashes, too, have their drawbacks. Try slag sand. In cold frames it absorbs moisture, and thus is of much use in winter. It is perfectly clean and looks well. One can work amongst it more easily than in ashes. It is damp here, and the winds are probably more chilly than in any other part of England, so that whilst some Saxifrages and Primulas "went off" in ashes and river sand their comrades are all right in slag sand. My frames and open plunging beds are only small, as I am a beginner, and therefore I have so far abjured extremely difficult plants. The presence of worms in pots vexed me until I commenced to put a 1-inch layer of this sand over the Moss covering the drainage, thus keeping that right. Of course they were still in the pot, but a single dusting of soot washed in caused them to disappear. This is still the most satisfactory way I know. I discontinued growing

Orchids last year. It cannot be beatly spending much time in their culture, although pleasurable. Previous to so doing I grew for two seasons *Cattleya Loddigesii*, *C. Mendellii*, and *Laelia autumnalis* in slag sand covered with an inch of peat fibre. Orchidists may express surprise, but they grew wonderfully well in it. No roots appeared over and beyond the pots; the ends and sides of them were never gnawed by slugs and woodlice. I believe the advantage of the sand lies in its mechanical condition, for the degree of moisture could be regulated with the greatest nicety. Be as assiduous as one can, still the hygrometric state of the Orchid house cannot always be just right. The keystone of successful Orchid growing is healthy roots; anyhow this applies to most Orchids; and for a major portion of the year, when pots, particularly the perforated ones, are full of corks, it is impossible with a blazing sun to maintain the moisture at one point. Some will say the chemical properties of the sand will be inimical to Orchids. I reply when an Orchid root clings to a substance, that substance cannot be harmful to it, and I have seen *Cattleya* and *Laelia* roots dotted over with the sand (in presumable preference to the pot) which cannot be separated without breakage. We all know how tenaciously *Laelia* roots will adhere to pot and cork. I induced a small nurseryman to strike his autumn cuttings in soil mixed with one-fourth slag sand. He told me the other day he did not think he had lost a cutting from worms pulling them into the ground, slugs eating them off, and few from damp. Cost of railway carriage is the only thing that militates against its use. R. C.

"This is an Art

Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

WINTER COLOURING IN THE ALPINE GARDEN.

IT is interesting to observe the colour effect produced by a grouping of rather large patches of the dwarfest plants at the present season: just before the fresh spring growth begins. As bright green colouring is the rule in spring, so now, when they have only the natural foliage that has clothed them through the winter, many of these little plants appear to assume a colouring as far from positive green as their nature allows. In planting carpets of dwarf growths in the alpine garden (a nearly level space with only a few large stones partly rising out of the earth) no effort was made to avoid green, yet the present effect of the whole is a mass of rich red, purple-bronze, and deepest olive broken with mysterious greys and velvety gleams of golden olive, with jewels of brilliant colour flashing here and there in the mass of sombre richness. On looking closer these are some of the details: *Sedum Lydium*, bright bronze-red; *Gaultheria procumbens*, dull and bright crimson; various *Houseleeks*, deep bronzy red; varieties of *Phlox setacea*, deep greens heavily tinged with warm bronze; many of the mossy *Saxifrages*, bright red, but some of the larger-leaved, such as *Wallacei*, bright green; *Saxifraga muscoides* green beneath, but red-tinged above by the tips of the rising flower-shoots; *Androsace carnea*, some tufts dark green, some red, both with lovely rose-coloured flowers; *Phlox verna*, with cheerful sunny colouring, approaching red and yellow; *Acena microphylla*, hardly distinguishable from the bronzy Moss-covered ground; *Linnaea borealis*, deep dull red-bronze; *Thymus lanuginosus*, ashy grey with shadows inclining to purple; silvery *Saxifrages*, a greener grey, rosularis and some of the kinds near it tinged with a delicate pink like pink-madder; *Sedum glaucum*, bluish beneath with warm-tinged tips; *Antennaria tomentosa*, with foliage daily whitening; *Veronica saxatilis*, lapping round a large stone, deepest bronze-olive approaching black; groups of *Heaths*, all manner of deep red and green-bronze, and *Ledums* of rich golden-olives and crimsons; *Menziesias*, darkest purple-bronze, the white variety dark green. Where the ground shows in some parts of the garden it has a natural carpet of the short velvet-like Moss that grows in dry peaty soil, rusty in shade, golden in sunlight; it is carefully preserved, the surface of the ground never being disturbed in weeding, and adds greatly to the harmonious colouring of the whole.

This rich mass of "subdued splendour" is jewelled with bright points and patches. The bright rosy *Erica carnea* fringes a sombre mass of later-blooming *Heaths*; *Draba cuspidata*, sown in place, and therefore falling into little natural groups such as can never be purposely planted, shows off its bright closely-tufted lemon-coloured flowers to great advantage on the dark mossy earth. Close by is another sown group of some scores of *Draba boeotica*, soon to flower, but as yet only showing the pale yellow buds on its neat, darkest, red-bronze rosettes. *Scilla bifolia taurica* is a pool of brilliant blue on a carpet of pale green *Arenaria balearica*; stars of a still stronger blue, though of quite a different quality, are the first flowers of *Gentiana verna*. Thickly-flowered tufts of *Saxifraga oppositifolia* are beautiful against a wide, even carpet of *Spergula*. *Sisyrinchium grandiflorum*, white and purple, with graceful nodding flowers, rises in rush-like tufts towards the centre of the garden; the little arching stalk that joins the flower to the flower-stalk is so frail that one wonders the wind does not twist it off. The last flowers of *Iris reticulata* show well above a green ground of mossy *Saxifrage*. The effects of colouring were noted in strong sunlight,

G. J.
Surrey.

NARCISSI AND PSEUDO-NARCISSI.

So much interest is shown in this tribe that I need scarcely apologise for making a few remarks upon some specimens I send. 1. *Garden Daffodil* with full double flower. 2. *Garden Daffodil* with trumpet double. 3. *N. obvallaris*, perhaps with as much claim as *Telemonius* to be the single of the preceding. *Garden doubles* vary so much that their parentage is probably not always the same; they are as old as the time of Gerard, in fact named Gerard's *Narcissi*; he found the plant in Wiltshire growing in the garden of a poor old woman, in which place formerly a cunning man, as they vulgarly term him, had dwelt. That these should be the double of the Tenby Daffodil seems impossible. 4. The Tenby Daffodil (Mr. Wolley Dod's), of which Mr. Burbidge has given us the probable history, is evidently neither *obvallaris* nor *lobularis*, but seems to answer well to *Narcissus major* (var. *c. flore minore*), *Botanical Magazine*, 1301; not to *N. major* nor to *N. major b*, whose corolla is different. 5. Wild Devon Pseudo-Narcissus. Single. 6. Wild Devon Pseudo-Narcissus with trumpet only double. 7. The same full double; both doubles are scarce, but the full double much more so than the other. 8. A variety of wild Devon Pseudo-Narcissus, approaching the Tenby Narcissus in shape, but not in colour. 9. Capax, Queen Anne's Daffodil which after being lost for many years was recovered in an old cottage garden; such at any rate was the source from which mine came. "Veronica" speaks of the duplication of its perianth only, and certainly the regularity of the corolla segments is very striking; nothing is known of its single form, but we may conclude that it was a one-coloured species from the fact that the small central divisions of the trumpet present no contrast to those of the corolla. In Queen Anne's Jonquil (*N. odoratus fl.*), which is, I fancy, intended by Gerard's Pseudo-Narcissus luteus multiplex, and also in the common double Jonquil the trumpet appears to be not less obliterated than in Queen Anne's Daffodil.

South Devon.

J. H. ARCHER-HIND.

THE TENBY DAFFODIL.

MR. WOLLEY DOD tells us, firstly, that Mr. Peter Barr is responsible for the name *N. obvallaris*, and that he himself originated the popular name the "Tenby Daffodil" some twenty years ago on receiving a few bulbs of it from a meadow at Tenby. We could not have better authorities than these, and I at once acknowledged the name bestowed upon this favourite Daffodil by so worthy a godfather, and shall adopt it in future as our reverend friend's own Tenby Daffodil. Never mind if Haworth fifty years ago confirmed and corrected a previous writer, in the same name, as belonging to *N. lobularis*, "which grows wild near Tenby." Nobody cares for *lobularis*, and as the name thus appropriated to it has become obsolete, let it so remain, and let it belong instead in all the future to Mr. Dod's Daffodil. The interesting quotation given by "F. W. B." may well apply to this Daffodil, which in all probability was brought originally from Spain. I would, however, rather attribute its introduction directly to the Spaniards and not by them through the Flemings, who are stated to have settled at Gower in the reign of Henry I., at which date there were no Spaniards in Flanders. There is a popular belief that one of the ships of the unfortunate Spanish Armada was wrecked off the Welsh coast, and I have heard it stated that the traces of Spanish blood are to be seen in the inhabitants of the peninsula of Gower, which is only across Carmarthen Bay from Tenby. There are traditions of Orange trees which were imported into the peninsula of Gower by Spaniards who had settled there, and who brought over from Spain their garden favourites, and why not Daffodils? This is the most probable solution of the question, and possibly some of your antiquarian readers may follow up the clue and throw some light upon it. Certain it is that in the reign of Queen Elizabeth Daffodils became popular in England, and they were called originally Spanish Daffodils, and probably enough the Tenby Daffodil was one of these.

Two years ago the subject of self and bicolor Narcissi was introduced by me in your columns, and led to a pretty warm discussion with Mr. Burbidge, who maintained that all Daffodils were bicolor. The matter was summed up by Mr. Burbidge in THE GARDEN for July 16, 1881 (p. 57) when he offered a copper kettle to whoever first sent him a Daffodil in which the perianth segments and the crown should be of exactly the same tint of yellow. Now the Tenby Daffodil is in my opinion a self, and especially when flowered under glass its colours in the crown and in the perianth division are precisely the same. I therefore sent to Mr. Burbidge on the 16th instant a Tenby Daffodil bloom which fulfilled his conditions, and claimed the kettle accordingly. Two similar flowers were sent to the editor of THE GARDEN, and before sending these away they were judged by very competent parties here, and it was held that viewed from the stalk, so that transmitted light and shadow did not come into play, the shades of yellow were the same, and the flowers were true selfs. Mr. Burbidge could not deny this, but he claims a much more crucial test, which I demur to, as "twas not in the bond." He says, take scissors and cut a piece half-an-inch square out of one of the perianth segments, and a similar piece from the crown; lay them in a strong light upon purple silk, and then judge if they are precisely of the same shade. Of course they will not, because the crown is thicker in substance than the outer segments, and the shades must vary accordingly. However, I have not got my kettle, and this is the plea. I hold that there are self Daffodils, and that the Tenby is one of them, especially if grown under glass, when its colour is of the richest and deepest golden.

Brockhurst, Didsbury. WM. BROCKBANK.

Narcissus monophyllus.—"Veronica" must be relieved from responsibility for the statement (p. 130) that the name cantabrica had reference to Cambridge, or for the erroneous use of "Gerard" in the same paragraph, as the whole matter—including the quotation from Mrs. Loudon—is found in Mr. Burbidge's work on the Narcissus (p. 22). Did Mr. Burbidge take Mrs. Loudon's authority for the whole? It seems likely since the reference to "Gerard" in Mr. Burbidge's paragraph is also incorrect, i.e., p. 34, fig. 5. There is nothing on the subject in either edition of "Gerard" on p. 34, but on p. 134 of Johnson's "Gerard," fig. 5, there is figured and described (by Johnson) Pseudo-Narcissus albo flore in the same chapter, and a few lines preceding the reference to Master Nicolas Belson. Now neither "Veronica" nor Mr. Burbidge could confound a white variety of *N. Pseudo-Narcissus* with *N. monophyllus*. As has been pointed out in your pages, if *N. monophyllus* is figured by Johnson, it is figured as *N. omnium minus montanus albus*, and this on p. 137, fig. 8. Who first used cantabrica as the specific name of this Narcissus?—RHO.

THE CHRISTMAS ROSE.

(HELLEBORUS NIGER ANGUSTIFOLIUS.)

WILL you allow me space to protest against "F. W. B.'s" proposal to call this beautiful Christmas Rose after the name of a saint. I, for one, see no fitness whatever, and neither charm nor beauty in the proposed name of Saint Bridgid's Christmas Rose, and most certainly I shall never associate the flower with such a long-winded and far-fetched appellation. There is no reason whatever for it beyond the fact of a few plants of it growing on the Hill of Howth, and "F. W. B." has no right whatever to christen it that I can see. We must give Miss Hope the credit of first bringing this variety before this generation of florists. Even if it be Mr. Barr's *H. intermedius*, he tells us he had it from Aberdeen. I trust it may simply retain its own name, "The Christmas Rose." Its greater rival, *H. niger maximus*, is the great Hellebore. It is not a true Christmas Rose. It flowers in October, and is over by Christmas; whereas the true Christmas Rose (*H. niger angustifolius*)

tifolius) comes with the holidays, and adorns all our Christmas festivals and feasts. I do hope, therefore, that we shall not adopt "F. W. B.'s" suggestion, but adopt the simpler title of the Christmas Rose for our favourite.

WILLIAM BROCKBANK.

Brockhurst, Didsbury.

[We consider the best name for *H. niger* maximus to be *H. altifolius*, a name given long ago by Heyne, and its popular name should be the Great Christmas Rose, inasmuch as it flowers in many localities at Christmas time. Our correspondent has, we think, misapprehended "F. W. B." The name *St. Bridgid's* Christmas Rose is applied on account of its having been found in an Irish garden, the owner of which writes under the *nom de plume* of *St. Bridgid*.]

St. Bridgid's Christmas Rose.—I am very pleased indeed to see this plant brought into notice so prominently, although but scant justice is done in the illustration to its unsurpassable merits. Some blooms I saw about Christmas time with Mr. Burbidge were very much larger than those shown in the woodcut. I was impressed at the time that they were by far the finest hardy winter flowers I had ever seen, and their large size, fine form, and snowy whiteness have haunted me ever since; moreover, the new name it receives is the first occasion on which I have ever had an inclination to even lean towards an English name. This is a good one; the Latin one is bad, and not at all characteristic of the plant, which is entirely distinct in various ways from all forms of *H. niger*; the erect compact mass of noble foliage entirely hides the blossoms not alone from cruel storms and from dust and dirt, but from the gaze of all who will not stoop and push the leaves aside, a characteristic of the plant which ought to have been recognised at the christening.—T. SMITH, *Newry*.

QUESTIONS

Kæmpferia Roscoeana.—How am I to manage this pretty little plant so as to get a good specimen of it? It starts well into growth, but never fails to damp off after making a couple of leaves. Do I keep it too wet and warm?—H. H. C.

Iris Kæmpferi.—Will some of your readers kindly inform me of the best way to rear purchased roots of this choice kind of Iris? What is the best time for planting, what soil, and if they require much moisture whilst "settling"?—W. T.

Space for Vine roots.—I have sunk a pit in the chalk and put in hot-water pipes. I want to put in some Vines; what sized pits must I dig out in the chalk to take soil enough for the Vine roots? In other words, the bottom drainage being good, what number of cubic feet of soil is necessary for Vine roots to ensure a vigorous growth of the canes?—W. E. M.

Single-handed lawn mowers.—Will some practical persons give us the benefit of their experience as regards these handy little machines? My own experience is that two men, each using a 14-inch "Archimedean" or "Climax" will do as much as three men (two pulling and one guiding) with a 28-inch machine; and further, the two men do their work with comparative ease. All the small (14-inch) machines, however, have not reversible cutters (i.e., cylinders on which the knives are fixed), so that they are not self-sharpening, as are the larger kinds. This drawback may be remedied to some extent, however, with a good file or knife sharpener of American manufacture. Wanting just now to purchase a couple of new 14-inch machines, I am anxious to hear of the most approved kind from a *bona-fide* observer.—J. D. B.

Tar varnish.—My gardener, having unfortunately blacked some hot-water pipes in a conservatory with some black varnish obtained from a neighbouring ironmonger, and said to be harmless, finds to his chagrin that the scent arising from it kills the blossom of everything that is put into the place, and Azaleas, Camellias, Roses, and such like, after being in a day or two, present a withered, or rather scorched, appearance and drop off. The scent is as of creosote or some preparation of tar, and the ironmonger calls it tar varnish. Can any of your readers tell me how to get it off or kill it? We have tried soft soap and soda, oil and grease, and have scoured it with sand, &c., but all to no avail. I should be glad of any suggestion or advice.—SUBSCRIBER.

FRUIT GARDEN.

HYBRIDISING VINES.

THOSE of your readers who have read my remarks on this subject in "Vines and Vine Culture" do not require to be told that "Grower" (p. 259 of THE GARDEN) has deliberately misrepresented what I have there stated. It would be scarcely necessary to reply to it further were it not for the prominence given to the article in THE GARDEN which lends to it a certain importance which it would not otherwise possess. To fair criticism I have no objection. "Grower," after fortifying himself with the reflection that he has never read or been told before that Grapes usually reproduce themselves from seed, goes on to state that he has reproduced Mr. Barron's full statement, although actually using the marks thus (. . .) to show that something is omitted, that something being the qualifying sentence, and other words are put into my mouth which I never used, as when he speaks of Venn's Muscat and Bowood Muscat reverting to the original type, and white berried seedlings turning black, an idea that I should think never entered any other head but that of "Grower." It is a useless and a hopeless task, however, to point out all the mis-statements and misrepresentations that are contained in "Grower's" letter. Let the following suffice. In "Vines and Vine Culture" the *modus operandi* of preparing the flower of a Grape Vine for the purposes of hybridisation or cross-fertilisation so as to make certain that you are attaining your purpose is minutely described, and this preparation is stated to be "rather a ticklish operation, requiring the greatest care and patience, all the parts being so small and difficult to get at." "Grower" very cunningly alters this to "he (Mr. B.) states that cross-fertilisation is a ticklish operation," which is a deliberate misrepresentation. I state nothing of the sort. Every intelligent grower knows that cross-fertilisation may and often does take place by natural agencies, and is the work of an instant. Many Grapes are probably cross-fertilised without our knowledge. "Grower" does not consider in hybridising Grapes that any precaution is required against this, or any care in securing the result aimed at. He prefers the haphazard system of "suspending or shaking a bunch of another variety over the bunch to be fertilised." This is a mode of setting certain Grapes recommended in "Vines and Vine Culture," and the berries are most likely cross-fertilised. That certain Grapes were so produced may be perfectly true; but there is no security that a certain cross has been effected, or what is the true parentage of any Grape raised in this slipshod manner.

"Grower" is certainly less well informed than we would be inclined to have given him credit for when he states that he cannot remember any variety reproducing itself except the Black Hamburgh. What of Venn's Muscat and Bowood Muscat cited as "reverting"? What of Josling's St. Albans, Cranford Muscat, Horsforth's Seedling, the Abercainey Seedling, &c., and scores of others we have seen, many of which never lived to get a reputation? "Grower" may perhaps answer that none of these originated with him; but still they are evidences that Grapes do reproduce themselves from seed. "Grower" deserves credit for the adroit manner in which he makes quotations to suit his purpose and the ingenious way in which they are manipulated.

A. F. BARRON

Early Strawberries.—There was quite a handsome sight of these to be seen on the 3rd of this month at Cuerden Hall, near Preston, the seat of Mr. T. Townley Parker. They stood in a row in the Pine stove, 63 feet long. The colouring of the fruit was excellent. The sorts, I was informed by Mr. Roberts, the gardener, were Keen's Seedling, Vicomtesse Héricart de Thury, and La Grosse. The largest fruit was borne by the last named, some of which measured $4\frac{1}{2}$ inches in circumference: each pot had from eight to a dozen fruits.—COR.

Cropping fruit tree borders.—The annual cropping of fruit tree borders with vegetables is a great evil, and some of the diseases of wall trees are due to this cause. Not only is the nutrient taken out of the border, but the spade drives the roots down beyond the reach of solar warmth, which is so essential to the proper ripening of the wood. Moreover, all fruit trees thrive and bear best in a firm soil (I do not mean an unworked soil), and especially is this firmness necessary for the Peach and the Apricot. If the whole border cannot be given up to the trees, at least 5 feet running along the back should be left uncropped, and, beyond surface culture, undug.—E. HOBDAY.

INDOOR GARDEN.

CONSERVATORIES AS THEY SHOULD BE.

HIGH as the present state of gardening undoubtedly is in this country, it cannot surely be said that much, if any, real progress has been made as regards the arrangement of our conservatories, though a subject, it must be admitted, of great importance. When we consider how few are the examples of correct taste in this matter, and how abundant the examples of what plant houses should not be, we see at a glance how deplorably behindhand we are in a matter that is really one of the cardinal points of true gardening. What is meant by a picturesque arrangement of plants is more clearly explained by the accompanying illustration than by words. Contrast such an arrangement with that to be seen in conservatories of the ordinary stamp and their inferiority as regards tasteful arrangement will be at once apparent. In the one every plant is effective, and in the whole the expression of beauty is unique both as regards colour and form. In the other we have ugly stages and still uglier pots and tubs to contend with, rendering the very name of greenhouse a misnomer; and, moreover, plants seldom develop themselves so freely and fully when their roots are restricted as when planted out. There is no reason whatever why every greenhouse, or rather conservatory, in the country should not present such a charming appearance as that represented in the annexed engraving, but in order to effect such an arrangement there must be a radical change from the old stage-and-pot system of culture. Some seem to misapprehend the meaning and character of naturally arranged conservatories. They are under the impression that such houses must necessarily be monotonous in appearance. They think that such an arrangement excludes gay spring and other greenhouse flowering plants such as usually enliven the stages of ordinary houses. But that is a mistake. In a properly arranged conservatory, such as that here represented, there should be places set apart where groups of flowers in pots could be placed at convenient distances from the eye so as to be fully enjoyed. And how much more beautiful do masses of bright flowers appear when their pots are hid from view, and their surroundings the greenery of fine foliaged plants. Under such an arrangement they could be exchanged for others just as in the case of plants on an ordinary stage. In order to maintain a bright display there should of course be supplementary, or what may be termed growing, houses from which seasonable flowering plants could be brought to the conservatory when required. It is a pity that examples of naturally planted conservatories are not more frequent in our large public and private gardens. If good examples existed in these of properly arranged conservatories they would have much influence for good among smaller gardens, and if the natural style were more practised there would be a use for hosts of plants which, under the pot system, do not find a place, simply because they are unfitted for it. A glance through the houses at Kew reveals a wealth of plant life unknown in private gardens, but which could be readily obtained if there was a demand. Aroids, Ferns, Marantads are particularly valuable for the purpose, and a long list could easily be furnished of suitable subjects. W. G.

TOP-HEATING.

THE system of top-heating at Swanley has been so misrepresented, as Mr. Cannell, jun., says, that it is difficult for one who has not actually seen the houses to speak at all correctly about them. I have proposed seeing for myself, but am not able to do so before writing, being anxious to remove at once a wrong impression given by Mr. Cornhill (p. 275), quite unintentionally, as to what he is pleased to call my theory. I have not said that "top-heat alone will not create a buoyant atmosphere," but that if all the heating pipes were above

the plants raised on a stage, then the lower cold air would be drawn across the foliage from lower inlets (such as doors) by the very buoyancy created above, and so the plants would suffer. From the corrected accounts now given of the position of the pipes, it seems there is very little difference between the arrangement there and one that was often carried out years ago by my late firm of putting one pipe above the open stage next the wall and one or two below, or near the path if a bed was used instead of stages, and which is and was regularly carried out in pit frames. As to stages, too, I must disclaim a recommendation of the common practice of using 2-inch laths and 1-inch spaces between. With such stages the bottom soil must get dried up, as the holes of the pots are right over the spaces between laths, and so the lower roots get all the dry heat while the tops are steaming with the escaping moisture, causing, as Mr. Cannell says, "more injury to horticulture than all other erroneous notions put together that have from time to time been published." The open stages, in my mind, were boards 5 inches to 9 inches wide with half-inch spaces, so that the heat can percolate through the leaves while the

tops of boards are moist under the pots. The faults of most plant houses are narrow laths, large spaces, and pipes close down to the damp earth below, which most people will have in preference to using concrete slabs 3 feet by 2 feet on iron bearers with (or without) small spaces between, and a 2-inch space next the outer wall for heat to rise through. One great advantage of solid beds at the sides (as advised by Sir Joseph Paxton) to stand plants on is (irrespective of cheapness) that there is 20 per cent. less cubical contents than with stages, and as there is nothing to absorb the heat but the plants and soil, some spare moist heat can be allowed to escape above and keep up a better circulation of the internal air.

Whether the top pipe is called a flow or return does not much matter; the question is whether it is a hot or a cool pipe. If it is not hot, it will have no effect on the plants or the necessary movement of the warm dry air and might as well be omitted. If it is hot (which is admitted) it will be found in practice to be as hot in the middle of its length as the bottom pipes at the same point. The far end of an ordinary flow is always cooler than its commencement, but when everything is in full swing, say at midnight, the iron pipes hot, the air warm, and the fire at its fiercest, the difference in tem-

Put three 2-inch pipes below for flows, and one 4-inch as an upper rising return, and the difficulty in getting up heat in 200 feet long houses will be immense as a rule, and yet there is only the same heat-radiating surface and less water to heat.

Because the sun gives heat from above it does not follow that hot-water pipes act similarly, and yet this would seem to be implied in some remarks that have been made. To test the so-called radiation from a hot-water pipe, the following figures are taken as I write. The room is at 49° only near the centre, the iron about 140°; at three

inches below the pipe the thermometer will not rise above 47°, or 1° above the floor temperature; at 2 feet away on the same level as the pipe it is 49°, while at 6 inches above the pipe the thermometer rises to 80° in a few minutes. What, then, is the value of the heat radiating downwards? What takes place in these houses is something like this: The air is set in motion as the pipes become hot; from the path it rolls up the pit walls and is drawn across the surface of the soil towards the new current created at the side by the upper pipe, after which it rises along the roof, partially escaping, and being there cooled and mixed with cold air entering by some of the laps, falls down again in the centre to take the place of hot air rising from the large heated surface of bottom pipes. This movement is varied somewhat according to pressure of external air. The heat radiated from the bottom pipes into the pit walls also warms the earth slightly on which the pots are standing. Mr. Cannell's theory is mine too as to keeping out frost and damp, but air must come in somewhere to replace that continually escaping; the question all of us should ask ourselves, therefore, is how best to take off its rawness, and

A naturally arranged conservatory.

perature between the two pipes will be inappreciable, if it should not happen that the top one is the hottest. The quantity of water in top 2-inch pipe being only one-sixteenth that contained in two lower 4-inch pipes, it follows that only the hottest or lightest water ascends into it and back to the boiler as an ordinary return, the heavier cooler water in the 4-inch flow falling into the lowermost pipe and converting it into a return pipe back to its junction near the boiler, where it partially mixes with the freshly heated water and re-circulates in the flow. This may seem incomprehensible, but one 4-inch pipe can itself be made to act as both flow and return if divided at each end, the hot water along the top surface and cooler water below.

I admit that his system is about the best with his long and narrow houses protecting one another by their juxtaposition. With an isolated house of another construction, 20 feet by 15 feet, such an arrangement would not answer well. For many years I have been fighting against the "grooves" that Mr. Cornhill wishes to see a thing of the past, both in building and heating, but gardeners themselves are often against me by running out of one groove into another. Four years ago in a large lean-to greenhouse I wished to place two pipes near the front and two at the back of the path, but the gardener insisted on two close to the back wall and two at the path 5 feet from the front. The following severe winter the gentleman sent for me, as

the plants on the front stage were killed by frost, though the registered minimum in the centre was 45°; the pipes were then altered to my first proposal, after which the average temperature increased because frost could not enter. It is possible that Mr. Cannell's experience some years ago as a hot-water engineer has served him well in his present houses. B. W. WARHURST.

FORCED FORGET-ME-NOTS.

I NOTE (p. 224) "J. S. W.'s" remarks on forcing Forget-me-nots in a cool greenhouse. When so grown they are very useful for conservatory or house decoration at this season of the year, when blue flowers are not over plentiful. The way in which I have found them to succeed best is as follows: We employ considerable numbers of *M. dissitiflora* in our spring beds. After they have finished blooming, say in May, they are taken up to make room for summer-flowering plants, and are laid in on a west border, where from the base of the plants they produce a quantity of cuttings. These are taken off and inserted in a cold frame any time during August, and if kept moist and shaded they soon make roots. When well rooted we pot them in whatever sized pot is most suitable for the purpose for which they are intended, say 4-inch ones, and return them to the cold frame until they have made fresh roots; after that they are set out-of-doors on an open piece of ground, where they grow strong and hardy. If housed early in October in a cool greenhouse they commence to bloom early in February, and continue to do so for about three months.—E. MOLYNEUX, *Swanmore Park, Bishop's Waltham.*

—I send you flowers of Forget-me-not (*Myosotis dissitiflora*) gathered from plants growing in a greenhouse. Early in November we potted up into 6-inch pots about three dozen plants from the open border, placed them for a few weeks in a cool frame, and then removed them to the greenhouse, where they soon began to flower, and for the last six weeks they have been one mass of bloom. Anyone wishing to have their greenhouse gay with this pretty *Myosotis* can do so with very little trouble.—J. FIELD, *Stanley Hall, Bridge-north.*

BEDS IN A SPAN-ROOFED STOVE.

IN a narrow 12-feet wide house like that described by "W. K.," p. 256, I should not advise the formation of beds such as he speaks of, but a simple flat stage on each side the path running down the centre. The thin stone slabs he mentions are just as good as slate; if they can be had from 2 inches to 2½ inches thick, it will be ample. They should rest on light flat bars of iron, with one end let into the side walls of the house, the other supported on 9-inch brick piers next the path. This will admit of the flags being kept an inch or two away from the wall, so as to allow a cavity for some heat to rise up next the glass, without which in severe weather the plants are liable to be too cold. Presuming that the house is built with side lights from 2 feet to 2½ feet in depth, the slabs should be fixed so that the upper surface will be about 3 inches below the bottom of the wall plate; if there are no side lights, but simply a roof resting on the side walls, then, as a matter of course, the stage must be lower to allow head room for the plants. Strips of flat iron should be fixed lengthways back and front of the stages, standing an inch or two above the surface so as to hold some moisture-holding material for the pots to stand on, such as sand or finely sifted coal ashes, which are of great assistance to the plants through the moisture they give off to them, correcting the otherwise over-dry condition of the air immediately in contact with them. This damp standing medium is not only conducive to free growth, but it does much to discourage such insects as red spider and thrips by the moisture that it throws off to the underside of the leaves. The hot-water pipes will, of course, run under the stage on each side, resting on the floor. This arrangement will be found better and more economical than enclosing any portion of them within a

continuous wall, either covered with gravel or with the slabs above them, so as to form the bed in the way "W. K." speaks of. If a propagating bed is wanted, it is only necessary to put additional material sufficient to plunge the striking pots in on the required space at the warmest end of the house, either enclosing this with a glazed frame, or the more simple means of covering the cuttings with propagating glasses. T. B.

Mignonette.—I noticed the other day some good samples of this universal favourite at Cuerden Hall, near Preston. They were natural shaped bushes from 2 feet to 3 feet high, and the same in width, furnished with foliage to the pot. The flower-spikes were remarkably fine. Such plants are seldom seen in the north of England. We have, however, read of them sometimes being exhibited in London.—COR.

Candollea cuneiformis (X. Y. Z.).—This may be struck from cuttings in the same way as the *Rondeletia*, but as it is a greenhouse plant the cuttings will of course require correspondingly less heat, nor will they produce roots quite so readily as the *Rondeletia*. When the cuttings stand without rooting in a greenhouse temperature, or, better still, in one a few degrees higher, if callused shift them into the stove, which will at once induce the formation of roots, but if good cuttings are obtained they strike readily enough as a rule to render such a change unnecessary.—T.

Viburnum odoratissimum in fruit.—A plant of this, about a foot high, in the temperate house at Kew, is bearing a number of small, but highly coloured berries. They are arranged in the form of a somewhat open corymb, and in colour are a bright shining crimson like sealing-wax. If this free-fruited quality be maintained, a large bush would be a handsome object during the winter, for this plant has been some months in beauty. I never, however, remember this species fruiting so freely before, and possibly the fact of its being propagated from a cutting, and kept restricted to a pot, may have had something to do with its fertility. This kind of Guelder Rose is too tender to withstand severe winters around London.—ALPHA.

Primula verticillata.—This pretty little Primrose well deserves attention; for, although requiring the shelter of a greenhouse, it forms a very pretty object therein during the early spring months, when its tuft of meal-covered leaves is surmounted by a whorled spike of bright yellow blossoms. The perfume, though not strong, is sufficient to scent the surrounding air, when in flower, with a fragrance reminding one of that of the Cowslip. It is of easy culture, and will be found to flower very freely in small pots. If plunged out of doors during the summer, its growth is firmer, and the spring show of flowers greater than if kept in frames at that time. Like some of the others, I find that the seed of this *Primula* germinates freely if sown as soon as ripe, but when kept a little time its appearance above ground is very erratic, and sometimes it refuses to grow altogether.—H. G.

Steam heating.—Notwithstanding "P. G.'s" strictures on this subject (p. 166), steam heating is here a decided advance on the older methods of heating plant houses, especially where a strong heat is required for forcing winter flowers, and the fact that steam can be turned off and on the various structures at pleasure is a decided point in its favour, as this gives complete control of the heat, which in very changeable weather is a matter of first importance. We heat a range of five houses each averaging 21 feet wide by 132 feet long, with one 18 feet by 42 inches Lancashire boiler, and find that much better results (and more cheaply) can be secured than formerly with the best hot-water system. Thirty years ago steam was experimented with here, and owing to ignorance of what are now well-recognised principles it was a failure, and it is only recently that the prejudices then created have been removed.—JOHN R. MURDOCH, *Pittsburgh, Pennsylvania, U.S.A.*

Streptosolen Jamesoni.—This fine shrub, lately introduced from South America by M. Edouard André and now being sent out by M. Victor Lemoine, of Nancy, grows in its native country (the Cordilleras of the Andes) at a height of from 7000 feet to 9000 feet above the level of the sea. It grows about 4 feet to 6 feet high, and bears fine glossy leaves and flowers in trusses from March until July. In the south it can be cultivated in the open air, but here about Lyons and farther north it requires a greenhouse in winter. It will make a very handsome shrub for pot culture and for forcing. It was introduced about forty years ago by Hartweg, and was named *Browallia Jamesoni* by Bentham, who soon perceived that he was wrong, and that it belonged to the genus *Streptosolen*, established by Miers. Mr. Wm. Lobb sent seeds of it to Messrs. Veitch, but for many years it has been lost sight of.—JEAN SISLEY.

Propagating *Rondeletia* (X. Y. Z.).—Cuttings of *R. speciosa* will strike readily if young shoots are taken just as they lose their succulent character and become slightly woody. When removing them from the plant take none of the old wood to form the base of the cutting, but make it entirely of young growth, and remove no more leaves than is necessary for the purposes of insertion. About 4 inches or 5 inches is a good length, and with the removal of the bottom pair of leaves the cuttings are complete; they should then be put in pots of sandy soil—say half-a-dozen around the edge of a 4-inch pot—watered thoroughly, and kept close either in a propagating case or under a bell-glass in the same stove temperature in which they have been growing. If a gentle bottom heat can be given them they will root in much less time than without it. Of course when rooted, air must be gradually given till the glasses are removed altogether; then the cuttings may be potted off singly in small pots.—ALPHA.

NOTES AND READINGS.

ROYAL HORTICULTURAL SOCIETY.—According to the *Chronicle*, the Royal Horticultural Society proposes going back to first principles by "restoring the Society to its old position as a scientific body, by encouraging the reading of and publication of papers from practical horticulturists and men of science, and by undertaking comparative and experimental researches at Chiswick and other means." No doubt horticulturists will welcome this resolution, and if it is adhered to and carried out in the right spirit, probably the Society will again become the acknowledged institution it once was; but it will have to rise to the occasion if it meansto take the lead it once did when horticulture was less understood. An acknowledged necessity to restore the Society to its old position is clearly a confession of failure of the present state of things, and we believe this is exactly how the matter stands.

SOUTH KENSINGTON v. CHISWICK.—When the centre of interest and work was transferred from Chiswick to South Kensington we all remember what great things the Society proposed to accomplish. Chiswick was simply put on one side, except in so far as it was still to be an "auxiliary" establishment, the principal duties of which were to consist in propagating bedding plants and the like for South Kensington. What has happened we all know. The real want of the society has never been an ornamental garden and chambers at the West End, but a garden for carrying on important horticultural work and experiments under the management of an able superintendent properly directed and assisted by an equally able executive. Once the society begins to do real work and take a leading part in horticulture it will become a source of interest to horticulturists, and will deserve and get support. When it has any "transactions" worth recording it should publish them, if not in a journal of its own, then in the horticultural papers, and in all of them. For a long time the society has been virtually inarticulate, and its doings have been a

sealed book to that portion of the community for whom the Society professes to exist. It must keep itself before the public if it is to create and sustain an interest among gardeners outside the "ring," the members of which meet periodically to gossip on current topics at South Kensington. Extinction would be preferable to the present condition of affairs. With horticulture in its present advanced and enterprising state, and so many good outside workers in the field, a horticultural society of the pretensions of the "Royal" will have to entertain higher aims and views of its duties and do work, else probably final disestablishment may result.

A SCIENTIFIC COMMITTEE, aided by practical workers, might do much; but people have ceased to believe in experts only. A good experimental garden would be an excellent adjunct to such a committee. Hitherto the scientific committee's duties have been frivolous and of little general interest, chiefly because it has always been short of materials to work with. With an experimental garden, whose aspirations rose occasionally a little higher than Peas, Radishes, and Chinese Primroses, &c., which the "trade" look after better, the committee should never be short of work, nor out of materials for study and lectures. Such a garden should provide quite a fund of interest of the most varied description for the "unemployed" scientists—having no other matters to care for—and a garden half the size of Chiswick would be sufficient for the purpose. Notwithstanding the faults and exclusiveness of Kew, one would almost wish to see Chiswick and the Royal Horticultural Society turned bodily over to it, brought under Her Majesty's Board of Works, and sharing in the Government grant, for it really does not look as if the Society would ever rise to the position to which it aspires at present constituted. It is hard to understand why a national horticultural society and garden should not share in the privileges of our national botanical gardens, which, hitherto at least, have done but little for home gardening.

"VINES AND VINE CULTURE" has so many good points, that its author can afford to be questioned about doubtful ones, and Vine forcers are already asking why he recommends such a high night temperature as 60° at night at the starting period if 55° "is quite high enough" two or three months later when Vines are in flower, as stated at page 88. Surely Vines do not require a higher temperature to break their buds than to bring them into flower and set their fruit. This is one of the things in Mr. Barron's book that needs revision. Vineries are usually kept at an out-door temperature short of severe frost before starting, and 60° at night to begin with is a jump of from 20° to 50° at once according to the season. No Grape growers adopt such a practice at present. If, as the author of "Vines and Vine Culture" says, 55° or 60° is high enough at the setting period provided there is the desired rise during the day, why is not a proportionately lower temperature high enough at starting under the same conditions? Starting the big vinery at Chiswick at 60° at night in April or May may answer, but beginning at any date between November and April is another affair, and 60° at night at these seasons means sheer waste of fuel.

MANUALS v. CYCLOPEDIAS.—An intelligent writer in one of the horticultural papers discussing this subject in an interesting manner does not represent the merits of "shilling manuals" in quite their true light. A young man, it is stated, "finds it best to spend a shilling or so on manuals detailing the routine of men exactly in his position. He finds he can learn more of the Vine in Barron's, Thomson's, or any other good manual; of Orchids in Williams' manual; of hybridising and propagating in Burbidge's 'Cultivated Plants,' and so on than he can otherwise." I acknowledge the value of all these works for young gardeners, and would really like to know where they are to be had for "1s. or so," or if any of them can be had for less than 5s., 10s.,

or 15s. "Cultivated Plants" is not a manual, but a cyclopaedia, price 15s. Readers in these days perhaps believe more in the horticultural weeklies that keep them abreast of the times than in either cyclopedias or manuals; but probably for a learner a cyclopaedia of garden practice, something like Thompson's "Gardener's Assistant," would be a better investment as the nucleus of a library than any number of manuals on special subjects. The latter are apt to reflect the prejudices as well as the opinions of the writer, and are often misleading.

HURRY IN FORCING.—At this season of the year gardeners are very apt to resort to high pressure means in the shape of artificial heat and moisture in forwarding crops. These means come readily to the gardener's hand, but they should be sparingly used, for nothing tends to impair the vitality of such subjects as Vines, Peaches, and plants as hard forcing. Besides, all hurried fruits are small as well as light proportionally. It does not matter whether it be a Strawberry or a Pine-apple, the fruit which is allowed the longest period of development, within the necessary limits of temperature of course, always makes the finest specimens in every way. Vegetable physiology and practice teach that the more leisurely the growth the solidier the tissues and the better the quality. It is better in forcing to begin soon and give longer time than to hurry.

ORCHID SALES.—"T. B." presumes it is imported stock "Peregrine" means, and proceeds to write a column on that presumption. I did not specify imported or other stock, but left that to the discretion of the salesman, who, no doubt, knows his business best, as "T. B." indicates; hence his opinion need not be regarded as final. There are many who think a judicious selection would sell well at some of the large towns during show weeks, and as the trade does already take collections of Orchids to provincial shows and sell them there, they could probably transport for other purposes as well.

NEW EUCHARIS.—For a long time gardeners have been familiar with the old *Eucharis amazonica*, to which somebody has recently appended "grandiflora," and collectors do not seem to have thought it worth while looking for other varieties, but the recent addition of two new varieties to the list, viz., *E. candida* and *Sanderi*, encourages us to expect still more and probably even finer kinds. We need not wonder if the *Eucharis* family turns out to be as varied as that of our common Daffodil, and if both double and single kinds be found. *Eucharis candida* is very distinct and pretty, blooms oftener and more freely than the old sort, and in some cases has shown a tendency towards the double form.

VARIETIES OF *CELOYGNE CRISTATA*.—This is another plant of which improved varieties have recently been introduced by the Colchester Bulb Company and others. Some of these have been distributed, and we hear of them being named as the exclusive possessions of certain cultivators. Hitherto only one typical variety has been in cultivation, but some of the new arrivals are a distinct advance on the old variety as regards the size and quantity of flowers, which, for the size of the bulbs, are more numerous than in the type, the spikes being also longer and of a more drooping habit.

MILTONIA SPECTABILIS.—We are so accustomed to see this usually ill-managed Orchid with yellow, unhealthy-looking leaves, that many people believe that to be their natural colour. That, however, is a mistake. When well grown its leaves are of a deep green hue, and when it is in this state of health the flowers are proportionally fine and high coloured. We lately saw a specimen plant of this Orchid 2 feet across, with leaves as green as Grass, and covered with flowers, many of them not much less in size than some forms of *Odontoglossum vexillarium*, which it resembles in shape, but beats in richness of colouring. Grown

in this way, it makes a remarkably fine specimen. It requires moderately cool treatment and shade.

WONDERFUL CROPS.—"W. C. T." no doubt means well, but should be accurate. The facts speak for themselves. The writer whom he defends grows his Vines 4 feet from the glass and 7 feet asunder, but says 10 feet would be better. His bunches are not more numerous than other people's, and run generally from 1 lb. to 4 lbs. in weight. These are what constitute one of "the most wonderful crops in the kingdom," according to the author's own showing. We had a photograph of the crop at its best, and it bore out these statements. The wonderful thing about this vinery is the space lost laterally and longitudinally. We doubt if anyone would care to test such a practice; it is known to be a wasteful one, and people are satisfied. To have to grow Vines 10 feet asunder does not look like "luminous rays," but speaks of the days of our forefathers and opaque roofs, for it has ever been recognised that the darker the roof the more need there is for room inside. We must say that we mistrust a writer's observations who dwells on the important differences between a "purple-black" and a "blue-black" in the colour of the Black Hamburg, the latter being the mark of perfect finish and flavour.

PEREGRINE.

KITCHEN GARDEN.

EXHIBITION POTATOES AND THEIR CULTURE.

IT may occur to some of the readers of THE GARDEN that my remarks are offered somewhat late in the season, and to a certain extent they will be justified in forming that opinion, as no doubt there are many who have already made considerable progress with their Potato planting. At the same time I believe there is still much ground to be planted, and experienced growers especially do not commit valuable sorts of Potatoes to the ground very early in the season for fear of injury from late frosts, and neither should the novice. Again, it must not be thought that this paper is intended solely for the benefit of would-be prize winners; on the contrary, it is intended for Potato growers generally, and may be said to be also a

Plea for handsome varieties. My meaning will be plainer when I assert that those who grow really good exhibition tubers can, and oftentimes do, grow heavy and profitable crops—more so, in fact, than the majority of growers for ordinary purposes. At least this is my experience, as I invariably find we obtain much the heaviest crops, and of the best table quality too, where the ground is prepared and the sets are planted with the primary motive of securing abundance of tubers suitable for exhibition. It is a mistake to think that exhibitors of Potatoes, and indeed of any kind of vegetables, grow a few only of each sort, giving these abundance of room and otherwise unduly favouring them. An experienced exhibitor grows as many as he possibly can of each, in order to have abundance to select from, as now-a-days it is useless to show a dish or collection not perfect throughout. There is no denying the fact that the rage for exhibition varieties of Potatoes has to some extent interfered with the cultivation of a few superior, if uglier, older sorts, but for this the individual is to be blamed and not those generally who may be the means of promoting exhibitions. No gardener should neglect the proper precautions for supplying the dining table with the best eating Potatoes the garden is capable of producing, and in my opinion a few varieties only should be relied upon for this purpose. Where the evil lies is when the gardener grows as many varieties as he possibly can procure; and as varieties vary considerably in quality as well as in appearance, the frequent changes from good to bad and *vice versa* serve to irritate the employer, and eventually militate against the gardener. But if the gardener, by his perseverance and superior judgment, continues to grow suffi-

cient good Potatoes for the table as well as a quantity of exhibition varieties, then I hold the employer will best consult his own interests and encourage the gardener by at least abstaining from interfering. Again, by annually trying a few novelties the grower is enabled occasionally to select a very superior sort for growing in quantity for the table. We are told that no real progress has been made in the

Improvement of Potatoes, and that for ordinary purposes we must still rely exclusively on the older sorts. The sooner this notion is exploded the better, as I am convinced some of the latest introductions especially must eventually supersede many older sorts. Neither is it to America we must look for varieties suitable for our soils and climate, but to our own skillful and persevering raisers. Of the many of the latter none have been more painstaking or so successful as Mr. R. Fenn. It is true we have to thank him for the worst Potato, as far as quality is concerned, that was ever introduced, this being the famous prize-winner, International Kidney, and which, in common with Porter's Excelsior and a few American varieties, has more injuriously affected the prestige of exhibition Potatoes than all the rest put together. However, Mr. Fenn has amply condoned his offence, if I may so term it, as we have to thank him for such sturdy growing, heavy cropping, early maturing sorts now known as Sutton's Favourite, Lady Truscott, Sutton's Fiftyfold, Reading Russet, Standard, Sutton's Prizetaker, Sutton's Early Regent, the older and better known Rector of Woodstock and Woodstock Kidney, and others I have grown and proved to be both distinct and good in every respect, being valuable alike for the exhibition and dining table. Mr. Dean has also done good service in the way of raising new varieties, these including Bedford Prolific, Cosmopolitan, and Lord Mayor; and Mr. Ross has been successful in the same line, his productions including Dux, Sutton's Magnet, and Fidler's Victory. Mr. Clarke, fortunately for all of us, succeeded in raising the disease-resisting, heavy cropping Magnum Bonum and Reading Hero, both of which are available and should be grown for either exhibition or culinary purposes. Of those of American origin, the best with me, and I have grown the majority of them, are American Purple, Beauty of Hebron, Triumph, Snowflake, and the newer Matchless and Adirondack. In addition to the foregoing I grow and much like Veitch's Improved Ashleaf or Mona's Pride, Lapstone Kidney, Vicar of Laleham, Covent Garden Perfection, and Schoolmaster, and from the whole may be selected twelve or more varieties equal to, if not superior, in every respect to any varieties grown elsewhere. I have no doubt many who have planted a considerable quantity of Potatoes find they will not have sufficient sets to complete the breadths, and to them and to all who in any case have some ground yet unplanted I say add a few of the above newer sorts, notably Fenn's, by way of experiment. If it prove inadvisable to eventually retain all, the probability is they will be able to select a few sorts suitable for and otherwise well worthy of being extensively grown on their particular soil.

A change of seed is also of great advantage, and this noted exhibitors especially are constantly procuring. In this case it is a conclusive proof that it is conducive to the production of heavy crops, and is well worthy of imitation. Our best crops invariably result from seed obtained from a distant friend from a reliable firm of seedsmen, although this seed at the commencement is at a disadvantage, owing to having unavoidably sustained damage to the sprouts during transit. We never plant choice varieties unsprouted, and take great pains, especially when extra choice, in

Preparing the tubers for cutting and the sets for planting. When received (usually during March) they are placed in the shallow boxes previously used for storing and preparing for planting the home-grown seed of early sorts, covered with fine moist soil, and placed in a warm Peach house, vinery, or frame to commence growth. This they quickly do, and at once emit roots,

but before they are an inch long the tubers are cut into as many sets as there are eyes, which are returned to the boxes of soil, disposed about 3 inches apart, and covered. In the case of very choice sorts which cost say from 2s. 6d. to 4s. per pound, and which we naturally are extremely anxious to increase as much as possible, the eyes after starting are divided into as many sets as there are shoots and potted off singly into 3-inch pots. All are kept in warmth till established, when they are gradually hardened off, yet protected, so as to have them sturdy and fit to plant out say the second week in April or later, according to the time the seed has been in hand. Potatoes not previously sprouted much, cut up and at once planted, are apt to prove disappointing, but well-rooted shoots carefully planted are capable of producing crops equal in weight, if we except the Ashleaf type, as are growths which are attached to whole or large parts of tubers. Those sets of our own saving are always prepared for planting generally on their ends and thinly in shallow boxes, the end in view in all cases being to secure a single strong sprout. One strong stem invariably yields a heavier and handsomer crop than two or more weaker ones, and by first securing good sprouts and then planting after the danger of severe frosts may reasonably be considered past, we seldom fail to grow heavy crops if we do not preserve them. If it is necessary to carefully prepare the sets, it is equally imperative to

Well prepare the ground, and this should not be delayed till near planting time. On page 212 of the present volume of THE GARDEN reference is made to American experiments which proved conclusively that the Potato should have a deep root-run. Whether this is new to the Americans, I am unable say; but this I do know, our most successful Potato growers are frequently double-digging or trenching the ground for Potatoes, well knowing that the superior crops resulting amply repay the outlay. We have long found Potatoes do remarkably well on newly trenched ground, and that subsequently the same ground, owing to having become firmer, is in a better condition for producing good crops of Strawberries, Onions, Peas, and the Brassica tribe generally. We prefer to bastard trench whenever the weather permits after December, always leaving the surface as rough as possible. When trenching is impossible deep digging is resorted to. Autumn digging or ridging we do not practice, as we find the ground works best when dug after the usual soaking rains of November and December—any dry time in January, February, or March being preferred. Frost, wind, and rain soon make their pulverising influences felt, and this season especially recently dug ground is in splendid condition for seed sowing and planting. Rough stable manure is freely dug in, and at planting time a liberal dressing of either soot or malt dust, wood ashes, and leaf-soil is well forked into the intended rows. These are disposed 42 inches apart (this distance allowing of a row of Broccoli Sprouts or Kale being grown between), and are drawn out with heavy hoes, the sets being planted usually 12 inches asunder, and carefully covered with the hand. The soil is generally levelled over, but in the case of forward sprouts, these have soil lightly ridged over, or otherwise they may be injured by frost. The pot plants are put out with the trowel. By this it will be seen that our Potatoes have a deep root-run, are cheaply, yet well manured, and have the requisite light, open soil in which to form their crops of handsome tubers.

The after-treatment consists of keeping the ground clear of weeds and frequently stirred, and in moulding up as the haulm advances, the final moulding succeeding a heavy shower or showers of rain when the haulm is about 9 inches high. Jensen's method of moulding up one side considerably higher than the other, so as to throw the haulm on to one side as a preventive of disease, tried on a small scale, was most encouraging, and we intend to adopt the plan on a much larger scale this season. Early lifting, unless performed before the disease has shown itself, is merely a

waste of labour, and the same remarks apply to pulling the tops. If we anticipate the disease, all well and good, but when the germs have effected a lodgment on the haulm, this occurring during damp weather, we find it the least trouble to leave the tubers to sort themselves, not liking heaps of sound and rotten Potatoes in mixture. In the matter of selecting good dishes, many "beat themselves," that is to say, they leave better tubers at home than they take to the shows. It is not large sized ones we should prefer, even supposing they may otherwise be perfect; the present taste rightly inclines to medium sized tubers which should all be as even and perfect as possible. This evenness should extend through a collection. Polishing is not much in my line, and probably polished tubers are not awarded the premier prizes simply because they are so beautifully clean and even, but because the judges know them to be the best whether polished or not. No amount of polishing will transform one that is scarred into a clear skinned and faultless tuber. Ours are washed with a sponge before the soil has dried upon them, are wrapped in paper, and stored in a dark room till required, when from a large boxful of one variety, we perhaps are able to pick two or three good dishes.

GROWER AND EXHIBITOR.

POTATO DISEASE.

A SHORT report is given THE GARDEN of the 17th inst. (p. 257) of objections offered by Mr. George Murray at the Royal Horticultural Society to certain views of mine on the so-called sclerotia of *Peronospora infestans*. He says that "a microscopical examination of certain specimens did not clearly reveal any organic connection between the sclerotia and the *Peronospora mycelium*." But it has to be kept in view that generally the edges of the sclerotia plasmodiate before myceliation begins, so that in point of fact the granular plasm from which the *Peronospora mycelium* arises has lost all organic connection with the undissolved part of the sclerotia. On rare occasions, however, excessively delicate threads in considerable numbers can be distinctly seen to arise from a sclerotium. These sclerotia have been seen already by Mr. W. G. Smith and perhaps by others, and whether they are truly called sclerotia (as Mr. Murray denies) is a mere matter of classification. Mr. Murray says sclerotia are "a compact mycelium." But sclerotia are not going to be tied up in this narrow way. It is true that some sclerotia consist for the most part of compact mycelium; but in addition to the short anastomosing lines there is the hornified plasm which holds these lines together. If they are "caught young" something more may be made of them. It is then seen that the mycelic lines arise from exuded plasm around the mass already formed. But in the case of the best known of all sclerotia ergot the mass consists for the most part of agglutinated spores. If a white young ergot is squeezed out on the slide it is seen to consist of whole oceans of spores (variously named) arising from a spongy mycelic axis.

A. STEPHEN WILSON.

JERUSALEM ARTICHOKE.

No vegetable with which I am acquainted is more easily cultivated than this Artichoke. It will grow in almost any soil or situation. I know of no disease which affects it or insect which attacks it, and to these exceptional recommendations may be added the great value of the roots, which are both nutritious and wholesome. I am sure that if those who have neither grown it nor used it would take it in hand now, they would not regret doing so. It is at this time that its cultivation for the year should begin, and I hope many may be induced to try it. A bushel or so of seed roots will plant a large piece of ground and be enough for a fair trial. As has just been observed, they are not particularly dainty as to soil. I have, indeed, seen them growing and fairly remunerative even in waste corners; but the heaviest crops and the finest and best flowered tubers

are to be had from good ground. It is not throwing away labour or manure to prepare Artichoke ground in the same way as is generally done for Potatoes. The ground should be deeply dug and well manured, and the crop will undoubtedly be heavy. Where roots have been dug up for use throughout the winter the largest only of each should have been used, and the medium-sized ones put aside for seed. In this way a good deal of seed may be in store now; but if there are still some of last year's crop remaining in the ground, they should be lifted, the seed selected, and the large ones stored for use until the new ones are ready. Some cultivators do not replant annually, but leave them in the ground year after year, much to the detriment of the crop. This is an unprofitable way of treating them; we would have them all lifted and replanted every spring. Growing them too close together results in undersized roots; 3 feet from row to row and 18 inches set from set is a distance from which the finest roots may be had. In planting they should be placed about 3 inches below the surface, and after they are put into the ground hoeing to destroy weeds is all the attention required. From seed planted now there will be roots large enough for use in September, and after that the supply will be continuous. The roots are very accommodating; they may either be taken up and stored in a shed at the beginning of winter or they may be left in the ground and dug up as required. As Jerusalem Artichokes grow from 6 feet to 8 feet high, they may be planted to form profitable and effective summer screens, and they will also afford shelter or shade for more tender plants. J. MUIR.

FLOWER GARDEN.

THE PIGMY DAFFODIL.

Of all that section of the genus *Narcissus* popularly known as Daffodils, this little plant is certainly the smallest, a veritable Commodore Nutt, or let us say General Mite in its way compared with *N. Emperor*, *N. maximus*, *N. lobularis*, and other giants which represent the Changs, Daniel Lamberts, and Magraiths of Daffodildom. We used formerly to find this little plant offered for sale by Messrs. Backhouse, of York, and Mr. Barr once grew it at Tooting, but it is now a rarity for which many lovers of hardy bulbs must seek in vain. Even Mr. Ware, who has so many good things in stock, does not offer this dainty little plant in his lists. Now and then we find its name on labels here and there, but *N. minor* or *N. nanus* in reality generally represents it in most gardens.

Parkinson's description in his "Paradiseus," p. 105, leaves but little doubt as to this plant having been grown in English gardens so long ago as 1629, but whence it came is not quite so apparent, unless, indeed, we take Parkinson's word for it that it is the smallest or least Spanish Daffodil. After his description of *N. Pseudonarcissus hispanicus*, *medius*, and *minor luteus*, he speaks as follows in reference to

Narcissus minimus: "The leaves of this small kinde are smaller and shorter then the former, seldom exceeding the length of 3 inches, and very narrow withal, but of the same greyish green colour with the former; every flower standeth upon a small and short foot-stalk, scarce rising above the ground, so that his nose for the most part doth lie or touch the ground, and is made after the same fashion and of the same colour with the former, but much smaller, as his root is so likewise." Seeing that but few cultivators of Daffodils seem to know this "little gem," we are glad to be able to give an illustration of it. Several times already this spring we have had *N. minor* sent to us with the question, "Is this the true *N. minimus*?" but at last we have received the true plant from Messrs. J. Dickson & Son's nursery at Chester, whence Mr. Shortt writes to ask if it is true to name. We are very glad to say it is, and could wish we oftener had the pleasure of seeing it, so rare is it nowadays. As the annexed sketch represents the full size of the plant, three-

fourths of it being naturally hidden below ground level, it will be seen to be extremely small and dwarf when growing naturally. Indeed, Parkinson's quaint sentence, "his nose for the most part doth lie or touch the ground," is almost photographic in its truthful portraiture of the living plant, which truly flowers almost before the little glaucous leaves peep through the earth.

When we remember how *N. cernuus* fl.-pl. has died out in most gardens (although tolerably abundant, I am told, with Mr. Elwes) and of the luxuriance of *N. cystettensis* (or *N. Capax*) with Miss White, of Charleville, or Mr. W. E. Gumbleton at Cork, we are tempted to ask the question whether this Daffodil, although rare generally, may

Narcissus minimus.

not exist plentifully even in some few gardens in Britain or on the Continent. What says Mr. Ewbank, of Ryde; M. Max Leichtlin, of Baden-Baden; or other lovers of rare bulbous plants? The specimens Mr. Shortt sends us are nearer to the *N. pumilus* of Herbert's "*Amarylhidaceæ*" than ever we saw this plant before, *N. pumilus* being synonymous with *N. minimus*. F. W. B.

CONSTRUCTING A ROOTERY.

"BAGATELLE" (p. 278) asks for information as to how tree roots can be used. Local circumstances alone determinable on the spot could enable anyone to advise as to the best way these could be employed, as almost every garden presents something different in position and existent arrangements, all of which need to be taken into account in any arrangement of roots in the way proposed. But it may be said *en passant* that there are few, if any, gardens where a well-placed and well-constructed rootery cannot be introduced with advantage, in many cases with much better effect than follows the use of rockwork, with the still further advantage of not costing more in the making than a fraction of that which the use of stone necessarily entails. I have done a good deal of this kind of work from time to time, varying much in its extent, as also in the time it was calculated to last consequent on the materials used. The best looking and most enduring are Bog Oak and Yew; where either of these are procurable they are all but imperishable; but ordinary tree roots if of good size will last very many years, as, if well put together, they will keep in position if not interfered with

for a long time after they are so rotten as not to bear disturbance. If "Bagatelle" has anything in or about his garden that he wants to mask or shut out from view, he may do this effectually by simply building up the roots in the form of a screen or mound in height and length sufficient to effect the purpose, wholly or partially covering them with Ivy, Clematis, climbing Roses, and other plants of like description. In many gardens an arch or two over a walk, or a rustic bridge thrown over a ravine or run of water, if constructed with taste and a due conception of suitability to position, would be pleasing additions. Where the natural surface is too flat, a mound composed in part or entirely of roots and nicely draped with plants, can be made so as to relieve the too even appearance if the site is well chosen. On this latter much depends; the simple piling up of root or rockwork, as it is often done, with no apparent object beyond a disposition to do something, not unfrequently ends in dissimulation rather than improvement. I have thought it well to thus give a word of warning about the well-meant, but mischievous use of this kind of material in gardens. As to the

Putting together of the roots, some taste and forethought should be brought to bear on the construction; a little structural skill in tying the work together by so disposing of the materials that the pieces may bind the fabric together like the stones that compose a wall is needed; as a matter of course irregularity of outline must be secured. Anything that will give a formal appearance must be avoided. The larger roots should form the base with as many garbled projections as can be sticking up and out of the face of the mound, screen, arch, or whatever is to be made; with sufficient material in the shape of enough roots of various sizes, there will be no need of anything else to hold them together even if part of the erection is to have a wall-like character. In all cases the base should be broad enough as compared with the upper portion, so as not to give a top-heavy appearance. Soil of good character should be freely used in the bottom interstices between the roots for the plants to grow in. Such things as *Juniperus prostrata*, *J. sabinoides*, *Arthrotaxus Doniana*, *Cotoneaster buxifolia*, *C. microphylla*, *C. Roylei*, *Vinca major*, and *V. aurea reticulata*, being low creeping plants, are suitable for clothing the lower part; strong-growing hardy Ferns may also with advantage be introduced amongst them. The following are free-growing climbers, and will thrive in most places where ordinary plants will succeed, planting them in good soil at the bottom, and training them up as required; amongst Ivies, take *H. canariensis*, *H. canariensis argentea*, *H. Regneriana*, and *H. digitata*. At first these will need securing, so as to direct their shoots upwards; if put in rich soil they will soon reach the top. *Jasminum nudiflorum*, *Ampelopsis hederacea* (Virginian Creeper), *A. Veitchi*, *Clematis montana*, *C. Jackmani*, *C. rubella*, *C. Miss Bateman*; *Roses*—crimson *Boursault*, *Aimée Vibert*, *Lamarque*, *Rampante*; *Rhus leucodermis*, white-barked Bramble. The extent to which the covering with plants is carried is simply a matter of taste, but if the work is composed of suitable roots and well executed, it generally looks best when most of the garbled pieces are kept bare. T. RAINES.

Dimorphotheca nudicaulis var. *graminifolia* (the bare-stemmed, grass-leaved Cape Marigold).—This very old, but, I believe, exceedingly scarce and seldom met with composite is now nicely in flower in my conservatory. Introduced into Holland so far back as 1698 and into England in 1731, it first bloomed in the Chelsea Botanic Garden from seed received from the Cape in the last named year, but has ever since continued a scarce plant from its being, I fancy, difficult to propagate by cuttings, and from its not ripening seed in this country. It was figured in the year 1818 in the 4th vol. of the *Botanical Register* by Lindley under the name by which it was known to Linnaeus, Miller and the older botanists of *Calendula graminifolia*, but more modern authori-

ties have assigned to it the name at the head of this notice as more correct and appropriate. It is a very curious plant, of trailing habit of growth, with twisted stems, bearing tufts of light green grassy foliage at their ends, out of the end of each of which, when strong enough to flower, springs a single blossom, borne on a tall naked stem, and much resembling in appearance and colour the flower of the well-known annual *D. Pongei*, with bronzy purple under petals and creamy white inside. Like it also, it only fully expands when the sun shines.—W. E. GUMBLETON.

DOUBLE-FLOWERED DAFFODILS PRODUCING SINGLE FLOWERS.

UNDER the heading "The Tenby Daffodil" (p. 224) a passage is copied from Haworth's "Monograph of the Narcissus," recording that the offsets of a bulb of the double wild Daffodil produced in Chelsea Garden single flowers. This reminds me of an old story told by Cicero: A client went to consult a diviner. A marvel had occurred in his garden—he had found a snake coiled round his crowbar; what did it portend? "Are you certain," said the diviner, "that it was as you say?" "Quite certain," answered the client. "Then, my good sir," replied the other, "it is no marvel at all; the marvel would have been if the crowbar had been coiled round the snake!" In the same way there is no marvel in a Daffodil or any other plant which has been born double-flowered reverting to the single-flowered form; the marvel would be if a plant which has been born single flowered became double. The double forms of *Narcissus incomparabilis* (particularly the "Orange Phoenix") and the double *N. tazetta* are especially given to this habit of turning single, as many growers of Daffodils have observed. Such plants continue potentially double, and under favourable conditions may revert to double. This is not the case with Daffodils only, but with many other flowers, and I have fresh experience in my garden every year of plants producing at the same time double and single flowers. Double Primroses often do so with me, and the single flowers appear quite perfect, with anthers and pistil. Amongst Sunflowers, too, I have often seen *Helianthus multiflorus* with double and single flowers on the same plant. But I will offer a premium of £5 to anyone who, under strict supervision, will succeed in cultivating the bulbs of single Daffodils which I will send him into producing double flowers.

Llandudno.

C. WOLLEY DOD.

Abutilon vexillarium.—As open garden plants during the summer months Abutilons are most valuable, and amongst them none more so than *A. vexillarium*. It is often met with as a carpet plant in formal bedding, and sometimes in vases; but it is as a border plant I have to speak of it. Grown in front of a shrubby border it is very ornamental, especially if allowed to grow in its own free way. Its slender shoots, clothed with long blooms hanging down in all directions, make it very graceful looking. Recently I saw it associated with such things as *Daphne Cneorum* and *Skimmia japonica* with the finer kinds of *Retinosporas* and *Thujas* at the back, and the green Grass in front, and the effect was all that could be desired.—J. C. F.

SHORT NOTES.—FLOWER.

Cinerarias (*J. C. Wheeler & Son, Gloucester*).—The flowers you send represent an uncommonly fine strain, particularly as regards solidity and perfect shape. The colours, too, are brilliant and varied.

Golden Feather.—To those who grow *Pyrethrum aureum* for carpet bedding, let me recommend the neat and pretty form *selaginoides*. We liked it exceedingly last season; it is all that the catalogues describe it to be.—A. M. Cranmore.

Narcissus Bulbocodium.—It may interest Mr. Burbridge to know that we have this Daffodil very beautiful here just now. Six bulbs in one pot bear eighteen expanded flowers and ten buds. One bulb is remarkably floriferous, having three buds and six expanded flowers, one stalk having nine flowers, which I think very unusual.—F. NEWMAN, *Ferniehurst, Shipley, near Leeds*.

Alpine Auriculas.—The term "alpine" as applied to the Auricula is perhaps rather misleading if thereby when border kinds are meant it should be imagined by some that the term really applies to the beautiful kinds grown by Mr. Turner at Slough and by others in such perfection. "J. C. C." no doubt means robust border kinds when he writes of alpinas, just as I do now, though mine are of the laced strain of alpinas, and I think the most charming strain of all for the open ground. Now it is perhaps not remarkable that having a soil naturally stiff and clayey I cannot get Auriculas to thrive well in it when employed partially as a potting compost. On the other hand, it has surprised me to see that seedlings put out early last spring in a stiff, clayey soil, and which was through the winter not only full of water, but now as hard as a brick, have stood without losing a single plant, and that all look far better and healthier than any in pots, though sheltered by glass all the winter. Most probably we kill many of our pot Auriculas by confining the roots too much, for any of these plants lifted from the open would show the roots had gone 6 inches in depth and 9 inches in width. In the case of plants in pots, giving similar root space, would be to kill them speedily, and yet in the open ground they will need nearly as much root space as a Cabbage. My plants—several hundreds—are fully exposed to all weathers and have no protection. I do not term the Auricula a bedding plant, but if I were employing it for that purpose I should plant about 12 inches apart each way, and carpet the intervening soil with seedling Aubrietias. The result, I think, would be a bed worthy of admiration.—A. D.

When to sow Castor-oil Plants.—Few plants that are grown for the beauty of their foliage are more ornamental than the different varieties of *Ricinus* or Castor-oil plants, which are not half so much grown as their merits deserve, as not only are they fine for pots, to use for the embellishment of large conservatories or halls, but they are grand outdoors, where, if planted as single specimens on lawns, dotted here and there in borders, or grouped in masses, they produce a striking effect. If arranged in the last-named way, the stronger sorts should be placed in the centre, and the weaker around, that the group may assume uniformity; and where single plants are used in prominent positions, the most robust look the boldest and best. There is one among the weaker growers deserving of special mention (*R. Gibsoni*), which has leaves and stem as darkly coloured and rich looking as *Iresine* or *Delf's Beet*, and if planted with an edging of *Abutilon Thompsoni*, the contrast between the two is most pleasing, as they associate and look well together. As these Castor-oils are gross feeding plants, the soil should be specially prepared for them by being trenched or deeply dug, and at the same time heavily manured with rotten manure; and if this is done, they will develop magnificent leaves, and have a shapely appearance the whole of the summer. Many make mistakes with *Ricinus* in sowing too soon, and starving the plants at first starting, for if they become drawn and checked then they run up with weak, naked stems instead of being furnished with foliage below. As the seeds germinate so quickly and the plants grow so fast, the middle or end of April is quite time enough to sow, as it is not safe to plant out till the first week in June, and they get to a large size in a month or six weeks if well treated and nursed on in heat. Before planting out it is necessary to harden them by gradual exposure, and directly they are in the beds they should be staked and securely tied, or the wind will break and destroy them.—D.

Lent Lilies and their varieties.—If any bunch of imported wild Daffodils be carefully examined it will be seen that there are a great many varieties answering in type to the several sorts found in our gardens, and very different from the common wild Daffodils of our English meadows. I was struck with this fact on examining a bunch which my little boy had bought at the florist's, and placed on my library table as a pleasant

token of his love. To-day I walked round the market with my friend Mr. Okell, and we were both struck with the variety we observed in every bunch. I send herewith an outline sketch very carefully made by admeasurements, showing three of the most marked varieties, and it will be seen that they are the types of some of our best known garden favourites. It would be interesting to know where these Daffodils come from, and whether they may be taken to be the original forms of our cultivated varieties. I should be glad if someone would import the bulbs for us in quantities, as they would form very welcome additions to our wild gardens.—W. BROCKBANK, *Brockhurst, Didsbury*.

NOTES FROM GLASNEVIN.

PROBABLY one of the best times to visit this botanic garden is in the spring, before the early flowers of the year have lost their freshness. Whatever one may think of the sister isle or its people in these troublous times, it is certain she can give us floral offerings at the present time superior to any at either Kew or Edinburgh, be the same indoor Orchids or outside alpinas. In a stroll through Glasnevin on the 8th inst. I observed blooms of the Japanese *Forsythia* (the golden bees alluded to in "Veronica's" notes), *Helleborus atrorubens*, Wallflowers, Snowdrops, the white *Arabis*, Siberian Squills, sheets of the bright purple *Erica herbacea carnea*, Primroses of all kinds, *Triteleia uniflora*, a double Periwinkle, and a white one with pretty variegated foliage, Daffodils, *Iris reticulata* with its beautiful deep purple flowers and golden anthers, a few plants of a *Ranunculus* in bloom, *Viola lutea* and odorata, *Aubrietia grandiflora*, *Pulmonaria grandiflora*, *Anemone fulgens*, and *Saxifraga oppositifolia*, white and purple varieties. No mean show of blooms this with a gale blowing from N.E. for nearly a week.

In the general collection I noticed a great improvement in the way of labelling plants. Instead, as in some collections, of each individual specimen being marked by an immense wooden T-shaped label painted white with black letters, an oval iron one is used, painted black with white lettering, the more conspicuous and unsightly ones being only used at intervals to designate the natural orders; there is therefore a more distinct lettering without the glaring amount of white paint generally so much used.

Beds of Hybrid Perpetual Roses had been pruned. I suppose they know best here from previous experience which is the right time to perform this operation, but I submit that their Roses need not all have been pruned alike, each plant and each twig to the same height as if cut over with a scythe. Surely, pruning should be performed in accordance with the growth and habit of the individual plant, the weak growers being closer pruned than the moderately-vigorous ones, and these again closer than the very vigorous kinds. A beautiful natural effect is obtained by training varieties of Jackman's *Clematis* round the outside columns of the house containing aquatic plants. Shoots of these having already grown 6 inches in length show what an effect the mild weather has had upon them, though I fear the 20° of frost registered at Leeds the night after my visit to Glasnevin will have told anything but a flattering tale. Can anything be said, in these days of cheap glass, in extenuation of the use of panes from 3 inches to 4 inches square, such as I noticed in the house containing Tree Ferns at Glasnevin, though, truth to tell, it has been utilised very sensibly in that particular case? On entering the first of a long range of houses an almost overpowering cloud of perfume assailed me, proceeding from *Ilyacinthus*, *Narcissi*, *Freessias*, and other scent-yielding plants. *Cytisus fragrans*, with its *Cattleya-citrina*-like perfume, would, I think, make a good basis on which to work in forming bouquets of scented flowers. Indoor bloom here was nowhere wanting. *Camellias*, *Amaryllides*, *Primulas*, *Polygalas*, *Epacrises*, *Cinerarias*, *Correas*, *Chorozemas*, *Habrothamnus Newelli*, a fine plant trained to a central column and bearing pendent

spikes of shining vivid crimson blossoms, *Beaufortia decussata*, 12 feet high, *Monochætum ensiferum*, the pearl-like *Erica physodes*, and *E. melanthera*, one of the loveliest. Among other plants were also *Hardenbergia Lindleyana*, with pendant purple blooms; a *Brugmansia*, with very large tubular blossoms; *Solandra grandiflora*, with pale yellow trumpet-shaped flowers; *Franciscas*, and *Ixoras*, all in bloom, and presenting quite a gay contrast of colours. The iron supporting pillars in one of these houses are thickly wrapped in peat and Moss, in which *Ferns*, *Tradescantias*, and fine-foliated *Begonias luxuriante* and produce quite a charming effect. What a beautiful bouquet green we have in *Asparagus plumosus*! no Fern can surpass, and few equal it as regards fine tracery.

On entering the Orchid houses I observed that the opportunity of creating a good first impression had not been lost, for in the vestibule some of the choicest specimens had been artistically arranged, supported by *Poinsettias*, *Euphorbia pulcherrima*, and *Gesnera cardinalis* where bright colour was at all deficient. Beyond was a *coup d'œil* for further investigation; indeed, such a staging of Orchids as is seldom seen. *Cypripedium Boxalli*, a fine form; *C. Argus*, not only having handsome flowers, but the double advantage of having beautifully marked leaves; *C. villosum* and *C. Lowi*, both fine specimens. *Odontoglossum pulchellum* and the *majus* variety, so sweetly scented; this is one of the few Orchids in which the lip is erect. *Lycaste Skinneri*, a fine variety, with reflexed sepals, the upper one quite backward, giving a quaint bold air to the plant; *Lælia harpophyllum*, of dazzling scarlet, too rarely seen and never surpassed. *Odontoglossum Roezli*, 5 inches across the upper sepals, which were deep purple half-way up, the lip being beautifully marked pale yellow and orange; a white variety not far off, and in comparison the further off the better; these amongst others were in the vestibule, whilst just within the next door came the sheet of bloom just alluded to. A spike of *Lælia superbiens*, bearing twelve blossoms, another of *Odontoglossum triumphans*, bearing fourteen, the pot containing this last being hung up against the light, thus giving richness and colour to its golden, chocolate-spotted flowers; behind it five blossoms of *Vanda Cathcarti*, in the rear of this again a noble specimen of *V. tricolor*, whilst in front came *Phalenopsis Schilleriana*, *Dendrobium Wardianum*, *Lycaste Skinneri*, *Trichopilia suavis*, and *Calanthe vestita*, intermixed with large pots of *Adiantum amabile* and *A. tenerum*. The *Stanhopeas* when in bloom must be a great treat, as I counted fifty baskets of them hanging consecutively. Altogether, for Orchids, few public collections can approach that at Glasnevin.

Horsforth, near Leeds.

R. A. H. G.

Graft influences.—Some dispute this influence; lately, however, my friend, Alphonse Karr, has cited an example—that of Hybrid Perpetual Roses flowering better when grafted on the common China Rose than on the Brier. In my opinion that influence is general, although not always perceptible. Let those who entertain doubts make an experiment. Let them plant two wild Briers, like those used for standard Roses, near one another; graft one of them with a Tea Rose, a delicate one, and let the other grow at random, and after three or four years it will be found that the grafted one has scarcely grown thicker than it was at first, while the other has nearly doubled in circumference. Who does not know that Pears are grafted on the Quince in order to obtain pyramidal forms, check vigorous growth, and in consequence promote earlier fruiting? Let those not acquainted with the practice graft the same variety of Pear on a Quince and on a seedling Pear of the same age, and they will soon perceive that the latter is by far the more vigorous. In the severe winter of 1870 I had the mortification to find that all the Pear trees in my garden grafted on the Quince were killed, while those on Pear stocks resisted the frost. Why do Tea Roses, especially the more delicate varieties, acquire more

vigour when grafted on the seedling Brier than on their own roots?—JEAN SISLEY, *Monplaisir, Lyons*.

TREES AND SHRUBS.

BLACK AUSTRIAN PINE.

THIS fine hardy tree, introduced into Britain about the year 1835, has proved to be a great acquisition not only in an ornamental point of view, but also as a first-class timber tree. On the calcareous mountains of Lower Austria it attains an average height when at maturity of about 100 feet. There is no other species of conifer with which I am acquainted capable of accommodating itself to a greater variety of soils and situations than this Pine; in fact, I have planted it in Scotland with success in all positions from the seaboard up to some 1000 feet above that level, and in soil composed principally of poor gravel, resting upon both granite and limestone rock. In Armagh I have planted it extensively on deep peat bog, in which it thrives admirably, and if allowed plenty of room retains its side branches, and is invaluable for cover, shelter, and general utility. At Loughball, in the same county, it makes rapid progress on calcareous soil resting upon limestone; and in the vale of Avoca and Glenelly, in Wicklow, it is quite at home on poor inorganic fragments of clay slate containing but very little soil. It is admirably adapted for planting as a screen in out-of-the-way corners, and forming a background for trees and shrubs of different habits and shades of colours. It likewise makes a grand specimen tree when planted singly on a lawn, its finely-balanced conical top rendering it very effective; the large terminal buds of the side branches, too, get capped in spring with a white downy substance, which looks at a short distance off like burnished silver, contrasting strikingly with its beautiful, dark green glossy foliage. When the trunk is cut up for use, the timber is found to be of a close, firm texture, full of resin and very durable. In cases, however, in which the trees have been grown for ornament and their side branches retained, the timber is rather knotty and coarse, but when planted and reared up as forest trees for utility, and the thinning regulated in such a way that the side branches die and fall to the ground of their own accord, they acquire fine clean stems comparatively free from knots, quite workable, and useful for all ordinary purposes. Young trees used in the round state for fencing purposes last equally long as trees of the best Scotch and Irish Fir of the same age. Irish Fir is identical with the true Highland Pine (*Pinus sylvestris*); fine specimens of the latter are to be found in many parts of Ireland. I have propagated it from seed, as well as the true Highland Pine in the natural forests of Braemar, and likewise cut up the trunks of both trees extensively for constructive purposes, and have not the least doubt that the two are identical.

Propagation.—The Austrian Pine is propagated from seed, which should be sown in April on well pulverised soil, formed into beds about 4 feet wide. Should the soil be of a stiff character, I have found a dressing of lime to be beneficial; it renders the soil more friable, and infuses activity into its dormant constituents, thus rendering it not only workable, but also capable of supporting and nourishing the young plants. Sow evenly over the surface, but not too thickly, as the plants under such circumstances get drawn up, weakly from want of proper space in which to develop their side branches. When they attain a height of from 4 inches to 6 inches, they should be planted out in nursery lines at a distance of about 8 inches apart and about 14 inches asunder between the lines, thus affording room for weeding and keeping the ground in proper order. Care should be taken to spread the roots properly out, an operation on which much depends. The ground which I use for these nursery plantations is in an exposed locality at the base of a hill, and consists of three kinds of soil, viz., good strong loam, light sandy soil, and light peaty ground. It is protected from the inroads of cattle by a common wire fence con-

structed in the usual way, with a web of wire netting about 30 inches high stretched along the surface and fastened to posts; this prevents hares and rabbits from getting within the enclosure. Thus the young trees have no shelter whatever, and being inured to the blast from infancy they receive no check as regards growth when planted out on exposed situations. On properties where

Extensive planting is contemplated it is a good plan to form a nursery for young plants as near the ground to be planted as possible. I have sometimes had four such nurseries at different places on the same estate, and have found them to be useful in every sense of the word. In selecting and enclosing ground for such nurseries preference should always be given to such as contain different kinds of soil, in order that the different species of young trees can be planted on the description of soil most suitable for their development. J. B. WEBSTER.

TRANSPLANTING EVERGREENS.

THERE are those who aver that autumn is the proper time for transplanting evergreens, and they sometimes do very well at that season if moved early, but much depends on the winter following, which, if severe, sadly cuts them up, and no wonder, for with roots disturbed and their vitality at a low ebb the sap is dried out of them, and they become withered sticks and cease to exist. If they can be planted in September so as to get fresh hold of the ground they may weather through, but if moved much later they stand a poor chance, as though the winter may be mild, like the past has been, there is March to contend with, with its searching east winds and keen blasts, is often the worst of the whole. This fact has been brought forcibly home to us this year, and those who have deferred their transplanting will have reason to congratulate themselves on the escape of their plants. The time I like to commence the work is the first week in April, and the things to start on are those that begin to grow first, as the great point is to catch them before their buds burst and they get young shoots, which in their thin, tender state are sure to suffer. Box, *Rhododendrons*, *Aucubas*, and others of that class that lift with large balls may safely be left till the last, and the more important, such as conifers, taken first. To ensure success with these, wide trenches should be opened around them at varying distances from the stems according to the size and age of the plants to be operated on. For a tree 10 feet to 12 feet high the trench should be at least a yard off, into which trench the earth can easily be forked from amongst the roots when their points are all clear. After tracing them back in this way, and working well under them, the plant may be lifted bodily by placing a lever beneath the ball and put on to a low "rulley," and thus dragged to the positions required. In doing all this great care should be exercised not to bruise or injure the roots, and it is equally important that they do not become dried. To prevent this it is necessary to have them covered during transit with wet mats, and to have the holes all in readiness for putting them in. These should be dug much larger than the roots are likely to extend, and the bottom also broken deeply up, the object being to give the plants every chance to work freely in the soil, which they would not be able to do were the earth undisturbed, and the progress of the trees under such adverse circumstances must therefore be slow. When placing them in the holes, the chief point is to see that the roots are properly spread out with the points leading down, and that the collars of the plants are on the same level with the ground as before, for to bury them deeper is very injurious, and when done, ends in throwing trees out of health. Another thing that is very apt to do this is leaving cavities among the roots by not filling in the spaces, and the only way to do this thoroughly is to wash the soil there, which may be done effectually by throwing a quantity of water quickly and with some force into the holes, when at the same time the plants should be gently

swayed to and fro, and then left still and quiet for it to settle and subside, after which the final filling up may take place. With this complete, the next thing is to

Mulch around the plants by giving a good thick coating of litter or long manure, which will prevent the earth cracking and the moisture escaping, and thus favour the formation of young roots. To keep the trees perfectly steady, which is a very important matter, they should be securely staked and tied, and if of large size it will be necessary to have three poles for each placed triangularly with the large ends on the ground and then brought in a rapidly slanting direction together at top, so as to take the stems about three parts of the way up, and if made fast there, the plant will stand perfectly rigid and quite undisturbed by the strongest of winds. Where neatness is an object, as it always is on lawns in sight of windows, galvanised wire may be used in lieu of poles, as by running it to stout pegs driven well into the earth, the plants may be supported equally well, but a collar of some kind should be used round the stem to prevent injury to the bark from chafing by the friction it gets. If the weather should set in dry later on after moving the plants, it will be a great help to them to wet them well over-head late in the evening by a jet of water from the garden engine, which will do much towards keeping the rind plump and the leaves fresh till the roots start, and this, when so favoured, they very soon do. With small shrubs there is no trouble or difficulty, as all that is requisite in their case is to lift with as good balls as possibly can be got, and in planting to make the soil firm around. For Rhododendrons it cannot well be too solid, and it is a good plan with these to ram it, as, owing to the hair-like nature of their roots, they cannot get hold of loose earth, and water when it is in that condition drains much too quickly through and leaves the plants famishing for want of that which they almost entirely live on. S. D.

Pernettyas.—The branch I sent you, cut from a bush in the garden here, will, I think, supplement your advice to grow this very pretty berried shrub as extensively as possible. It has been in about its present condition since last October, and neither frost, hail, snow, nor wind seem to have any effect on it, and we have plenty of all sorts here. I wish to endorse what "Rho" (p. 222) says about specifying locality when correspondents are writing as to hardiness and culture of plants. Their observations are often useless for want of this addition. In reply to your request I may say that the Pernettyas alluded to in THE GARDEN (p. 280) grow in a good sandy, well-drained loam—no peat. It suits them, for suckers come up all over the ground about the old plants. Of course, all are not so furnished with berries as the plant from which I cut the branch I sent you.—A. RAWSON, *Windsor mere*.

A curious Fir tree.—M. Louis Pire, President of the Royal Botanical Society of Belgium, has found a Fir tree in the forest of Alliaz, Canton of Vaud, which he believes to be older than the Linden of Fribourg, and considers entitled to be regarded as the oldest and most remarkable tree in the canton, if not in the whole confederation. It is growing near the baths of Alliaz, at a height of about 4500 feet above the sea, surrounded by a forest of Firs, which it over-tops by more than 30 feet. The trunk of this tree is a little more than 30 feet in circumference at the base. At about 1 yard from the ground it puts out, on the south side, seven offshoots, which have grown into trunks as strong and vigorous as those of the other trees in the forest. Bent and gnarled at the bottom, these side-trunks soon straighten themselves up and rise perpendicularly and parallel to the main stem. This feature is not, perhaps, wholly unparalleled, but another most curious fact is that the two largest of the side-trunks are connected with the principal stem by sub-quadrangular braces resembling girders. These beams

have probably been formed by an anastomosing of branches, which, common enough among angiosperms, is extremely rare among conifers; but it has been impossible to ascertain the manner in which the ingrowing of one branch into the other has been effected. The adaptation by which a limb, originally destined to grow free and bear foliage, has been converted into a living stick of timber is a strange one, and affords a new illustration of the power of Nature to fit itself to circumstances. The space between the rough flooring formed by the growing together of the offshoots at their point of departure and the girder-limbs is large enough to admit of building a comfortable hermit's hut within it.

Cost of Osier planting.—In THE GARDEN for March 17 (p. 242) is an article by Mr. J. Smith on Osiers and Osier beds. I have here about an acre of Osiers planted one year ago on a clay soil for the digging of which deep I paid 10d. per pole. The sets, about 18 inches long, were all planted by a master basket-maker and his men, and the cost of planting was about £3 15s.; the sets, 33,000, cost 12s. per thousand, and the whole cost amounted to rather over £30, a result widely different from that of Mr. Smith, who sets the cost of planting an acre at about £12. We are offered for Osiers by the basket makers here 1s. 1d. per bundle, and each bundle must be 3 feet 2 inches round at one foot from the butt. Mr. Smith says the produce the second year should be eighty bolts to an acre. Each bolt should be 18 inches round at 14 inches from the butt. Now, 18 inches round is about 6 inches through, and surely there must be more than eighty bolts of that size to an acre. Knowing but little about Osiers myself, some of your correspondents may perhaps be good enough to enlighten me upon the matter and tell me where I can get 5s. per bolt for the Osiers, as stated by Mr. Smith.—R. G., *Monmouth*.

Eurya latifolia variegata.—This pretty variegated evergreen shrub seems better able to resist the winter than is generally supposed. I recently saw some fine bushes of it which had experienced a dozen degrees of frost without the least injury, not so much as the very youngest leaves being in any way discoloured. This amount of frost would, of course, be no criterion as to its ability to stand a severe winter, yet in sheltered spots it might withstand one. This Eurya makes a very pretty shrub for conservatory decoration, as its leaf variegation is always bright and cheerful. In texture the leaves are somewhat like those of a Camellia, but more elongated, of a bright shining green, extensively marked with creamy white, and in the young state beautifully flushed with pink when exposed to light and sunshine. It is seldom met with in private gardens, yet it is sometimes grown as a market plant, so that, in all probability, it will after a time become more plentiful. This Eurya does not strike very readily from cuttings—that is to say, they often remain some time before roots are formed. It succeeds best when cuttings of the young shoots, just as they commence to become a woody texture, are used, and put in close cases on a gentle heat.—ALPHA.

SHORT NOTES.—TREES AND SHRUBS.

Garrya elliptica.—"Veronea" can procure young plants of this for about 5s. each from Mr. T. Smith, Messrs. Rodger, McClelland's, Warren's Point Road Nursery, Newry, Co. Down, Ireland.

Town trees.—Twenty trees have been planted, stretching from Mile-end Gate to Stepney Road, by the Metropolitan Playground and Public Garden Association, at a cost of little over £40, and presented for the public use, the Mile-end Vestry undertaking to keep them in order.

Red-berried Mistletoe.—The fruits of *Viscum cruciatum* (Lieb.) are perfectly red (baecis globosis rubellis teste; Boissier "Flora Orientalis," iv., 1068). I have gathered it most abundantly on the Olive trees of the Mosque Shefa-Omar in Jerusalem, April, 1880. Webb has given to M. Boissier one sample gathered at Gaucia, Southern Spain. Its only other localities are Jerusalem and Naplouse.—WM. BARBEY, *Valleyres, Vaud, Switzerland*.

Pruning Rhododendrons (*Lockhart*).—As part of your Rhododendrons are in flower just now, and others will be coming in in succession during the next three months, your best plan will be to prune each plant as soon as it has done flowering, cutting back all rambling straggling branches, so as to bring the bushes into proper shape. In this way the work will be done gradually, and by the time it is finished, say three months hence, the plants first pruned ought to be well furnished with healthy young wood and foliage. Thus the bed will never have had during the operation too naked and bare an appearance. Examine the plants in order to ascertain whether they are growing upon their own roots, or grafted upon the common *R. ponticum*; if the latter, they will be apt to produce a succession of young shoots from the roots below the graft; these ought to be pinched off, not cut, otherwise they will rob the plants.—J. B. WEBSTER.

GARDEN FLORA.

PLATE CCCLXXXII. DENDROBIUM BIGIBBUM.*

THIS Dendrobe, so gracefully represented in the accompanying plate, is in its way a "professional beauty of the most dainty kind"; but, alas, neither its grace of inflorescence nor its charm of colouring has saved it from harsh criticism. It has been stated to be "an Orchid very troublesome to grow; and when one has succeeded in blooming it a few blossoms have been gained about as beautiful as those of a Sweet Pea"—not an encouraging statement; but the fact that the plant is really difficult to establish in a satisfactory way will undoubtedly recommend it to the notice of all who excel in Orchid culture. The desire to succeed with species and genera notably "hard to grow" has ever been characteristic of all good cultivators, whether of Tulips, of Auriculas, of Heaths, of Ferns, of alpine plants, of fruits, or of vegetables; and in the case of Orchids this chivalrous spirit is perhaps more evident in our own time than ever it has been before. So the graceful little Orchid in question from the warm shores of South-eastern Australia is sure to secure both attention and admiration. The annexed illustration is so nearly photographic in its accuracy as to pose and form, and so much more than photographic in the all-important matter of colouring, that there is but little need to describe either its form or size or rosy tincture. I write this having before me a photograph taken from a healthy specimen of *D. bigibbum* some ten or fifteen years ago, at a time when healthy plants—very tiny ones they were mostly, I remember—were worth from five to twenty guineas each, or say just as many sovereigns then as shillings in this our import-everything-in-quantity epoch. This photograph represents a vigorous plant which grew in a Teak wood basket, suspended in the full sunshine in one of the old tan bed Pine stoves in the then Fairfield Nurseries at Manchester. It was at the time, about 1871 or 1872—I forget the exact year—considered a very remarkable specimen, its leading growth bearing a flexuose spike of eleven blossoms and buds. It was purchased by Dr. Ainsworth, of Lower Broughton, whose love for Orchids has

* Drawn from a plant in Mr. Peacock's collection at Sudbury House, Hommersmith.

Growers or introducers of new plants will oblige us much by early intimation of the flowering of new or rare species, with a view to their representation in our "Garden Flora," the aim of which is the illustration in colour, and in all cases where possible life size, of distinct plants of high value for our gardens.

outlived that of many other amateurs whom one could name. I am not quite sure, but I think the price was fifteen guineas; and yet the plant had only three pseudo-bulbs, the best about 13 inches in height, bearing seven good healthy leaves. An imported plant of it to-day of equal proportions would be dear at fifteen shillings. Seeing how quickly and surely imported plants take leave of us soon after flowering, sometimes before that little ceremony takes place, it would be interesting to know if this specimen is yet in the Cliffe Point House collection. Perhaps Dr. Ainsworth or Mr. Mitchell will satisfy our curiosity some day on this point. More recently Messrs. Veitch and Sons succeeded in importing a form with larger and more showy blossoms, albeit similar in colouring to those of the type represented in the annexed plate. To this the varietal name of "superbum" was most appropriately given, and a fair figure of it appeared in the *Floral Magazine*, t. 229 (third series). It also was honoured (the plant, I mean) by a first-class certificate by the floral committee of the Royal Horticultural Society on August 16, 1876, as being distinct and more showy than the Lindleyan type, which had been introduced ever since 1855, when it first bloomed in the then famous collection of the Lodiges at Hackney. The first living specimen which came to this country was sent by Dr. Thompson, who is said to have discovered it on Mount Adolphus, Torres Straits, on the north-east coast of New Holland, where it grows in company with D. Hilli, D. Johannis, and D. Tattonianum, together forming an interesting group, all requiring warm, light treatment. D. Hilli may, perhaps, best be considered as a long, thin-bulbed variety of the "Rock Lily" of Sydney (*D. speciosum*). In November, 1878, Mr. B. S. Williams, of Holloway, was fortunate enough to obtain a form in an importation received from North-east Australia with white blossoms delicately flushed with lilac-purple or pale violet—altogether a most beautiful rarity. The sitting for a portrait is not quite a novelty as regards this species, seeing that a good likeness appears in "Flore des Serres," t. 1143; then in Warner's "Select Orchidaceous Plants," t. 28, Mr. Fitch illustrates a remarkably pretty phase of its beauty from a plant then in the late Mr. Rucker's collection at Wandsworth. Then comes another picture in the *Botanical Magazine*, t. 4898, and the same plate again appears in Bateman's "Second Century of Orchids," t. 169, and finally the plate now before us. As to

Culture, I am not entitled by experience to speak, but I trust that some Orchid grower, whose efforts on its behalf have been successful, will oblige us with his experience in this matter. All the records I can find agree that a high temperature and plenty of light and sunshine are necessary to its welfare, and further that if the pseudo-bulbs are allowed to shrivel from want of water, even when at rest, it is difficult to bring back the plants which have so suffered to their original health and vigour. It is interesting to note, however, that the more robust D. Hilli, from the same habitat, is by no means fastidious or hard to please, growing, as it does, in any moderately warm plant stove, and, as a rule, blooming freely; it is also more showy than its congener, *D. speciosum*, which we have seen blooming quite freely in a sunny greenhouse. If we could but find out how best to grow *D. bigibbum* strongly, so as to bloom it regularly, it would soon rise in value and become one of the most highly prized and ornate of all

the many species of the group to which it belongs.

F. W. B.

ORCHIDS.

NOTES ON ORCHIDS IN FLOWER.

THE following are some of the most noteworthy Orchids in bloom in Mr. B. S. Williams' nursery, Upper Holloway, where there is now a gay display. Amongst *Dendrobies* the greatest novelty is

Dendrobium luteolum chlorocentrum, a variety recently named by Prof. Reichenbach. It may be at once distinguished from the type by its larger flowers (2 inches across), the segments of which are broader, particularly the labellum, which is strongly coloured with a deep primrose-yellow. The other part of the flower is a soft creamy white. It has, moreover, a sweet perfume. Like the original, it possesses the desirable character of producing its flowers on the young growth, the foliage on which gives quite a charm to the delicate colouring of the blossoms. The old form is really a pretty plant, but this variety is superior. Both may be seen in bloom in this nursery at the present time. That pretty, yet still uncommon species, *D. Findleyanum*, which we have praised so much of late, is thought much of here, and it may be seen in perfection. Its large mauve-tinted blossoms and ample yellow-stained lips make it conspicuous even among the gayest of its compeers. The fine old *D. Dalhousianum* was producing its large drooping racemes of splendid blossoms creamy-yellow and blotched with crimson. This, together with the golden clusters of *D. fimbriatum*, *densiflorum*, *thyrsiflorum*, and the long wreaths of such kinds as *D. Wardianum*, *crassinode*, *nobile*, *Freemanni* contributed largely to the display. Besides these one of the greatest beauties was

D. primulinum giganteum, which is unquestionably the finest of the group to which it belongs. The flowers are fully twice the size of those of the type, being over 3 inches, and with a labellum fully 1½ inches across. The colour of the sepals and petals is a carmine-magenta as near as it can be described. The ample lip is shell-like and of a delicate creamy white inclined to primrose. The whole flower sparkles with crystalline brightness, which makes it so lovely, and the delicious perfume adds to its charm. It is so seldom that we meet with this variety, that we infer it must be rare, though some good forms of the type pass under the name of *giganteum*. It is a gem of the first water, and it should be the aim of the Orchid lover to have it in his collection.

Calanthe Veitchi, even so late in the season, lit up the East Indian house with some very fine spikes of flowers, the colour of which is far more brilliant than that of the flowers produced in mid-winter, a circumstance, no doubt, attributable to the clearer atmosphere and solar heat. In order to obtain this late bloom the plan here is to keep the plants as cool as possible, so as to retard their growth. It is a great gain to have a crop of bloom of this Orchid to intermingle with others at this season, for it is so unlike any other in colour. The naturally later-flowering *Calanthes* were in full beauty also, particularly *C. Turneri* and *vestitivalis*, a variety with spotted white blossoms, and one that is still a comparative rarity.

The *Odontoglossums*, as may be imagined, are in the height of their flowering season, and a houseful of them, as here, is indeed a beautiful sight, the greatest beauty being obtained from the long, gracefully arching spikes of *O. Pescatorei* and *crispum* (*Alexandrae*), which latter is represented by some of the very finest forms, characterised by large, symmetrically shaped flowers, with broad, crisped-edged, overlapping sepals and petals—in short, what are called first-rate varieties. Among other kinds in beauty are *O. Halli leucoglossum*, remarkable for the labellum of the flower, being white instead of yellow. Of the typical *Halli* there is a specimen carrying a spike of fourteen expanded flowers, a beautiful specimen, which fully showed the beauty of the species. *O.*

radiatum, one of the luteo-purpureum group and a rarity, is a handsome Orchid. It has flowers 3 inches across, borne on erect spikes. The colour is a citron-yellow, heavily blotched with chocolate-brown. It is among the finest of its race. The rarely-met-with *O. cristatum*, in the way of *O. Lindleyanum*, but with much darker flowers, is in bloom, as are also *O. Andersonianum*, a fine variety; *O. cariniferum*, a handsome, but not often seen species; and the beautiful *O. nebulosum*, of which there is a grand specimen bearing half a dozen flowers on one spike. Amidst a group of *O. Rossi majus* we were much struck with a variety called *roseum*, which had the segment and lip of the flower suffused with a beautiful rose, as in the variety *rubellum*.

Ada aurantiaca, also in the *Odontoglossum* house, is worthy of note, the specimens of it being fine. On one of these we counted no fewer than twenty spikes, each of which bore a crowded cluster of bright orange-red blooms, a colour rarely met with among Orchids. It is an extremely showy Orchid, elegant in growth and very easy to grow well in a cool house, as it is so floriferous; it is, moreover, a capital subject for cutting from, and the cut spikes last for weeks in good condition in water. A few plants of it grown in an *Odontoglossum* house light it up brightly, and bring out more prominently the quieter tints of the *Odontoglossums*. Another Orchid, with flowers of much the same colour, is *Lælia harpophylla*, and here there are some uncommonly well flowered specimens. The glowing vermilion hue of the flowers of the best of the varieties is exceedingly attractive and very telling in an Orchid house. There is a wide difference between the best and the worst forms of this *Lælia*; in the poorest the colour is a washy orange. Mr. Williams grows it admirably with the *Cattleyas*.

Other Orchids in flower included the still rare *Epidendrum Wallisi*, noted in these columns last week. *E. evectum*, *Cymbidium eburneum*, *Colax jugosus*, *Pleione humilis* and its variety *tricolor*, both pretty plants, the first with large lilac flowers, the other with its labellum stained with yellow. *Cypripedium Harrisianum superbum* is the best variety we have met with of this handsome Lady's Slipper, the flowers being larger and the colour richer than the type. *C. Lowi*, *Haynaldianum*, *Argus*, *Warneri*, and *biflorum* are also in flower. *Galeandra Devoniana*, a rare and handsome species, has just begun its flowering season; also *Zygopetalum Clayi*, the new hybrid variety sent out recently by Mr. Williams. It is a most persistent flowerer, spikes of large flowers with bright violet lips being produced plentifully for several months in succession. Among the *Vandas* which form such a grand feature in the Orchid collection here there were several in bloom, and notably *V. tricolor Patersoni*, the splendid variety which was the subject of a coloured plate in THE GARDEN a short time since. It is one of the finest among the numerous forms of this species. In the *Masdevallia* house, already bright with flowers of *M. ignea*, *Lindenii*, *Harryana*, *Veitchiana*, there is the grotesque-looking *M. trochilus* (the Hummingbird Orchid) in flower, the blooms of which are fully 8 inches across. In contrast to this are such pigmy species as *M. Estradae*, and *Wagneri*, which have an interest to those who love flowers for their own sake, and not for their gay colours. W. G.

Sale of established Orchids.—On the 21st inst., the collection of Orchids belonging to Mr. J. Batten, Highfield, Bickley, Kent, was disposed of at Stevens'. There were 262 lots, the number of plants in each varying from one to six. The plants being on the whole well grown and in excellent health fetched good prices. The following are some of the highest which they realised, viz., *Cattleya exoniensis*, a fine healthy plant, with twelve bulbs and nine leaves, £78 15s.; *C. Mendeli*, a fine variety with fourteen bulbs, £19 8s. 6d.; another with twenty-three bulbs, £13 13s.; *C. labiata*, true autumn flowering variety with seven bulbs, £13 13s.; *Vanda cœrulea*, with twenty-three leaves, good variety, £10; *Cymbidium eburneum*, a fine specimen, twenty-two

growths and fourteen flower-spikes, £10; *C. Lowianum*, fine variety, £9 9s.; *Lælia purpurata*, £7 7s.; *Cattleya aurea*, £7; *Angraecum sesquipedale*, with twenty leaves, £8 18s.; *Dendrobium thysiflorum*, £5 15s. 6d.; *Cypripedium hirsutissimum*, fine plant, in 10-inch pot, £6 6s.; *C. caudatum*, specimen plant, with twenty-four growths, £11; *Cattleya maxima*, £5; *C. Mossiae*, nineteen bulbs, £4 10s.; and *Vanda Cathcarti*, with thirty-three leaves, £4.

Cœlogyne cristata Lemoniana.—The finest form of this lovely Orchid that has come under our notice is now in flower in the Kew collection. Its flowers are quite as large as those of what is known as the Chatsworth variety of the typical *C. cristata*, and like that kind it seems to flower later than the ordinary form of *Lemoniana*. There are few lovelier Orchids than this primrose-crested *Cœlogyne*, and when represented so finely as it is just now at Kew it is hard to say which is the most beautiful—it or the pure white (*alba* or *hololeuca*).

ORCHIDS IN AMERICA.

THE following are in flower at Kenwood, near Albany, the residence of the Hon. Erastus Corning, viz., *Phaius irrorata*, a scarce hybrid, the result of a cross between *Phaius grandifolius* and *Calanthe vestita*. In habit it resembles the former; the flowers, which are produced on a pubescent upright spike, are $3\frac{1}{2}$ inches across, sepals and petals cream coloured suffused with pink, lip roundish white, throat stained with yellow. Of *Phalenopsis Veitchi* two specimens are in flower; though scarce, this is not a striking variety; the leaves resemble those of *Schilleriana*; the flower measures about 2 inches across; sepals and petals roundish, same colour as those of *Schilleriana*; lip tapering as in *P. rosea*, but notched at the tip, and of a bright rose; probably a cross between *P. rosea* and *P. Schilleriana*. *P. delicata* is a new species with dark green leaves; flower same size as that of the preceding; sepals and petals white, the latter shaded with amethyst at the base; lip same shape and colour as that of the majority of *P. rosea*, of which this seems only to be a giant form. Of *P. intermedia Portei*, three specimens are in flower; it is a very pretty kind, supposed to be a hybrid between *P. rosea* and *P. amabilis*, and is about intermediate between these species. Good examples are in flower of *P. casta* and *leucorhoda*, natural hybrids between *P. amabilis* and *P. Schilleriana* and *vice versa*. The magnificent new *Phalenopsis*, *P. Stuartiana*, of which we have some 30 plants, is now in full bloom, and when its long branching spikes are seen intermingled with those of older species it is extremely difficult to determine what rank it should hold in this lovely genus; the variety *nobilis* is greatly superior to the type, but the variety *punctatissima* scarcely deserves a distinctive name. The flowers of *P. Corningi* are conspicuous, being the only ones of that type open at present, though those of *P. sumatrana*, *violacea*, and *Luddeemanniana* are developing rapidly. The flowers of two other species are anxiously looked for, viz., *P. Mariae* and *P. fasciata*. In addition to the species just named our *Phalenopsis* house contains over 400 spikes of *P. Schilleriana* and *P. amabilis*. *Dendrobium endocharis*, the result of a cross between *D. heterocarpum* and *japonicum*, besides being fragrant and very pretty, has the additional good property of lasting very long in bloom. The plant in question has been in flower over two months, one night of which was spent on a dinner table in a gas-lighted room, and it is still comparatively fresh. Of *Dendrobium suavisimum* we have several large plants each bearing from eight to thirteen spikes of flower; this species is apparently the better for a very long rest. Several plants of the free-flowering *Acerides Lceanum* are in bloom; though of recent introduction it is identical with a plant that has been here some years under the name of *A. Thibautiana*. A small plant of *Cypripedium barbatum nigrum* has nineteen spikes of flower on it, eleven spikes being twin-flowered, a mode of flowering by no means constant even in the case of this plant, as last year all the spikes

were single flowered, and the year before only some five or six spikes produced twin flowers. We have also *Schomburgkia* in flower a good deal in the way of *S. crispata*, but the sepals and petals are of a bright orange, and the lip and column pure white—a very showy species. It was imported by Mr. Corning from the Rio Janeiro. *Lælia Pilcheri* and its white variety, the result of a cross between *Lælia Perrini* and *Cattleya crispata*, are both in lovely condition. *Cœlogyne ocellata*, also in bloom, is a very pretty free-flowering useful Orchid, and one which lasts long in perfection. Cool house treatment suits it best. Two plants of *Dendrobium Pierardi* are finely in flower; they have bulbs from 4 feet 10 inches to 6 feet 3 inches in length, each carrying from 60 to 110 blooms. This species, when growing, requires abundance of heat, and it flowers best when rested in a temperature of not less than 60°. Other noteworthy species from among a collection of over one hundred kinds in bloom are *Lælia harpophylla*, a kind with bright orange-red flowers; some fifty plants of *Cattleya citrina*, *Cypripedium Domini*, *C. Lowi*, *vernixium*, *nitens*, *alba-purpureum*, *calurum*; some scores of *Dendrobium Wardianum* and *crassinode*; a few *D. primulinum giganteum*, the remarkably curious *Cirrhopetalum picturatum*, and an immense plant of *Vanda gigantea* with two spikes and twenty-seven flowers. On plants of *Odontoglossum Alexandræ* there are some hundred or so spikes at present open. *Oncidium bicallosum* and *O. obryzatum*, two very showy yellow-flowered species, and that extremely handsome variety of *Cymbidium giganteum*, called *Lowianum*, are all in good condition.

F. GOLDRING.

Odontoglossum sceptrum.—A plant of the true form of this Orchid that has just flowered in the New Plant and Bulb Company's nursery at Colchester shows it to be a very handsome species. It belongs to the *O. luteo-purpureum* class, but is quite distinct from any other of the group. The flowers, borne on an erect spike, are $2\frac{1}{2}$ inches across; the sepals are chestnut brown, barred and tipped with golden yellow; the petals, nearly an inch broad, are deeply jagged at the margins, and are yellow blotched with chocolate-brown. The lower part of the lip is, as it were, goffered, and being canary-yellow and brown makes it highly attractive. The plant in question bore a dozen flowers on one spike. It appears to be a very scarce plant as yet.

Longevity of Odontoglossums (p. 246).—It may interest "Peregrine" if I direct his attention to one of the original plants of *O. vexillarium* which is still in existence. The plant in question formed part of one of the first importations of this species made to this country, and was purchased by Mr. Michel, of Highgate, who kept it until his collection was dispersed; the plant then fell into the hands of Mr. Bull, of Chelsea, and in 1878 it was sold for sixty-five guineas to its present owner, and, strange to say, again came under the care of the man who grew it at Highgate. The plant was in perfect health when received from Mr. Bull. It produced seven spikes of bloom early in May, and from that date it has continued to improve. It now occupies a very large pot and has some five or six "leads." Curiously enough, it flowers a fortnight earlier than any of the others amongst which it is grown, and it looks as if another nine years would find it as healthy as it is at present.—B. ROOTS.

SHORT NOTES.—ORCHIDS.

Dendrobium Wardianum (*J. Almond*).—A very fine variety, both as regards size and depth of colour on the sepals and petals.

Abnormal growth of Dendrobium (*C. W.*).—The young shoot which you send of *D. nobile* with a flower produced from its side is quite an abnormal production, and if removed the young growth will be injured thereby. Normally the flowers of this *Dendrobe* are borne on the preceding season's growth.

Cocoa fibre for Orchids.—I fear that but little good will come of the attempt to grow Orchids in this. Shortly after Cocoa fibre was brought into notice by the late Mr. Donald Beaton it was tried rather largely in several London nurseries, notably, I think, at the Messrs. Rollisson's Tooting. At first it was thought that the plants would do well in it, but the roots eventually either did not move properly or decayed. I am no great friend of Cocoa fibre for potting purposes. There is no nourishment in it; at any rate plants potted in it in a pure state merely linger on. I fancy that, unlike Moss, it is naturally very cold indeed. I have been told that unless specially heated it is always several degrees colder than the house.—J. CORNHILL.

Odontoglossum Wilckeanum.—The finest form of this handsome hybrid we have seen is in Messrs. Shuttleworth & Carder's nursery, Park Road, Clapham. It may be best described as being about midway between a fine variety of *O. crispum* and *O. luteo-purpureum*. The flowers are $3\frac{1}{2}$ inches across; the petals, about three-quarters of an inch broad, are distinctly toothed at the edges, and with the rather narrower sepals are of a pale citron yellow heavily marked with irregular blotches of chestnut brown. The broad labellum has a fine frilling at the extremity, which is pale yellow, while in the centre of the lip is a large blotch of rich brown; altogether it is a most distinct and very handsome Orchid, and the plant in question, which bore ten flowers on one spike, showed the variety to perfection. In growth it resembles *O. crispum*. There appears to be several forms of this Orchid in collections, for only last week we saw two dark kinds and a very light tinted one called *pallens*, but the one we have just alluded to appears to be nearest that originally described. Another handsome hybrid Orchid in flower in this nursery was one called *O. mulus*. It is allied to *O. luteo-purpureum*, which it resembles in habit of growth and flower-spike. In size and form of flower, too, it resembles it, but is different in colour, which is a rich yellow heavily blotched with rich chestnut brown, so much so that the flowers look wholly of the latter colour at a distance. The frilled lip is yellow blotched with brown.

Orchids in flower at the College Gardens, Dublin.—Besides the lovely little plant *Angraecum citratum*, especially alluded to a few weeks since, there are two or more—says the *Irish Farmer's Gazette*—of the larger species in flower—stately plants, no doubt, but to our mind, as regards real beauty and interest, nowhere in comparison with that little gem of the genus. A meet companion of it is a pretty and rather rare variety of *Pleione humilis*, with pale, rosy lilac flowers, the lip suffused with yellow, blotched with pale cinnamon, the edge deeply and prettily fringed. *Dendrobes* are represented by the old and favourite *D. nobile*, the elegant *D. Devonianum*, the beautiful *D. Wardianum*, and the little less lovely *D. lituiflorum* var. *Freemani*. *Cattleyas* are represented by *C. Trianae* and the white-flowered *C. Warscewiczii*; *Odontoglossums* by *O. Insleyi* and others; and *Oncids* by the pretty purple sweet-scented *Oncidium cuculatum*; *Indian Moth* plants by some charming little specimens of *Phalenopsis Schilleriana* and *P. grandiflora*, growing in miniature shallow pans not more than 2 inches or so in breadth and 1 inch in depth. These tiny plants, suspended from the roof, are particularly pleasing and interesting, and show off their lovely flowers to great advantage. *Dendrochilums* are particularly neat and attractive little Orchids, and *D. glumaceum*, now in flower, is not only pleasing in its aspect, but agreeably fragrant. A small specimen of the beautiful *Lælia harpophylla*, with its rich cinnabar flowers, adds a pleasing variety, its colour being flaunted by only one or two others of the tribe—at least of those in cultivation.

Plants by rail.—My experience of the new parcel rates which were put forth by the railway companies as a materially reduced tariff is that I have much more to pay for a hamper of plants than

heretofore. A small hamper from Ilford, containing only six Auriculas in 4-inch pots, cost me 3s. 2d.; one from Aberdeen, quite small, cost 3s. 6d., and so forth. It is a mistake to send plants in boxes, and in most instances they will come quite as well without the pots, and with all the soil shaken off except a ball round the roots. Carriage is now charged by weight, and light packages wrapped in matting come cheaply enough, whereas a box containing plants in pots with heavy moss to prevent breakage costs thrice the amount.—BROCKHURST.

SEASONABLE WORK.

FLOWERS AND PLANTS IN THE HOUSE.

WILD Daffodils and their garden relatives are now some of our most valuable plants for indoor decoration. About a hundred flowers of the common single garden kind (*N. Pseudo-Narcissus*) placed in a large china bowl with leaves here and there have a fine appearance. They stand upright in bold masses, supported by Moss below the water; the heads stand at various heights, the stalks being of different lengths, and all touching the bottom. Such a mass of delicate yellow is cheerful in a living room. A bold group of the great Golden Daffodil (*N. maximus*) in an upright jar of dark blue porcelain also looks well; they are cut their full length of 22 inches. In a broad, shallow bowl are profusely flowered sprays of scarlet Japan Quince and Almond blossom; it stands high, and is well seen against an ebony cabinet. Another china bowl, large and deep, is filled with an important mass of blood-red Wallflowers; they are at their best when only the lower flowers are expanded, leaving a good space of the brown-purple buds in the centre—the whole year gives us few such feasts of rich colour as this bowl of Wallflowers. From the greenhouse there are Tea Roses Madame Falcot and Souvenir d'un Ami. In an entrance hall stands a large white Indian Azalea, a mass of bloom about 3 feet through, not trained in the stiff pyramidal shape so commonly seen, but grown as a graceful and naturally shaped bush; it is accompanied by plants of *Aralia Sieboldii*.

FLOWER GARDEN.

General work.—In order to get all extraneous work out of hand, we are as rapidly as possible finishing up Laurel and hedge cutting, applying mulchings to recently moved trees and shrubs, and edging and regravelling roads and walks. These done, mowing and the general preservation of neatness will constitute the whole of what we term our "far-afiel" duties. Local ones consist in affording beds of spring flowers timely attention; Hyacinths must be tied, and the less hardy flowers protected from the sharp frosts that generally prevail at this time. Where any of the beds are vacant, summer bedding arrangements may be determined, and the edgings and ground-works of hardy plants got out. *Herniaria*, *Cerastium*, *Sedum*, *Saxifrage*, *Thymes*, *Violas*, *Pansies*, and small shrubs are a few of the kinds the planting of which we hope soon to finish. As used here in the formation of upright edgings, 4 inches high, *Herniaria glabra* makes the most perfect green fretwork wall that can be conceived, and naturally grows so dwarf and dense, that it requires no attention to keep it in form. As edgings of *Echeverias* and *Sempervivums* have become so common, and look so formal and artificial, and as for such purposes there are so many better plants, their use in this way should be discontinued, but as a ground-work for taller succulents they are in every way appropriate, and when so used and allowed to flower, which they do profusely, succulents may safely be classed among the most quaint, yet gay, of all summer bedders, and in all weathers effective.

Bedding plants.—*Alternantheras* are growing so freely that abundance of cuttings may now be had from them at any time, and the hotbed mode of propagation described in a former paper is by far the best way to strike them, the frames

being moved or thrown quite open as soon as the plants have become well established. *Coleuses* and *Iresines* may still be struck, and those cramped in cutting pots may be potted off. These are both so long in starting when first planted out that, with a view to immediate effect, the aim should be to get the plants large before planting-out time. As increased space will daily now be needed for the tender kinds of seedlings, all sorts that will stand a degree or two of frost should be put out into pits or sheltered spots. *Lobelias*, *Verbenas*, and *Petunias* we put in turf pits and cover up with straw hurdles or felt frames. *Calceolarias*, *Gnaphalium lanatum*, and *Abutilons* are placed at the foot of the fruit walls, where they have the benefit of the wall covering. Most kinds of *Pelargoniums* are also quite safe under the same conditions. The tricolor section must, however, yet have glass shelter, but be given abundance of air on all favourable occasions. Seedlings of *Solanums*, *Wigandias*, *Daturas*, single *Dahlias*, and others sown a few weeks ago will now be quite ready to pot off, and when done place them in a close, warm atmosphere, and shade them for a few days till the roots have started in the new soil. Castor-oils should always be sown singly in pots, as they are bad subjects to handle in the seedling state. There is yet ample time if sown now to have good plants by the end of May; those sown earlier will be ready to remove to a cooler atmosphere to be grown on in plenty of light, otherwise the growth becomes attenuated and the plants liable to be severely crippled when first planted out. The same remarks apply to *Tobaccos*, *Ferulas*, *Acacia lophantha*, and *Grevillea robusta*. In mild weather draw the lights entirely off frames in which seedling Stocks, Asters, *Phlox Drummondii*, *Everlastings*, and others of the annual and biennial sections are growing, and prick them off or thin them out as soon as they can be handled; even if the surplus seedlings should be destroyed it is better than that all should be injured by overcrowding.

PROPAGATING.

Cyanophyllums.—Any of these that have lost their leaves during the winter, or that have become too tall, should be cut down and the tops inserted as cuttings. If put in now they will root quickly; the old plant will break out freely, and yield a goodly number of cuttings, which, if it be required to increase the stock, should be taken off and struck as soon as they attain sufficient strength. In preparing the tops leave about three pairs of leaves, and cut them off at the joint immediately below the bottom leaf; then insert them in pots of sandy soil and plunge them in a close case in a bottom-heat of from 75° to 85°. Before plunging them give a good watering to settle the soil, and keep them afterwards moderately moist till rooted, which will soon take place, especially if in a vigorous condition. It will be necessary to shade during sunshine, the object being to keep the leaves in as perfect condition as possible.

Rhododendrons of the greenhouse section, such as *Princess Royal*, *Alexandra*, and *Helena*, besides the newer kinds called *Taylori*, *Duchess of Edinburgh*, *Duchess of Teck*, and others, will, if in good condition, by this time have made new shoots, which will root without much difficulty and form useful plants. As these shoots, which should be about half ripened, consist of a cluster of leaves with a good length of bare stem below them, they form when taken off ready-made cuttings, but in removing them always leave two or three buds on the plant, in order to give it the means of furnishing itself with new growth. Sometimes the shoot removed is too long to be used in its entirety; in that case, it may be cut to the required length, but the buds at the base hasten the rooting process, and should be left on if possible. The soil most suitable for such cuttings is fine sandy peat, with a liberal admixture of crocks broken very small or pounded charcoal. In this they will root far more readily than in peat and sand alone, the young roots evincing a great partiality for the broken crocks by clinging closely

around them. Use small, clean, well-drained pots for the purpose, and insert the cuttings firmly; then give them a good watering, and place them in a close case in a temperature of from 65° to 75°; water and shade them as may be required; if too damp, give air for a little time. A sharp outlook must be kept for thrips, which, if once a lodgment is gained, will increase rapidly in the confined atmosphere, and greatly disfigure the leaves.

Phloxes and Pentstemons may, where scarce, be propagated now in the same way as *Chrysanthemums*, viz., as the young shoots come up cut them off and make cuttings of them, which should, however, if possible, be put where there is a little heat, say on a gentle hotbed. If the plants are in pots they should be kept close a few days before the cuttings are taken off. Cuttings struck in this way make good little flowering specimens the first season, but of course the above method will only need to be used for scarce kinds, but where large masses exist division is the best mode of propagation.

INDOOR PLANTS.

Heaths.—If the different varieties of soft-wooded winter-flowering Heaths, such as *hyemalis*, were cut back freely after blooming they will now have started into growth, and should be potted at once. Pots 2 inches larger than those they are already in will, in most cases, be sufficient; no disturbance of the roots should be attempted; merely remove the crocks from the bottom of the ball. Stock of this kind is often pot-bound, and therefore the new soil must be rammed more than ordinarily solid, otherwise in watering the water will be sure to pass through the new material, leaving the old ball dry. A mistaken impression often exists as to the time Heaths generally should be potted. Early in the spring before the weather gets hot, or in the early autumn after the dry, parching season is over, are the safest times for repotting, and where any portions of the younger description of stock are suffering from want of root room, we should not hesitate to move them now, even though their blooming season is approaching, as if the potting is managed with the care it should be, so as not to injure or disturb the roots, the flowering will be little interfered with. The principal thing is to see that each plant has the soil well moistened before being shifted, and to place them for two or three weeks afterwards in a pit or house with only a little air given at the roof, or one side, so as to avoid the drying effects of a thorough draught, for although Heaths are essentially air-loving plants, and will not succeed for any length of time with a deficiency of it, yet for the short period named, until the roots begin to move, no harm will be done. A word as to the description of soil suitable for the different sections of these plants. The hard, black, hungry peat that used at one time to be all but exclusively used for Heaths in general is anything but the best, and its use alone should be confined to the slowest growing, hardest-wooded varieties. All the freer growing kinds will make much better growth in peat of softer texture, which contains much more vegetable fibre, and is usually brown in colour. This seldom has much sand naturally in it, and consequently in its preparation proportionately more must be added.

Hard-wooded greenhouse plants.—In potting these, commence with the freest growing sorts, such as *Genistas*, *Acacias*, *Boronias*, *Eriostemons*, *Polygalas*, *Clianthus*, and others of a like description, giving them pot room proportionate to the more or less naturally vigorous habit of the respective kinds. It may be well to remind those who may not have had much experience with plants of this character that they will not bear partial removal of the old soil in the operation of potting, and that unless they have sufficient pot room they soon get naked and deficient of foliage at the bottom, a condition which makes them more eyesores than ornaments.

Vallotas.—These handsome late summer flowering plants will now be making growth, and, where required, larger pots should be given them, yet discrimination here is required, for in common with most bulbous subjects of a similar character they do not succeed well if over-potted. Vallotas may be increased by the quantities of offsets which they produce, and which if allowed to remain attached to the old bulbs soon impoverish and over-crowd them. It is therefore well at this season to remove all the little bulbs, putting them in small pots about 1 inch apart just within the rim like cuttings, and using, as in the case of old bulbs, good holding loam with a little sand, making it firm, as they do not succeed with light potting. An ordinary greenhouse temperature is sufficient during the growing season, but, like a good many kindred species, these Vallotas enjoy a few degrees more warmth during this and the following month if at the same time they are accommodated with a light position, otherwise the extra heat would induce over-lengthening of the leaves.

Brugmansias.—Few plants are more easily managed than the Daturas, or rather Brugmansias, yet they are not so generally cultivated as they deserve to be. Cuttings put in now in the ordinary way and placed in a little warmth will soon strike and make nice flowering plants in a year, forming beautiful objects when in flower in conservatories, halls, and similar places; they also come freely from seed, which, if sown at the present time and placed in a little warmth, will soon germinate, after which, when large enough, the seedlings must be put singly in 3-inch or 4-inch pots, giving them more space as the season advances. Old plants that require more room should now have a shift, using pots or tubs, regulating the size of these by the extent available for the plants, as they will bloom fairly well in 15-inch pots; still, so confined the size and quantity of the flowers are much less than is attainable with more root space. Large plants that were cut back after blooming, and that have made some growth, should now be repotted, giving them good turfy loam with some sand added, and as soon as they begin to make free growth, manure water ought to be given regularly.

Double Primulas.—The flowering will have somewhat weakened the plants, and it is better to now pinch out the bloom-stems as they appear; this is the more necessary where an increase of the stock is required. Where large plants exist these may now be divided, separating the crowns and inserting them singly in small pots, placing them in an intermediate heat, and so far confined under propagating glasses as is requisite to prevent flagging, but no more than this, as if kept so close as some things require damping off will follow.

Propagation of winter-flowering plants.—If, as advised some weeks ago, a sufficient number of cut-back plants to furnish the requisite quantity of cuttings have been placed in heat enough to induce free growth, the cuttings should now be ready for putting in. A brisk stove temperature is necessary to strike them, and no time ought to be lost in getting them rooted, for on this much depends their becoming strong enough to flower well.

FRUIT.

Peaches and Nectarines.—Now the sun is gaining strength, timely ventilation, good syringing with tepid, soft water, and liberal supplies of warm, diluted liquid will be imperative. Let the night heat range about 58° when mild. Stop the fires early on bright mornings, and syringe as the temperature begins to rise. Give a little air when it touches 65°, gradually increase it until 75° is attained with a free circulation, reduce in like manner, and finally close at 70° with a copious syringing. Although we have often drawn attention to the importance of mulching inside borders, we must again urge the necessity of getting the surface roots well covered with short manure for the twofold purpose of exciting them into activity, as well as for giving off atmospheric

moisture so much needed by the tender foliage through the hottest part of the day. All the base shoots having been neatly heeled down, pinch in intermediate growths to form spurs and avoid laying in more wood than is wanted to furnish the tree and carry next year's crop. Allow weak growths to have freedom and balance the flow of sap by stopping those which are likely to become gross, and tie them down to the trellis. Look well to mid-season and late houses and see that trees having their roots in external borders do not suffer from want of water. It does not often happen that outside borders get dry before midsummer; but this has been an exceptionally dry spring, and radiation under a powerful sun being very great, a good covering with old lime rubbish followed by a little long litter, while admitting warmth will prevent the escape of moisture from the surface roots. Keep late houses fully ventilated until the fruit is set, and syringe freely when the petals begin to fall. If the ripening is to be delayed until late in the season, retard as much as possible through the early stages, when a low night temperature is so beneficial to all kinds of stone fruit.

Figs.—If the early pot trees started in November have been kept in a bottom-heat of 70° the fruit will now be swelling rapidly, and, favoured by one of the most genial winters on record, some of the most forward fruits may be expected to ripen early in April. With a continuance of favourable external conditions allow the temperature to range from 60° to 65° at night, 70° to 75° by day, and 80° to 85° after closing with sun. Give air at 70°, gradually increase it as the day advances, and economise fire heat by closing early. Syringe well twice a day, otherwise the foliage will soon be infested with spider, and keep the roots well supplied with diluted liquid or guano water until the fruit begins to ripen, when more air and a drier atmosphere will be necessary, but even then a liberal supply of water must be given to the roots, as anything approaching a check would cause the trees to cast all the best fruit. As Figs in pots or internal borders make very quick growth, see that stopping, thinning, and tying receive regular attention, and carefully guard against getting the young shoots crowded, as it is simply impossible that closely-shaded fruit can have colour or flavour, and a flavourless Fig is the most insipid fruit imaginable. Trained trees in succession houses will require mulching with good manure and liberal watering. Ventilate freely through the early part of the day to keep the young growths short-jointed and fruitful. Thin out the spurs and tie in leading shoots where there is room for extension. Trees in late houses may be pruned and tied in to the trellis, as there is now little danger of damage from frost, but unless the structure is supplied with hot-water pipes it will be well to retard for the present by ventilating pretty freely on all suitable occasions.

Strawberries.—As ripe fruit is gathered let old plants be destroyed or removed quite away from the houses, and thoroughly cleanse the shelves before they are again occupied with the succeeding batch. Where exposed shelves in vine-tries and Peach houses are occupied with plants in various stages of growth incessant syringing and watering will be needful if they are to be removed without leaving a legacy of red spider behind them, for which a heavy price will have to be paid before the end of the season. Good forced Strawberries are always a great acquisition to the dessert; but it is not known to every employer who is told he may grow everything in two or three small houses, that his tasteless Strawberries are often the cause of his Grapes remaining red and his Peaches ripening prematurely, when a properly constructed house would give comfort and satisfaction to employer and employed. Where proper arrangements do not exist a long season of ripe fruit may be secured by allowing a quantity of plants to set, swell, and ripen if need be, in the pits in which they are wintered, and by planting north borders with some of the best late kinds, including Oxonian, Elton, and Frogmore Late Pine.

Where British Queen is grown for coming in through May and June, remove all weak trusses and blooms, and fertilise the finest. Keep the plants near the glass with plenty of air; tie the fruit to sticks when set; feed and syringe well. In low, damp gardens, or imperfectly ventilated pits and houses, some kinds, notably President, Paxton, and Napier, are subject to mildew, which soon spoils the fruit. The best remedy is good cultivation, abundant ventilation, and frequent syringing with clear sulphur water. Forced plants of Vicomtesse Héricart de Thury will require protection from frost until they are sufficiently hardened for planting out. If placed on a west border they will sometimes give a few dishes of fruit after late kinds on north borders are over.

Cucumbers.—If old plants cannot be dispensed with, thoroughly renovate the beds by forking out as much of the sour soil as can be taken away without injuring the roots, and replace with good rich turf and lime rubble. If worms have got into the pots or beds this operation will afford a favourable opportunity to apply lime water for their destruction, as Cucumbers cannot succeed where the soil is exhausted by these pests. Woodlice, very often the cause of canker at the surface of the soil, may also be greatly reduced by the application of boiling water, as they heat a hasty escape to the edges of the pits for temporary shelter. Continue to cut the plants over until all the old foliage is renewed, then train thinly and keep the foliage clean by syringing with warm soft water, light cropping, and early closing with solar heat and moisture. If it is needed, spring-sown plants may now be allowed to carry a few fruit; but light cropping is imperative. Ventilate freely through the early part of the day to keep the foliage firm and healthy, and avoid shading as much as possible, or altogether where the fruit is not affected by the sun. In light houses the fruit of Telegraph is very liable to morning scalding; but a thin shade for a short time until the fruit is dry, and early ventilation will always correct this evil.

Manure beds.—Although plants in frames have had a favourable time of it, linings will now require regular renovation to maintain a steady minimum of 70°, and good dry covering must not be neglected. Add a little fresh soil as the roots protrude, peg down the young shoots, train thinly, and rub off all male blossoms up to the time their services are needed. Be guided by the weather in the application of water; if bright and fine and the heat is strong overhead watering about 2.30 p.m. will do good, but for the present the wetting of the foliage must be conducted with great caution.

KITCHEN GARDEN.

DOUBTLESS many will have Snow's Broccoli sown on the plea that second sowings form a good succession, but this is a mistaken idea. If this Broccoli is sown just now, or any time before this, it grows quite out of all character—becomes large, soft, and succulent, and the first sharp frost prostrates the foliage, leaving the heart unprotected. If sown the first week in May it will be fit for cutting the first week in November, and the plants will be close to the ground and have much the same appearance as Walcheren Broccoli. Onions, Carrots, and a few Turnips may now be sown. We are at present briskly employed in planting our main crop of late Potatoes, consisting of Beauty of Hebron, Schoolmaster, and Paterson's Victoria chiefly. The Champion, but for that objectionable deep eye, would be largely planted. So far as flavour goes it is excellent. Early plants of Celery will now be ready to prick out. A slight hotbed is the best place for them, but they will do well in boxes under glass. Early Cauliflowers will also now require attention in the way of pricking out, in order to obtain good plants for the second batch of this indispensable vegetable. Onions may be sown; the two varieties which we grow are White Spanish and James's Long-keeping; the latter we are now supplying firm, and not shot in the least. The main crop of Carrots may also be

sown. Sweet Basil, a really useful herb, should be potted and grown in Cucumber frames for use green; all kinds of herbs may now be sown under glass.

PUBLIC GARDENS.

THE *TIMES* ON THE PARKS AND THE METROPOLITAN BOARD.

WITH regard to the great requisite of healthy town life—the supply of fresh air—London is more happily endowed by Nature than any other large town in the kingdom. Not only is she situated on a noble river, but she rejoices in a considerable acreage of royal parks, and she is surrounded by breezy heaths and commons. It has been computed that within fifteen miles of Charing Cross—an area nearly the same as the Metropolitan Police district—there are over 16,000 acres of open land, while if the radius is extended for another ten miles this acreage is more than doubled. Parliament has for many years been dimly conscious of the value of this heritage. So early as 1845, when the tide of enclosure was at its height, the rule was laid down that no common should be enclosed by the newly created Commissioners within fifteen miles of the capital without the express sanction of Parliament. Ten years afterwards, when the Metropolitan Board of Works was formed, one of the powers conferred upon it was that of submitting to Parliament proposals for the formation of parks. In exercise of this power Finsbury Park and Southwark Park were formed, but in each case the Board was too anxious to make the project pay its own expenses, and gave to the builders land which they might have thrown into the park. In the ten years which followed the formation of the Board the question of open spaces grew with a rapidity which the Board could not comprehend, and in 1865 the whole subject was discussed at length by a large and influential committee in the House of Commons. Before this committee the Board propounded views which, if they had found favour, would have deprived London of the greater part of its open spaces. The lords of manors and the commoners were to be bought out, and the Board was to recoup itself by selling part of each common for building. Fortunately, wiser councils prevailed. The commoners were exhorted to assert, in the interests of the public, their rights of grazing and Furze-cutting, and thus to prevent enclosure; the Commons Preservation Society was formed, under the chairmanship of Mr. Shaw-Lefevre; and that series of legal contests began which culminated in

The great Epping Forest suit.—Throughout this struggle the Metropolitan Board never stirred a finger, but looked on with cold disapproval. Not so the Corporation of London. When Epping Forest was in imminent danger of being lost from want of funds to contest the claims asserted by the lords of manors, the Corporation boldly came to the rescue. It spent its wealth freely in the Courts, in Parliament, and before the special tribunals instituted to settle the complicated questions which arose. The consequence is that nearly 3000 acres of forest land have been rescued from actual enclosure, and a tract of nearly 6000 acres in all has been dedicated to the public use. This is a splendid service, which not even a reformed municipality can surpass. But such a municipality would not have been hampered in its performance as the Corporation was. The Metropolitan Board, so far from seconding its

efforts, interested itself only in advancing its own claims to assume the management of the open space reserved from enclosure in place of the body by whose efforts the rescue had been effected. Needless to say its efforts were fruitless. But, as in all such cases, the ratepayers' money was spent—spent by their representatives in a contest of rivalry with another public body, also drawing its funds (in this instance) from the taxation of the metropolis. In other instances the action of the Board has been more directly hurtful. In 1870 the Corporation obtained Parliamentary sanction to commute its dues on the metage of grain entering the Port of London for a fixed duty of 3d. per hundredweight, on condition that it laid out the proceeds in the preservation of open spaces. The Metropolitan Board opposed the Bill, and, unable to throw it out, obtained as the price of abstention from further contest the insertion of words limiting the application of the fund to the City on the one hand, and to the district outside the boundaries of the metropolis on the other. Thus, in the area which is essentially London, from Whitechapel to Kensington, from Hampstead to Camberwell, the Corporation are powerless to use

The fund specially devoted to the preservation of open spaces. It cannot be used in the acquisition of Lincoln's Inn Fields, in the formation of Paddington Park, in the preservation of such spots as Kingsland Green, or of any common within the metropolis. The district which pays the main part of the duty is deprived of direct participation in its benefits, and that at the instance of a Board which is supposed to exist for the protection of its interests. It is impossible to conceive a stronger condemnation of the present system of dual government, or of the existing constitution of the only body which is representative in any way of the metropolis at large. Nor have the ratepayers the consolation of knowing that, though taxed twice over for the purpose, all that is possible in the way of providing open spaces is being done for them by the Board. The total acreage of the parks, gardens, and commons under the management of the Board, as shown by their last report, is, indeed, 1698 acres, much of which has been obtained at a very great and, in the opinion of many who are qualified to judge, a needless cost. On the other hand, the Board actually opposed the Bill by which Wimbledon Common, 1000 acres in extent, and by far the most important of the London commons after Epping Forest, was dedicated to the public, because it was not proposed to invest the Board with its management. They have done nothing to open the gates of the numerous

Square gardens which lie in the midst of crowded neighbourhoods, and which, at the expenditure of a little trouble in negotiation, might be made to subserve the interests of the inhabitants generally without injury to the occupants of the square houses. Notably, they have refused in any way to aid in the opening of Lincoln's Inn Fields, a space of seven acres, surrounded by business premises, the tenants of which never step inside the gardens from one year's end to another. Nor do they make any effort to acquire land for the purpose of forming new parks in districts not possessing commons, and towards which building is extending. In the case of Paddington Park it will be remembered they gave but a lukewarm support, which resulted in the loss of the Bill, objecting to the great amount of money involved, while at the same time they took no steps to

supply the undoubted wants of the north-west of London by taking other land which might be obtained at a cheaper rate. They have not even been able to preserve the area committed to them, for only within the last few weeks large spaces have been abstracted from the Thames Embankment Gardens for the purpose of providing vent-holes by which the underground railway may vomit forth foul air to counteract the beneficial effect of the surrounding trees and shrubs. It is true that the Metropolitan Board opposed this project in the approved way before a Parliamentary Committee, but does anyone believe that a really representative corporation would have suffered itself to be beaten on such a question, and would have surrendered, after a mere argument by counsel, part of the most central open space in London in order to save the shareholders of a railway company the expense of building proper ventilating shafts? The extension of the Corporation to the metropolis at large will enable such unworthy considerations to be dispensed with, and it will not be long before London will find how greatly the conditions of town life may be improved by the existence of a central authority, capable of taking a comprehensive view of its duties, and strong enough to give effect to its intentions.

HULL BOTANIC GARDEN COMPANY.

AN extraordinary general meeting of the Hull Botanic Gardens Company was held the other day in the George Hotel, Whitefriargate. The chairman (Dr. Rolitt), after some preliminary observations, went on to make a statement in regard to the position of the company at the time when it was taken over by the new administration. The company was based on an agreement with the North-Eastern Railway Company, which agreement comprised two classes of land—the land on which the gardens were situated and the adjoining land to the north and east, and also the leasehold land situated on the east. In regard to the financial position of the company, he said it was very unsatisfactory; in fact, they had no funds at all for the payment of rates and other debts, and unless Mr. Dauber had found the money and paid the claims made the company must have been prosecuted. The liabilities amounted to between £700 and £800, and they had also a claim of £2600 from Sir James Walker. Their creditors had exercised a fair amount of forbearance in the past, and were still willing to do so. Their assets, even if the plants and other things were sold, would not bring more than from £2000 to £3000 value. In reference to the North-Eastern Company, he said they had declared that they must have matters brought to a close and that some definite arrangement must be come to either for the purpose of fulfilling the contract with them with regard to the purchase of the land or of cancelling it. They had given them notice that the tenancy of the leasehold land must be terminated, and in that action the Botanic Company had no defence. The directors had tried to negotiate with the railway company and they had expressed their willingness to defer taking possession until the 30th of June, and in that way the movable effects of the garden should practically be saved for the company. Every effort had been made to prolong that time till the end of October, for the obvious purpose of conducting the gardens during the season and to get subscriptions, which would not otherwise be obtained. They should either have to determine whether they should resist the proceedings of the North-Eastern Railway, or whether they would concede to the order and place themselves beyond all question in the hands of the railway by not paying the amount of the purchase money. The amount due was about £23,000, and if it was not paid they must be prepared to allow the railway to take possession, if

not in June at the latest in October, and the question for their consideration was, were they to extricate themselves from that position or not? If it were not possible to extricate the company there would be very little left for the creditors, and certainly nothing for the shareholders, besides a great loss to the town. Would the town permit the gardens to cease? or would they, by public spirit, or some solution of the difficulty they were placed in, manage to allow those gardens to be continued, and thus allow the inhabitants of the town an additional ground for recreation, and also the facilities for the study of scientific subjects? There were four courses open to them, of which they would have to choose one. In the first place they might assent to the order proposed by the railway company, of which they had the alternative, and they could then sell the building plots lying on the north side of the gardens, or, in other words, they could not pay the North-Eastern Railway while they held the land, but if they divided it and sold the plots which ranged in price from £190 to £300, they might thus raise sufficient money to meet the claim of the railway company. Of course there were other claims beside that of the railway company, but these were of a minor nature, and he asked them to join in aiding the disposal of the eighty-six plots as suggested. The second course open to them if they could not get rid of the plots was to sell the land for whatever it would fetch, as the land was undoubtedly sinking the gardens. The third course was to allow the directors to let it or sell it to a syndicate, which was a fair opportunity for private speculation, and if this object could be obtained they would save the gardens, and also preserve the botanic element for the benefit of the town. The fourth course was to let the town take the gardens on the condition of freeing the Botanic Company of their liabilities, and thus secure the open space as a park to the town at a comparatively cheap rate. These, he said, were the courses open to them, and he concluded by calling upon them to save the gardens from the hands of the railway company, as on their enterprise and the town's public spirit depended the retaining of the gardens for the inhabitants. A discussion took place afterwards, the majority of those present supporting the course of inducing the Corporation to negotiate with the North-Eastern Railway Company for the taking over of the gardens. It was ultimately moved from the chair—"That the proposed order allowing the North-Eastern Railway Company to take possession of the gardens at an early date be assented to, and that the town be approached by the directors with a view of saving the gardens for the benefit of Hull, either as gardens or for a park." Mr. C. Wilson, M.P., seconded the resolution, which was carried unanimously. At the close of the meeting the chairman spoke in the highest terms of the ability and energy of the curator, Mr. Macmahon, who, he said, had done all that any man could do for the gardens under the most trying and difficult circumstances.

We learn that the liabilities, including contracts to make roads, &c., are estimated at about £30,000, and the assets about £2000. During the past twelve months £4000 of the debt has, we believe, been paid off.

Regent's Park enclosure.—A contest is going on between the public and the neighbouring householders and others in regard to that portion of the Regent's Park near Clarence Gate which has up to the present time been kept as a private garden. The strip of land in question is about three-quarters of a mile long and about 50 yards wide. It contains fourteen acres, or more than three times the area of Blgrave Square; and it is now devoted to the private use and enjoyment of about a hundred householders of adjoining houses, who pay one guinea per annum for the privilege, and about sixty people who live rather farther off, who pay two guineas per annum. The chief point urged at a recent meeting held on the subject in Regent's Park was that persons entering the park by the Clarence Gate from Baker Street, if they wish to cross the park, have no

choice but to go round by York Gate on the one side or Hanover Gate on the other, while but for the enclosure of the fourteen acres aforesaid a bridge might be thrown across the lake, and a speedy and convenient approach to the park be provided. If it be true, as alleged, that the householders have no shadow of a legal claim to the exclusive enjoyment of the garden in question, it is clear that a very great advantage would accrue to the public from its being thrown open, as the region behind the Clarence Gate is very populous. On the other hand, the residents in Hanover Terrace, Sussex Place, and Cornwall Terrace will lose the privacy of a very charming garden, which doubtless they have enjoyed none the less because they have had no legal and permanent right to enjoy it. It may be a consolation to them to reflect that if they lose their present private garden, and if the bridge asked for by the agitators be built, they will still be within a few hundred yards of one of the most retired and beautiful gardens in London, that of the Royal Botanic Society. The case, therefore, will not be one of very great hardship to the householders, while to the public the benefit is obvious.

Improvements in Brighton.—The Brighton town council having applied to the Local Government Board for permission to borrow £6000 for "the purpose of street improvements," Mr. S. J. Smith, C.E., attended the Town Hall yesterday to hold an inquiry on behalf of the Board. The town clerk explained that the money was required to lay out two enclosed lawns, 300 feet by 50 feet, with lavatories, covered seats, and the band-stands on that portion of the beach between the Western Pier and the Western boundary of the borough. A long discussion, raised by the inspector, then took place as to whether the money should not have been applied for under that section of the Public Health Act relating to the provision of public parks and pleasure grounds; but it was shown that the esplanade adjoining the ground had been repaired at the public expense for twenty-four years, and that the beach only commenced on the southern side of the proposed enclosure.

The Alexandra Park Bill.—The London correspondent of the *Manchester Guardian* writes: There is a bill which will probably some day this session come before the House of Commons raising a point of peculiar interest with regard to land. This is the measure by which the parties in possession of the Alexandra Park and Palace at Muswell Hill propose to obtain power to convert the property without reserve to building purposes. This intention will be stoutly opposed, and probably with some success. It is alleged that when a company obtains parliamentary powers to devote land to public amusement for a certain charge of money not necessarily specified, interests grow up in the neighbourhood in connection with the undertaking which the Legislature ought not to neglect, and it is said that so conservative an authority as Lord Redesdale holds this view of the Alexandra Park Bill. Anyone will understand the case by reference to that at Sydenham. Could the Crystal Palace Company convert all their land into building land, and if they came to Parliament for such powers, would not Parliament be justified in saying that the public had acquired quasi rights in the land, and that its conversion to exclusive purposes could not be permitted without some regard being shown to those rights? At all events, this view so strongly prevails that the Alexandra Park Bill will hardly be accepted without considerable modification.

Enclosure of Commons Bill.—Among the most hopeful legislative promises of the session is a Bill to amend the laws relating to the enclosure of commons, which has been brought in by Mr. W. James, Mr. Bryce, Mr. Cheetham, and Mr. Story Maskelyne. In point of form the Bill is as patchy and unintelligible as most others; but the substance of the measure constitutes a decided advance in the great cause of the protection of commons. If it becomes law, no common within a certain distance from towns—the distance varies from one mile in the case of a town of 5000 inhabitants

to six miles in that of a town of 200,000—can be enclosed without an Act of Parliament. Even in the case of more distant commons—up to fifteen miles in the case of towns with 100,000 people or upwards—power is given to the urban sanitary authority to resist enclosure before the commissioners, and to contribute to the maintenance of commons as open spaces. Facilities for the management of commons devoted to that purpose, a provision against encroachment upon roadside waste, and some clauses removing the technical difficulties which often lie in the way of the assertion of rights of common, make up the rest of the Bill. The measure certainly does not go too far in the right direction, but it goes some way, and it deserves the hearty support of all who amid the distractions of party controversy still remember the health and welfare of the people.

AMERICAN NOTES.

Tree sports.—Mr. Robert Douglas, the veteran nurseryman, of Illinois, says that he is sorry to be compelled to confess that all his attempts to produce something good from hybrids have been absolute failures. Whatever he has produced of value has been produced by sheer accident, and in nearly every instance from common seeds sown in the nursery beds or nursery rows.—*Prairie Farmer*.

Fruit from primitive forms.—With seeds of fruits with an abnormal development of pulp, like does not produce like. As an instance, the Acme Tomato was not produced from the seeds of the largest and finest specimen, but from the small hardy Plum Tomato fertilised by the best known variety on the score of size and perfection of fruit. So the Rogers' Grapes came from the seeds of the wild Sage Grape fertilised by the best foreign sorts. The Hovey seedling Strawberry was from the seed of the native species fertilised by the South American. The Wealthy Apple was from an Astrachanic Crab seed fertilised most likely by the Fameuse. The scuring of hardy and vigorous seedlings from nearly primitive forms is also illustrated by the remark of our Joseph Harris in his seed catalogue for 1880: "You can raise, he says, more plants from an ounce of poor Cabbage, Onion, Lettuce, Carrot, Parsnip, and Beet seed than you can from the best and choicest." Again we have the authority of Dr. E. L. Sturtevant, who says: "As a rule to which as yet I have noted no exceptions, the larger the Apple the greater the number of abortive seeds. It also appears to be a fact that in general the improved varieties of Apples contain fewer seeds and a larger proportion of abortive seeds than do wildling Apples." Still again we have the word of Mr. Robert Manning, and other good authorities in America and Europe, that the seeds of the best cultivated Cherries are usually abortive, and that hardy new varieties are produced by planting primitive forms fertilised by sorts with the best fruit.—*New York Tribune*.

Rose growing in California.—Mr. David Tisch, of Oakland, spoke as follows of Roses at a recent meeting of the State Horticultural Society, San Francisco: Parkinson, in 1620, stated that there were but twenty-four kinds of Roses at that time known in England, including the Sweet Brier. Among others of his twenty-four sorts is the parti-coloured Rose, called by some York and Lancaster. "The double yellow Rose, of great account both for its variety and doubleness, was first brought into England by Master N. Lete, a merchant of London, and a great lover of flowers, from Constantinople, which, as we hear, was first brought thither from Syria, from which is sprung the greatest store that is now flourishing." The Moss Rose was introduced into England at the beginning of the last century, and was first mentioned by Fimber in 1721. After alluding to the classification of Roses, he said: There is one variety of Rose that I have grown for many years, and I think it is the best one we have in the State. It is Safrano. Lamarque is one of the best climbers we have. In the East people have given up growing white Camellias, and use the

Lamarque Rose in their place. In place of the red Camellias they are using the Pauline Rose. The following is a list of Roses which will flower the year round: Hybrid Perpetuals—Beauty of Waltham, Cardinal Patrizzi, Eugène Verdier, General Washington, General Jacqueminot, Gloire de France, John Hopper, Jules Margottin, La France, Madame Rivers, President Lincoln, Princess Mathilde. Noisette—Lamarque, Climbing Devoniensis, Maréchal Niel, Claire Carnot. Banksia—James Sprunt, Cherokee, Ophir, Non-plaisir, Queen of the Prairies, Chromatella. Bourbon—Souvenir de Malmaison, Charles Duval, Hermosa, Louis Odier, Mrs. Bosanquet. China Roses—Agrippina, Louis Philippe, Madame Breon. Teas—Bon Silene, Bougère, Cels-Multiflora, Devoniensis, Elise Sauvage, Emperor of Russia, Gloire de Dijon, Isabella Sprunt, La Sylphide, Lady Warrender, Safrano, and Triomphe du Luxembourg. Proper pruning and irrigation had a great deal to do with Rose growing. Dr. Gibbon said that for three or four years past he had been paying some attention to the Castilian Rose. He pruned it up as a standard, trimmed it up closely, and it improved vastly. Last year it bore two crops of Roses.—*Pacific Rural Press*.

Water Lilies.—Mr. Sturtevant says: "In regard to Nymphaea Sturtevantii, I am sorry to state that it does not flower as freely as N. devoniensis. It flowers constantly, but does not produce so many at a time. It has the same odour as devoniensis, which I do not think is very pleasant. It opens in the evening, and closes about the middle of the next forenoon. Each flower lasts four days. I started my plants in warm water under glass, then planted them out in a basin with a cement bottom where they received no artificial heat whatever the whole season. There is quite a difference between the temperature of the water in one of these basins and that of a basin of bare earth. When, however, I wish to have the plants bloom early in summer and late in autumn, I introduce heat by running a flow and return pipe from the greenhouse boiler into the tank and leaving both ends of the pipes open. The circulation of the water between boiler and tank maintains the desired temperature. It might seem to anyone who has not tried it that water coming from the inside of a boiler and passing through rusty iron pipes would be injurious to aquatic plants. But with me their rapid growth and perfect health testifies to the contrary. Of course this plan of heating is not recommended for tanks under glass. I have tried it for several years, and it works well. I do not give artificial heat to any of the Lilies in midsummer, not even to the Victoria regia. No artificial heat is given in hot summer weather. In my largest tank none was given at any time last season, and N. devoniensis and others bloomed till quite late in October. I have been troubled with aphides and water snails. My remedy is to keep an abundance of fish in the tanks. I have gold, silver, and sunfish. Next season I am going to try the European carp. As to varieties, I have a new form of the dentata type emitting a delicious odour like that of ripe Apples. It is a fine acquisition. N. pygmaea is a charming thing and a free bloomer. I have left it out to test its hardiness, and yesterday examined it and found it all right. I am quite confident that it is hardy. N. alba candidissima is a superb kind, with large white flowers. N. alba rosea I flowered last summer. It is very fine, but not quite equal, in my opinion, to the Boston variety of N. odorata. I wish to give great emphasis this season to the fact that Nelumbium speciosum is perfectly hardy. It blooms with me from July until frost." It is difficult to keep Lilies in ponds free from aphides, but the plants grown in tubs and tanks, which can be got at conveniently, can, with proper attention, be kept perfectly clean. In our little pond there is a multitude of gold fishes, but they do not seem to lessen the aphides at all. The only remedy I use, and can suggest, is to wipe off the insects with a sponge. In tubs I keep clear of them by showering the plants overhead freely from a water-pot rose, and letting the aphides thus washed off disappear with the overflow.—

WM. FALCONER, *Cambridge Botanic Garden, in Country Gentleman*.

Does snow protect the soil from frost?

—The numerous experiments which it was necessary to make to obtain a precise answer to this question were carried on last winter in the Jardin des Plantes. The aim of these was to ascertain—first, to what extent the temperature of the ground was influenced by the temperature of the air, both under bare ground and in sodded soil, with and without snow; also to ascertain what depth the temperature of the air was able to make its influence felt. In these complicated investigations the electric thermometer invented by Becquerel was employed. Simultaneous observations were made of the temperature of the air at the height of 33½ feet and 66½ feet, and of the soil at the depths of 2 inches, 4 inches, 8 inches, 12 inches, and 24 inches. They were made under sod and bare ground. On November 26 a dry frost began, which lasted without interruption until December 3. At this date the air had a temperature of 7° Fahrenheit, and a heavy fall of snow began that covered the ground to the depth of 10 inches. From the 6th to the 19th of December the cold steadily moderated, until on the morning of the 19th and 20th it was above 32°. A variable cold weather followed, and the snow sank to less than 8 inches. Observations showed that both before and after the snow fell the temperature of the soil, where it was covered with sod, remained above the freezing point even on the coldest day. On November 26, at a depth of 2 inches, the temperature was 40° Fahr. From this time it sank continuously until December 14, when it reached 32½° Fahr., but it never fell below this minimum. The results were quite different in soil not covered with Grass sod. On November 26, the day when the dry frost began, the temperature at a depth of 2 inches fell below 32° Fahr.; on November 29 it stood at 26½° Fahr., and on December 2, before the snowfall, it was 25° Fahr. During the whole time when its surface was covered with snow from 10 inches to 8 inches deep, the temperature never rose above 32°, but only varied, at a depth of 2 inches, between 28° to 30° Fahr. It was thus proved that changes in the temperature of the air make themselves felt to a certain distance in the earth even when the surface is thickly covered with snow. Hence the generally received opinion that a mantle of snow keeps the earth warm is in general erroneous. Snow does not protect the soil and seed at all from freezing, but only hinders to a certain degree the too extensive radiation of heat from the soil, and is converted into water at 32°, which sinks into the earth and somewhat raises its temperature. These experiments also prove that the best protection for the soil is a heavy sod, which does more to raise its temperature than ever so thick a layer of snow. The matted roots of the sod form a sort of felted covering which not only excludes the cold in a high degree, but also draws up the moisture from the lower strata toward the surface.—*Scientific American*.

RECENT PLANT PORTRAITS.

PELLIONIA PULCHRA (*Illustration Horticole*, plate 479).—A pretty ornamental-foliaged trailer with curiously variegated green leaves resembling those of a small-foliage Begonia. A native of Cochin China, already described in a contemporary by Mr. N. E. Brown.

ODONTOGLOSSUM MADRENSE (same work, plate 480).—A handsome conspicuous flowered Orchid with a spike of large white flowers with brown centres. A native of the cooler parts of Mexico, where it is oftenest found growing as a parasite on the Oak.

ECHMEA LALINDEI (same work, double plate 481).—A very handsome Bromeliad from New Grenada, named by M. Linden after M. Lalinde, who sent him the plant in 1867. The plant has been in flower for the last three months in the stove of the Compagnie Continentale at Ghent, where its handsome spike of rosy white flowers with conspicuous deep rose-coloured involucre have been much admired.

STREPTOCALIX VALLERANDI (*Belgique Horticole* for January).—This rather ornamental Bromeliad is portrayed on a double plate, with foliage somewhat resembling that of a Pine-apple, and a tortuous spike of purplish flowers with bright red involucre. It is by no means a new plant, having been figured under the name of Lamprococcus Vallerandi by M. Carrière in the *Paris Revue Horticole* so far back as 1877. M. Morren, however, now describes it at length, and gives reasons for its new name.

The February number of Dr. Regel's *Gartenflora* contains coloured plates of PHLOX SUBULATA, group of eight pretty hybrids raised by the late Rev. J. G. Nelson, of Aldborough, Norwich, and already figured in THE GARDEN; and of EXACUM AFFINE, a pretty herbaceous warm greenhouse plant, with bluish lilac flowers with yellow stamens somewhat resembling those of one of the Solanums.

DENDROBIUM EBURNEUM (the Ivory Dendrobe).—The second number of the *Revue Horticole* for March gives a portrait of this very ornamental Orchid producing bunches of pure white flowers with bright red centres, making a most charming contrast. It was first introduced by Mr. Parish, from Moulmein, who sent it to Messrs. Low, of Clapton, and more recently in the course of last year, for the first time direct to France, by M. Augustin Regnier, from Plumbat, in Cambodge. This number also gives a woodcut and description of M. Brant's perpetual-blooming Thorn (*Crataegus oxyacantha semperflorens*), showing the almost ripe haws of the early bloom in May on lower part of branch, which is crowned with a fine bunch of open flowers and buds, forming the August bloom, while there had also been an intermediate flowering on the same branch in the early part of July.

W. E. G.

PLANTS IN FLOWER.

HEPATICA VARIABILIS.—We saw lately at the Hale Farm Nursery, Tottenham, a very pretty and interesting plant under this name. It is said to be a Pyrenean plant, and possesses the peculiarity of producing flowers white, blue, and intermediate shades. The blooms are somewhat larger than those of the common Hepatica, but appear about the same time.

RHODODENDRON MULTIFLORUM.—A very pretty shrub bearing this name came under our notice the other day at the Victoria Nursery, Upper Holloway. It is of dwarf growth and twiggy, has rather small foliage, inclined to be downy, and clusters of flowers borne at the tip of nearly every shoot. The blossom is about 2 inches across, of thin texture, and wavy at the edges; the colour, a delicate mauve, is most pleasing and the flowers being plentiful the plant is attractive. It was growing in the new Rhododendron house, a capacious span-roofed structure specially fitted up for the culture of greenhouse Rhododendrons, of which Mr. Williams possesses so rich a collection.

TOXICOPHYLEA SPECTABILIS.—Those who like to have sweet-scented plants in their greenhouses should make a note of this one—a small-growing evergreen shrub from South Africa. It is a compact-growing plant, of much the same habit as an Ixora, to which it is allied. The tiny white blossoms are produced in dense clusters from the tips of the branches and smaller ones from the axils of the dark green leathery leaves all along the branches. The odour of the flowers is delicious. The plant flowers at no particular season, but seems in its best state just at this time of the year. It may be seen well grown and flowered in the Victoria Nursery, Upper Holloway.

LEONTICE LEONTOPODIUM.—The finest cultivated specimen we have seen of this plant was one in Mr. Ware's nursery, Tottenham, a short time since. It was planted out in a bed in an unheated house, which evidently was just suited for it, as it had grown quite out of our recognition. The flower-stems were some 2 feet high, widely branched, and covered with bright golden flowers. The glaucous foliage, too, was large. Though not what may be termed a garden plant, it is a most inte-

resting one, and it is also one of the oldest of cultivated plants, having been introduced at a very early date from the East. It belongs to the Barberry family.

IMANTOPHYLLUM MINIATUM SPLENDENS.—There are now a good many varieties or rather forms of the well-known *Imantophyllum*, some superior to others in point of colour, others in point of size. A week or so ago we made note of some of the finest in Messrs. Veitch's nursery, and these we can supplement by one or two others we saw the other day in Mr. Williams' nursery, Upper Holloway, where the plant is made quite a speciality of. As regards colour, there are none in flower at present that surpass the variety named *splendens*. Both flowers and trusses are large and the colour, a glowing orange-scarlet, is grand.

family, these are arranged in a spreading vase-form manner. From the heart of this huge tuft of foliage the stout flower-spike rises erect for about a foot in height. On the upper portion are arranged in a dense cylindrical spike to about 4 inches in length small stalkless flowers, which, as they come out of the greenish calyx, are tipped with deep blue changing to a pinkish hue. The great beauty of the plant, however, lies in the large membranous bracts which clothe the lower portion of the flower-spike. These are some 4 inches in length, at first boat-shaped and horizontal, afterwards quite drooping. The colour of these bracts is a rich rosy carmine, a colour at once pleasing and highly attractive, and set off well by the noble foliage. It remains in perfection for several weeks together, hence its great value as a

form they are very refined, and the colour, a fiery crimson, is spread uniformly throughout the bloom, so as not to leave a trace of green or other tint, which so often mars the beauty of otherwise splendid sorts. This variety is so distinct that it may at a glance be singled out from a hundred others, and it is doubtful if it will be surpassed. Another great beauty is a pure white flowered sort called *Mrs. B. S. Williams*, and one that has been so much admired wherever exhibited. The flowers which are not large are funnel-shaped; and white flowers being so uncommon among *Amaryllises* give to this one a greater charm. One remarkable for large flowers was a new one called *Masterpiece*, the flowers of which measure over 7 inches across; they are of good shape and of a brilliant scarlet-crimson veined with light lines.

Plan of the garden at Munshead;

arrangements of the various departments in relation to the lawn and house.

Another, named *crenatum*, though rich and good in colour, is not equal to *splendens*, and still another called *aurantiacum* is distinct from all the rest, inasmuch as the colour is more of a yellow than a red. It is good also in size and form of blossom. The grand variety *Martha Reimers* figured last year in *THE GARDEN* is not yet in bloom, which, perhaps, is as well, for others could not stand beside her in beauty. There is something so fine about the form and habit of these plants that makes them so desirable to cultivate (which is a simple matter), and the handsome foliage, being evergreen, adds much to their decorative value.

ECHMEA MARLE REGINÆ.—This very fine Bromeliaceous plant, which, without doubt, is one of the finest of the family in cultivation, may now be seen in perfection in Mr. B. S. Williams' nursery, Upper Holloway, where some grand specimens of it are in bloom. It is a large growing species, with broad spiny-edged leaves from 1½ feet to 2 feet in length, and, as in most of the

decorative plant. It is a plant of easy culture in an ordinary moist and warm stove, potted in a compost of loam, peat, and sand. During the growing season the plant is much benefited by abundance of water, especially overhead, so that the axils of the leaves may be filled. It is a native of Costa Rica, in Tropical South America.

THE AMARYLLISES in flower just now in the Victoria Nursery, Upper Holloway, make a brilliant show, though a small portion only of the collection is in flower, it being the aim of Mr. Williams to spread the *Amaryllis* season over as long a period as possible, and not to have the major portion of the collection in flower at one time, and consequently only for a few weeks. At the present time there are large numbers of kinds in flower, and among these are some remarkably fine varieties both named and unnamed seedlings. Some of the most conspicuous are *Dr. Masters*, than which there are in many respects few finer varieties in cultivation. The flowers are not very large, being some 6 inches across, but in

Cruenta and *Fascination* are also both superb sorts; likewise one called *Leeana*, which has flowers of a deep crimson and of excellent shape. Some of the seedlings of the *marginata* type promise to develop into grand varieties, and one in particular, apparently between *Mrs. Rawson* and *marginata grandiflora*, was uncommonly fine. The above are but a few of those in bloom, and these will be soon augmented by a large number which will be in perfection in a few weeks.

SAXIFRAGA VIRGINIENSIS with double blossoms is among the prettiest and most interesting of the *Saxifrages* in flower at Kew at the present time. Those who know only the type—a somewhat weedy looking plant—would hardly recognise its handsome variety, which bears dense clusters of miniature, pure white rosettes, on stems ranging from 3 inches to 6 inches in height. It is a neat and pretty plant for the rock garden, perfectly hardy, of simple culture, and interesting as being about the only double-flowered *Saxifrage* known. If well grown in pots it would make a handsome

plant for greenhouse decoration in spring. Though not new it is scarce, and is, we believe, one of the numerous introductions of M. Max Leichtlin, of Baden-Baden.

ANEMONE CORONARIA THE BRIDE is a lovely flower with cup-like flowers $2\frac{1}{2}$ inches across and pure white. A flower brought us by Mr. Gumbleton shows well its beauty.

SIPHOCAMPYLUS NITIDUS.—This pretty stove plant, now in flower at Kew, is worthy of general culture. It is dwarf and neat in growth, and produces an abundance of tubular blossoms, about 1 inch long, and bright scarlet tipped with clear yellow. It needs precisely the same treatment as other species belonging to the genus.

A DOUBLE PEACH from Mr. Crawford's garden, at Lakelands, Co. Cork, is the finest we have yet seen, the flowers being perfect rosettes about $1\frac{1}{2}$ inches across, and of the loveliest deep rose-pink imaginable. Such a hardy tree as this is alone sufficient to make our too often flowerless shrubberies and lawns bright with colour during March and April.

BOUGAINVILLEA SPECIOSA.—I send you a few sprays of this climber, now an object of great beauty in our plant stove. It is trained under the roof and covers a space of 10 feet by 8 feet. It is a sheet of bloom and a conspicuous object even at a distance.—F. FORD, *Swadcliffe Park, Banbury*. [A lovely plant with bracts deeper and richer in colour than either those of *B. glabra* or *spectabilis*. They are produced in dense terminal clusters. It is one of the finest of all stove climbers.]

A NEW WATER LILY from Zanzibar named *Nymphaea zanzibarensis* is now in flower at Kew for the first time under cultivation. Though the plant bearing the flower is but a pigmy compared with the size of a fully developed plant, there is sufficient to show that the species is a most attractive one, and a welcome addition to the garden flora. The blossom just expanded is about 2 inches across, and rich violet-purple in tint, different from any of the other cultivated *Nymphaeas*. When fully matured the flowers will probably be thrice the size, and the colour doubtless even brighter.

HYACINTHS, TULIPS, CYCLAMENS, and other spring-flowering plants may now be seen to perfection and in large quantities in Mr. Williams' nursery, Upper Holloway, where a capacious span-roofed house is solely devoted to them together with the *Amaryllis* collection. The brilliancy of such a mass of gay colours is indescribable, and the perfume from the flowers is almost overpowering. Anyone desirous of making a leisurely inspection, so as to make a selection of Hyacinths and other bulbous plants, can do so here far better than at an exhibition.

STIFFTIA CHRYSANTHA.—One of the rarest plants that has been sent to us for some time is this handsome Brazilian composite shrub, which comes from Mr. Crawford's garden at Lakelands, Cork. The whole flower-head, including the protruded styles, is 3 inches in length. The dense tuft of tubular florets is 2 inches long and a reddish orange colour, hence very showy. It is a shrub of robust and bushy habit, attaining naturally from 6 feet to 10 feet high, and the flower-heads are borne from the tips of the young shoots. A poorly coloured drawing of it may be found in the *Botanical Magazine*, tab. 4438.

TWO BEAUTIFUL ACACIAS for flowering in a small state in pots for conservatory decoration are *A. Drummondii* and *A. lineata*, both now in full beauty. The first is a neat, compact grower, forming twiggy bushes with small evergreen pinnate foliage. The flowers, produced in small cylindrical spikes like miniature bottle-brushes, are pale sulphur-yellow, a tint just in harmony with its dull deep green foliage. It is a most abundant bloomer, and will continue in beauty for several weeks to come. It is one of the very best of the hosts of Acacias to be seen at Kew, and one of the few that are grown by the thousand for the London flower market. *A. lineata*, which is showier when in full bloom, is quite of a different stamp;

as its name indicates, the foliage is long and narrow, and not being very dense, the plant has a much lighter look about it than the other. The flowers, produced in tiny globose heads, are bright yellow and borne in great profusion, so that the whole plant is a mass of yellow. It flowers freely in a small state, i.e., from 1 foot to 3 feet high. In the greenhouse (No. 4) at Kew both of these species are made free use of during the spring, and some attention is given to their culture. Both may be readily procured from any good nursery.

LACHENALIA NELSONI.—Of this extremely beautiful variety Mr. Smith sends us from the Caledonia Nursery, Guernsey, some wonderfully fine flower-spikes, each about 12 inches in height and covered fully half their length with drooping golden yellow blossoms. The foliage, too, is remarkable as regards size, being over 12 inches in length and 2 inches in width, and copiously blotched on a bright emerald green ground. As Mr. Smith observes, such a lovely plant as this cannot be too highly praised or too widely known. The Guernsey climate does indeed favour the growth of bulbous plants.

FOUR KINDS OF FREESIA from Mr. Gumbleton's garden are all distinct as regards their flowers, and all extremely beautiful and deliciously scented. The largest is *refracta alba*, the flowers of which are $2\frac{1}{2}$ inches long, with along attenuated tube and a spreading limb. The colour is pure white, with a dash of yellow in the lowermost sepal, and the lower part of the tube is stained with yellow. On the exteriors of the sepals there is an inclination to flushings of purple. *F. Leichtlini* major has the flowers rather shorter, the tube more suddenly contracted in lower part. The colour is a yellowish white, deep yellow on the lower sepal and base of the tube, and flushed with purple on the outside of the limb. *F. Leichtlini* has much smaller flowers than those of the major variety, and has the tube even more contracted. The whole colour, too, is a deeper tinge of yellow, and the blotch on the lower sepal bright orange. The flower scarcely exceeds $1\frac{1}{2}$ inches. *F. aurea* is the smallest of all, and is the most distinct of all, inasmuch as the bracts, which in the others are herbaceous, are in this quite dry and membranous. The flowers, moreover, are under an inch long, erect, scarcely curved at all, and gradually, not abruptly, narrowed towards the base. The stigma, too, as in *F. refracta alba*, equals in length the perianth segments. The colour is a rich, warm yellow. This is a most interesting and distinct plant, and probably is the true *F. Leichtlini* of Klatt.

PLAN OF A GARDEN.

THE relation of the house and lawn to the more interesting portions of a garden is a very important question for many who take a higher view of the garden than as a receptacle for everything that can be crowded into it. Few think as much as they ought about the matter, judging by what we see of complicated beds, vases, statuary, small ponds, hedges, dead walls, old houses, and frames, where there ought to be a little quiet breadth or a pleasant bit of Grass. In the very smallest class of gardens such considerations are out of place. In a cottage garden we do not seek breadth; the effect is often very good there without it. The "nest" of flowers is relieved in other ways, and all are pleased at the unpretending beauty of the spot. But in the many gardens of a larger kind a little attention given to this point would improve the effect greatly. The delightful quality of repose, good in all cases, is now more than ever essential, owing to the noisy and confused conditions of our lives in great cities. The spread of brickwork over vast areas near London and other large cities which were once among our prettiest districts and full of trees and fair gardens makes it almost the duty of those who have a garden to see that it at least is not a waste of confusion or a mere mass of incoherent units. The garden shown by the annexed plan is free and quiet near the house, for little work need be done there, and that takes very little time. The flowers are not spread out

before the windows till we get tired of them there, but bits of the colour of the various gardens may be seen from some of the windows, and all are within a minute's walk. Pansy, Pink, Rose, rock flowers, Primroses, Auriculas, flowering bushes and Ferns all have their allotted nooks and plots where they get what shade, sun, water, or soil can be spared them, and where the most radical preparations may be made for their reception and health without disturbing the quiet desired near the house itself. The lawn is free from any but the most permanent kind of gardening—Scotch Firs and other "hardy plants" that fear no changes. On the left the *pergola* (Italian for trellis-covered way) is for American Vines and the more vigorous creeping Roses, and it forms a screen. The alpine garden is one without "rock-work" cropping naturally out of the heathy ground, which covered the whole space a few years ago. It is quite near, and yet concealed from the richest and most effective border of hardy flowers that we know of near London. The reserve garden, too, a place for hosts of fine things that deserve special culture, and are worth cutting and having in plenty, is well sheltered and concealed, and yet may be entered as easily as one of the rooms. The arrangements otherwise are those that suit the site, soil, and the taste of the owner; imitating these would not perhaps be right under other circumstances, but good examples of places where some of the essential principles in design are not lost sight of and yet every convenience for good gardening secured are worth seeing. The plan is that of Munstead garden, near Godalming.

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 27.

On this occasion, besides the ordinary committee meeting, the first spring show was held in the conservatory, rendered gay by the masses of spring flowers which it contained. These consisted chiefly of Hyacinths, Tulips, Cyclamens, *Amaryllises*, and Roses. There was a conspicuous absence of tender plants owing to the coldness of the weather; consequently there were comparatively few novelties placed before the floral committee.

First-class certificates were awarded to the following:—

RHODODENDRON TRIUMPHANS.—A greenhouse variety of the Japanese type. The flowers were about $2\frac{1}{2}$ inches across, of a brilliant crimson-scarlet colour, and produced in massive trusses. This is the richest coloured variety, combined with high quality of flower, that has yet been obtained by Messrs. Veitch, who exhibited it.

ANTHURIUM FERRIERENSE.—A new hybrid variety, raised and exhibited by Mr. Bergman, gardener to Baron A. de Rothschild, Ferrières-en-Brie (Seine-et-Marne), France. It is the result of crossing *A. ornatum*, a species with ivory-white spathes, with *A. Andreanum*, the comparatively new species with brilliant scarlet spathes. It is precisely intermediate between the parents. The foliage is large and heart-shaped, and much resembles that of *A. ornatum*; the flower-spike just overtops the foliage and carries a heart-shaped spathe, 5 inches long and 4 inches wide, of a bright cherry-red colour, thus forming a most pleasing contrast with the spadix, which is as erect as in *A. ornatum*, and about 4 inches long, and of ivory whiteness.

ANGRÆCUM ARTICULATUM.—A small growing species in the way of the rare *A. Ellisi*. The foliage is small and of leathery texture. The flower-spike on the plant exhibited was about 9 inches long, and bore eight flowers arranged on a two-rowed spike. The blossom is about 1 inch across, of white waxy texture, and possesses a tail-like spur about 3 inches in length, giving the plant a singularly grotesque appearance. Shown by Mr. B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway.

HYACINTH SOUVENIR DE J. H. VEEN.—A very fine new variety somewhat resembling King

of the Blues, but the colour is deeper and the spike much more massive; the bells, too, are larger and of better shape. All the plants shown of it by Messrs. Veitch were uniformly fine. It may be considered as the best of all the deep purple-blue single sorts yet produced.

HYACINTH PINK PERFECTION may likewise be said to be the finest of all the pink coloured sorts; indeed there is no other that at all approaches it, whether it be in size or colour. The spike is unusually large and inclined to be conical, while the blossoms are also very large and of a delicate pink shade. Shown by Messrs. Veitch.

ROSE WILLIAM FRANCIS BENNETT.—A new seedling variety, raised and shown by Mr. H. Bennett, Shepperton. It is a beautiful Rose, particularly in the bud state, the form being admirable, and the colour, a rich crimson-carmine, is most pleasing. It was certificated as a decorative variety, and as such it has but few rivals.

AMARYLLIS BYRON.—A splendid variety quite unlike as regards colour any that have been raised by Messrs. Veitch who exhibited it. The flowers are of the largest size with broad, slightly reflexing segments, forming a handsomely shaped flower. The colour is a rich carmine-magenta as near as it can be described. The plant exhibited bore six flowers on one spike and five were expanded.

AMARYLLIS LADY OF THE LAKE.—Flowers very large and of perfect form, the sepals and petals being unusually broad and of firm texture. The colour is almost a pure white, except that here and there are streaks and dots of crimson. This is by far the finest light-coloured variety yet produced, and it is one of a class that should be encouraged. Messrs. Veitch.

AMARYLLIS TENNYSON.—This has extremely large flowers, measuring nearly 9 inches across. The segments are proportionately broad, so as to make a symmetrical flower, while the colour is of a uniform brilliant scarlet, rendering the flower exceedingly handsome. One spike bore four such huge blossoms. Messrs. Veitch.

AMARYLLIS WORDSWORTH.—Flowers $6\frac{1}{2}$ inches across with wide divisions. The colour, a vivid scarlet, is streaked with white and flushed with a peculiar shade of purple. This splendid variety also came from Messrs. Veitch.

CINERARIA DUKE OF EDINBURGH.—An extremely fine sort, with flowers fully 3 inches across, having broad, overlapping florets of firm texture, and forming a perfectly circular flower. The colour is a rich velvety purple. **C. MRS. HERBIN.**—Flowers as large as those of the preceding, and as fine in form, but of a glowing maroon-crimson. **C. PRINCESS OF WALES.**—With very large flowers, but scarcely so perfect in point of form and substance as the other two. The colour is a bright magenta, very beautiful and pleasing. These are all extremely floriferous, bearing broad clusters of flowers, and are all that can be desired as regards habit of growth. Mr. James.

HYACINTHS, now in the height of perfection, formed the main feature of the show, being represented abundantly by three of the largest growers, Messrs. Veitch, Williams, and Cutbush. The hundreds of spikes not only made a brilliant display, but their perfume pervaded the whole conservatory. The most extensive collection came from Messrs. Veitch, who had no fewer than 240 plants, of which fifty were new kinds. From this large number of novelties the committee selected but two for certificates, though several of the others were of considerable merit and distinct from older varieties. It could be plainly seen among the novelties that the Dutch raisers are aiming at not only obtaining a massive, symmetrical flower-spike, but also large flowers, and the two certificated were remarkable in these respects. Large, bold flowers, not too crowded on a spike, seem to be the most admired now, and among the older varieties the beautiful white *La Grandesse* and *Czar Peter* are noteworthy examples of this style of flower. Messrs. Veitch were awarded a silver-gilt Banksian medal for their fine group, which was the perfection of skilful culture. It also contained about a dozen new varieties of *Amaryllises*.

A very extensive and attractive group came also from Mr. B. S. Williams, Upper Holloway. It consisted of about 150 *Hyacinths*, a similarly fine collection of *Tulips*, a large group of *Cyclamens* admirably grown and flowered, and some uncommonly fine pots (12 inches across) of *Lilies* of the Valley, which were much admired. The *Hyacinths* and *Tulips*, which comprised most of the leading varieties, were remarkable for high quality, and, with the other plants, constituted one of the most attractive parts of the exhibition, and to the exhibitor of which a silver Banksian medal was appropriately awarded.

A similarly large and fine group of *Hyacinths* and *Tulips* was exhibited by Messrs. Cutbush & Sons, Highgate, who for so long have been among the leading exhibitors of spring bulbous plants. Like the others, this collection consisted of a good selection of first-class sorts, and they were finely cultivated. A bronze medal was awarded. In this group was a new variety of *Azalea mollis* called *John Coward*, the flowers of which are of a delicate salmon-pink, distinct, we imagine, from any older variety, and decidedly a beautiful and most desirable spring flowering shrub.

The group of *Roses* exhibited by Messrs. Paul & Son, Cheshunt, was a much admired feature of the show. The plants, about thirty in number, were all admirably flowered, particularly having regard to the early time of year. The most conspicuous of the whole group was a new kind called *Mignonette*, one of the varieties of *Rosa polyantha*. In growth, size, and form of flower it much resembles the *Paquerette* variety shown so finely by Messrs. Paul at the meeting, but the colour, instead of being white, is of a beautiful rose-pink. The blossoms are produced in large clusters, and it is so floriferous that every shoot is terminated by a truss of bloom. Of this charming *Rose* there were some admirably grown specimens about 2 feet across, all literally covered with blossoms. The most prominent amongst the other varieties were, of *Tea-scented* sorts, *President*, *Catherine Mermet*, *Mad. de St. Joseph*, *Souvenir d'Elise*, *Souvenir d'un Ami*, and *Alba Rosea*. Among *Hybrid Perpetuals* were *Mrs. Laxton*, *Marquise de Mortemarte*, *Duke of Teck*, *Mad. Therèse Levet*, *La France*, *Mad. Victor Verdier*, *Annie Laxton*, *Magna Charta*, *Dr. Andry*, *Mad. Montet*, *Marie Rady*, all of which seem to be admirable sorts for forcing into early bloom. A silver-gilt Banksian medal was awarded to the exhibitors.

Some blooms of new seedling *Roses* were shown by Mr. Bennett, Shepperton, which were uncommonly fine for the season; indeed it is doubtful if some of them could be surpassed at midsummer. Among them were such lovely varieties as *Lady Mary Fitzwilliam*, with large, finely-shaped flowers of a pale blush tint; *Earl of Pembroke*, a splendid variety with large, perfect-formed blossoms of a glowing crimson; *Mary Bennett*, of fair size and excellent shape, and of a rich deep rose tint. This trio of new *Roses* undoubtedly has a bright future among rosarians.

A group from Messrs. Carter and Co., High Holborn, was an attractive one, as it consisted for the most part of a brilliant collection of *Cinerarias*, which this firm grows so extensively for seed. *Chinese Primulas* were also shown by Messrs. Carter in great variety, and though rather late for these flowers, the plants were in admirable condition, such beautiful sorts as *Vermilion Queen*, *Holborn Pearl*, *Rosy Morn*, the blue *Holborn Gem*, and the singular yellow-leaved variety called *Golden Leaf* being uncommonly fine. Added to the above were some admirably grown specimens of *Deutzia gracilis* and the graceful *Dielytra spectabilis*, the latter being particularly fine. A bronze Banksian medal was awarded to Messrs. Carter for this group.

CINERARIAS were shown splendidly by Mr. James, the well-known raiser and cultivator of these flowers, who brought an extensive collection, consisting of about seventy plants, from his nursery at Farnham Royal, Slough. Among these there were no fewer than twenty considered of sufficient merit to be named, and from those the committee selected three for certificates, Pro-

bably there never has been such an exhibition of seedling *Cinerarias* of such exceptional merit as these, and Mr. James seems to have reached the climax of perfection in his strain, taking every point into consideration. A bronze medal was deservedly awarded to the exhibitor of this group.

Among the *Orchids* and stove plants sent by Mr. B. S. Williams were the pretty *Odontoglossum Oerstedii*, with small, but pretty pure white, yellow centred flowers; *Dendrobium luteolum chlorocentrum*, the new variety alluded to elsewhere; *Masdevallia Shuttleworthii*, and *Leptotes bicolor serrulata*, a charming little *Orchid* with round fleshy leaves and showy blossoms, having pure white sepals and petals, and a bright amethyst lip; a splendid new *Amaryllis*, named *Shirley Hibberd*, had small, but finely shaped blossoms of an intensely rich crimson-scarlet; and as a contrast to this there was a plant of *A. virginalis* bearing seven flowers on one spike, a most unusual number.

Messrs. Cannell & Sons, Swanley, exhibited three new double *Cinerarias*, viz., *Sir Drummond Wolff*, with large globose flowers of a rich purple; *Miss Simpson*, bright magenta, also large; *Hermia*, deep violet-purple, all of good habit and floriferous. The same firm also showed a plant of a new zonal *Pelargonium* called *Edith George*, which is by far the finest of its colour yet produced. The trusses are immense (to use a relative term), and the pips are of perfect shape and of a pleasing deep rose-pink.

AMHERSTIA NOBILIS, one of the most gorgeous of all tropical plants, was sent by Mr. Speed from the Duke of Devonshire's garden at Chatsworth. The raceme sent was an uncommonly fine one, and the large singularly formed blossoms of a vivid scarlet blotched with yellow a great attraction, the *Amherstia* being so much heard of, but so seldom seen.

HYMENOCALLIS MACROSTEPHANA.—This new bulbous plant, allied to *Pancratium*, was shown in splendid condition by Mr. Woodbridge from the Duke of Northumberland's garden, Syon House, Brentford, where it is grown better than anywhere in the country. It is a most beautiful plant, bearing huge clusters of pure white flowers twice the size of *Pancratium fragrans*, and quite as sweet scented. It is a plant that deserves to be more widely known than it is, although it seems to be gradually becoming distributed.

A large gathering of cut blooms of *Anemone fulgens*, expanded in the genial clime of Southern France, was shown by Messrs. Collins & Gabriel, Waterloo Road. The brilliancy of these scarlet blossoms in such a mass was a very telling feature, and well illustrated what fine effects can be obtained by massing together flowers of one colour. Some uncommonly fine blooms of *Crown Anemones* were also shown, representing a great variety of colours. The large size of these, as well as those of *A. fulgens*, plainly showed to what perfection they attain in a warm congenial climate far finer than we can expect them to be in our gardens here.

Fruit.—Half-a-dozen remarkably fine bunches of *Lady Downes Grape*, large in size, good in colour, and in excellent condition, were exhibited by Mr. Hudson, gardener to Mr. Atkinson, Gunnersbury House, Acton, to whom a cultural commendation was worthily accorded. A like recognition was voted to Mr. G. Summers, Sandbeck Park Gardens, Rotherham, for a fine dish of fruits of *La Grosse Sucrée Strawberry*, which were large and highly coloured. A most important exhibit was that from Mr. S. Ford, gardener to Mr. W. E. Hubbard, Leonardslee, Horsham; it consisted of about half a hundred dishes of Apples and Pears, all of which were in excellent condition. The Pears included *Uvedale's St. Germain* and *Allman's variety* of it, *Beurré Rance* and *Beurré Berkman*. Among the Apples were good examples of *Cockle Pippin*, *Blenheim Pippin*, *Cherry Orchard*, *Mitchell's Seedling*, *Norfolk Beefing*, *Adam's Pearmain*, *Mère de Menage*, *Reinette du Canada*, *Pronger's Pippin*, *Stone Pippin*, and *Scarlet Pearmain*. For this excellent display so late in the season the committee voted to Mr. Ford a cultural commendation.

THE PRIZES FOR AMARYLLISES offered by an amateur were competed for on this occasion. Though the few plants exhibited for the prizes were poor compared with the splendid varieties shown by Messrs. Veitch, they showed a creditable effort on the part of amateur cultivators. There were three classes, the first for the best seedling variety, the second for six varieties, the third for the best light variety and the best dark variety shown in the class for six. There were but two exhibitors of seedlings, Mr. Wiggins, gardener to Mr. Little, Hillingdon Place, Uxbridge, and Messrs. Paul & Son, Cheshunt. The former had seven seedlings, and out of these the judges selected two for the first and second prizes; the first was given to Ameer, a large well-shaped flower, scarlet tipped with white; the second to Queen Mab, a handsome sort of the Leopoldi class, with large scarlet flowers tipped with white. Out of the three shown by Messrs. Paul, the one named Mrs. Hird was selected, it being one of the vittata type. There were two exhibitors of six plants, Mr. Wiggins again being first. He had Mad. Titens, Iolanthe, Comet, Coronet, Princess Dagmar, and Dr. Masters. The other six were not considered worthy of award. The two best light varieties among the six were Iolanthe, belonging to the Leopoldi class and of good form, and Comet, of a similar stamp, but lighter in colour. The two best dark sorts were Princess Dagmar, a bright scarlet flower of good form, and Dr. Masters, of a vivid uniform scarlet. Mr. Wiggins was the prizetaker in both of these classes.

The prizes for six Cinerarias, offered by Messrs. Sutton & Sons, Reading, were to have been competed for on this occasion, but only one collection was exhibited, and to this the judges only awarded the third prize, as but three of the plants were in a creditable condition.

A lecture on the Amaryllis, delivered during the afternoon by Mr. Shirley Hibberd, will be given at length in our next issue.

Scientific committee.—*Sclerotia of Peronospora infestans*.—Mr. W. G. Smith called attention to the fact that these so-called sclerotia, described in the paper by Mr. Wilson, read at the last meeting, were observed and figured by Von Martins so long ago as 1842 ("Die Kartoffel Epidermis"), and by Berkeley in his paper on the Potato disease in the first volume of the *Horticultural Journal*. They are also subsequently figured by Broome in 1875 and Professor Buckman. Mr. G. Murray said that from his examination they often seemed to consist of discoloured and disorganised contents of cells which they completely filled, though in Martins' figure two or three were in a cell; but Dr. Masters noticed that they are often outside the cells and of an angular character. The question was raised whether they might not have been expelled from the cells by the covering glass. Martins figured them with coniferous threads proceeding abundantly from them. Further investigations of their true nature appeared to be desirable.

Abutilon and Hibiscus "bigener."—Dr. M. T. Masters described a very dark flowered Abutilon which was said to be due to an original cross between Hibiscus Rosa sinensis and Abutilon striatum. The original plant was a dark flowered seedling, which was fertilised by Mr. George for two or three generations with the pollen of the Hibiscus, and though the character of the flower is that of an Abutilon, it has the truncated column and foliage of Hibiscus. In one plant the leaves were blotched with a dark crimson spot. Hence it is probably a true bigener, or case of generic crossing.

Pelargonium peltatum or *Ivy-leaved cross*.—Mr. George sent foliage of this cross showing reversion to the peltate type, several of the leaves assuming a funnel shape or other irregular form, thus betraying its origin from *P. peltatum*.

Orange diseased by insects.—Mr. McLachlan exhibited stems and leaves of Oranges badly attacked by *Mytilaspes citricola* received from the Bahamas. He read a communication by Messrs. Dunlop & Roker, communicated by the Governor of the Bahamas to the British Government request-

ing information. The insect was therein named *Aspiditis Gloveri*. Mr. McLachlan offered some remarks and suggestions on the method of attack by the insect and remedies to suppress it.

Pilobolus roridos.—Mr. W. G. Smith showed some Geranium leaves covered with the sporangia of this fungus, which had apparently been shot upon it from the fungus in the earth in which the plant grew.

Solanum species.—Sir J. D. Hooker read a communication from Mr. Lemmon, Oakland, California, upon the discovery of three species or varieties of Solanum bearing tubers from the border-land of Arizona and Mexico: "We found them first," writes the author, "on the cool northern slopes of the high peaks of the Huachuca range; then, afterwards, where least expected, invading the few rudely cultivated gardens of the lower foot-hills. One kind is called S. Jamesi. This has white flowers and tubers. Another was S. Fendleri (Gr.). It has smaller purple flowers and flesh-coloured tubers. This Dr. Gray lately concludes to be but a variety of the old Peruvian Potato, and he calls it var. boreale of S. tuberosum. The third form or species, found at 10,000 feet altitude, has mostly simple orbicular leaves, one or two berries only to the umbel, and small pink tubers on long stolons; grows in loose leaf-mould of cool northern-forested slopes. . . . I have great faith in the successful raising of one of these species (or varieties) to a useful size, for the following reasons: (1) while the S. tuberosum var. boreale bears long stolons and but a few tubers, the other kind, S. Jamesi, makes many short stolons, terminated by 4-8 large round white tubers; (2) while the first kind has been partially tried and then given up, the latter species is known to have become enlarged to the size of domestic hens' eggs during the accidental cultivation of three years in the embanking of a rude fish-pond."

ROYAL BOTANIC.

MARCH 28.

THIS was the first spring show held in the Regent's Park Botanic Garden this season. As is always the case here, there was a goodly muster of exhibits, crowded for the most part in a narrow corridor, one of the worst places possible for a large concourse of people to thoroughly enjoy the flowers. It is to be regretted that the society does not see its way clear to make a better arrangement as regards these beautiful spring shows, which, if properly carried out, could be made quite as enjoyable as the large summer exhibitions which have acquired a world-wide reputation for picturesque effect. Instead of cramming such a host of plants into what is little better than a passage, and where the plants can only be arranged in long monotonous rows, why not show them in the conservatory, which is close at hand? there is always sufficient material in these spring shows to convert such a noble building into a perfect floral paradise by tasteful arrangement, and the effort would not entail much additional labour. The exhibition was a very good one on the whole, and some really first-rate exhibits were shown in some of the classes.

CYCLAMENS, for example, have seldom been seen finer than those shown by Mr. Little's gardener (Mr. Wiggins), a veteran in the culture of these fine flowers. From Mr. Little's garden alone there came a hundred or more plants, and this number constitutes but a small portion of the entire collection at Hillingdon Place. The dozen plants shown from this garden for the first prize were simply perfection. The pots (9-inch ones) held a broad spreading tuft of foliage from which arose a perfect sheaf of blossoms, varying from snow white to the intensest crimson. This dozen was shown in the open class, but another scarcely inferior dozen competed for the prizes for amateurs. A poor dozen also shown in this class only served to bring out more prominently the superiority of Mr. Little's plants. A market grower (Mr. Clark, of Twickenham) also grows the Cyclamen to perfection, and had splendid examples of skilful culture, consisting of a group of two or three dozen good

sized plants fairly smothered with bloom. Mr. Clark also carried off second honours in the open class with twelve admirable specimens.

HYACINTHS were, of course, a prominent feature, but there was not a brisk competition either among nurserymen or gardeners, especially considering that the cultivation of this flower is so popular. There were but two amateurs' collections, and, as usual, the first place was taken by that well-known cultivator, Mr. Douglas, now of Great Gearies, Ilford, but still Mr. Whitbourne's gardener. His plants were perfect examples of what Hyacinths should be when the utmost is obtained from good bulbs. All the spikes were massive, dwarf, and firmly beset with bloom (two great points). The selection, too, was good, an important matter in Hyacinth showing. Here are the nine sorts Mr. Douglas had in his doz., viz., General Havelock, fine dark blue; Grandeur à Merveille, one of the finest whites; King of the Blues, a king indeed amongst blues; Lord Derby, pale blue, large bells; Grand Lilas, also a pale blue, but a distinct shade; Von Schiller, deep salmon pink, one of the finest; Ida, a delicate yellow; Vurbaack, bright crimson; Fabiola, rich pink. It is worthy of remark that there is not a double-flowered sort among them, and it seems that Mr. Douglas always prefers the singles and shuns the doubles. His rival collection (shown by Mr. Baxter) was a very creditable one, and was well worthy of second place. There were three nurserymen's collections. The best, from Messrs. Williams & Son, Finchley, was a fine one indeed. It was made up of La Grandesse, white; Gigantea, pink; Lord Derby; Mont Blanc, white; Koh-i-nor, double red; King of the Blues; Grand Lilas. Messrs. Cutbush showed the next best collection, which was also a fine one—a select dozen of some hundreds of plants grown by this firm. That from Mr. Wood, Haverstock Hill, was also a good collection.

TULIPS were even less numerous in the competing classes than the Hyacinths. There were but two collections from amateurs—one from Mr. Easom, the other from Mr. Douglas. Though twelve potfuls have to be shown, the schedule restricts the varieties to four for some reason or other. Mr. Easom's plants were placed first; but if first in the morning when judged, they appeared not to be the best in the afternoon; moreover, his plants were more drawn than those of his rival. The kinds shown were Joost Von Vondel and its white variety, a beautiful sort; Proserpina and Keizer's Kroon, a good four. Mr. Douglas had the same sorts except the white, which was the White Pottebakker, also a beautiful sort, which opens its flowers in a handsome cup-like manner. This dozen was more sturdy in growth, better foliage than the other, but perhaps the judges thought differently.

FORCED ROSES were a great attraction, though the only exhibitor of them were the Messrs. Paul, of Cheshunt, who had in the class for six some really fine specimens profusely covered with blossoms of high quality. The sorts were: Madame Victor Verdier, La France, Caroline Kuster (very fine), Edouard Morren, Mad. Therèse Levet, and Marquise de Mortemart. All these seem to be admirable for forcing. Besides these Messrs. Paul showed a similarly fine collection as at Kensington the day previous, and were awarded a silver medal.

DEUTZIAS are always shown admirably at these spring shows here, and on this occasion they appeared to be finer than ever. The six Mr. Douglas showed for the first prize were beautiful in the extreme, each of the plants being about 4 feet or 5 feet high and a yard through, and literally smothered with snow-white blossoms. When grown thus, *Deutzia gracilis* is a lovely shrub. Mr. Douglas has certainly the start among London exhibitors, but Mr. Little's gardener follows closely at his heels. Though his plants are not yet so large, the six showed for the second prize were really fine examples. The other six were poor. Narcissi and Lilies of the Valley were not numerous. Of the first, Mr. Douglas was the only exhibitor of nine plants, all of which were fine, the sorts being Mesmerus, Newton, Queen of the

Netherlands, and Bazelman major, all of the Polyanthus class. Why is it that other species of Narcissi are never shown at spring shows? How beautiful would, for instance, potfuls of The Empress and Emperor, Horsfieldi, obvallaris, Bulbocodium look at this season. If grown well they would make a charming display. The schedule does not prohibit them. Among the three collections of six pots of Lily of the Valley there were none that equalled the splendid examples of this flower brought into Covent Garden Market by such growers as Messrs. Hawkins & Bennett, of Twickenham.

AZALEAS as a rule are not remarkable for high quality at these early shows, and the present occasion was no exception, for the best of the collections was scarcely worth notice. Some of the exhibitors seem to aim at forcing as big specimens as they can; consequently they have but ill success. If they were to bring small and profusely flowered plants, or half specimens similar to those Mr. Turner usually exhibits at the summer show, and which everybody admires, then the Azaleas would form an important feature of a spring show. The half dozen showed on this occasion by Mr. Little's gardener were small, untrained, free-looking bushes covered with flowers of high quality. A plant of *A. grandis* with flowers 4 inches across was a remarkable specimen, far better than huge, poorly flowered specimens.

CROCUSES were good, though the only exhibitor of them was Mr. Douglas, who had a dozen admirable potfuls of yellow, purple, and striped sorts, which in the sunshine expanded widely, and were highly attractive. Chinese Primulas could scarcely have been expected in a fine condition, seeing how late the season for them is.

AMARYLLISES were shown by three exhibitors. Among the first six were two splendid varieties, Empress of India, one of Messrs. Veitch's hybrids, and another called Crimson King, which was without exception the richest coloured Amaryllis that has yet come under our notice. The flowers were small, but if their colour could be infused into a larger variety the result would be a great gain. The inferior quality of most of the plants in the competing class showed more plainly the great advance Messrs. Veitch have made in Amaryllis improvement.

HARDY PRIMULAS and herbaceous plants were shown by Mr. Douglas. Amongst his nine Primulas he had capital plants of *P. nivalis*, a perfect mass of white bloom; a similarly fine specimen of the charming *P. rosea*; fairly good lots of *P. cashmeriana*, *marginata*, *intermedia*, *Polyanthus* Cheshire Favourite, a green-edged Auricula, and another called Fanny. The same exhibitor's nine herbaceous plants included a fine potful of a Narcissus called princeps, which is apparently identical with the true single *N. Telemonius*; also good specimens of *Primula rosea*, Solomon's Seal, *Primula Sieboldii* lilacina, *Fritillaria Meleagris* alba, *Pulmonaria virginica*, white and blue Grape Hyacinths (*Muscari botryoides*), and a fine potful of the rarely-seen North American Blood-root (*Sanguinaria canadensis*). There was one other collection in which there was less variety.

NEW PLANTS were abundant, there being no fewer than ninety submitted to the judges. That these were not all absolutely new may be seen from the fact that one exhibitor thought it worth his while to send flowers of the common Corn Marigold (*Chrysanthemum segetum*) to be judged for a certificate. This and numerous others ought to have been vetoed before coming under the judges' notice. Out of these ninety plants there were about thirty selected for certificates. Botanical certificates were awarded to Anthurium ferrierense, shown by Mr. Bergman; Andromeda japonica, by Mr. A. Waterer; Corylopsis pauciflora, by Messrs. Veitch; and Masdevallia Shuttleworthii, by Mr. B. S. Williams.

Floricultural certificates were awarded to Messrs. Veitch for Amaryllises—Homer, Meteor, Henry Little, Lady of the Lake, Wordsworth, Byron, and Southey; Hyacinths—Pink Perfection, Empress of India, and Souvenir de J. H. Veen; and Rhododendron Triumphans.

To Mr. James, florist, Farnham Royal, Slough, for Cinerarias—Sir P. Rose, Brightness, Mrs. Herrin, Mr. A. F. Barron, Duke of Edinburgh, Lord Beresford, Albert Cox, and Lord Wolseley.

To Messrs. Paul & Son, Cheshunt, for Rose Mignonette. To Mr. H. Bennett for Rose Mary Bennett, Mrs. F. Bennett, Rosa polyantha Anna Maria Montravel. To Mr. Todman, Tooting Common, for Azalea Duchess of Albany and Mrs. J. Connell. To Mr. Coombes for Pansy Exoniensis. To Mr. H. Little for Amaryllis Queen Mab; Cyclamens, Mrs. Little and Amethyst; and Azalea M^{de}. J. N. Verschaffelt.

Besides these the following new plants were exhibited: From Mr. B. S. Williams, Dendrobium luteolum chlorocentrum, Masdevallia xanthina, Leptotes bicolor serrulata, Odontoglossum Erstedii, Angracum articulatum, Cattleya Trianae pulcherrima. Mr. H. Bennett showed Roses Earl of Pembroke, Duchess of Albany, Princess of Wales. Mr. Little showed Amaryllis Ameer and Irmia, and Azalea W. J. M. Verschaffelt. Messrs. Paul & Son, Amaryllis Mrs. Hird. Messrs. Carter & Co., Primula Gold Leaf. Messrs. Cannell & Sons, Cineraria A. F. Barron and Sir Drummond Wolff (both double), and Pelargonium Edith George. Messrs. Veitch, Amaryllis Robert Burns, Cowper, Tennyson, Sir B. Seymour, Olivette; Hyacinths Safrano, Mauve Queen, Balsamiflora, Duchess of Albany, Lord Wolseley, Fleur de Parade, President Grey. Mr. J. James, Cineraria Mr. Herrin, Countess Lonsdale, J. Cox, Captain Williams, Captain Drake, Sir F. Roberts, General Hicks. Mr. Frost, Sir E. Wood. Mr. G. Wright, Capt. Edwards, Colonel Clarke, Mrs. Cox, Princess of Wales, Sir R. Cross. Mr. G. Bolas, Chrysanthemum segetum. Mr. Coombes, Pansy W. Coombes. Mr. Baxter, Mignonette odorata major.

THE MISCELLANEOUS GROUPS contributed in a great measure to the success of the show. Conspicuous among these were the extensive groups of Hyacinths, Cyclamens, Lily of the Valley, and Tulips from Mr. B. S. Williams, Victoria Nursery, Upper Holloway, similar to that shown at South Kensington the day previous. A large silver medal was awarded to this exhibitor. A similar medal was awarded to Messrs. J. Veitch & Sons, Chelsea, for their large collection of some 250 pots of Hyacinths, all in splendid condition, and a large group of new Amaryllises, which together made an attractive display. Messrs. Cutbush won a silver medal for a grand display of Hyacinths and Tulips, like that shown at South Kensington. Silver medals were also awarded to Messrs. Paul & Son, Cheshunt, for a group of Roses; to Mr. H. Bennett, Shepperton, for a new Rose; to Mr. Wiggins, gardener to Mr. Little, for a group of Cyclamens; to Messrs. Carter & Co., High Holborn, for a group of Cinerarias, Dielytras, Dentzias, &c.; to Mr. A. Waterer, Knap Hill Nursery, Woking, for an extensive collection, consisting of nearly 200 plants of Primroses and Polyanthes in great variety, and which won a fair share of admirers.

Bronze medals were awarded to Mr. Clark, Twickenham, for Cyclamens, and to Mr. James, Farnham Royal, Slough, for a large collection of about five dozen plants of Cinerarias, two dozen of which were named sorts of great excellence. This group attracted a deal of attention, as Cinerarias have never before been seen so finely. A bronze medal was also awarded to Mr. Douglas, gardener to Mr. Whitbourne, Great Gearies, Ilford, for an uncommonly fine specimen tree of St. Michael's Orange, which bore about a dozen and a half of full-sized fruits, well coloured and said to be of excellent flavour.

A full list of awards will be found in our advertising columns.

The Primrose as an emblem.—An absurd and persistent attempt has been made by a correspondent of the *Times* to connect the Primrose with the memory of the late Lord Beaconsfield. In the endeavour, a great deal of useless derivative erudition has been shown in the way of exhibiting what the writer himself calls barbarous Latin and defective Italian. This point being settled, and it being proved satisfactorily, at least to the writer, that the yellow Primrose, the flower in

question, is capable of being confounded with the Daisy, he enters a strong protest against the yellow Primrose "being degraded to the base purposes of a party badge," the very purpose to which his entire correspondence, if it has any purport at all, would dedicate it. But it is gratifying to feel that this confusion of thought will have no further practical effect than its own exemplification. If the age of chivalry has not closed—Burke notwithstanding—the age of symbolism certainly has. Floral emblems, with many other things, went out with the French *ancienne régime*, and no attempts, however desperate, will in our day make either the Violet or the Primrose individually representative.

Sea weeds and land weeds.—The papers say that "the secretary to the Royal Botanic Society recently tried the novel experiment of planting seaweeds in ordinary earth. It would naturally be supposed that these 'flowers of the ocean' would not flourish away from their native element, but this is not the case, most of the specimens planted having grown admirably in soil which is constantly kept in a moist condition."

* * We should like to see the Society with a few more good houses to grow the beautiful tropical land weeds a little better than they are usually seen in its gardens. The outdoor department is much neglected. The improvement now beginning in many private gardens in hardy plants is as yet unknown here, and more's the pity, for the example of the garden is powerful for good or evil.

Charcoal in Vine borders.—"Constant Reader" may venture to use charcoal in his soil for Vines with safety and derive good results therefrom. With regard to quantity, his border must be taken a little into consideration—as to whether it is elevated and well drained or the reverse. Should it be elevated and well drained, he may put one bushel of charcoal to every six bushels of soil, or one cartload to six cartloads of soil. Should his border be on the level with the walk or garden outside—the same as I have had to contend with—he may put one bushel to every four bushels of soil, or one cartload to four cartloads of soil. If bones are obtainable they should not be left out of his mixture in making a new border; he can add them in the same proportions as the charcoal.—J. HOBBS, *Torquay*.

Exhibition at Ghent (B.).—This commences on the 15th of April next and lasts until the 22nd.

Cinerarias (T. Moss).—The blooms you send represent a fair strain, but much inferior to the best strains, such as those exhibited in London this week. Cinerarias, however, cannot be judged by single blooms sent in a small box through the post.

Hybrid Vines.—At an exhibition held during last autumn at Bordeaux Grapes were shown which were the produce of hybrid Vines obtained by crossing some of the American species with the best wine-producing varieties. The fruit is said to be of good flavour, and it is hoped that these new kinds may resist the attacks of the Phylloxera.—J. C. B.

Names of plants.—*Nemo*.—1, *Clomene comamontana*; 2, too small to name; 3, *Cypripedium hirsutissimum*; 4, *Hebeclinium atrovirens*; 5, *Dendrobium nobile*.—*Mac*.—Common wild Daffodil (*Narcissus Pseudo-Narcissus*).—*C. "This is an Art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

NOTES ON BIRDS

In the Garden, Sheen Lodge, Richmond Park.*
BY PROFESSOR OWEN.

AMONG the observations made on birds in my garden* I have noted that those which come to breed migrate from the south, and those which come to feed from the north. The term "feeders" is, of course, used only to express that food is the sole or main object of the visit; the "breeders" are necessarily also feeders. The general conclusion was that all the migrants, flying from their feeding to their breeding latitudes, went from south to north, and from their breeding latitudes to their feeding ones in the reverse direction. The natatorial and grallatorial orders (swimmers and waders) furnished mainly the north-to-south travellers which tarried for subsistence in our latitude and locality, but with them came also the fieldfares and the handsome redwings. The latter are, then, busy in the garden, with short wheeling flights, stripping the Hollies of every scarlet berry, and the Barberry bushes of as many of theirs as our own home thrushes and black-birds had left.

At this, with us, wintry season, the immigrants which came during summer to breed had fled to their warm or tropical feeding-grounds, with their fledged broods, for sustenance during our hard season.

In occasional wintersojourns in Egypt, following the migratory example of my summer feathered friends, I have nodded to the flycatcher busied, in my study at Cairo, in diminishing the insect plague, and have said, "Glad to see you, my little friend! Hope you will repeat your visit to Sheen Lodge next June; you will be very welcome. I duly admired your skilful evolutions, darting from the garden seat to pounce on the fly skimming unconsciously across the lawn, and wheeling back with your prey to your post of observation."

At the opening of the spring season my redwings and fieldfares are off to their more northern and arctic breeding grounds. The season of love there puts the vocal power in tune, and the skilful practice of the instrument has gained for the male *Turdus iliacus* its name of "Swedish nightingale." Occasionally a late tarrier has given me a parting specimen of his notes.

Our larger and more numerous winter immigrants are to be seen in the park (Richmond), and especially in the large sheets of water known as the "Pen Ponds." There in a secluded bay, fringed by the foliage of adjoining preserves, and far from the drives and established walks, might be seen, ere a continued frost had iced over the water, the wild mallard with his mate, and occasionally the teal, the widgeon, and the golden-eye.

In the earlier years of my residence the woodcock could generally be sprung from some tempting shelter at the winter season; and occasionally the peculiar notes, "humming and drumming," with the "peet-peet" of the snipe might be heard. But since the thorough drainage of the park, prior to the visit of Her Majesty to the White

Lodge in 1861, the winter immigrants of the wading and swimming kinds have been few and far between. By the herons from a neighbouring heronry the ponds are visited at all seasons. Angling at early morn, I have always seen those patient waders similarly occupied near the opposite margin.

I can well understand the condition of our latitude and environment which tempts the nightingales to our groves and gardens for their breeding ground.

In the warm or tropical regions which they have left the insect food may be in abundance, but it is mostly in the comparatively dry and chitinous state of the "imago." At least, in Egypt and North Africa, there is not that moisture and other conditions favouring the development of buds and leaves so suitable, as with us, for the sustenance of greedy grubs. When I have come upon strings of fat, green larvæ dangling from branches of the Blackthorn, and at the same time listened to the trill of the father bird from a topmost twig, I have said, "This is the soft nutriment which you and your faithful mate select for the early digestive powers of your callow brood."

And here, I may remark, how rarely I have succeeded in finding a nightingale's nest, though more than one pair annually rear their brood in the garden. On one of these occasions the nest was hidden near the base of a Holly; the soft warm nursing chamber was walled round by a ring of dead and shed Holly leaves stuck upright with their margins overlapping each other.

The variety and abundance of larval food afforded by the gardens and shrubberies in an English spring I deem to be one of the conditions, if not a main one, of the desertion of their warmer and more sunny latitudes by little immigrants with less volant powers than the swifts and swallows which seize their insects on the wing.

For three successive years I have noted the first hearing of the nightingale in my garden on the 15th April. I have not made any observation which affects the belief that the males precede the females in the date of their arrival, and that the sexual migratory flocks are apart or distinct. But, however this may be, the question forces itself, how came these little African or Asiatic birds to know the distant country appropriate to their reproductive needs, and the way to it in the dark? The conjectural biology in vogue may affirm that a primeval pair of nightingales accidentally strayed into a latitude in which they succeeded in rearing and finding fit food for exceptional broods; that this offspring, when winter compelled, followed their parents back to the summer clime. The younger birds repeated the old ones' course northward at the breeding season. Successive generations perfected the ancestral habit or instinct, and thus was selected the migratory songsters.

Returning to prosaic matters of fact, I have to meet a question more commonly asked, Why our nightingale immigrants are subject to the well-known geographical limitation of their nesting work in Great Britain? To this my reply is, I suppose it relates to a corresponding limitation of the numbers annually arriving. The assemblage reaches the south-eastern base of England and finds the needful room without migrating more northward than the Trent, or westward than Devonshire. Exceptions may prove the rule.

I have never witnessed what I could interpret as the first arrival or descent of any immigrant species.

Those naturalists who have enjoyed the opportunity of observing the singular phenomenon testify that the flight is by night, and undertaken by countless numbers of the same species, occasionally associated with similar myriads of the old and young birds of other species. One may comprehend the cause of superstitious interpretations, such as the nocturnal chase of the spectral hunter, by wakeful charcoal burners, foresters, and fishermen, of the strange sounds aloft, sweeping over them in the darkness of the night—sounds due to such invisible passing flocks at the migratory season. The smashed pane of a lighthouse window of thick plate glass, with the fractured beak and skull of the wild duck impinging thereon in its headlong flight, and falling dead upon the floor of the light chamber, is a specimen in the British Museum worth contemplating in attempting to realise the rate at which the migrating bird flies by night. The largest sum of observations on avian migratory phenomena is due to wakeful, keen-eyed residents of the lighthouse island rock of Heligoland.* How far each beat of the wing is an act of volition, or whether the main flight be due to involuntary, automatic reflex, nervo-muscular, actions which do not tire, is a moot question in comparative physiology. The glare of the lighthouse in the mid route to and from an arctic nesting-place attracts and may guide on either hypothesis. The perfection of vision in the keen-sighted, far-seeing bird may be reckoned among the causative conditions of successful arrival at the fitting breeding localities. And while on this track of thought I am reminded of the way of education of the useful carrier pigeon. The young bird is first taken a moderate distance from home; it returns, having noted in such short flight some object which guides its course. The distance is then increased by the trainer before the dove is let free, and guiding objects, still more remote from home, indicate the way back. The distances are again increased until steeples or other conspicuous objects many miles apart are recognised through the carrier's singular instinct as pointing homeward.

Gerard and Parkinson.—In continuation of Mr. Archer-Hind's note (p. 277) it would be very interesting to have fuller information as to the dates and variations of the different editions of Gerard and Parkinson. I fancy that the first edition of Gerard was published in 1598, and not in 1597, on the ground that although "the address to the reader" is dated December 1, 1597, the portrait of the author bears date 1598. Johnson published his edition in 1633, with large additions. Are there any other editions extant? Parkinson's "Paradisus" again appears to have been published in 1629 and republished in 1656. Do these editions vary, and are there any others? There is also Parkinson's "Theatrum Botanicum," published in 1640. Is this book of any value? It seems to make no mention of Narcissus or Daffodil, and is therefore useless on that quest. Johnson's edition of "Gerard" is evidently much more frequent than the original, as nearly all Gerardian references which have lately appeared in THE GARDEN have been taken from the former and are in reality Johnsonian. The editor took great care to avoid any such misapprehension, for he not only prefaced the book with a detailed list of his interpolations, but also marked them in the body of the work by enclosure between [. . .]—the more inexcusable, therefore, the misreference, and although Gerard may have profited by the association with Johnson by the attribution to him of acquaintance with many plants which he never described, he has in another respect suffered a severe loss by the handing down

* See THE GARDEN for February 13, 1875.

* Seebohm's "Siberia in Europe," p. 249.

of his name in the incorrect form "Gerarde." The name is "Gerard." He signs his own name to his dedication and address to the reader as "John Gerard;" but Johnson, on his title-page, terms him "John Gerarde," and so, I presume, laid the foundation for the now widely-accepted mis-spelling of the name, although the reader has but to turn over the next page of Johnson's edition to see the correct form printed at the foot of the dedication. The error should be corrected. Mr. Burbidge, in his work on "The Narcissus" spells Gerard's name correctly until he comes to his list of authors dealing with the subject, and then we find, as usual, "Gerarde's Herbal." The power of association was too great.—RHO.

PLANTS IN FLOWER.

KENNEDYA RUBICUNDA is one of the prettiest of greenhouse climbers now in flower. It has long slender stems clothed with trifoliate leaves, and each little lateral shoot bears a cluster of deep red blossoms like miniature lobster claws. So abundant are the flowers, that the whole plant looks a mass of red. We saw a few days ago a fine plant of it in Messrs. Low's nursery, at Clapton, which is among the few London nurseries where hard wooded stove and greenhouse plants are still grown on a large scale.

THE AMARYLLISES at the Royal Exotic Nursery, Chelsea, are still in great beauty, and since our last note there have been in flower many beautiful seedlings, in many instances eclipsing those that have flowered previously. The houseful of these plants as it is now is one of indescribable beauty, and those who would like to see what Amaryllises really are when grown as well as they can be and represented by the finest varieties should see this exhibition. The collection will be in perfection for quite three weeks yet to come.

DOUBLE YELLOW WALLFLOWER.—In a charming and fresh series of spring flowers from the Manor House, Bessingham, Norwich, we have a fine example of the old double yellow Wallflower, which one would like to see more frequently on dry banks or borders in our gardens. Notwithstanding our recent severe weather, the flowers from Norfolk look quite fair and fresh. There are so many things budding up in the well-stored garden, that a few fine days help to obliterate the marks of the east wind and cold.

AZALEA OBTUSA ALBA.—Of the host of so-called new plants shown at the Regent's Park show last week few were so meritorious as this Azalea, which is chastely beautiful. It is the exact counterpart of the original, except that the flowers instead of being Indian red are snow white. They are borne in profusion even on small plants, and though the individual flowers are small, they cover the plants so thickly as to make them look like masses of snow. It will doubtless prove a valuable decorative plant. It was exhibited by Messrs. Veitch, in whose nursery at Chelsea it may still be seen in perfection.

PRIMULA MULTICOLOR fl.-pl. is the name given to a pretty double Primrose exhibited last week by Messrs. Veitch and Son, and now to be seen in their nursery at Chelsea. Its flowers are produced in umbels on stalks about half a foot high, like a Polyanthus, which indeed it is. Each flower is about the size of a halfpenny, and the duplication of the petals is so complete that the flower is a perfect miniature rosette. The colour is a deep maroon, but the yellow bases of the petals are clearly seen between the folds. It is a free-flowering plant, and one, we presume, that is as hardy as any other Polyanthus.

THE PERSIAN IRIS is just now one of the chief attractions of Mr. Ware's nursery at Tottenham, where it is grown better and more extensively than we have seen it elsewhere. The whole plant when in bloom is only about 6 inches high. The flower is unlike that of most other Irises, inasmuch as the erect sepals or standards are almost suppressed. The colour of the falls is bluish, with a bright yellow

crest and a heavy blotch of velvety plum tint. The petaloid styles are a pale blue, so that the flower is really an attractive one, and quite unlike any other species. Iris persica is a very old cultivated plant, and is interesting, as being the first plant figured in the *Botanical Magazine*. This was in 1790. It is successfully grown at Tottenham in light soil in raised beds, and if the winter is severe the beds are covered with glass lights. The flowers emit a delightful perfume akin to that of Violets.

SPRING FLOWERS FROM DUBLIN.—In a beautiful series of early bulbous flowers from the College Botanic Gardens we notice with pleasure the white *Scilla bifolia*, large and good in tone; also the double form of the common wild *Narcissus*, and some of the newer forms of the Greek Grape Hyacinths. Many of these plants are so often disturbed in gardens and nurseries, owing to the desire to increase or distribute them, that one does not often see them at their best in established tufts. But until we see them well and long established in good soil, we shall not be able to fairly judge of their merit.

RONDELETIA AMÆNA.—This is very different in appearance from the better known kinds of *Rondeletia*, the flowers being of a different hue, the foliage larger, and the growth more vigorous. The blossoms of this are bluish-coloured, with a quantity of yellow hairs in the centre, and are borne in large, dense clusters. It is now in flower in the Palm house at Kew, and though not so showy as some of the others, is both pretty and interesting, especially as it is but a small, weak plant; well grown it would probably be very ornamental. This *Rondeletia* is also known under the name of *R. macrophylla*.

THE DOUBLE NARCISSUS CERNUUS is sent to us by Mr. W. E. Gumbleton from his garden at Belgrove, Queenstown. It is a lovely flower, larger than the English Daffodil, and with both the sepals and crown of a soft creamy white. The doubleness is confined to the crown, which is filled with petals. Mr. Gumbleton also sends the large double sulphur Daffodil and the charming little Rush-leaved Daffodil (*N. juncifolius*), which is about the tiniest of all the species. The flowers are not 1 inch across, wholly yellow, and the crown forms a perfect cup. It is a delicate little species and needs careful attention to grow it well.

CORYLOPSIS PAUCIFLORA is a singularly pretty species quite out of the ordinary run of hardy flowering shrubs. It at once suggests such shrubs as *Chimonanthus fragrans*, as in its case the flowers are borne on leafless branches, and are, moreover, of the same peculiar yellow tint. They are, however, quite different from *Chimonanthus* flowers in structure. They are produced abundantly all along the branches, which are slender and erect, and these being numerous the whole shrub is a mass of yellow blooms, rendering it quite attractive. Some plants of it in flower at Messrs. Veitch's nursery at Chelsea are dwarf and twiggy in growth, and, we presume, quite hardy.

HEBECLINIUM IANTHINUM AND ATRORUBENS.—These are useful for flowering at the present season, for, though there is a great variety of plants available for conservatory decoration now in bloom, these composites supply a colour which is but sparsely represented. The better known kind, *H. ianthinum*, is a free growing plant requiring much the same treatment as a *Salvia* or a *Eupatorium*, to which it is nearly allied, and its pale lavender *Ageratum*-like flowers are borne freely in large flat terminal corymbs, and last in beauty a long time. *H. atrorubens* is a conspicuous and showy plant. It differs from *H. ianthinum* in having larger leaves, the midrib of which, the leaf-stalk, and the young shoots are densely covered with dark coloured hairs, which also extend over the exterior of the calyx, so that the head of flowers has collectively a much darker appearance than the other kind, although the actual difference in colour is not great. Cuttings of both strike easily, and both are plants of simple culture; the principal point to be observed is that

they do not suffer from want of water when the pots are full of roots. A temperature above that of any ordinary greenhouse during winter is essential to their well-being, the most suitable place being an intermediate house. These two plants are among the most noteworthy now in flower in the conservatory (No. 4) at Kew.

TWO NEW CYCLAMENS named Mrs. Little and Amethyst are probably the finest in their respective colours that have yet been raised. The first has medium-sized flowers, with broad petals of firm texture. The colour is an intensely deep crimson, much deeper than in any that have been raised previously, making it a strikingly beautiful variety. The other is a descendant of that fine purple-flowered variety called Royal Purple, and its alliance to that sort may be seen at a glance, for its flowers have all the refined form of the other, but the colour is even a richer purple. These two fine Cyclamens were shown last week at the Regent's Park show by Mr. Wiggins, from Mr. Little's garden at Hillingdon Place, Uxbridge, where both were raised. To each a first-class certificate was awarded by the Royal Botanic Society.

AZALEA J. N. VERSCHAFFELT.—Though the varieties of the Indian Azalea are now almost innumerable, there is still room for a new variety if an advance upon older kinds, and such is, we consider, the one in question, being one of the finest white sorts with which we are acquainted. Its flowers are some 4 inches across, of solid texture, and perfect in form, while the white is pure, with the exception of a dash of green on the upper petal, which, however, does not mar its chasteness. It is a remarkably free flowerer, the plant of it which Mr. Little showed at Regent's Park last week, though only a small specimen, being covered with bloom. The judges rightly awarded it a first-class certificate. Two other new Azaleas exhibited on the same occasion were worthy of note. These were called Duchess of Albany and Mrs. J. Connell. The first had pure white flowers of small size, but borne in profusion. The other was similar in size and floriferousness, but the colour was a bright Indian red. Both are pretty sorts and particularly useful for forcing. Both were shown by Mr. Todman (gardener to Mr. Connell, Bushey Down, Tooting Common), who has for some years devoted both time and skill in hybridising Azaleas, and has originated some valuable sorts.

Wallflowers in pots well repay the little trouble which they entail in order to have them in bloom in February and March. Their fragrance is much appreciated, and when suitable kinds are grown they are useful either for conservatory or house decoration. Harbinger and Belvoir Castle are the kinds grown here. Their seed is sown in prepared beds outside at the end of May, and as soon as the plants are large enough we plant them out in an open piece of ground facing the west, where they become strong bushy plants with numerous side shoots—a great advantage. If sown later than the time named they do not make side shoots of any service for blooming. Early in October they are taken up and potted in 6-inch or 8-inch pots in rich soil. They are then placed in cold frames, if at hand; if not, then under a north wall, where, if kept moist overhead, they soon recover from the check sustained through lifting. Towards the end of the month I move them into a cool house, give them plenty of air and liquid manure occasionally, and early in February they commence to bloom. This year they have been most useful, as the severe frost which we have recently had has killed nearly all those planted here out-of-doors for spring bedding.—E. MOLYNEUX, *Swanmore Park, Bishop's Waltham.*

Amaryllises.—Allow me to say that the first prize for six Amaryllises at the Royal Botanic Society's show was awarded to me, not to Mr. Wiggins, as stated in your issue of the 31st, he being second. Crimson King was raised by me and exhibited in my group.—E. BAXTER, gardener to W. S. Parker, Esq., *White Lodge, East Barnet*

GARDEN IN THE HOUSE.

FILLING FLOWER VASES.

THE subjoined illustration may perhaps afford a hint or two as regards the arrangement of cut flowers and foliage in vases, work that is often done in a tasteless and unskillful manner. The stately majolica vase represented in the annexed woodcut is filled with a variety of flowers and foliage, arranged in what may be termed a free and easy style, the very opposite of the monotonous, insipid arrangements with which one often meets. As

admirably in a cool greenhouse; in fact it is almost hardy. A companion plant to this and one that thrives well in its company is the German Ivy (*Mikania scandens*), the elegant shoots of which look well in vases. These are a few plants not so often used in vases as they might be. Another hardy plant that should always be grown in a garden for cutting from is the Alexandrian Laurel (*Ruscus racemosus*); it has erect stems a yard or more high, and is furnished with small, shining, green foliage which remains on the plant throughout the year, making it a capital subject for cutting

lucida, *Lomatias* of different sorts, *Asplenium bulbiferum*, various *Scolopendriums*, *Farfugium grande*, *Ligularia Kämpferi*, *Pittosporum tenuifolium* and *eugenioides*, *Yucca Whipplei*, *Y. albo-spica* and *angustifolia*; *Choisya ternata* is also a most distinct and accommodating shrub. I have seen various Bamboos tried for indoor decoration, but always with unsatisfactory results. Both forms of *Aspidistra* prefer a shady situation, as of course will the few Ferns mentioned. If these are kept well supplied with water at the root the atmosphere will always be moist enough. Occasional spongings of the foliage is of importance, as also is a good shower bath outside, either with tepid water from a watering-pot or a warm shower of rain.—W.

ARRANGEMENT OF FLOWERS.

FOR a good effect, flowers, whether arranged in bouquets, baskets, or vases, for either the parlour, the dining-table, or the platform, should in all cases be made to appear as if on growing plants. They should appear perfectly natural instead of artificial, as they too commonly seem, especially when arranged by the mechanical florist. But very few persons, relatively, show any taste in the arrangement of flowers. They do not fill a vase or basket in such a manner that it is a pleasure to look at it; on the contrary, the confused way in which flowers are crowded, crushed together, excites your sympathy for the poor, distressed objects. Of all the various mistakes made in floral decorations, the most common is that of putting too many in a vase; and the next to that is the mistake of putting too great a variety of colour into one bouquet or vase. Every flower in a collection should be so placed that its individuality should be determinable without having to pick the bouquet to pieces. The calyx of a Carnation should never be hidden by being plunged into the head of some other flower, however well their colours may harmonise; not more than two varieties of them should be in a vase of loose flowers, and these should be such as afford the greatest contrast of colour, together with the most perfect harmony. Carnations should be cut with long stems, so that their own foliage would furnish sufficient green to give the mass a natural appearance, if any other green is required, and a due proportion is always necessary; in fact, in all arrangement of flowers, appropriate foliage should be in excess of the flowers. With the Carnation there is nothing more beautiful than the fronds of the Maiden-hair Fern. We have never had more satisfaction in the arrangement of flowers, in any design whatever, than by taking the hardy Carnation that is so freely produced in summer, a few stems of flowers and partly opened buds, put in a tall vase with a liberal amount of Maiden-hair Fern, the whole so gracefully united that every flower, bud, and frond of the Fern could be seen in its integrity.

Sweet Peas never look so well in the hand as they do on the plant, amid the boughs over which they climb, because they cannot be carried without crowding them; but put them lightly into a vase with an equal number of Mignonette; or, rather, ornament a vase half full of Mignonette, with a few blooms of Sweet Peas, and you get a charming effect, because you follow the natural arrangement by avoiding crowding the natural blooms, and putting them with the green foliage which they want to set them off. Few people are aware until they try it how easy it is to spoil such a pleasing combination as this. A piece of yellow *Calceolaria*, a truss of scarlet Geranium, or a spray of blue *Salvia* would ruin it effectually. Such decided colours as these require to be grouped in another vase, and should not be placed even on the same table as Sweet Peas. They also require a much larger preponderance of foliage than is wanted by flowers of more delicate colours. When we have a basket of flowers of all shades of colour and variety of form before us to arrange, we know full well the difficulty of resisting the temptation of just putting in this or that flower, because it is such a beauty. A beauty it may be, but beauty is not beautiful when out of place, and

Flower Vase, tastefully arranged.

may be seen by our illustration, free use is made of Fern fronds and other elegant foliage for intermingling with the flowers, and each is so placed as to be seen to the best advantage, not huddled together in a meaningless way. Sprays of slender trailing plants such as *Ficus repens* and *Saxifraga sarmentosa*, it may be observed, fall gracefully over the sides of the vase, and there are hosts of other plants equally well suited for such a purpose. For instance, the common Ivy in certain stages has extremely beautifully tinted foliage, and is all that can be desired as regards elegant growth. This with other hardy trailers is useful for winter decoration. Another elegant plant from which to cut long leafy sprays is *Myrsiphyllum asparagoides*, a slender twining plant that thrives

from to mix with flowers in large vases. There is much to learn, speaking generally, with regard to vase embellishment, but the practical hints given from time to time in THE GARDEN cannot, we think, fail to work good in course of time.

Plants suitable for permanent cultivation in drawing-rooms.—If "West Highlands" will make a selection from the following list pretty and permanent groups will be the result: *Aralia Sieboldi* (two variegated forms), *A. quinquefolia*, *A. q. gracilis*, *A. heteromorpha*, *Dianella tasmanica*, *Aspidistra lurida* and *A. l. variegata*, *Dracena australis* and *D. a. congesta*, *Rhodea japonica* and the variegated varieties, *Griselinia*

it is not in its proper place when it does not harmonise with its surroundings.

Lilies rarely look well when mixed with other forms, and there are scarcely two varieties of these that look well in the same vase. For large vases each class or variety should be used singly, with sufficient foliage to form a proper natural contrast. With the white Lily (*Lilium candidum*) the most beautiful and pure of all known Lilies, a few sprays of *Delphinium formosum* makes a pleasing contrast, and for foliage in combination with these there is nothing equal to the more delicate species of Ferns; if these cannot be obtained, the *Asparagus*, used sparingly, produces a pleasing effect. For church decorations there can be no arrangement more chaste, beautiful, or appropriate than this. Later in the season the *Lilium lancifolium præcox* can be used in the same manner, and with very nearly the same effect. White and green, happily blended, is the best possible arrangement. Where flowers are to be seen at a great distance, then the flowers should be large and distinct, and in tall vases with some drooping plant to relieve the vase, like the *Passiflora* or German Ivy; the vase should always stand in a mass of Ferns or Lily of the Valley. For the same purpose *Gladioli* make a beautiful display, and in their arrangement harmony of colour is of the greatest importance. Where

Flowers are to be seen at a distance. white and scarlet or crimson varieties only should be used; these colours can be used singly or together. For foliage, either Ferns or *Asparagus* leaves can be used with good effect. The *Eulalia japonica* and *zebrina* harmonise well with the *Gladiolus*, and for large displays it is the best for foliage of anything we have tried. For a basket of flowers in their season, for any purpose whatever, whether for the platform or the parlour, there is nothing more beautiful than Apple blossoms; these should not be mixed with any other flowers. Cut such as are just opening, arrange in such a manner that your basket resembles a miniature Apple tree, and your arrangement is perfect. If the *Viola pedata* can be obtained, place the basket in a mass of these flowers with their own leaves as foliage, and the effect will be very pleasing. The proper arrangement of flowers may be stated in a few words. Never put more than three varieties or colours in the same vase or bouquet, and let those colours be such as perfectly harmonise. Arrange the flowers so that each one can be seen entire. In all your arrangements imitate Nature in hers. [The above extract we take from the *Ladies' Floral Cabinet*, an interesting American monthly, published at 22, Vesey Street, New York.]

PLANTS IN ROOMS.

FROM long experience and always having a growing plant and cut flowers in all my sitting rooms, I can answer your correspondent's inquiry, "What evergreen plants will grow and thrive all the year round in sitting rooms?" I tried Ferns; they looked well for a time, but do not thrive, and require continued changes where a constant nice healthy graceful effect is required, and without this effect better have no plants. I tried Palms; they do fairly well for a time, and look graceful, but when growth commences the lower leaves are sure to show decay; they look best if the base of the plant is surrounded with small Ferns, the fronds of which conceal the naked stem of the Palms. Some years since, in wandering through Covent Garden Market (and in all my London visits I like to go through the markets, the scent and sight of the many flowers and fruits and vegetables is so pleasant) I purchased a small plant of *Aspidistra lurida*; it then had only three leaves of about a foot in length, the leaves rising from hard naked stems quite green, and then expanding into wide, thick, graceful foliage of a dark rich green colour; the flower is peculiar, and would scarcely be noticed, as it is on the surface of the earth. There was a peculiarity about the plant which struck me, and I have not been disappointed. It is the only plant I know which tho-

roughly adapts itself to domestic life, living always with you, the leaves seldom dying, and with the most ordinary care always showing form and colour of the most beautiful kind. The original plant, after three plants have been taken from it by division, has now thirty leaves, the longest about 27 inches and 5 inches in the widest, the whole forming a mass of vegetation which cannot be excelled, considering the conditions to which it is subject, and these conditions it enjoys thoroughly. The glare of the sun it does not like; a shady window and plenty of water it enjoys, and it will bear an occasional open window, which Ferns in a room will not. At certain times the plants are just taken on the terrace and syringed to take off the dust, which, with every care, must accumulate on the leaves. The three plants taken from the original are not quite so large, but in equally good health. I have heard this plant is common on the Continent; it certainly is not in England. Three good nurserymen I applied to could not supply me with it some three years since when I wanted more plants, but I obtained four plants of the variegated sort having long stripes of white with the green. I do not much like them; they do not grow so well, appear more delicate, and are not so well adapted for every-day domestic life; in the conservatory they flourish.—K. K., *Tuddysford*.

Room plants may consist of *Arum Lily* (*Calla*), *Aucuba*, *Aspidistra lurida*, New Zealand Holly Fern, and red and green *Dracenas*. A Walnut put into a pot of rich earth as soon as ripe makes a very handsome and uncommon pot plant the next summer, and has a delightful perfume. A Spanish Chestnut, too, is useful planted in the same way. All these plants are kept in good foliage by occasionally sponging the leaves with tepid water and if allowed to get too dry they are recovered by plunging the pot over its rim in water for an hour or so. This drives out the air and lets in the water. Heaths will live in a room for a long time if occasionally thus treated.—R. B.

ROSE GARDEN.

DWARF & STANDARD ROSES.

A MILD winter and a wintry spring are not the most favourable conditions for Roses, but as we must take the seasons as they come, our best way will, I think, be to cultivate our Roses in such a way as to reduce as much as possible the chances of failure through weather, not that we shall succeed in this entirely, but by paying attention to the form of growth and the selection of proper sites, we may do something to mitigate the evils arising from our variable climate. As at present cultivated, no one will deny that the majority of cultivators invite the frost to kill their Roses. They do this unwittingly by giving them too rich feeding, which promotes succulent growth and renders them an easy prey to frost. They also select unsuitable positions for them, perching them high up in the air, as if so placed to show that the cultivator was anxious to give the frost every possible chance to kill them. In the cultivation of the Rose we must pursue a natural course of treatment if we wish to attain success over a long course of years. Standards cannot be said to be a rational mode of culture, and no wonder that Roses grown in this form are the first to suffer from severe cold. I may be told that I am prejudiced against this form of Rose growing, but I may state that when I plant a Rose tree I want it to grow and prosper for a reasonable length of time. If I plant standards I have to renew them frequently, because they die off so mysteriously after being planted a couple of years or so, that I have neither the time to prepare new stations for them nor the opportunity of purchasing relays of trees to keep up the stock. I must, therefore, grow Roses in such a form as will insure their living and flowering for several years without requiring to be renewed. I may here mention that I manage a large garden in which there is not a standard Rose grown in

the open air. It will, therefore, surprise no one to hear that we grow the major part of our Roses

As bushes. A good many are grown in beds pegged down, and some are made to form hedges, which reach a height of 6 feet, but we prefer the bush form to all others, and these on their own roots chiefly. I prefer the latter, because if a severe winter kills all the branches down to the ground line the portions left have such recuperative power that in one season they become re-established. Our beds of pegged-down plants have been planted fifteen years. Every plant was struck from cuttings made in the autumn previous and the plants are as vigorous now as ever they were. Our loss from all causes has not been more than 1 per cent. during all that time. It is, however, only right to say that all the varieties of Hybrid Perpetuals of which I am writing do not grow so well on their own roots as others. In such cases we have to resort to the Manetti as a stock for the weak growers, and as a rule it answers very well. In the case of varieties that do well on their own-roots, I find that they are really more vigorous than when budded on foster roots, a valuable fact, and certainly a strong argument in favour of own-root Roses. The greatest difficulty lies in getting very dark coloured Roses to grow away well, or, in other words, it is found that a greater number of comparatively light coloured Roses are more vigorous on their own roots than dark ones. Our best dark sorts on their own roots are Charles Lefebvre, Maréchal Vaillant, Pierre Notting, Annie Wood, Exposition de Brie, Lord Clyde, Alfred Colomb, and Duke of Wellington. The best light coloured kinds for our own root plants are *Cécilia rosea*, John Hopper, Edouard Morren, Elie Morel, Anna Alexieff, Baronne Prévost, M^{me}. Vidot, and Nardy Frères. There are, however, many more in both cases that will grow fairly well on their own roots. We find the following a very good way of growing the more choice and tender varieties of

Tea-scented Roses: Get some strong plants and put them into 8-inch pots. The best time to do this is early in February. Use a compost of half fibrous loam and one quarter each of leaf soil and thoroughly rotted farmyard manure. To keep it porous add a good sprinkling of coarse sand or roadside grit, and pot the roots moderately firm. It is not absolutely necessary to pot the plants in the first instance in February, but in their future management that month ought to be selected. When potted, place them in a cold pit or frame, and keep them secure from frost, and the soil just moist about the roots. On all favourable occasions after the middle of March give them a liberal supply of air, the object being to keep them steadily growing, but, at the same time, the more hardy they are treated without the tender growths being exposed to frost the better. About the end of April they may be taken to a sheltered spot in the open air—either under a warm south wall or some similar place. What may be called their summer treatment should commence in the middle of May; they should then be taken to a warm position either in the frame, ground, or to a warm border in the kitchen garden, where it will be convenient to water them in dry weather. The pots should at once be plunged up to their rims, and then both pots and the surface immediately around them should be mulched with a good thickness of well-rotted manure. This rich mulch will quickly encourage the formation of roots on the surface, and in a few weeks the plants will be growing vigorously, and as good growth means plenty of flowers, the cultivator will reap a rich harvest both of buds and blossoms. Before severe frost sets in in autumn it will be necessary to lift the plants, pots, and all, and take them to some cool light structure, where they will be secure from frost during winter without being in any way excited. A cold pit or Peach house not forced is the right place for them. Throughout the winter very little water need be given to the roots. Early in February the plants should have what little pruning is necessary to keep them in shape, and then about two-thirds of the old soil should be

shaken from the roots, repotting in a fresh compost, and making the same sized pots serve for the first three years, after which they may have pots 2 inches larger. After being potted they should be returned to their winter quarters, giving the preference to a cold pit or frame from which the light can be withdrawn during mild weather, for the less they are excited the better. If from any cause the young growths have not got pretty forward by the end of April they must be kept under cover ten days or a fortnight longer, and when taken from under glass they must be gently dealt with at first, so as to harden them off in a gradual manner. The treatment during succeeding years must be the same as that just described, and if skillfully managed the plants will last in good condition for many years.

Hybrid Teas.—These are for the most part indifferent growers, and but little if any harder than ordinary Tea-scented varieties, to which, as regards growth and form of flowers, they have a strong resemblance, and, like ordinary Teas, they do better under glass than in the open air. The first year we grow them in pots in a cool house, where they did fairly well, but in the open ground they do not seem to take kindly to their new quarters. So far as I have seen of them, the following are the best, viz., the Hon. George Bancroft, Michael Saunders, Jean Sisley, and Viscountess Falmouth. The second and last named gave us some good flowers last year, but as to their being fragrant or deserving to be formed into a distinct section, I cannot see on what merits they claim such a distinction. J. C. C.

CATHERINE MERMET ROSE.

HAVING read with great interest the article in THE GARDEN the other day (p. 268) on this Rose (which, in my opinion, is one of the best of the Tea-scented varieties in cultivation), I take the liberty of describing a mode of growing it which I have adopted, and found to be most successful. Some five years ago I purchased a small plant of this variety budded on the Manetti stock. I being very pleased with it when it came into bloom, I determined to endeavour to grow it as I had grown the Gloire de Dijon and Maréchal Niel. Having successfully struck some cuttings (as I am one of those who prefer Roses on their own roots), I selected one of the strongest, and grew it on in a pot until I got it about 5½ feet to 6 feet high. I then planted it with its roots outside the conservatory and brought the top in—that was in the month of March. That year it made a good deal of wood, and bloomed moderately; the second year it had got half way up the conservatory, and I cut over a hundred Roses from it, and ever since the tree has improved each year. My only difficulty has been that I have been obliged to prune it more severely than I otherwise should to bring it within bounds. As regards the blooming capabilities of this Rose, I need only say that I shall in a few days cut the first Rose, and that for the last three years it has bloomed continuously from March to November. The quality of the blooms, also, far exceeds those grown in pots.

Marshfield, Huddersfield. T. P. CROSLAND.

Autumn transplanting.—Having been obliged to make some alterations on ground on which one of our Rose beds stood, the Roses, dwarfs and standards, had to be taken up on September 21. They were taken into the kitchen garden, and laid in by the heels till they could be finally planted. Having completed our work, we planted a new-made bed with the dwarfs we had plunged, and some own-root Roses put in as cuttings last November. This took place on November 3, and when we came to remove the plants from the kitchen garden we found that they had made fresh roots in great abundance, some more than 1 inch long. When taken up in September the leaves and young shoots flagged a little, but soon recovered. On taking up those struck from cuttings which were still growing, we did not find so many fresh white roots as in the case of those

laid in by the heels, and on examining some old plants in permanent beds we did not find any fresh white roots at the beginning of November. I do not think that Roses suffer through their roots being disturbed early in the autumn, especially if replanted quickly; on the contrary, I believe that in my case had they been planted in their permanent positions at first they would have started and done as well as if they had not been disturbed at all. A few years ago six Roses taken out of the open ground at Bath on August 16 were brought me to place in pots. They were potted, the shoots being green, and hung down, although set in the shade for a week or so and syringed. To my surprise, however, after being pruned back they all yielded three or four good blooms in the May following, having been kept in a cold pit from December to that time.—J. C. F.

When should Roses be pruned?—Great differences of opinion exist as to the time for pruning Roses. If we prune in autumn, do we get better results than if we defer it until spring, or *vice versa*? If we prune in autumn, after the growth is matured, there can be no material harm done—to the roots at all events. And again, if we prune in spring, say the end of March or the beginning of April, the roots are then in action, and the buds perhaps bursting; but, although this is the case, I hold that spring pruning will give the best results, as it retards growth a little at a time when it is liable to be cut back by frost and cold cutting winds. If the situation is good and well sheltered, autumn or winter pruning may be an advantage, but in exposed situations, where Roses have to stand a severe winter, I should recommend spring pruning.—J. B.

THE BLACK FORTNIGHT IN MARCH.

MOST of us had hoped the weather had done its worst from the 6th to the 20th, but this does not seem to have been the case. After the snow melted we had two of the most destructive frosts of the season—that is, on the evenings of the 22nd and 23rd. These seem to have cut deeper into vegetation and to have done more damage than all that had gone before. Roses that had struggled through or up against the frost and snow of the foregoing fortnight succumbed to these clear, biting severities. Violets, such as the Czar, Victoria Regina, Marie Louise, and Neapolitan, and the early Forget-me-nots, especially the larger variety of *M. dissitiflora*, are killed in masses, and seem quite rotten. Even Pear blossoms that appeared to have passed through all the previous frosts now seem black through their centre. These two or three frosts after the snow had melted have also finished the major part of the Broccoli, while Cabbage stumps, so useful for sprouts at this season of the year, are also killed outright.

In looking through our Roses they seem even in a worse plight than we had anticipated. There are, however, some degrees of injury even among them, and the following are among those that have suffered most severely. Among the Perpetuals the darkest varieties seem to have been hit the hardest. Probably this may have arisen in part from their being the more forward in growth. Certain it is that the Duc de Wellington, Sultan of Zanzibar, and Prince Camille de Rohan have suffered very much. Among others most severely punished apparently beyond the average are such popular favourites as Marie Rady, Souvenir de Victor Verrier, Alfred Colomb, Pierre Notting, Madame Victor Verrier, Madame Eugène Verrier, Julie Touvais, Madame Prosper Langier, Duke of Teck, Jules Chrétien, John Stuart Mill, La France, Mrs. Harry Turner, and Dr. Sewell. The Teas seem to have suffered nearly all alike on this occasion. Even Gloire de Dijon, undoubtedly the hardiest of all the Teas, probably from being more advanced than the others, appears to have suffered as much as any of them. Even plants on walls and protected look half dead. On the other hand, Maréchal Niel seems to have withstood the frost quite as well as any of the other Teas, if indeed it be a Tea, for it has very much of the cha-

acter about it of a Noisette. Among the few of the latter class grown Souvenir de la Malmaison has suffered by far the most, but that is always a tender Rose. In stating that the Teas appear to have suffered about all alike, exception should be made for Homère; this seems to have suffered but little here, and is now, after the storm, the freshest and least injured of all the Teas.

The more the present state of the Roses is examined, the more certain it appears that standards of all sorts have suffered most, and of these immense numbers are so much injured that it seems absolutely impossible that they can recover, for not only are the buds and young shoots killed, but the bark is blackened or browned, and even the wood itself injured. D. T. FISH.

TREES AND SHRUBS.

HEDGES AND SCREENS.

MR. SHEPPARD begins his excellent article on these (see page 263) with the statement that next to walls hedges are the most important fences round a garden. While no practical man would question the correctness of this assertion, yet there can be little doubt that for the purpose of mere shelter hedges or screens are the more efficient. These, as it were, exhaust the force of the wind by a process of fining down or absorption. The wind comes with full force on the exposed side of the hedge, and little or none of it is left to escape on the other side, every branch or twiglet of the hedge having done its part towards baulking or exhausting its energy. The case is widely different when wind hits a solid wall. There is for a time an arrestment and a change of the course of the air in motion, and but little more or better. The air bounds up over the wall, or diverges to one side, and almost immediately after sweeps along afresh, at times apparently with an augmentation of force through the temporary interruption. Destructive whirls or eddies of air are thus formed and intensified, and it is no uncommon thing to find what may with much propriety be termed scathing lines in close proximity to and following the course of solid walls. Now-a-days, and in this age of iron, stone, and brick, the efficiency and power of living shelters are very much underrated. Our not very remote progenitors had but little choice in these matters, and hence largely their more general employment of hedges and belts or screens. It was natural for them to hedge round their gardens with living fences, being so much cheaper than any other, and also, in many cases, the only ones available. To assure more warmth, as well as command greater security, the fences frequently widened out into screens or belts of shrubs or trees.

The wider the living hedge or fence the warmer, on the principle already explained. It by no means followed, however, that the wider the fence the stronger the defence. Often, no doubt, it was far otherwise, and as far as protection from enemies of human kind was concerned, the defence not seldom became also a harbour and a refuge for lurking foes. Possibly for this and other reasons the screen got narrowed into a mere hedge, and by selecting prickly and close-growing plants, such as white Thorn, Holly, and Sloes, the narrow hedge grew into practical impenetrability. The newer, narrower, more stately, and slightly fence, however, was less warm and cosy than the older and more rambling screen, though the trimmest hedge is still in some respects a better and more efficient protection than a brick wall. The late Mr. Thos. Rivers, of Sawbridgeworth, was so keenly alive to the efficient shelter afforded by hedges, that he placed some of his earlier orchard houses against them. The ventilation was so equally diffused through their myriad interstices, that it would be impossible to command a more equable temperature or more genial atmosphere than I have noted in these structures. When the external atmosphere was low at night they parted with their heat slowly; but as the sun shone on the roofs and the air got heated, its greater sub-

tlety and buoyancy cleared numerous passages for it through the myriad living meshes of the hedges. Similar useful results were noticed in a large pit with glass top, and back, side, and front walls formed of Furze. This pit was found to be much warmer in winter and cooler in summer than others with brick walls standing to the right and the left of it. But these may be looked upon as the exceptional uses of vegetable shelters living and dead. Their legitimate use in or near gardens might in many cases be greatly extended, not only to the obtaining of greater warmth, but to the creation of much higher landscape effects. No one, however gifted by genius or inspired by the love of beauty, can make much of a brick or stone wall, or a wooden fence, clothe it how he may. A good deal more may be done with hedges, but let these broaden out into a belt and meander away into a plantation here and there, and the merest novice can hardly fail to create an effective landscape out of such materials. Another great advantage the hedge has over the wall lies in the fact that if we select proper plants, such as the Yew, the older the hedge the more beautiful it becomes. Such is pre-eminently the case with such Yew hedges as are found at Hatfield, in Herts, and Campsey Ash, in Suffolk, the latter referred to by Mr. Sheppard. With ordinary care they live on and renew their youth for century after century, and grow into historic interest, and special artistic and picturesque value. But enough has been said for the present in support of the claims of living hedges and belts as superior in sheltering power and in landscape results to walls. D. T. FISH.

TRANSPLANTING TREES.

THIS is to many quite a fascinating occupation; possibly, therefore, a few remarks on such methods as tend to secure success in such work may not be uninteresting. It should be borne in mind that plants have an evaporating and an absorbing surface. The surface of the roots and rootlets, in other words the underground portions, absorb moisture, and with the moisture food, but through the surface of the parts above ground moisture evaporates—to a small extent through the bark, and to a very large extent through the leaves. In order that a tree may live and grow well, therefore, these surfaces must bear a suitable proportion to one another. When trees are transplanted it is practically impossible to prevent, to some extent, the breaking of roots and so disturbing somewhat the balance which before existed between the two surfaces, viz., that above and that below ground. Trees, however, when in a healthy condition, are endowed with a certain amount of recuperative vigour, which enables them, if the balance has not been upset to too great an extent, to readjust it by means of the strength stored up within them. Trees which have this recuperative power to a great extent are easy to transplant, and trees which have it in a small degree only are difficult to transplant successfully.

Willows and Poplars may be cited as notable examples of the former, and the common evergreen Oak and the Cedar of Lebanon of the latter class. Pieces of Willow, cut from a tree, and thrust a short distance into tolerably moist ground, usually grow, although in such a case they start without any absorbing surface at all, except their cut section, through which a small quantity of moisture drawn by capillary attraction may serve to prevent exhaustion till roots are formed. Plants having the inherent vitality possessed by the Willow propagate readily by means of cuttings, while those which have but little of it can either not be increased by means of cuttings at all, or only with the exercise of great care and skill. Much care in the transplanting of Willow trees would be thrown away. Trees which have but little of that kind of inherent vitality or recuperative vigour which is required to enable them to restore the balance between their absorbing and evaporating surfaces—their root and head—should have greater care taken in transplanting them, and economy, of course,

demands that this should be of the proper kind. If a tree which is being transplanted has had (as all trees have more or less in undergoing this operation) a portion of its roots broken off, and has also so much of its head pruned off as will serve to lessen its evaporating surface in the same proportion as the broken off roots lessen its absorbing surface, no further check to its growth need necessarily be experienced by that tree from being transplanted. If the transplanting has been very roughly done, however, although there may be sufficient absorbing surface put into the ground, it is quite possible that this surface will be unable to perform its functions, viz., to absorb food and moisture for the support of the tree. The roots may have been injured in such a manner that the passages for the conveyance of the absorbed material are bruised or broken. Each root and rootlet, so far as possible, should be surrounded with soil. The greater the surface of root which any given tree presents to the soil, the greater the support which it, other things being equal, will be able to derive from it. The wonder is not that so many trees die after being transplanted, but that so many live, seeing the hardships they have to undergo.

The amount of moisture which a tree drains from the soil is infinitely greater than one might suppose to be possible. Experiment has shown that a plant has evaporated from its leaves 300 lb. of water for every single pound of solid matter added to its own tissues. Some plants probably exceed, while others evaporate less than this quantity for every pound of solid matter they permanently incorporate. The Eucalyptus in semi-tropical and the Willow in temperate climates will frequently turn swamps into firm ground by sucking up and evaporating moisture. This characteristic of trees extracting moisture from the earth and pouring it forth into the atmosphere partially explains why counties denuded of trees are so liable to suffer from severe droughts. Although, as a rule, the roots of a tree or plant present an absorbing, and the leaves an evaporating surface, yet experiment has shown that, so far at least as the leaves are concerned, the process can sometimes be reversed, and that a plant whose roots are in a medium from which all the moisture has been extracted may have its vitality to a considerable extent kept up, or even revived by moisture imbibed through the foliage; and for this reason syringings overhead are very beneficial to fresh transplanted trees in dry weather. Allegorically, the roots of a tree may be called collectors of raw material; the spaces between bark and wood the storehouses for the material after collection; the leaves, the workshops in which the raw material is converted into manufactured produce; and the wood of both branches and roots, the manufactured produce itself. When it is taken into consideration what an important factor in the healthy growth of plants a sufficiency of moisture is, and also what an immense amount of moisture growing plants extract from the soil, it can then be well understood what great injury is done to fresh transplanted trees in dry soil if weeds are allowed to grow unchecked. It is not so much the plant food which weeds absorb that does the injury; it is that they take away that without which no tree can consume food, viz., moisture. When a tree once becomes established in a suitable situation and soil, it soon gets the better of annual, biennial, or herbaceous perennial weeds—the yearly decay of these even assists in the formation of a supply of food and moisture for it. In transplanting trees such as Box, Yew, Ash, and many others, if they have been previously transplanted within the space of one or two years, it will be probably impossible and quite unnecessary to spread out the great abundance of fibrous root so that every one is quite surrounded by soil, but the more this is done to a reasonable extent the better will the plant grow after being transplanted; and care taken to prevent rootlets from being strained, sharply bent, or broken when filling in and pressing down the soil will not be thrown away. As before stated, the greater the root surface presented to the soil the better the chance a plant

has of extracting nutriment from it. The tree which in undergoing transplantation has the balance between its absorbing and evaporating surfaces the least upset, other things being equal, will have the best chance of rapidly recovering the shock caused by the operation.

Norwich.

J. E. EWING.

FORESTRY FOR APRIL.

PLANTING operations should now be finished without delay. All recently transplanted trees and shrubs should be examined, and large plants properly staked. For ordinary sized young trees stakes about 2 feet above the surface and one tie will be sufficient; stakes 5 feet or 6 feet long are apt to be blown aside; whereas, trees tied to a 2-foot stake yield to the blast and keep their position much better. Trees of a large size may be kept in their proper position by means of three wires and a collar, the latter fastened round the stem, and the wires stretched out at equal distances from each other and fastened to strong pegs driven into the ground. In exposed situations, newly planted evergreen trees and shrubs will be greatly benefited by being mulched and by having a few Spruce branches stuck into the ground around them, to protect them from cold cutting winds, and also to screen them from the warm noon-day sun. Nothing sets off a place to so much advantage as well-kept roads and well regulated shrubberies; the former should always be kept in thorough repair, and the latter never allowed to become a jungle. All straggling branches should be cut back so as to keep the plants within due bounds and from intermixing. In places in which fine old trees grow near the sides of drives, all scrub and underwood should be cut away, in order to show their trunks off to the best advantage. From conifers, all superfluous leaders should be repressed by pinching out the terminal bud, or cutting back the shoot, or perhaps off altogether as circumstances may dictate. Stunted Deodars may be improved by cutting back straggling branches so as to form a uniform conical top, and in cases in which the lower branches are lying on the ground, such if desired may be removed, and a dressing of well decomposed manure spread on the surface; if it can be applied a good soaking of liquid manure from the farmyard will work wonders in restoring them to health and vigour.

Young plantations of Larch and Scotch Fir should be examined, and such trees as have been cropped over by hares, and are producing several leaders, should be connected by cutting them off, leaving the most central for the future leader. Recently planted moor ground, where the work has been executed by the notch system of planting will require attention, more especially in places where the surface is of a mossy character, as the notches are apt to open, and the sod curl back through drought, thus exposing the roots that in such cases a tread with the foot will prevent a number of deaths. This is also a good time to sow

Tree seeds on bare, rugged, inaccessible places; the following may be introduced with the best results, viz., Scotch Fir, *Pinus Cembra*, *P. montana*, Larch, *Cupressus Lawsoniana*, weeping Birch, *Quercus coccinea rubra*, and mountain Ash. Others to suit different localities and peculiar circumstances may be added to this list. Now is the proper time to collect all dead wood, branches and rubbish in the Pine forest, as the Pine beetle (*Hylurgus piniperda*) and the Pine weevil (*Curculia pini*) hibernate in such during winter, and in the beginning of April commence their subcortical burrows in order to deposit their eggs. The *débris* should be collected into heaps in open places here and there, and burned towards the end of the month; in this way both insects and rubbish will be got rid of at one time. All bridle paths in the deer forest and grouse moors should be examined, and where necessary repaired. I have found it a good plan to sow in loose gravelly places with natural Grasses, the matted deep penetrating roots of which assist to bind the

gravel. For this purpose the following Grasses are very suitable, viz, lime or sand Grass (*Elymus arenarius*), and Sea-reed (*Amphiphila arundinacea*). Prepare and construct embankments, viaducts, roads, and bridges that have been torn up and swept away during winter by excessive floods. The ground itself will show the weak points, and provision should be made to guard against a repetition of the evil. Examine and repair fences in forest, field, and park, and see that all gates are in proper working order. Finish nursery work without delay, clean young hedges and keep down weeds everywhere.

J. B. WEBSTER.

WALNUT TREES BLEEDING.

"J. C." (p. 278) asks how a Walnut tree is to be stopped from bleeding. When this or any other tree liable to bleed has had branches removed at a time that does not admit of the cut surface healing up before the sap begins to move, it is next to an impossibility to stop the bleeding. Amongst several instances of a like nature that have come under my notice, one was a large Elm that had a branch of considerable size broken off a short distance from the trunk in felling another tree that stood near it; the flow of sap was so much, that the continual dripping made a hole in a gravel path over which the tree hung, as big as would hold a good sized Cocoa-nut. I had no apprehension that it would do any perceptible harm to the tree; but it afforded an opportunity for testing what could be done in the way of stopping the great force which the rising sap has. I tried burning with a hot iron, collodion, painter's knotting, and the different styptics generally used, applying them both before the burning and afterwards, but without the least effect. I then took some strong bullock's bladder, using it four or five thicknesses, and bound the whole round the stump of the branch with stout twine, laying on under it a coat of thick white lead, but in twenty-four hours it burst the bladder, after distending it to a size that would have been supposed impossible for the material to have stretched to. After this the bleeding went on until enough leaf was made to attract the flow. The natural supposition would be that after this the cells would have healed up; but this was not so, for each ensuing spring for the six years I had to do with the place the bleeding regularly came on to an extent equalling the first year, but it did no apparent harm to the tree. Neither should I suppose any mischief will come to "J. C.'s" Walnut unless several branches of considerable size, proportionate to that of the tree, have been removed, and from which the bleeding is going on.

T. B.

Tree planting by railway companies.

—There being in the United States about 100,000 miles of railway, the advisability of tree planting by railway companies for construction and maintenance has become an important question. There are from 2200 to 3000, and even 3500, ties used in a mile of rails. The average duration of sleepers is from five to eight years, and consequently from 30,000,000 to 50,000,000 a year will be required for 100,000 miles of railway. Putting 500 as the product of an acre of woodland, from 60,000 to 100,000 acres will have to be cut every year, and as it takes thirty years for a tree to grow to the right size, the railways will require from 2,000,000 to 3,000,000 acres—or 3126 to 4687 square miles—of forest to keep up the supply.

Gaultheria Shallon.—For growing under trees or anywhere I find this to be invaluable. It tillers out in the same way as the *Pernettya*, and also grows freely from self-sown seeds and bears beautiful racemes of white Lily of the Valley-shaped flowers on a pink or rather red stem. Both this and the *Pernettya* are perfectly hardy; no kind of weather hurts them, nor do rabbits or insects molest them, and being evergreen they are a perpetual pleasure without alloy. I may say the same of the small *Gaultheria* (American Wintergreen) and the little *Vaccinium*, which both bear white

flowers and red berries, and completely cover the ground.—R. B.

INDOOR GARDEN.

MEXICAN BUTTER-WORT.

(*Pinguicula caudata*.)

ONE of the prettiest of all little bog or moisture-loving plants now in bloom in our collection is this little gem of gems, in the floral way, from Mexico and other mountainous provinces in Central America. Its blossoms are solitary, on hairy scapes, 4 inches to 10 inches in height, and are of a vivid magenta colour, most exquisite in its intensity when seen in the sunshine. At present the plant is not often seen in private gardens, but the time will, I hope, soon come when this little species will be grown by the dozen, especially in those now numerous gardens where cool Orchids

Pinguicula caudata.

are already cultivated. The illustration shows the spring aspect of the plant just as its flower-spikes and thin, broad, summer foliage are making their appearance, for, as is the case with our native species, this South American plant also forms a sort of bulb-like mass of thick and fleshy scale-like leaves ere it goes to rest, or rather ceases growing in the autumn. A moderately warm greenhouse temperature is amply sufficient for its requirements during the winter months, but we find that it fully appreciates the return of spring warmth and sunshine together with a little extra artificial heat likewise, as it then begins its summer leafing and the flower-spikes are thrown up in quick succession. The plant has been growing at Kew for a year or two, and also at Chelsea, and the wonder is that a plant so interesting and compact, both in leafage and blossom, should have remained so long ere its distribution becomes general, more especially as its culture and propagation are so easily carried out. As soon as ever my little specimen came to hand from a generous friend—who continually exchanges good things with me—I potted it in a 2½-inch pot, using a compost of living

Sphagnum and small crocks only. This small pot was then plunged in a little shallow Orchid pan to prevent extremes of moisture and hung up at the cool end of a Cattleya house, where it is now flowering quite freely. When I received it the plant reminded me of a hulk of *Lilium superbum*—I mean of a cluster of its fleshy scales torn off the rhizome—and as some of these outer scales were loose, I took them off in order to test for myself a statement I had somewhere seen that this Butter-wort might be increased by means of leaves inserted as cuttings. The result was past all expectation. They were inserted in the living Sphagnum on the surface of an Orchid basket, and we were delighted to see signs of the young plants appearing near the bases of

I

these leaf cuttings in a few weeks after their insertion. Some of our strongest and most fleshy leaves showed two buds each, but a friend tells me that he has leaves showing four little plants at their bases. Knowing the great liking that all *Pinguiculas* have for living Sphagnum Moss and grit rather than for any mere earthy compost, I did not venture to try any of the leaves in soil, and I am inclined to believe that to the use of Sphagnum Moss instead much of the success in this method of leaf propagation lies. Other cultivators may, however, have observed differently, and of course their records will be most welcome to all lovers of plants, like this, of interesting beauty as well as to myself. The general aspect of the plant and a flower, both of their natural size, are well shown in the accompanying wood engraving, and the leaf cutting as inserted (No. 1) and the appearance of the young plant after an interval of five weeks are also shown (No. 2). I consider this plant one of the most interesting of plants imported for many years, and can only regret that numbers of the other exotic species known to exist are at present unrepresented in our gardens.

F. W. B.

SELECT STRAINS OF CINERARIAS.

THERE can be no doubt that the easiest way to obtain a good display of *Cinerarias* is to grow seedlings, and the seeds may be sown between the months of April and July in order to secure a succession of blooms. We generally sow the seeds from which we get our earliest plants in a shady part of a hotbed, the heat of which is nearly spent. They speedily vegetate, and when the young plants are large enough to handle they may be pricked out, about six or nine of them in a 3-inch pot, still keeping them in a frame where they are not exposed to the direct rays of the sun. In a little while they are potted off singly in small pots, and when repotting on as require they will flower in 6-inch or 8-inch pots about Christmas, earlier or later as the case may be. The later sowings require much the same treatment. Many are not aware that the *Cineraria* may be grown from offsets from the main stem; these are thrown out after flowering is over close to the base, and they may be removed with a portion of roots attached to them. Two or three of them may be planted round the sides of small pots, and as the process of propagation will not take place until about midsummer, the best position for the plants would be under hand-glasses behind a north wall, where they will take hold of the fresh soil slowly, but surely, and make good stout plants before the dark days of the late autumn months set in, when they should be removed to a cool pit or greenhouse, and be treated the same as seedlings. Good useful decorative plants may be grown and flowered well in 6-inch pots. Large specimens adapted for exhibition or

other purposes may be flowered in 8-inch or 9-inch pots. Specimens 2 feet across may be grown, and even larger than that, in such pots if pains are taken to tie the flowering stems out. Weak manure water may be used until the flowers are open; this gives substance and rich colour to the flowers.

This much have I been tempted to write, owing to seeing the fine varieties exhibited by Mr. J. James, of Farnham Royal, Slough, at South Kensington and Regent's Park last week. Mr. James has been a grower for many years, and he has also been the raiser of numerous very fine varieties, but his last exhibits surpassed any that have been shown in previous years. On looking over his collection of sixty or seventy plants it was difficult indeed to make a choice of varieties for purposes of floral distinction. The committee of the Royal Horticultural Society selected three for the highest award given by them to new plants. While from the same batch the judges at the Royal Botanic next day selected seven, and they left out as many more possessing almost equal merit to those certificated. It may be premised to begin with that the flowers are of the largest size (3 in. across) and of the true florist type with broad, well-rounded petals, forming a perfect flower. Duke of Edinburgh, certificated by both societies, was one of the best of them; the colour is a rich bluish purple with a narrow white ring round the disk; Princess of Wales is a rosy red self with a dark disk; Mr. Herrin, a fine crimson self; Brightness, rich crimson-scarlet; Lord Wolseley, a brilliant and distinct purple self with a deep red ring round the disk—this was also certificated by both societies; Lord Beresford, rich reddish purple with a white ring round the disk; Albert Cox, scarlet with a shade of lake; Sir P. Rose, blue with a tinge of red at the base of the petals, and a greyish disk; Mrs. Herrin, rich rosy red with a broad white ring round the disk. Mr. James has been very successful as a propagator of named Cinerarias, and it would be desirable if he would propagate his fine collection for trade purposes; they would undoubtedly be much sought after.

Mr. Cannell, of Swanley, possesses some new varieties of sterling merit, and he seems to have hit upon a method of propagating them very freely indeed. He has also exhibited and obtained certificates for propagated plants, whereas those exhibited by Mr. James were seedling forms merely. Some had a notion that not only the Cineraria, but the Pelargonium had been brought to such a high point of perfection, that future progress could only be expected to be slow. The results of the labours of the last few years have dispelled that delusion and shown us once more that there is no end to the infinite variety to be found in these flowers that have been so long in the hands of those who know how to guide them aright.

J. DOUGLAS.

Steam heating.—Noticing an article in THE GARDEN (p. 178) on steam heating by Mr. Warhurst, I have thought it might possibly interest your readers to know the temperature here. In the present month (March) the mercury has been as follows: 2nd, 2° below zero; 5th, 15° below zero; 8th, 10° below zero; 12th, just zero; 16th, 4° above zero, and we will probably get as low once or twice more before April. When the mercury indicates 40° below zero (Fahr.) outside and the houses are wanted to mark 60° inside, you can imagine it takes some attention in the way of coal and quantities of piping to do it, and leave the fire for from 5 to 6 hours, especially if there is any wind. We maintain the temperature nicely with hot-water pipes (4-inch ones), but can do it much cheaper, both as regards coal and help, by the use of low pressure steam with automatic damper regulators, &c. The pipes can be 1½-inch or 2-inch, or even 3-inch wrought iron, or the present 4-inch cast iron pipes can be used, as there is only an average of 5 pounds to the square inch of steam wanted. Mr. John Thorpe, of Hallock, Son, and Thorpe, Queens, N.Y. (an Englishman), could give you a good practical paper on this

subject, as he uses steam. Mr. E. H. Bochman, of Pittsburgh, Pa., could also give you an article on the subject worth reading.—S. FLETCHER TERWILLIGER, *Saratoga Springs, New York.* [If the gentlemen just named or Mr. Murdock, who wrote in THE GARDEN last week (p. 284), will kindly furnish us with details as to the way in which steam heating is now carried out, we shall be greatly obliged, and will have much pleasure in publishing them.]

CHRYSANTHEMUM ROOTS V. CUTTINGS.

"J. S. W.'s" remarks on this subject (p. 267) are likely to cause a good many gardeners and others who grow Chrysanthemums to differ from him respecting their propagation. I, for one, fail to see the advantage of root propagation as respects economising labour. I think his argument on that point utterly fails, or his mode of propagating by cuttings must be different from that of the majority of growers. The following is the course which I adopt with them: The old plants are generally cut down about the last week in December and removed to a cold frame, where they remain about ten or twelve days in order to allow the young growths to become sturdy and ripened, as when the plants are grouped for effect in the greenhouse or conservatory the young growths at the base are apt to become weak from want of sufficient light. As soon as the cuttings are in good condition they are taken off and inserted in 2½-inch pots, and plunged in a cold frame previously filled with fresh collected leaves, which affords a gentle bottom heat. After being well watered the frame is kept closed until they commence to make roots, when air is gradually admitted. During January and February watering is rarely necessary, and shading seldom required. About the beginning of March they are shifted into 6-inch pots, and afterwards treated in the usual manner.

I propagate generally about 200 plants, and were I to keep those in a cold frame they would occupy six times more space than cuttings would, and I venture to assert take six times more labour than cuttings. They would require covering to protect them from frost the same as cuttings, and the pots being full of roots they would require more watering. The labour involved in breaking up portions of root is much greater than that of taking off cuttings, and who wants to have such work to perform in April when so many other operations make time precious? His argument with regard to the size of the plants may doubtless suit some growers, but the majority, I think, would prefer smaller plants and more of them. There are so many good varieties of Chrysanthemum, that growers generally like to have as many sorts as possible; whereas if the practice which "J. S. W." recommends was adopted, many would require to confine themselves to a few kinds. As to the "pinching and pegging," I never practise either; my plants are staked, and I presume his are the same, especially if they reach the height of 8 feet or more, as plants raised from cuttings do. With regard to the question, is a herbaceous plant cutting stronger than the root? has "J. S. W." ever noted the difference between a Phlox raised from a cutting and a piece of root cut from an old plant? The flowers in the former case are much larger and finer than those in the latter. I think, to quote "J. S. W.'s" own words and apply them inversely, there is no comparison as regards time and trouble in the two cases.

Hall Court, Botley.

A. DEWAR.

Allamanda violacea.—Is this plant in cultivation anywhere? I have made inquiries of the leading London nurserymen, some of whom catalogued it a few years ago, but do not possess it now. Since I saw a painting of it in the possession of a friend some time ago I have been on the look-out for living plants of it. The only figure of it I have been able to find is in Fielding's "Sertum Plantarum," which appears to have been prepared from a dried specimen and the pic-

ture just mentioned. Fielding says, "This is certainly the most beautiful species of the genus, the flowers being large and of a rich violaceous colour not unlike those of *Gloxinia speciosa*. It is mentioned in the supplement to Johnson's "Gardener's Dictionary" that it was introduced in 1859. With a plant so beautiful, free blooming, and moreover blue flowered in a genus essentially yellow-flowered, it seems strange that so little has been done, and it is to be hoped that if lost to cultivation it may soon be reintroduced. In habit and size of flower *A. violacea* is not unlike *A. cathartica*, while the foliage is covered with short downy hairs. It is a native of Brazil.—B.

TOP-HEATING.

SINCE writing last week I have been to Swanley, and I find I was wrong as regards the actual number of pipes which previous descriptions had led me to understand were in use there. Most of the houses have but one pipe on each side of the path, and one smaller one suspended 2 inches or 3 inches below the rafters, and 10 inches to 12 inches from their foot. The chief benefit of this position is that it saves useful space on the stages or beds, and does not dry the row of pots which would be touching the pipe all the way along. The houses are 100 feet long, span-roofed, with top ventilators only, the sides facing about north and south instead of east and west, as is most usual. The reason for this was not asked, but it seems more convenient in the planning of the grounds, though some would choose this because the sun's rays, when wanted, penetrate better, and, when not wanted, one side alone would require shading. A few houses stand the usual way, with slate stages in centre, and side ones having a pipe under and one by the side of the path as flow and return, and a separate top pipe which can be used or not at pleasure. The greater number of houses have inner walls about 2 feet high next the path, with soil filled in up to the sides, which are 3 feet high only, but some had open lath stages in use. On these beds of earth the pots stand, and as an evidence of the course taken by the "column of air" ("A. D." notwithstanding), as explained in my last, it is found that if—owing to a sinking of the bed—some of the pots are an inch or two lower than the others, those plants are as much as two weeks' later than those placed in the sloping line of the heated current from the lower pipe drawn across the plants towards the upper pipe. This top pipe is usually 2 inches in diameter and the lower one 3 inches, but in some the upper pipe on the north side is 3-inch and in others the lower one is 4-inch.

The temperature of the upper pipe (being a continuous rising flow) scarcely differs from that of the lower one, except when the fire heat is low, and except in those cases where the upper pipe is connected by a small 1-inch pipe from the lower one, which checks the circulation considerably. This slower circulation would also take place if the bottom pipe was 2-inch and the top 4-inch, and so lower the general temperature. Even if the present pipes were used in houses double the length there would not be the same results as now, as the top pipe would be nearly cold; while to take the top pipe direct from the main flow it would be very hot, and the lower pipe being simply a return would be comparatively cool. The pit pipes are 2-inch flow at front or low side, with 1-inch near the top or back as a return, but being a falling return and so small, it is not sufficiently hot to draw the warmth all the way up the flat glass, allowing the frost to penetrate about the middle when severe weather sets in. Anyone adopting the same arrangement of beds and pipes as at Mr. Cannell's, in houses with side-lights 2 feet or 3 feet high, would discover with the first severe frost (if not earlier) that the mere copying of another is not sufficient to secure success, and that something more is wanted, that something being the scientific knowledge so much decried by "A. D." which every hot-water engineer ought to possess.

B. W. WARHURST.

NOTES.

After the storm.—Surely the Ides of March must now have left us! What a "roaring moon of Daffodils" it has been to us! And yet the Daffodils have withstood the dry east winds "in all their bravery;" indeed, in this season of all others I remember have the winds of March been taken with their beauty. All cultivators of Daffodils will be glad to read an essay on "The Flower of March," which will be found in *Longman's Magazine*, p. 663. "Heigh-ho! the Daffodils." A genial shower or two on the 25th softened the dry clouds and revived the shrivelled leaves of Anemones, brightened the blue of the Scillas, washed the dust from the big Saxifrage leaves, and gave additional strength and encouragement to the Lily shoots now spearing up like giant Asparagus in sheltered nooks along our old borders. The song birds are merry, so I trust that the storm has gone.

*

The blue alpine Clematis (*Clematis alpina*) is a favourite here, and presents a curious aspect just now, its tendrils and ash-grey stems appearing to be lifeless as they twist and twine in utter confusion on the stems and twigs of a dead wall shrub. It is not an attractive object, and a stern lover of neatness in a garden might be tempted just now to sweep it away as a droary, worthless lot of litter. A closer examination, however, shows that at each of its numerous joints or axils a couple of grey-coated buds are bursting forth. They are plump, bold, and in vigorous strength, reminding one of the well ripened Lily of the Valley crowns which the stolid Dutch gardeners taught us how to grow for winter blooms. Very unlovely to a strange eye is our *Clematis alpina* (*Atragene coerulea*, some will call it) just at the present time, but in six or seven weeks' time it will be one of the sights of our garden—a mass of tender young leaflets, amongst which the blue flowers nestle very cosily.

*

Hardy bouquet flowers.—This year of all others hardy flowers have been the most fashionable amongst artistic and tasteful people. All Lenten-tide the Daffodil has been queen of all the blossoms used for personal adornment, and bouquets of the common double variety have been proudly borne away by our friends in preference to Orchids and other tropical blossoms. A well-made bouquet of Daffodils garnished with sprigs of winter Heaths and Asparagus spray is a revelation to most people, and with a black dress is most effective. One of green Hellebores (*H. argutifolius*) and buds of *Cydonia* caused quite a sensation amongst good judges of floral ornaments, and even in the months of January and February a request for half-a-dozen bouquets and a funeral wreath or two does not in the least alarm us, so confident are we in the powers of old-fashioned hardy flowers, Crocus buds, Snowdrops, Scillas, &c., to please, if prettily arranged. Neatly mounted on wire—a necessary evil—with plenty of fresh green wood Moss, we may do most, if not all our decorations with hardy flowers alone.

*

A successful experiment.—It is very pleasant to sit down before an experiment of this kind: In a sheltered yard were two beds in which nothing would grow, and certainly the persistency with which many good plants dwindled away therein was worthy of a better cause. Even if not before (which is best) when things get to their worst a new departure has to be decided upon, and so when some scarlet Geraniums gave out and failed us we awoke to action. Out came the soil in barrowfuls until numerous graves 3 feet deep appeared, and two or three loads of stable and cow manure were next thrown in, then soil from the potting shed yard, until the beds were once more full. This was in October, and Tulip (old cottage garden kinds) and Narcissus bulbs were planted pretty thickly. In March following the surface of both beds was sown with Anemone coronaria seed, this being covered with sifted earth from the potting shed as before. This is two years ago, and the result is a floral display

for six or eight months of the year, and plenty of Anemone flowers for cutting at a time when flowers outside are scarce. A sprinkling of Mignonette and red Flax seed (*Linum grandiflorum*) sown in March girdles the year with flowers for us after the Tulips fade.

*

Helleborus foetidus.—There has been a tendency to despise one of the most graceful of all the Lenten Roses, and yet many greenhouse Aralias are far less graceful in form and in leafage, and when the spreading dark green leaves are crowned by a gracefully towering spire of apple-green buds and bracts, it is of all hardy plants one of the most distinct at this season. Its leafage is an especial feature, being more finely cut than that of other kinds, and admirably adapted for arrangement along with the blossoms of other Lenten and Christmas Roses. One trait possessed by this plant is its hardy vigour, which thus renders it especially suitable for planting here and there among trees and shrubs, alongside woodland walks, or massed in the nooks of old shrubby borders. It may be easily raised by the thousand from seeds sown as soon as they are ripe, and these once well planted will render out-of-the-way parts of the grounds interesting, especially if common Daffodils bear them company, seeing that both bloom together thus early in the year.

*

Broad-leaved Kalmias.—These are now flowering in the greenhouse and yield abundance of their quaint umbrella-shaped flowers and pretty fluted buds which are as fine in their way as any tropical blossoms can well be. Some varieties are of snowy whiteness, others very softly and daintily tipped and flushed with pink or rose colour; and either alone with their own leaves in a shallow vessel of fresh Moss, or in bouquets along with filmy Asparagus or Maiden-hair Fern, they are most lovely. Kalmias are as bardy as Laurels, but they love shelter and a peaty soil, although they grow vigorously in loam fibre and leaf mould in equal parts. We shall never fully know the richness, variety, and beauty which is yielded by hardy herbaceous, evergreen, and shrubby plants alone until we bring their blossoms regularly into the house to live with us. Distance in landscape effects may lend enchantment, but hardy blossoms grow upon us more and more as we bring them indoors and near to the eye.

*

A fragrant weed.—Tobacco is sometimes "a leetle" objectionable, especially to ladies, but a plant of *Nicotiana affinis* is just now perhaps one of the least objectionable of all the forms and phases which Tobacco assumes. I think Mr. Cullingford, who introduced it to our gardens, once said it would rival the Tuberose. So it does. Its fragrance is even more agreeable, and "in the long run" its culture and endurance are far more satisfying. There are not many amateurs who can boldly say that they have propitiated those evil spirits whose duty seems to be to thwart successful Tuberose culture, but anyone who can grow Mignonette or scarlet Geraniums for winter and spring flowering may grow this large-flowered sweet-scented Tobacco to perfection. Just now we have a plant a yard or more in height, with three or four stems and a dozen or more of its big white blossoms. At night or during dull, wet days its odour is delicious, and cut flowers last for several days indoors in fresh water. Sow now for plants to bloom next winter. Mr. Thompson, of Ipswich, sent me seeds last season, and now for some weeks its blossoms have been much admired.

*

Feeding fruit trees under glass.—Now that Vines and Peaches are in bloom under glass roofs, I hope their owners or cultivators will see to their due nourishment. Mr. Meehan has told us many facts relating to the feeding of fruit trees at a time when especial strain is laid upon their energies. To ensure a "good set" of fruit, proper pollen distribution may be, and often undoubtedly is, necessary; but what about root fertilisation? I am convinced a good soaking of diluted liquid

manure, guano, cow manure, and soot, or drainings from the stable yard, applied just now, would make an appreciable difference in the produce of Peach house or vinery, to whichever applied. If more encouragement in this way were given we might hear less of trees refusing to "set" their fruit, and also less of "stoning" and "shanking." Of course, in all good gardens these things are properly attended to, but amateurs often forget these little matters of cultural detail until unproductive trees remind them that a "screw is loose" somewhere.

*

Crown Anemones.—This is the proper time to sow seeds of the Crown or Poppy Windflower for blooming during next autumn, winter, and spring, but the great question is, where can seed of a first-class strain be purchased? The greatest difficulty is to be sure of good seed, for unless seed of a good strain is obtained as a commencement, time, land, and energy are in a manner thrown away. All of us cannot be sure of obtaining good seed from friends, although I have much to be grateful for in that way. Anemones are gross feeders, and before sowing the seed we dig in cow manure and otherwise prepare the bed as if for sowing Onions or Lettuces. The seed soon germinates if not sown too deeply. The best plan is to mix the cottony seeds with sand and sow on the surface of a finely raked bed, covering the seeds afterwards with a sifting of fine soil the eighth of an inch or so in thickness. After germination thin out the seedlings to 3 inches apart, and give good soakings of liquid cow manure in dry weather. So treated, a bed or two of Windflowers forms one of the best features of a garden of hardy blossoms during the dullest part of our year. But, as we have already said, the seed, the seed! that's the question!

*

A rare greenhouse shrub.—Not often seen in flower is *Greigia Sutherlandi*, flowers of which have just been sent to me by Mr. Smith, of Newry, to whom we must look for "notes" on its culture. Its blossoms are very pretty. A spire of deflected orange-scarlet flowers half an inch across terminates a branch. The long-stalked anthers protruding from the short and shining petals give to it quite a peculiar elegance. Previously we have only heard of it as having flowered at Chelsea Botanical Gardens, and at Glasnevin in the late Dr. Moore's time. The spires of ruddy blossoms are so distinct and showy, that the plant would soon become a favourite if we could devise some "dodge" in order to be quite certain of flowering it every year. It comes from South Africa, and is nearly related to the Saxifrages.

VERONICA.

KITCHEN GARDEN.

SOWING AND PLANTING ASPARAGUS.

ALTHOUGH the cultivation of Asparagus has often been referred to in THE GARDEN, it may probably not be out of place just now to offer a few remarks on the seasonable and important operations of sowing and planting. Young Asparagus plants are as easily raised from seed as are Cabbages or Cauliflowers, and all who are inclined to take an interest in Asparagus culture will find seed sowing the most profitable way of securing a stock of healthy plants. The best of seed may be bought for about fourpence per ounce, and from this 100 plants or more may be raised. We lift and force many Asparagus roots annually, and in order to keep up the supply we sow several ounces of seed every spring. We have found this plan to answer so well, that I think its general adoption would be an advantage to all. The seed is sown in the first or second week in April if the weather is favourable. Beds are not formed, but row after row is sown on one of the borders. Previous to this the soil is manured with some slight material such as that of an old Mushroom bed, which is dug in then the surface is broken up fine with a fork, when it is ready for the seed. The drills are opened to the depth of 2 inches, and the seeds are dropped insingly about

3 inches apart; they are then covered over with some light soil from the potting shed and sowing is completed. In one month hence the plants will be visible above ground, and after that Dutch hoeing now and then throughout the season is all the after culture they require during the first year. The situation which we prefer for the young seedlings is one rather sheltered from wind, but fully exposed to the sun. In a windy spot the young growths are apt to be broken over occasionally, a circumstance very injurious to their after success. Plenty of sun, however, matures the buds and crowns, and perfects them for more vigorous growth the following season. We have sown seed in May, but this did not produce such fine roots by October as that sown a month earlier, and no favourable opportunity should now be allowed to pass before sowing. In addition to what has been said, a caution may be given not to sow thickly. When the young plants are only an inch or so apart it is impossible that the roots can have full scope; the consequence is, they are cramped and of a very inferior description by the end of the season. Rather than have such plants as these I would put the seeds in 4 inches or 5 inches apart, but if a space of 3 inches is allowed excellent roots will be the result. Besides this being the time to sow, it is also the

Season to plant. All new plantations of Asparagus should be formed at this time. When the roots are shifted while the buds are quite dormant a good many of them are liable to fail, and if planting is done after the young shoots have become 3 inches or 4 inches high many of them will be checked or killed, but if shifted just when the young stems are beginning to form, which is the case now, success will be the result. It is a great advantage to be able to plant again as soon as the roots have been dug up, and in this way especially home-raised seedling roots have always a much better chance of succeeding than those bought in and brought from a distance. One and two-year-old roots may be transplanted with better results than older ones. Three and four-year-old roots do not transplant well; they get checked just at a time when they should be useful. Plants from seed sown at this time last year are those we will plant now, and as they will not be shifted again, their fruiting or bearing disposition will not be upset, and in two years we will have plenty of good produce from them. Previous to planting

The ground should be well tilled and thoroughly manured, and on a fine day, when the soil is in good working order, the roots should be put in. The rows should not be closer than 3 feet apart, and the plants should stand from 1 foot to 2 feet asunder. Before any planting is done all the rows should be opened up with a spade; they should be taken out the full width of implement, and from 3 inches to 4 inches deep. When all the rows have been opened in this trench-like fashion, the roots which are to go in them should be dug up with a fork, care being taken not to break any of the rootlets, and each one should be carefully laid out in the position which it is to occupy before covering with soil. As the roots spread out naturally this is easily done, and in placing the soil over them it should be worked in about the roots and over the crown with the hand; then fill in with the spade. Should the soil be very dry at the time of planting or become dry immediately afterwards, each root should be watered through a rose-spouted can. If a small quantity of soil in which half-decayed manure, sand, and bones, or any other kind of artificial manure is mixed can be placed around and over the roots, it will induce them to become established earlier than they would do in ordinary soil, and growth of this kind is always to be encouraged, as stems can never be formed too soon or of too large a character. J. MUIR.

Margam,

Red fluid from Vegetable Marrow.—Last summer I had a very productive Vegetable Marrow, and I saved one seed-pod, thinking that I should get a lot of good seed. I had it placed on a shelf in the kitchen, expecting it to dry, and

it laid there until lately, when it began to exude a beautiful lake fluid, and I found that the pod was rotting. It gave out a large wineglassful of the fluid, which, curiously, did not stain or mix in the least with the pulp. On cutting it open I found that it came from the place where the stalk joined the fruit. Has any physiologist discovered the use of this fluid? This seems the more curious, because there is no other red colour observable at any stage of the plant's growth.—J. S. Q.

Chou de Burghley.—Having heard a great deal in praise of this new kind of Cabbage, I am going to grow it rather largely. I have tested its hardiness, for a pot of seedlings, before and since their second leaf, have stood 12° of frost uninjured. I am now desirous to ascertain from those who have partaken of it what are its real qualities on the table. I might indeed write to Mr. Gilbert himself in reference to this matter, but then, as we all know, that to every mother her own babe is the sweetest one in the world, he might not be an impartial judge. That my little mites of plants, without a rag to cover them, should withstand 12° of frost without being killed shows what a very mysterious thing vegetable life is.—H. P. J.

Propagating and growing new or expensive Potatoes.—I received a limited quantity of Cosmopolitan about a month since, as I was anxious to have a Potato that got the first prize amongst so many varieties at Birmingham last year for comparison with other kinds. After receiving it, I cut each into as many sets as eyes, and placed each eye in sandy loam. They are now getting established and I observe no misses. I should have said I put them in long boxes, almost within an inch of each other, as they are only temporarily located there, and then in a back cool room where the temperature must not exceed 50° Fahr. I observe, so far, that as compared with other varieties, such as Eight-weeks, it is a much slower grower, and does not promise to be at all one of the earliest. In this way money, convenience, and quantity of sets are gained.—W. J. M., Clonmel.

Early Cauliflowers in trenches.—Small growers who have neither the advantage of a sunny sheltered border, nor the convenience of hand-glasses or frames wherein to forward a few dozens of these, may gain considerably in point of earliness by planting them in shallow trenches. These should run north and south, allowing 3 feet from centre to centre of each trench, which should be just deep enough to afford protection from the biting spring winds, without depriving the plants of light and full sunshine. They may be prepared in this way. After marking out with a line and spade the space for the trench 15 inches wide, remove a few inches of the top soil, placing it on the left hand or west side; then dig out a good spade's depth of soil, laying it in a little ridge on the east side, and after well mixing some rotten manure with the soil in the bottom of the trench, return that taken from the surface, breaking it up well and in it plant the Cauliflowers, one row down the middle 20 inches apart. It is better instead of leaving the sides of the trench perpendicular, as is usually done in Celery planting, to break the sides down, so that the ground may slope gently back from the middle of the trench; and as the plants progress, the soil can from time to time be replaced around the stems, thus keeping them firm and comfortable. Where such is obtainable, a thick line of Spruce or Laurel boughs pushed firmly and upright into the ground midway between each trench will greatly mitigate the severity of harsh winds from which we do not now-a-days seem secure till the end of May, but they should not be left so high as to interfere with solar influences.—A. MOORE, Cranmore.

Garden screens.—A capital screen may be made as follows: Fix a good post the required height at each end of the space to be shut out, then from their tops strain a strong galvanised wire, also perhaps another half-way down if a rapid covering or a high screen is wanted. Now plant Virginian Creeper at the bottom, 12 feet

apart, and train it up to the top. It will sometimes run along the wires of its own accord, but if not, a very little trouble will cause it to do so; then it will hang down delightfully, swinging to and fro in the wind, and getting thicker and thicker every year. If in a conspicuous position, plant alternately with the Virginian Creeper Clematis Jackmanni or lanuginosa. These, running wildly through the mass of Virginian Creeper, with their lovely flowers peeping out here and there, will soon form a sight worth looking at.

GARDEN FLORA.

PLATE CCCLXXXIII.

AMARYLLIS MRS. GARFIELD.*

THE lovely plant represented in the annexed plate may be looked upon as the forerunner of a new and distinct race of hybrid Amaryllises which have already been brought to a high state of perfection. Amaryllis Mrs. Garfield was obtained by Mr. B. S. Williams by crossing *A. reticulata* and a variety called *Defiance*. The idea of effecting such a cross was a happy one, inasmuch as *A. reticulata* is very distinct from any other type species both in colour and in the season of flowering; moreover, it is an evergreen, while the others are all deciduous. The two great points gained by this cross are delicate colouring and reticulation, as in *A. reticulata*, and the distinct flowering season, which is invariably the autumn; whereas the majority of the other race flower in spring. It is an important step towards the goal which the hybridist has in view, viz., to obtain a race of Amaryllises that will yield flowers the whole year round. We only want now some sorts to flower from, say, about May to the end of August, then the cycle will be complete, for the hybrids of *A. reticulata* usually begin to bloom in September, and continue on till January, when the progeny of *A. aurica* and others come in by way of succession. In all probability some early flowering Mrs. Garfields will soon be obtained to fill up the interval, and the more the better. If the delicate colouring of this variety could be infused into some of the large spring-flowering kinds, it would be a great gain. Those who know the flowers of the typical *A. reticulata* will at once see how much superior this hybrid is to it in point of size and form, and, moreover, it is a wonderfully free flowerer, whereas *A. reticulata* is a notoriously shy bloomer. It was figured so long ago as 1803 in the *Botanical Magazine*, wherein it is stated the plant is a native of the Brazils, and flowers in April. It was first introduced in 1777. In Mrs. Garfield, one of the chief characters of *A. reticulata*, viz., the broad white band running down the middle of each leaf, is distinctly shown, and, as may be seen by the drawing, the beautiful veinings of the flower are very conspicuous.

The other hybrids of the *reticulata* type are very few, though this species was crossed in Dean Herbert's time, but they appear to have become lost. A beautiful hybrid of the same stamp was figured in THE GARDEN in 1879. This was *A. O'Brieni*, raised by Mr. J. O'Brien in the Pine-apple Nursery, Maida Vale. This appears to have been a cross between *A. reticulata* major (*striatifolia*) and *A. pardina rubescens*. It is a beautiful variety, with large well-formed flowers of a deep pink, netted with a deeper colour, and having a broad band of white down the middle of each sepal. Two forms

* Our plate was prepared from a plant in Mr. B. S. Williams' nursery, Upper Holloway, in December last.

are recorded of this hybrid, and these were named delicate and rubescens. Others in Messrs. Henderson's nursery with white banded foliage (thus showing the parentage of *A. reticulata*) are Henry Little, between *A. picta* and *A. reticulata*; *A. vittata striatifolia*, between *A. reticulata* and *A. vittata*; and *A. Pirloti*, between *A. gandavensis* and *reticulata*. Another new and very beautiful hybrid of this type is

Autumn Beauty. This was raised in Messrs. Veitch's nursery at Chelsea between *A. reticulata* and a seedling of the *A. Leopoldi* type. It resembles Mrs. Garfield, but the colour is darker. Like the latter, it has been frequently exhibited in London, and both have been distinguished by first-class certificates.

The culture of this class of *Amaryllises* is rather different from that of the ordinary type, inasmuch as the plants being evergreen and not deciduous must not be dried off, as in the case of those which annually shed their foliage. A mixture of loam, peat, and decayed manure is a good potting compost, and the plants are all the better if the pots be plunged to the rims in tan or other plunging material. During active growth, which is during spring and summer, the plants require a warm greenhouse temperature and plenty of water at the roots. Towards the close of midsummer, when growth is completed, water should be applied more sparingly, and more air should be given to the plants so as to harden the growths before flowering. W. G.

LECTURE ON THE AMARYLLIS.

At the last meeting of the Royal Horticultural Society, held on Tuesday, March 27, Mr. Shirley Hibberd gave a lecture on the *Amaryllis*. The occasion was made the more interesting by the exhibition of collections of these beautiful flowers, in some cases not for competition, in others for the prizes offered by an amateur desirous of encouraging the production of hybrid *Amaryllises* of high floral quality.

Mr. Hibberd said the name of the flower suggested that its history should begin somewhere in the 106th Olympiad, or, say some 300 years before the Christian era, in order to bring the country girl, *Amaryllis* herself, to furnish the subject of the opening chapter. But there is nothing to be gained for our present purpose from the pleasant verses of Theocritus or the later lines of Virgil, for neither of these poets give aught beyond the name, and as a matter of fact *Amaryllis* does not anywhere in classic poetry rise to the dignity of a heroine. But it is one of the glories of the Linnean nomenclature that by means of symbols selected from imperishable Nature we are brought into contact with the sweet stories of old, the flower of to-day taking us to the very fountain-head of pastoral poetry—the idylls of the poet of Syracuse. The *Amaryllis* in some form was known long before the time of Linnaeus, for John Gerard had the one now known as *Sternbergia lutea*, which he figures at page 113 as *Narcissus autumnalis major*. John Parkinson had this same plant, and figured it at p. 75 of the "Paradisus," and he had another which he figured at p. 71 as *Narcissus indicus*, the Indian Daffodil, with a red flower. This became known as the *Jacobæa Lily*, and was figured in the *Botanical Magazine* (t. 47) as *Amaryllis formosissima*. This *Jacobæa Lily* is now catalogued as *Sprekelia formosissima*, having been so named by the German botanist Heister, in honour of Dr. Sprekel, and not, as is generally supposed, by Dean Herbert, who, however, adopted it and thereby sanctioned it. The plant has been of late years met with in Guatemala, but its native habitat was long unknown. It appears to have been introduced to Spain before the year 1593, in which year, according to Linnaeus, it began to be known generally in Europe.

Linnaeus classed as *Amaryllis* a number of plants that have since been separated under other generic designations. But he made considerable progress, nevertheless, towards a clear definition, preparing the way thereby for the labours of Dean Herbert half a century subsequently. This good churchman devoted to these plants an immensity of labour in determining distinctive characters, raising hybrids, and reducing to order all the *Amaryllids* known in his time. The first publication of his views occurred in the *Botanical Magazine* in the year 1820, under the description of *Amaryllis reticulata* (t. 2, 113). These views were illustrated in a remarkable manner in a paper on "The Production of Hybrid Vegetables," published in "The Transactions of the Horticultural Society" in the year 1882. In a treatise on the order published subsequently, he developed a complete system of classification, one result of which was to give to *Amaryllis Belladonna*, otherwise known as the *Belladonna Lily* of the Cape of Good Hope, the sole honour of representing the classic beauty *Amaryllis*. The South American plants that are nearest allied to the *Belladonna* were classed under *Hippeastrum*, this generic designation being in reality adopted from Linnaeus, who had at least supplied the idea. It is necessary here to be explicit. In the "Paradisus Batavus" of Paul Hermann, published 1698, is a description of a plant called *Lilium americanum puniceo*, the red American Lily. This plant Linnaeus named *Amaryllis equestris*, and it is so entered in the "Hortus Kewensis," and under the same name is figured in the *Botanical Magazine* of the year 1795 (t. 305) and the *Botanical Register*, 1817 (t. 234). The flower of this species is somewhat irregular in form, and the spathe of two leaves stand up like a pair of ears, and thus, according to story number one, the specific name *equestris* refers to a fancied resemblance of the flowers to the head of a horse. But story number two alters the case. In a description of the lovely *Amaryllis reticulata*, by Dr. Sims, in the *Botanical Magazine* of the year 1803 (t. 657), the learned editor says, "We take this opportunity of correcting a mistake of the late Mr. Curtis, in saying that Linnaeus gave the name *equestris* to the *Amaryllis* referred to as such. The fact is, this name was given from the remarkable likeness the front view of it has to a star of some of the orders of knighthood." Thus the Hon. and Rev. William Herbert followed out the suggestion of Linnaeus when he made a bold separation between the *Amaryllises* of Africa and those of America, re-naming the western group *Hippeastrum* (the Equestrian Star), the justification for which will be found at p. 144 *et seq.* of his treatise on the *Amaryllidaceæ*. The distinction is not geographical merely, but is founded on minute details of structure and the order of the leafing. It is proper here to say that to Dean Herbert we are not solely indebted for scientific knowledge of the *Amaryllis*. Of the labours of the professional botanists it is not needful to speak in a special manner, because we must refer to them again and again in the treatment of a subject of this kind. But at this point I feel bound to mention that concurrently with the study of these plants by Dean Herbert they were collected and cultivated with spirit and discretion by Mr. Griffin, of South Lambeth, to whom the *Botanical Register* was often indebted for figures of the more characteristic species. Mr. Ker named the pseudo-genus *Griffinia* in honour of this gentleman. In a few of the references cited it will have been noticed that the *Amaryllis* has been at one time designated a *Narcissus* and at another time a *Lily*, and again the compound term *Lilio-Narcissus* has been used. The distinction between a true *Amaryllis* and a true *Lily* rests on the position of the ovary. For the casual observer—or, say, for a visitor to the flower show—there are some obvious distinctions that will be found of service. The *Lilies* have leafy flower-stems without spathes; the *Amaryllises* have naked flower-stems, and the flowers spring from a spathe such as Parkinson would describe as a "skinny husk." But these distinctions have no scientific value as the orders are at present defined. To give an account of

The several species would needlessly prolong this discourse. But a certain number must be referred to because of their importance as cultivated plants. One of the earliest and most distinct is *Amaryllis Regiæ*, which was flowered by Fairchild, of Hoxton, in the year 1728. A folio pamphlet containing a history of the plant was written by James Douglas, who named it *Lilium Regiæ*. Its first appearance in the *Botanical Magazine* occurred in the year 1799. The flower has a short funnel and a capacious limb, the colour is crimson, and the star is fully displayed. *A. vittata* was first figured in the *Botanical Magazine* in 1788 (t. 128). The flower is always smallish, with a decided funnel, and the petals are elegantly striped, and the progeny, even at two or three removes, partakes of this character. *A. reticulata* was introduced in 1777 by Dr. E. W. Gray, and was figured in the *Botanical Magazine* in the year 1803 (t. 657). It is of the most elegant form, approximating to that of a *Convolvulus*; the tube of moderate length, the limb delicately reticulated in shades of a rich lively rose. *A. equestris* dates from 1710. It is a fine flower of medium size, with short funnel, the limb crimson or scarlet, displaying a bold green star. A variety of this, named major, grown by Mr. Griffin, and figured in the *Botanical Register* of 1817 (t. 234), very strikingly resembles some modern hybrids of *A. pardina*, and in place of a green star it has a bold white centre, the outer portions of the limb being of a fiery vermilion colour. The more celebrated *A. aulica* was first figured in the *Botanical Register* in 1820 (t. 444). It was imported from Brazil by Mr. Griffin, and flowered with him at South Lambeth for the first time in December, 1819. In this the elements of a crown are perceptible, and the leafage is peculiar. The form of the flower is far away from what would be termed the florist type, the petals being narrow and separated. But in a variety named *platypetala*, obtained from the Organ Mountains by Mr. Harrison, of Aigburth, near Liverpool, about the year 1825, the most splendid floral characters are developed. The colour of this variety is rich deep crimson with a bold green star that is sometimes prolonged to the extremities of the divisions, which are short, smooth, and so broad as to overlap and form a noble flower. All the foregoing, and many more, that I cannot stay to mention, have been registered as *Amaryllis*. But in the year 1822 the characters of *Hippeastrum* were set forth by Dean Herbert, and the new designation was adopted in the *Botanical Magazine* in the year 1825, when there appeared a figure of *Hippeastrum solandriflorum* (t. 2573). Some others appeared under the new generic name, as, for example, *H. ambiguum* and *H. breviflorum* in 1837. Now, in

The history of the flower, it is proper to record another episode. In the *Botanical Magazine* it was an *Amaryllis* for a period of about thirty-five years. Then it became a *Hippeastrum* for a period of forty-five years. But in describing a splendid species, discovered in Peru by Messrs. Veitch & Son's collector, Mr. Pearce, in June, 1867, Sir J. D. Hooker named in *Amaryllis pardina*. Having done so, he felt bound to justify the proceeding, and he did so by saying that the differences recognised by Herbert were so slight and variable as to be of no practical value. Therefore the original generic designation was restored; Linnaeus triumphed, and *Amaryllis* is herself again. The introduction of *A. pardina* opens a new chapter in the history of this flower. Its name implies that it is spotted like the leopard, but that quality is not much valued by the florists. It is of more importance to say that this flower is distinguished by great breadth of petal and the absence of a funnel, a fact favourable to the expansion of the flowers to a symmetrical face. More than any of its race introduced up to the year 1867, *A. pardina* stirred the blood of florists and gave new zest to the labours of the hybridists, who, however, soon discovered that, with all its fine qualities, it is not the model for breeding from that they would themselves have created had they been permitted to assist in the work of the third day as recorded in the Book

of Genesis. But the model was ready for all that; like many other desirable things, it was made with the rest on the third day and remained to be discovered. This was secured in Peru by Mr. Pearce. It appears that the King of the Belgians, one of the most generous and enlightened patrons of horticulture in this flowery world, admired the flower when it was shown at South Kensington in the year 1869, and it was named in honour of his visit *Amaryllis Leopoldi*. It is as truly the king of the *Amaryllises* as *Lilium auratum* is the queen of the Lilies. It possesses all the elements of a perfect florist's flower in breadth of petal, depth of colour, a sharply-defined star, and petals superbly tipped with white or an approximation thereto. It is sufficiently defective as a florist's flower to afford work for the hybridist, and excitement to the critics, and to give peculiar interest to the splendid series of varieties that, chiefly by its aid, have been raised by Messrs. Veitch & Sons, of Chelsea. The hybrids figured in the year 1865 in Van Houtte's "*Flore des Serres*" were, in a way, wonders of their time, but we have got far beyond the flowers with funnels and indefinite green stains, and look for expanded flowers of the most perfect symmetry both of form and colour, and with novel markings to give the charm of variety to collections. At this point it seems proper to remark that

In cross-breeding plants varieties occasionally occur that have the individuality, the vigour, and the power of determining the characters of future generations that we associate with species. For all that we know to the contrary they are species, and although brought about by human agency, have, nevertheless, been brought about in Nature's way, and with none but Nature's materials. Some such we have in an *Amaryllis* called *Acramani pulcherrima*, raised by Messrs. Garaway, of Bristol, in 1850, from *A. aulica* platy-petala and *A. Johnsoni*. This *Acramani pulcherrima* is a narrowish flower of fine quality, the colour rich deep crimson with a subdued green star. It has the potentiality of a species for the purposes of the raiser, and has influenced the hybrids immensely. One of the finest varieties in which we see the influence of this plant is that named *Dr. Masters*, in which there is scarcely a trace of green, while the form and colouring are delightful. When we get amongst the varieties, however, it begins to be time to cease talking; therefore, it seems proper to devote the last chapter of this discourse to the general subject of the varieties. And the great question in connection with that general subject is, by what rules are we to judge the hybrids for a code of properties is very much needed. From the point of view of the critical florist, the funnel is objectionable, but happily that is pretty well got rid of. The shorter the flower the more complete, generally speaking, is its expansion, and above all things expansion is requisite to the display of the colour. Now let us, as severe critics, find as many faults as possible with the hybrid *Amaryllis*. The funnel is objectionable, even in its present severe limitation. The petals are unequal, and the front petal especially needs to be remodelled. For our present purpose we may regard all the divisions of the perianth as petals, although we might with propriety call the three outer divisions sepals, and the three inner divisions petals. The length of the lowest of the three is noticeable as a fault in all the varieties. Another fault is the green colour that so frequently occurs, but occasionally this assumes a beautiful form, and therefore I think it would be a mistake to condemn the green colour *in toto*. It will in due time change to white, and a soft creamy white would probably tell with great power if symmetrically associated with high crimson colour. In a good form of *A. Leopoldi* we see a well-defined star, and the petals are tipped with white. A self-coloured flower should be pure throughout, but we may recognise a star of good form and marginal colour corresponding, and thus we may have self-coloured flowers, starred or striped flowers, and tipped flowers. As a matter of fact, we have all these already, but the persistency of

the green colour is a common blemish. A great point in

The new race is the growth of leaves and flowers concurrently. This is an immense gain, and we must make it a point of importance in estimating the merits of a variety. It is likely, too, that as the plant learns to produce leaves and flowers simultaneously, it will also learn that the green star in the flower is no longer needed, and thus improvement of the leafage will operate to the advantage of the flower, and we shall obtain the white, and perhaps the yellow star, that seems to be so much needed for the attainment of perfection. It may be properly urged that there are many beautiful species and varieties that are far removed from the properties thus suggested as desirable. It is no part of my business to condemn any of them; rather, I would say, let us rejoice at the infinite variety of Nature, and feast upon beauty that is as yet "unadorned," and therefore is "adorned the most." We have but to do with these as with other flowers. All the Roses and Pelargoniums and Azaleas that are at once beautiful and useful, and yet wanting in the properties that constitute floral perfection, are classed as "decorative," and are judged as such. These we hand over to the gardeners and the world at large. But all the ugly and useless flowers that Nature appears to have produced for her own private enjoyment we hand over to the botanists, and those learned people appear to appreciate our generosity. We say of such things, "take them upstairs," and they forthwith go to delight the philosophers who dwell in our upper room. There are many beautiful species and varieties of *Amaryllis* that must for ever stand apart from the group that we judge as florists' flowers, and these cannot be disparaged by the operation within a certain circle of laws that have the sanction of experience, because consistent with the aims of Nature and the demands of common sense. The florists are sometimes regarded as a narrow-minded lot. But it will be found that their minds are broad enough to enable them to select for their own enjoyment the most beautiful flowers, and, if other people prefer the kinds that they reject, they are generous enough to leave them to the free exercise of their choice.

SEASONABLE WORK.

FLOWER GARDEN.

Chamæpeuce (Fish-bone Thistle).—Though there are upwards of a dozen varieties of this Thistle, two kinds only are worthy of note, viz., *C. Cassabonæ* and *C. diacantha*; the former has glossy green spiny foliage, and the latter white, both being equally deserving of culture, particularly for sub-tropical and foliage arrangements. No plant can excel the green variety for use as a marginal band or edging to light coloured or variegated foliaged plants, such as *Abutilon Thompsoni* or *Solanum argenteum*, and the white and longer leaved variety is equally pleasing in the same positions, but in association with dark coloured tall growers, such as *Ricinus Gibsoni* and the dark-leaved *Cannas*, we have also used them with excellent effect as dot plants in what is termed panel painting in formal or geometrical designs, and in such arrangements the most appropriate groundwork for the green variety is *Nesembryanthemum cordifolium variegatum*, and for the white variety, *Alternanthera* or the green *Sedums*. Both have proved perfectly hardy here, but as the second season they continuously run to seed, it is necessary to have fresh plants every year, which, to be in time for the summer bedding, should be sown in heat early in February. Our seedlings of this year are already fit to plant, and will be planted as soon as arrangements are completed.

Sowing and pricking out annuals.—The common varieties of annuals may now be sown in the open borders. Sweet Peas, Mignonette, Virginian Stocks, *Bartonia aurea*, Candytufts, Clarkias, Larkspurs, *Eschscholtzias*, Lupines, *Nemophilas*, Scabious, *Silenes*, and Sweet Sultans are amongst those that we usually sow in small

patches amongst Roses or on vacant spots in mixed borders, where most of the varieties not only do good service in filling up blanks, but are also invaluable for cutting. Though we sow annuals amongst Roses, it is only because, from want of space, we have no choice in the matter, as we would much prefer the ground being kept for the Roses alone, and any who are compelled to follow our practice in this respect would do well to sow the annuals at long distances apart, and as far removed from the Roses as under the circumstances is possible. It is also now time that ornamental Grasses were sown. These we find quite indispensable for winter decoration, and hitherto have had the best success with them when sown where they are to grow much in the same way as the flowers just named. A still better plan, however, is to sow them altogether in some sheltered border, arranged, as to distance of drills, according to the height to which each variety attains. The drills being drawn, as here indicated, fine soil should be sprinkled in them, and the seeds should be covered with the same material; if dry, they should be well watered. The soil drawn out of the drills should be left to serve as a protection to the young seedlings, and by-and-by, as soon as they have been thinned out, it should be levelled down with the hand, to serve as a mulching to the roots. Asters, Stocks, Zinnias, and *Phlox Drummondii* should be pricked off as soon as they can be handled, as, except for the germination of the seeds, glass cannot be spared here for these classes of plants. We have recourse to turf pits and coverings of hurdles or mats, and under such conditions they invariably do well. They are pricked out in light vegetable soil, half light loam, and half leaf soil. About 4 inches in thickness we find ample, and as this rests on a hard bottom, the plants lift with such an abundance of earth, that they scarcely feel the check occasioned by removal.

KITCHEN, GARDEN.

We are just now planting Cauliflowers out of pots. The cold winds we have experienced have been even worse than frost; but it is surprising how soon a large breadth may be sheltered if we only set about it in the right way. In our case we use the prunings of Laurels, placing a single piece to each plant—a plan which appears to suit them admirably. Our spring plants sown in February are now ready for pricking out in cold frames. Outside Mushroom beds should now be bearing good crops. Winds soon dry their surface, in which case they should be watered with lukewarm water through a fine rose. It is important to allow 1 inch or 2 inches in depth of straw to be on the bed while it is being watered, as in that case the water soaks into the bed instead of running away. Late Celery may now be sown outside, also Brussels Sprouts, Savoy, and curled Greens, and, above all, do not forget plenty of Parsley. All kinds of Broccoli—except *Veitch's Autumn*—should be sown later on. Our first early Potatoes are planted close under south walls. Three hundred feet have been put in this day. The soil is slightly broken, the Potatoes planted shallow, and a covering, consisting of burnt refuse and sand 3 inches in thickness, is placed upon the sets. The variety planted is the true *Myatt's*—undoubtedly the best of all early Potatoes if £ s. d. is a consideration. Earth up and water sparingly. Potatoes in pits and frames. Asparagus may be planted directly it begins to shoot. We have a large breadth to plant this season. We shall draw wide drills 3 feet apart, lay the plants in flat at the bottom, and cover them 2 inches deep with sand and burnt refuse. As regards Seakale, we are now cutting excellent heads from young plants planted last season, over the crowns of which we put a couple of forkfuls of half-rotten leaves. Just now is a capital time to form new beds. Seedling plants are better than cuttings. Vegetable Marrows and Gherkin Cucumber beds may now be formed by taking out a trench 3 feet wide and 12 inches deep. Any old material from Seakale or Rhubarb beds now done with may be advanta-

geously used with a little fresh material from the stables. Mix up all together, and earth up from the sides; place hand-lights on the top, and sow the seeds at once.

FRUIT.

Cherries.—While it is difficult to imagine a more lovely sight than a house of Cherry trees in full bloom it is impossible to name a crop which can be brought to maturity at so little cost in everything, with the exception of patience, and of this the successful cultivator, be he professional or amateur, must have a good stock, as the temperature of the house under artificial treatment should not exceed 40° at night and 10° to 15° higher by day, and even then a stagnant atmosphere should be avoided by having the ventilators a little open. It sometimes happens, as has been the case this season, that the temperature of the open air is many degrees above these figures, when a constant circulation of air gives the trees all the advantages, minus the risk attendant upon culture on open walls. These favourable conditions have brought about a bold blossom, a good set, and rapid growth, so far free from insects, but the everlasting grub which never fails is sure to put in an appearance which cannot be mistaken, and the first curled leaf must be the signal for daily examination and handpicking. When the fruit begins to swell the inside borders may be nicely mulched and well supplied with water at a temperature of 70°, and the trees will require good syringing twice a day, always with the ventilators closed, as it is the warm, genial atmosphere resembling that of a fine April day, which helps the fruit along. After the first syringing give air at 50°, gradually increase it to 60° under moisture, with a circulation of air, and ventilate to the full extent when sun-heat raises the house above these figures. Reduce in a similar way, syringe and kept close for a time, and reopen the ventilators for the night.

Orchard house.—Since our last notes appeared the trees in this department have made great progress, and the fruit on many of the most forward Peaches and Nectarines is now set. Later kinds, also Plums and Cherries still in flower, will require abundant ventilation when the external temperature is not below 40°, and to prevent disappointment a few minutes devoted to daily fertilisation with a bunch of soft feathers will be necessary. Continue the usual treatment with regard to watering, as dryness at the roots will be fatal, and while avoiding the wetting of the flowers damp the floors and other available surfaces, also the stems of the trees, once or twice on fine days, and keep the house dry and cool in damp, dull weather. When the fruit on all the trees is set, let the daily syringing be resumed, aim at a night temperature of 50°, run up to 10° by day, and shut up before the sun is off the house where hot-water pipes have not been introduced. Commence disbudding and shortening back where this has been deferred and plenty of fruit has set near the base of the shoots; also thin the fruit where set in triples or clusters, leaving, as a matter of course, an abundance of the finest on the upper sides of the shoots for future selection. Although the house may have been well fumigated before the trees came into flower, green fly is sure to be present, particularly amongst the Plums, and as these are the first to suffer, another smoking will save much disappointment. As trees in pots now commencing to swell off a crop of fruit cannot be overfed, lose no time in getting them top-dressed with some rich compost consisting of strong loam, good rotten manure, previously dusted with soot to destroy worms, and twelve per cent. of bone dust. Mix well together in a shed, apply it when tolerably dry, and if any is left over it will improve with keeping. Examine trees which have been planted in the borders, top-dress with half-rotted manure, and give plenty of water at the mean temperature of the house.

Vines.—Assuming that former directions have been followed, the Vines in the latest houses will now be ready for disbudding. If they have been

suspended in a horizontal position get them tied up to the wires before the young growths are too far advanced, syringe regularly until the bunches become prominent, and close with sun-heat at 75°. Attend to disbudding and tying down in succession houses, and remove all superfluous bunches from free setting kinds as soon as the most compact and best placed can be selected for the crop; fertilise when ready with Hamburg pollen, and thin out the berries when the size of No. 6 shot. When all the bunches have been thinned allow the laterals to extend over vacant parts of the trellis before they are again pinched, give the inside borders a good supply of warm diluted liquid, and add more fresh, but well worked, manure where the surface is not well covered. Keep up a circulation of warm air in houses where Grapes are in flower, and fertilise when the heat has reached the maximum on fine days. Maintain a minimum of 65° for Hamburgs, and allow 5° more for Muscats when the weather is mild and air can be admitted with the aid of moderate firing, but on no account abide by these figures when external conditions are unfavourable. Although I do not approve of syringing Vines when in flower, some Grape growers do, and attribute their success to the application of water, which is doubtful, as Grapes that will set with the syringe would, in all probability, set just as well, if not better, without it, provided the roots are in a warm, well-drained border, and sufficient atmospheric moisture to support the delicate organs is produced by damping the stems and floors on bright days. When the fermenting material has been removed from the inside of the early house, and the berries begin to show signs of colouring, pass the scissors over them for the last time and remove any stoneless berries where they can be spared, as their presence always detracts from the appearance of an otherwise perfect bunch. Give the borders the final watering with water at a temperature of 80°, and if necessary add a little more short stable manure to keep in moisture and throw off ammonia when the house is closed for a short time every afternoon. Maintain a constant circulation of warm air with moderate moisture where pot Vines are ripening up their fruit, and while reducing the supply of stimulating liquid to the roots see that they do not receive a check by going to the extreme of dryness, and add more covering to the surface roots to prevent the escape of moisture. Get vines which have been cut back and shaken out shifted into their fruiting pots as they become ready, plunge in a sweet bottom-heat and shade slightly for a few days. Train the young canes near the glass and insure short-jointed growth by giving plenty of light and air. Where spring planting is contemplated April is the best month in which to turn out growing Vines. These should always be planted in internal borders, and the compost should be made warm by the absorption of sun-heat before it is placed about the tender roots. Settle the soil as soon as they are planted by giving a little water at a temperature of 80°; shade slightly for two or three days, and then treat as has just been advised for pot Vines.

Melons.—When the roots of the earliest Melons begin to work round the insides of the pots, and a bottom heat of 85° is maintained, other conditions being favourable, a quick and vigorous growth will soon show whether the first laterals are capable of carrying a crop of fruit. Victory of Bath, the best we have met with for early work, throws out an abundance of side shoots laden with female blossoms by the time the leaders have covered two-thirds of the trellis, and earliness being the first consideration, these should be pinched in order to throw vigour into the side shoots. When the female blossoms begin to open keep the atmosphere dry, and give air on all favourable occasions, as a means of keeping the foliage stout and firm, and at the same time assisting the setting of the fruit. Having secured a sufficient number of Melons on each plant by artificial fertilisation, stop at the second joint, mulch with stiff loam and manure, and gradually increase the supply of stimulating food and atmospheric moisture. Keep the foliage clean by

good syringing on fine afternoons, but avoid wetting it on bright mornings. Aim at a night temperature of 70°, give a little air at 76°, run up to 80° or 85° under sun-heat, and a few degrees higher after closing. Keep a stock of healthy young plants by sowing once a fortnight, and throw away previous sowings before the confined state of the roots produces spider.

Cucumbers.—Old plants that have been in bearing throughout the winter will require very liberal feeding and copious syringing to keep them in a healthy and productive state. New compost, consisting of moderately strong loam and lime rubble, with a covering of short Mushroom manure, will also help them. Fill the evaporating pans with liquid manure, syringe the surface of the bed with the same, crop lightly, and give the the young growths plenty of room. If a compartment can be spared, clear out to the bottom, thoroughly cleanse every part of the structure, and make a new start with spring-sown plants. The varieties of Cucumbers are now very numerous, and the lover of novelties may grow as many kinds as he has room for plants; but for general all-round purposes a good strain of Telegraph is not easily surpassed. Young plants now growing freely should be pinched to secure as many vines as may be required. Avoid rich feeding until they begin to bear; run the blinds down at night to economise fire-heat, and, if possible, dispense with shading. Keep up the linings round frames, earth the plants with good dry loam previously warmed, make it very firm, peg out the growths, and run up to 90° with sun heat and moisture after closing; cover well with mats, and give a little night air. Make a sowing of some hardy kind for planting in frames after forced vegetables.

Pines.—The past winter having been against early Queens, the fruit in many places will be later than usual, at least through the early stages, but when fairly out of flower, the swelling of the first batch may be considerably accelerated by closing early under bright sunshine, with a corresponding supply of moisture, and stimulating the roots with alternate supplies of clear diluted liquid and weak guano water. Aim at a temperature of 70° at night, 80° by day, and 5° to 10° more after shutting up on fine afternoons. Keep the plants in a moderately moist growing state at the root, and prevent the plunging material immediately over the hot-water pipes from becoming dry by watering between the pots with tepid water at a temperature equal to that of the house. Many of the plants from which a successional supply of fruit, consisting of Queens, Cayennes, and Rothschilds, will be obtained will now be making growth before they throw up. Give them a good bottom heat of 85° to 90°; water sparingly until they show, but keep the atmosphere of the house well supplied with moisture, and dew them over after closing for the day. If any of the young stock remain unpotted, lose no time in getting it finished, using good loam, which must be firmly rammed when in a dry state. In some soils Pines do not root so freely as in others, and where this is the case, small pots answer better than large ones, as the swelling of the fruit is mainly dependent upon the stem roots, and a small quantity of soil made solid is more lasting and less liable to become sour than when used in larger quantities. If not already done, remove the remains of winter fruiters to a pit by themselves, or where they can have a dry, warm atmosphere when ripening. If wanted to keep for a long time, the plants may be removed to a dry, warm room. Propagate shy kinds by trimming off the leaves and laying the old stools in shallow boxes of leaf-mould plunged in a bottom heat of 90°. Keep plants in every stage of growth near the glass; give them plenty of room in the bed; if possible, dispense with shading, and secure stout growth by airing early on fine days.

Hardy fruit.—Enforced delay in the open-air departments will have given time for the completion of all pruning and training, and if not already taken in hand the nailing of Peaches may be proceeded with. The blossom buds on these

and Apricots are very backward, and it remains to be seen whether many of the flower-buds on Apricots have not been seriously injured by the intense frost. Get all temporary copings, poles, and protecting material ready for fixing upon the walls as the blossoms begin to open. If thick and opaque, some ready method of removing it by day must be provided; but a covering, consisting of several folds of pichard netting, may remain undisturbed until the fruit is set. If recent high winds from east and west have disturbed any of the newly-planted trees, see that the supports are readjusted, and ram the compost firmly when moderately dry. Cut back all stocks intended for grafting, and keep scions ready when the sap begins to ascend. Remove the old foliage from established Strawberries, thin the crowns if necessary, and give the beds a liberal dusting with soot prior to mulching with stable manure; the latter should be placed between the rows before the tender young leaves begin to push from the crowns. Autumn-planted beds have suffered severely; so much so, that in many places one row will have to be taken up to mend another. Where the formation of the new beds is anticipated the ground should be deeply trenched, heavily manured, and made very firm before planting. If strong runners of last season have been preserved in nursery beds defer planting until they are on the point of starting into growth, and if new heavy loam is at command give each young plant a good spadeful to start with. Tread very firm, mulch with short manure, and water in dry weather. Where a batch of strong plants were put out last August for giving the annual supply of runners for forcing, they should be well watered and mulched to encourage early growth, and all flowers should be removed before they open. Some growers obtain their first runners from early forced plants, but we have never succeeded in getting them so early or so strong as from maiden plants, which should be placed near the margin of walks and in proximity to a good supply of water.

FERNS.

BEST CULTIVATED FERNS.

(Continued from p. 279.)

Athyrium.—A handsome genus of deciduous Ferns, well represented by the numerous varieties of our Lady Fern or *Athyrium Filix-femina*, of which more than one hundred forms are catalogued by firms making a speciality of British Ferns. Although our native species has produced so many crested, depauperated, and cruciated forms, there is only one exotic species up to the present which is worthy of cultivation. It is the Japanese *A. Goringianum* tricolor, or *pictum*, as it is sometimes called. This remarkably pretty Fern, with foliage as brightly coloured as that of the better known, but more delicate, *Pteris tricolor*, is, like our own species, entirely deciduous. The fronds, which are lanceolate in form, are produced from an underground creeping rhizome; they are pendulous, and rarely exceed 15 inches in length. The stalk, reddish in its entire length, contrasts strongly with the bright grey colour of the pinnæ next to it on each side, which disposition forms a central grey band running through the whole length and is very effective. It is perfectly hardy, and has withstood without receiving the least injury the winters of 1879 and 1880 planted in an open rockery and without any protection; but to have it in perfection so that none of its beautifully coloured foliage should be affected by late frosts, cold winds, &c., it is necessary to grow it in a cold frame with simply glass protection. The soil that suits it best is a compost of two parts of leaf mould if procurable, one of fibrous loam, and one of silver sand. If any difficulty is experienced in procuring leaf mould, good fibrous peat may be substituted for it, but in any case great care must be taken that the compost be very porous and the drainage perfect.

Balanium.—This genus contains but one solitary species, *B. Culcita*, but it is a grand, conspicuous-looking Fern from Madeira and the

Azores, where it is found growing at considerable elevations, but at the same time in very swampy places, as is testified by the fact that most of the imported crowns of it arrive here covered entirely with *Hymenophyllum tunbridgense*. Year after year hundreds of crowns or clumps of *Balanium Culcita* are brought home from Madeira, and every time the little tiny Filmy Fern is brought with them. It is commonly called the Cushion Fern, on account of the densely hairy nature of the decumbent stem which produces noble, gigantic, hold-looking fronds from 4 feet to 6 feet in height; they are tripinnate, deltoid in shape, and of a bright shining dark green colour. It could not be strictly called a Tree Fern, inasmuch as the stem seldom, if ever, rises more than a few inches above the ground, but it is as highly decorative and as effective as any arborescent kind. Although a strong grower, it makes comparatively very few roots, which are very wiry, and seem to delight in an open compost of a soft nature, made of two parts peat and one part of chopped Sphagnum, without any sand, which should at all times be kept very moist. Greenhouse.

2 feet to 4 feet in length; they are lanceolate in form, rather inclined to be pendulous, getting with age into a nearly horizontal position; they are pinnate with pinnæ decurrent, and from 6 inches to 8 inches in length. Stove.

B. brasiliense var. corcovadense.—This variety differs essentially from the above-named species by its fronds being of a beautiful metallic hue when in a young state, by their being much more substantial, and of a more upright habit. It forms a stem attaining about the same dimensions as those of the type, and has quite a distinct appearance from it. Stove.

B. cartilagineum.—A very handsome Australian species of a highly decorative habit. It is a strong-growing kind, attaining the height of 4 feet to 5 feet, and forming with age a stem of smaller dimensions than the Brazilian species does. It is, however, quite an arborescent Fern, the crown and stalks of which are profusely clothed with long, black, chaffy scales. The fronds are pinnate, with pinnæ sessile, ovate-lanceolate in form, and of a bright light green. Greenhouse.

Blechnum brasiliense.

Blechnum.—This genus is composed of mostly handsome-growing plants, very useful for decorative purposes, although there are also included in it several dwarf-habited kinds particularly well adapted for growing in Fern cases. Like the *Lomarias*, to which they are nearly allied, but from which they differ in not producing separate fertile fronds, they are most of them of hardy, robust constitutions and of more rapid growth. Like them, also, they have a particular dislike to water over the fronds, which causes them to turn first brown and then black in a very short time unless the plants are in a very light, warm, and well-ventilated place, which, to a certain extent, counterbalances the effects of the extra moisture by not allowing it to remain on the foliage long enough to injure it. They are not at all fastidious as to their food, and will grow in almost any compost, but their fronds are stouter and of more consistency if grown in a mixture of two parts peat, one of loam, and one of sand, with good drainage, taking care that the roots never suffer from want of water.

B. brasiliense.—An evergreen species from Brazil of arborescent habit, the stem attaining an average height of 3 feet, but of rather slender dimensions in proportion to its height. The fronds, which it produces in great abundance, vary from

B. Lanceola (trifoliatum).—A dwarf growing Brazilian species, very useful for planting in a Fern case, where it thrives admirably and soon makes a beautiful little specimen. The fronds, which are produced in great numbers from underground rhizomes, are simple, about 6 inches long, and of a bright dark green on the upper surface, while the whole length of their underside is ornamented by a continuous central band of deep brown formed by the sori, of a most conspicuous nature. Greenhouse.

B. longifolium var. gracile.—A distinct and very pretty variety from Tropical America, making a very good companion to the above described species. The treatment suitable for them will suit it. It somewhat resembles in habit the last named kind, but it greatly differs from it in having its fronds pinnate instead of entire, and of a rich deep green colour. They also grow longer and often attain 12 inches in length, besides having their rachis of a beautiful red. Like the preceding one, it is an evergreen plant. Greenhouse.

B. occidentale.—This West Indian evergreen species is one of the best known and most appreciated among Ferns of dwarf habit, probably on account of its easy cultivation, as also from the lasting qualities of its elegant fronds, which re-

main fresh a very long time in water when used for mixing with cut flowers. Besides, it has been for years grown amongst Orchids, to which it forms a very effective background, the more so that it is a plant not given to insects of any sort, and that it grows as well in coarse sand, gravel, or Moss as in the best compost. The fronds, produced in great profusion from underground rhizomes, are somewhat pendulous, pinnate and lanceolate in form; they rarely exceed 15 inches in length, and are of a bright rich green colour. There exists also a beautiful variety called *B. occidentale multifidum*, which appears to be very rare. Its very elegant fronds grow to about a foot in length; they are pinnate, the pinnae being twice or three times forked at the extremity, giving to the whole plant a handsome tasselled appearance. The general habit is similar to that of the species, but the weight of the tassels makes the fronds more pendulous still. Stove.

B. orientale.—A very handsome species from the East Indies and the Malayan Archipelago and no doubt the most interesting of the whole genus. The fronds are produced from creeping underground rhizomes, and when fully grown they attain the length of 3 feet; they are leathery, pinnate, with pinnae set rather widely apart, and when young are of a most beautiful copper colour, changing with age to light green; they are of a drooping habit, which makes the plant a very valuable addition where Ferns are required for hanging baskets of good dimensions. Stove.

PELLÆA.

FLOWER GARDEN.

ST. BRIGID'S CHRISTMAS ROSE.

NOT UNFITTING does the graceful title of "St. Brigid's Christmas Rose," given to *Helleborus niger angustifolius* in honour of the famous saint of that green isle where "F. W. B." first saw its shining leaves and snowy blossoms, seem when we remember how long this plant has lived and flourished not many miles distant from the shrine of St. Brigid, in the old town of Kildare, whose name originated from that of the church founded by her about the year 495, which was called, from a great Oak tree close by, Cilldara, "Church of the Oak," the name extending to the monastery and then to the town that gradually sprang up around it, and finally to the country, of which it is the chief spot of interest and legendary lore. Such was the veneration of the Irish nation for St. Brigid, that in early times she was frequently called the "Mary of the Gaels," while the name of Brigid or Bride was to be met with in every part of Ireland. Scotland is full of commemorations of St. Bride. England has two Kilbrides in Cumberland. Near her most ancient monastery of Glastonbury was the church of Bride-hay. St. Bride's, in Fleet Street, London, received its dedication from the Irish saint, while in many parts of Europe there existed churches which bore St. Brigid's name.

Having read in *THE GARDEN* lately how some floral authorities were endeavouring to trace back the history of *Helleborus niger angustifolius*, I thought when in Kildare last week that I would enquire from the lady who gave me some years ago the first plant of *H. niger angustifolius* that I ever possessed what she knew of its origin. Her answer to me was, "When I came to reside in my present home, thirty years ago, I found the Christmas Rose here, and was then told that this old garden was famous for three things—its Christmas Roses, its Lent Lilies (*Narcissus minor*), and its yellow Cabbage Roses. The last have disappeared, but the Christmas Roses and Lent Lilies remain."

This lady's garden is one of those spots sacred to flower life. Here no ignorant hand has flung out at fashion's bidding the old treasures of bygone days; no ruthless spade, no piercing fork has torn and wounded the bulbs and roots that become lost to sight in transient slumber. No week is there in the whole year in which bright blossoms and graceful foliage are not to be found in the fine old borders of hardy plants; while,

when fullest of blossom, happy marriages and tender friendships follow this sweet companionship of colour and fragrance as the flowers lean side by side. We cannot tell how many years are needed to make a garden "famous" for any special favourite, but if my friend found *Helleborus niger angustifolius* in full possession of her garden thirty years ago, we may well suppose it has lived there for not much less than half a century.

On my own behalf, I would like to say a few words as to its hardness, for I am specially grateful to St. Brigid's Christmas Rose for its grand power of endurance and its vigour in resisting the ills of life. I have a garden in the county of Kildare. Alas, what was once fine Oak forests is now cut out turf bogs and swamps with stagnant water, and these extending wastes make the climate so cold and damp, that the air feels like a wet blanket wrapped around one. Yet here, in January last, amid all the desolation wrought by "Boycotting," where the Strawberry beds are lost in Couch Grass and Docks, the Gooseberry plot an impassable prickly thicket, the Raspberries a jungle of canes and nettles, the young fruit trees fallen from the walls as their fastenings rotted, the old espalier trees with unpruned shoots of 3 feet or 4 feet long straggling in all directions, the Vines hanging down in a tangle of two summers' growth untouched, the borders and walks covered with Moss and weeds and hollow trampings of cattle—the one welcome sight, the little oasis of happy life and health in my deserted garden was the luxuriant clumps of St. Brigid's Christmas Rose, tossing aloft and spreading their noble glossy leaves till the plants measured a yard across, while within lay the snowdrift of hundreds of blossoms, so thick that my fingers could scarcely press through to gather them. Though I have not found that the Christmas Rose likes shade especially (the clump with finest foliage and largest blossoms being in full sunshine), yet shelter it does enjoy, and demands somewhat imperiously, and given this it will retain its deep shining leaves in perfection for an entire year. Subjected to any strong blast or cold currents, the leaves grow weary and worn and lose their great charm—constant freshness.—ST. BRIGID.

—If Mr. Brockbank is inclined to be just, and will reflect on what he has written (p. 281), I think he must allow that I have equal rights with himself, *i.e.*, I may justly claim the right to name any plant I know for a certainty to be popularly nameless, and my title to do this is quite as clear as is his right to protest against such a practise. In speaking of St. Brigid's Christmas Rose, Mr. Brockbank says, "I trust it may simply retain its own name the Christmas Rose, but this name already belongs to the typical *Helleborus niger*, figured ninety-seven years ago (see *Botanical Magazine*, 1786, vol. i., t. 8), which is with us a wretched weed in comparison with this lovely pure white variety with blossoms "as large and as fine as *Eucharis Lilies*," and which, despite any little opposition Mr. Brockbank may feel disposed to offer, will henceforth be known in English as St. Brigid's Christmas Rose, being, as it undoubtedly is, the queen of all Christmas Roses whatever.

Miss Hope, no doubt, may have cultivated this variety about Edinburgh, but I have evidence that it flourished in Ireland long, long before Miss Hope was born. Mr. Lindsey tells me in a letter just received that he believes the variety to be abundant round Edinburgh. I hope it is, for when flowers of the true variety were sent to several of the principal hardy plant nurserymen in London and elsewhere, the avidity with which they offered to purchase roots of it did not suggest to me its very great abundance anywhere outside private gardens where it is here and there known, and where it is also a great favourite. Mr. Archer-Hind acknowledges its distinctness and noble port as contrasted with the Christmas Rose (*H. niger*), and he also agrees with me that St. Brigid's Christmas Rose is a good name for it in English, although he prefers—and mayhap rightly so—to call it in Latin *H. niger major* rather than

H. niger angustifolius. As I have said, the common or typical Christmas Rose is a wretched weed on our own soil as compared with St. Brigid's variety, and as we have here many visitors from all parts of Europe, and not one of them ever saw this particular variety before, I think I have good right and reason to sketch and describe it under a good and pretty English name; at any rate, as I have said, my right to do so is just as good as Mr. Brockbank's right to protest; hence so far we are equal. As to Mr. Brockbank's objection to tutelary dedication, does he object to St. Bruno's Lily, or to the genus *Veronica*, or, to put it in a familiar form, to his parish church because it is dedicated to a saint? Much correspondence and many observations of interest on *Hellebores* generally have come to me on this subject. One fact mentioned in Mr. Lindsey's letter is worth noting, namely, that while Miss Hope gathered abundant crops of seed from *H. niger angustifolius*, she never could find a single seed on her abundant stock of *H. altifolius*. It would be interesting if other cultivators could throw some light on this matter, and one would especially like to know if this great Christmas Rose ever produces seed in Holland, where it has recently been largely grown for exportation to English gardens. Mr. Archer-Hind kindly sends me (along with the finest leaves of *H. altifolius* I ever saw) foliage of a seedling raised from seeds of *H. niger* which seems to have the erect port, noble leafage, absence of red colouring matter, &c., so characteristic of St. Brigid's variety, and which suggests its origin, although, so far as I could judge by the direct comparison of leaves alone, it is distinct from that fine variety. The study of *Hellebores*, like that of the Daffodils, must ever be a difficult and critical one, since intermarriages, or natural, if not artificial, hybridism and selection, have in both cases been going on for ages. As to wild plant species or varieties in both genera, Mr. Baker's papers are most valuable; but garden forms we must work out, and describe, and illustrate for ourselves.—F. W. B.

LARGE SULPHUR HOOPED PETTICOAT DAFFODIL.

(*NARCISSUS BULBOCodium* VAR. *CITRINUS*.)

Now some years ago (I fancy it was in 1869), when Mr. J. G. Baker wrote his "Review of the Genus *Narcissus*," he placed *N. Bulbocodium* (the *Corbularia* of Haworth) and all its sub-varieties into his Group I., *Magnicoronate*—the large trunked Daffodils (or false *Narcissus*) of Parkinson. Of the *Narcissi* which have the crown in the middle of the flower as long as the divisions of the perianth, there are only three (I sometimes think only two, since I exclude *N. calathinus*) well marked species. These two are as follows:—

Tube inversely conical, varying from as long to twice as long as broad, with the stamens springing from the bottom; divisions of the flower more or less distinctly ascending. Filaments and style curved, divisions of the perianth linear-lanceolate, a line to the eighth of an inch broad at the base.

N. Bulbocodium (*Corbularia* of Haworth).—Of this plant Mr. Baker describes the type of the species *N. Bulbocodium*, the plant not uncommonly now grown in pots for early spring flowering in the conservatory, from Dutch grown bulbs. Now and then in the south of England, in the Isle of Wight, and in Ireland it becomes established as a hardy plant, but the failures are far more than the successes as to its general open-air culture. It is, however, not only quite possible, but indeed quite easy to grow it in pots if thoroughly dried off by turning the pots over on their sides as the flowers fade, and so ripening up the little brown bulbs, after which they should be wintered in a cold frame, or under the stage in a cold house, being top-dressed as they start into growth late in autumn or early in winter, and placed on a sunny shelf near the glass to bloom. All *Narcissi* are excellent early blooming plants when so treated; indeed, it is quite a waste of power and of trouble to throw them away, or to plant them out in the open borders after flowering, since all pot Nar-

cissi flower earlier and better the second year than they do the first. I remember this is even true of *N. poeticus* which Mr. H. Bailey, of the Feltham Nursery, used to force for early flowers; and about Christmas last year Mr. Smith, of Newry, sent me flowers of *N. Jonquilla* the produce of pot roots the second year after forcing. Grown on in pots year after year, *N. major*, *N. maximus*, *N. obvallaris*, *N. bicolor* Horsfieldi, *N. Emperor*, *N. minor*, *N. odoratus*, *N. Jonquilla*, and the different varieties of *N. Bulbocodium* are indeed the most beautiful of all early flowering cold house bulbous plants, flowering as they do just before *Iris* (*Moræa*) *chinensis* (or *I. fimbriata*), *Lachenalias*, and those lovely orange throated *Freesias* with fresh Grass-like leaves. But to return to our text, Mr. Baker in his "Review" describes

Five varieties only of *N. Bulbocodium*. These are, *N. Bulbocodium*, the type; 1, *N. conspicuus* (the showy); 2, *N. tenuifolius* (the long leaved); 3, *N. obesus* (the inflated or ventricose); 4, *N. nivalis* (the pale or snowy white); and 5, *N. monophyllus* (the one-leaved white from Algiers); at the time he wrote, in 1869, the "large sulphur" was unknown. A few years later Mr. J. D. Llewellyn found it, however, at Biarritz and brought over bulbs, and now, although yet rare, it is found in some if not many good gardens. Quite recently Miss Gertrude Jekyll, after whom one of the most boldly beautiful in form and softly beautiful in colour of all seedling Daffodils is named, sent me a tracing of a sketch in colour which she had made from some bulbs in a pot of this fine variety which had bloomed in her greenhouse at Munstead. It is a fine lemon-yellow or sulphur Hooped Petticoat; indeed, the largest of all in size; hence some of us think that Haworth may have had it in his mind's eye when he named his variety *Corbularia gigas*. *N. B. citrinus* was originally described by Mr. Baker in the *Florist* for 1880, with a woodcut sketch, and quite recently I noted that Herr Max Leichtlin, of Baden-Baden, offers bulbs of it. Naturally it flowers at Biarritz in January or February in the hot sunshine of that rocky shore where both this *Narcissus* and its beautiful associates bask in the hot spring sunshine, and are nourished by extremely heavy nightly dews. The glowing light sulphur colour of the flower is beyond description. It is indeed the largest and most beautiful of all of this particular section of *Narcissus*, and is said to be quite common on the Western Pyrenees. It may interest Daffodil lovers to know that the pretty little species or variety *N. minimus* is wild on rocky ledges and declivities above Pancorbo, in Spain. In Spain, also, are many distinct varieties of *N. Bulbocodium*; indeed, this species will prove, I believe, quite as variable as is the common Daffodil. ECHO.

MARCH FLOWERS.

OF these I have a few, though even in the milder parts of the country the weather has been severe enough to test the hardiness of spring plants, at least as regards impairing the beauty of their blossoms. Snowdrops and Crocuses escaped fairly well by being nearly out of flower before very hard weather set in. *Crocus aureus* is one of the earliest as well as one of the latest here. *Rhododendron ciliatum* shows how completely its beauty has been destroyed; but when the season is in its favour, its waxy pink-tinted white flowers are quite beautiful enough to make it well worth growing in spite of occasional failure from bad weather. Probably much might be done to save its blossoms by having the plants sheltered with Evergreen boughs during severe frost in winter or harsh weather in spring. The flowers of *Anemone fulgens* are much smaller and usually of paler tints than in milder weather; and although we have already had several hundred blossoms, hardly any have been as fine as they usually are at this time of the year. *Narcissus minor*, grown chiefly as borders to small beds, and *Scilla sibirica* have held their own through all the late hard weather, and brightened the garden more than any other flowers. Small beds of this *Scilla* bordered with *N. minor*

are especially pretty. As a mass of blue, perhaps even *Chionodoxa* will never eclipse *S. sibirica* in beauty. Flowers of *Narcissus cernuus* and of *N. odoratus* fl.-pl., our earliest *Narcissus* this year, except *N. minor*, have been plentiful, as have also been those of the Tenby Daffodil (at least, the early kind we have under that name). This time last year we had many April, and almost May, flowers in blossom, but in a March such as this, with several degrees of frost every night, hail and snow showers, bitter winds, and intervals of sunshine (to make all else still more trying to the plants), to have any spring flowers at all proves their value. Of course we have little to complain of in the weather here as compared with some parts of the country (I heard yesterday of 3° below zero in Northampton on the 9th), but the very wet winter has left plants badly prepared to encounter even such weather as we have here.

Knockmullen, Gorey, Ireland. C. M. OWEN.

Cheiranthus alpinus one would suppose hardy enough, but in every case where it has been fully exposed to the north and east winds, which have recently prevailed, it is blighted. All the leaves are shrivelled and many of the plants completely destroyed. It appears capable of enduring extremes of frost, but not the east winds.—BROCKHURST.

Hardy plant portraits.—Can any of your readers inform me if the plates which were issued in *Curtis's Botanical Magazine* and Sweet's "Flower Garden" are still obtainable? In *Curtis's* time they were issued separately with a fly-leaf attached, containing a full description of the plate, and with many valuable notes and references. These plates are most truthful representations of the plants, and are probably still to be obtained if one only knew where.—BROCKHURST.

Myosotis dissitiflora is not hardy in Lancashire, except it be placed in very sheltered situations. We used it largely for spring bedding this season, and the late frosts and cold winds have shrivelled it up and killed two-thirds of the plants, so that we have had to replace it all with *M. sylvatica* from the reserve garden. The fault of the latter is its over-rank growth, which we have to keep somewhat in check.—BROCKHURST.

Narcissus tortuosus (*Narcissus moschat* (*d*), smaller white Spanish Daffodil).—I find there is an excellent portrait of this Daffodil in *Curtis*, plate 1300. It is there represented as it comes when just opened, but after a few days the perianth segments begin to twist, and thus become shortened considerably, and they then bulge out stiffly like a fair lady in the costume which now again prevails. It is this feature which led Haworth to give the name *tortuosus*. *Curtis* states, "A much rarer plant in our gardens than the one already published (No. 924, *Narcissus moschat* (*a*), the white long-flowered Daffodil). We are indebted to Mr. Haworth, of Little Chelsea, for the specimen from which our drawing was made." *Curtis* also classes it as Parkinson's *Pseudo-Narcissus hispanicus minor albus*, and I see it is given with its peculiar twisted perianth segments in plate 101, fig. 4 ("Paradisus"). I have had a good many blooms sent me for identification, but the only true one is from Guernsey.—WM. BROCKBANK, *Brockhurst, Didsbury*.

Hardiness of *Dracæna indivisa*.—The locality in which this plant has proved hardy Mr. Ramshaw tells me is Perrystone, Ross, Herefordshire. The thermometer there during the present month has registered 17° of frost; therefore this *Dracæna* should be able to withstand our ordinary winters. Shelter from the north and east is the great point to aim at, and, above all, the soil should be well drained. Ours is, however, a fickle climate, and anyone wishing to have this handsome-leaved plant in perfection should give it the shelter of a glass roof. It is not altogether a question of hardiness whether it will live through our very trying winters or not, but whether it will be really ornamental under such conditions. There is no question as to the hardiness

of Snowdrops and many common border flowers, yet the gales and frost which we had during the early part of this month completely cut off not only the flowers, but the foliage as well. Phloxes and other plants that had made all their growth in the open air were completely blackened. We are on the extreme southern coast, but the country being quite level, there are no sheltered nooks or corners where plants like this *Dracæna* could be placed to save them from the withering blasts to which they are exposed. The merits of any open-air decorative plant cannot always be measured by its power to withstand a certain degree of cold. Although the thermometer seldom sinks very low here, we cannot hope to grow many comparatively tender trees, shrubs, and plants that attain large proportions in more inland situations. It is the wind, not the frost, that is our unconquerable enemy.—JAMES GROOM, *Seaford Nursery, Gosport*. [*Dracæna indivisa* will withstand ordinary winters, but not severe ones. Several plants of it were killed at Chiswick during a severe winter some years ago, though sheltered and in a well-drained position.]

Effect of cold winds on *Chionodoxa Luciliæ*.—The keen winds which we have recently experienced completely ruined the flowers of this plant, but a clump of *Scilla sibirica* growing close by was quite uninjured. True, my plants were in a somewhat exposed position, where the wind at times was very powerful, and the *Scilla*, in my opinion, owed its immunity to its sturdy growth, against which the wind made no impression. The flower-stalks of the *Chionodoxa*, being of a weaker habit, swayed about to such an extent as to completely spoil their beauty. This fact alone is greatly in favour of the older plant, which has also the merit of remaining longer in flower than the *Chionodoxa*, even when both are in a sheltered nook. The *Scilla* is easily forced into bloom too soon after Christmas, and so also, I should think, would be the *Chionodoxa*, but of that I have had no experience.—H. P.

The Tenby Daffodil.—In *THE GARDEN* (July 16, 1881, p. 57) I certainly did, as Mr. Brockbank observes (p. 281), offer a copper kettle to whomsoever should first send me a Daffodil having perianth and crown of exactly the same tint or shade of yellow. The kettle is here, but, alas! the Daffodil never came. *N. obvallaris* does not fulfil my conditions, not even when "viewed from the stalk," and on p. 281 Mr. Brockbank cuts short the argument on which he rests by himself speaking of "shades of yellow" in that flower, thus saving me the trouble of proving that the flowers are, in reality, not of one shade or true self. Mr. Brockbank is, perhaps unconsciously, unjust in trying to limit my testing his flower in my own way. Why should I be limited to a back-door view of the flower—a flower especially reared under artificial conditions, be it observed? If, as he asserts, *N. obvallaris* is all of one shade of yellow, no method of looking at it will alter that fact. My simple test (p. 281) will satisfy any unbiased observer that there is no such thing as a Daffodil yet known which has perianth divisions and crown both of exactly the same tint or shade.—F.W. B.

SHORT NOTES.—FLOWER.

Native country of the white Lily.—One of the Lazarist fathers of the College of Antoura, Lebanon, writes: "The mountains of Lebanon are covered in certain regions with this Lily. The Lilies are as fine as those cultivated in gardens."

Chionodoxa Luciliæ—I enclose two blooms of the flower-spoke of a seedling *Chionodoxa Luciliæ*. The spike bears nine bells, and is unusually robust. You will note the size of the bloom and its very rich colour.—H. STUART WORTLEY (Col.), *Rosstyn House, Grove End Road*. [A very fine variety.]

Paris Daistes (*A. L. Patton*).—The insects infesting your Paris Daistes are the grubs of a fly nearly allied to the Celery fly. Hold the leaves up to the light, and pinch them wherever you see the grubs. Though this will not save the leaves already attacked, by killing all the grubs possible the next generation of the flies will be much diminished in numbers.—G. S. S.

FRUIT GARDEN.

VARIABILITY OF GRAPE SEEDLINGS.

I AM surprised at the tone of Mr. Barron's reply as regards this subject, and his attempt to mystify the matter by raising side issues and making unfounded charges of misrepresentation that do not in the least help his case or affect the question between us. Allow me to say that I have not misrepresented Mr. Barron in the least, nor omitted qualifying sentences anywhere. If I did, why does he not restore them when he makes the charge? He says I "deliberately misrepresented" him in saying that he described cross-fertilisation as "a ticklish operation," and asserts that "he has stated nothing of the sort." I reiterate that he has, and here are his words in full:—

To hybridise, therefore, or to cross-fertilise one variety with another, it is necessary to take measures in advance of natural development, so that self-fertilisation may not be effected. To accomplish this, select, some days previously to the opening of the first flowers, the bunch which is to be operated on as the female or seed-bearing parent. Cut away all the flowers, with the exception of ten or a dozen, and have these enclosed in a thin muslin bag, which must be sufficiently close in texture to keep out all foreign pollen. It is necessary to watch and examine these flowers minutely until they appear as in fig. 6 b; then, being provided with a pair of finely pointed scissors or pincers, pull off the cap by force, and immediately cut away the stamens, as shown in fig. 6 d. This is rather a ticklish operation; it requires the greatest care and patience, all the parts being so small, and, as a rule, difficult to get at. It is, indeed, a very arduous task to do all this without injury to the pistil or ovary. To add to the difficulty, the bunch to be operated upon is in many cases difficult to reach, and the operation has always to be carried out in the forenoon of the brightest and hottest of days, so that, what with the perspiration almost blinding one, and the reaching and straining, it is one of the most trying of garden operations.

If the above passage is not an enumeration of the difficulties of cross-fertilisation, will he tell us what it does mean? His distinction between "the *modus operandi* of preparing the flowers for the purposes of cross fertilisation" and the final and simple operation of touching the stigma with a camel's-hair pencil—"fertilisation"—is too fine by half and a mere quibble. There are just two or three of Mr. Barron's statements that demand attention. He repudiates the idea that he ever supposed white Grapes turned black. Well, will he specify the "many varieties" that have turned out old sorts? (p. 25 of his book). Secondly, he now says "every intelligent grower knows that cross-fertilisation may, and often does, take place by natural agencies, and is the work of an instant." Exactly; I assent to this, and so will others; but in his book Mr. Barron states exactly the contrary. At p. 25 we read, "Excepting great care has been taken to properly cross or fertilise the flowers, the chances are a hundred to one that nothing new will be obtained. Is a hundred to one 'often?' and how are these two conflicting statements to be reconciled? And another to the effect (p. 28) that "if a single flower may be allowed to expand naturally it may ruin the whole experiment." In short, Mr. Barron in his book makes it out that cross-fertilisation is almost impossible without artificial aid bestowed under the great difficulties described, but in the face of discussion he now finds it needful to widen his views.

In support of his opinion that varieties "do not sport or vary" from seed he names three or four old varieties, the identity of which with other sorts is very doubtful, such as the Abercainey Seedling, for example. I take leave to doubt if Mr. Barron could vouch for the history of any of them. Nobody doubts for a moment that Vines may occasionally reproduce themselves from seed, but that is not the question, which is whether Mr. Barron is correct in stating in his book that varieties "do not sport or vary, or but to a very limited extent." This is the point at issue, and it is the point he does not answer. I thought, and I have no doubt many others thought also who have read "Vines and Vine Culture," that the new and original matter there on seedlings and fertilisation was the result of the author's own experiments

during the twenty-three years he has been at work in the great vineyard at Chiswick, where he has had such ample materials at his disposal; and it is disappointing now to find him referring us to such ancient sorts as Abercainey Seedling, Josling's St. Albans, Horsforth's Seedling, &c., in support of his views, and offering not a scrap of information of his own, all the while completely overlooking recent experience on the subject ready to his hand. The reputed history of the three old varieties named he is not able to tell us more about than we already know, and it is of little or no value for his purpose. In a book of the pretensions of "Vines and Vine Culture" the public look for something better than mere theories, assertions that have not a leg to stand upon. In order to prevent Mr. Barron from seeking to escape the consequences of his statements by charging me with misrepresentations, permit me again to state the case against him on the subject of seedling Vines. It is this—First, that his assertion that "varieties of Vines do not sport or vary, or but to a very limited extent," is contrary to general experience and opinion, and, although authoritatively asserted in "Vines and Vine Culture," is not vouched for by a scrap of evidence of any kind. Secondly, that the difficulties of cross-fertilisation are greatly exaggerated, and his opinions on self-fertilisation opposed to those of the most eminent authorities on such subjects, while he advances no proof in support of his views. In conclusion, I may just state that I have assisted at the fertilising, raising, growing, and forcing of scores of seedling Vines, witnessed every step of their culture from beginning to end, and taken ample notes, and I cannot remember any of the straining, osculating processes of fertilisation, described by Mr. Barron as absolutely necessary, being resorted to once. The seedlings consisted of crosses and seminal varieties, probably most of the latter, and, I think, almost every Vine was distinct in habit and fruit, and few like the parents, while the reputed crosses, with several of which Grape growers are now very well acquainted, I thought at the time, and still think, were *bona fide*, because they showed it in their fruit and foliage. Cases like this, I venture to think, are worth much more than Mr. Barron's unsupported statements.

GROWER.

STRAWBERRIES WORTH GROWING.

STRAWBERRIES used to be divided into three in Loudon's days—scarlet, black, green Pines, Hautbois, and alpine, but all these have been so much crossed and intermixed, that such a classification hardly any longer answers the purpose. The earlier grown varieties which are still distinct are the Hautbois and alpine, which we may say a word or two about first. The old Hautbois is rarely or never seen now-a-days, but old cultivators still speak of the variety and of its excellent quality and peculiarly agreeable flavour, which has probably, in some degree, been communicated by crossing to some of our newer kinds. This variety had the peculiarity of ripening two crops in the year—one in July and another in October. The fruit was about the size of our yet cultivated Black Prince, solid fleshed and delightfully flavoured. The plants did not occupy much room and were very prolific. As to the alpine Strawberry, although not commonly cultivated now-a-days, it still finds a place in many large gardens, and the wonder is it is not more popular than it is. It is not a large variety, the largest sized fruits seldom exceeding the bulk of an ordinary Filbert, but they are borne in great profusion, and the crop comes in during August, September, and October, when other Strawberries are over. The Paris market gardeners still grow alpine extensively, and piles of beautiful fruit are to be seen in the Paris markets in autumn. The usual plan of growing alpine is to sow seed in autumn or spring and plant out on a north border or slope, though the plants will succeed in any other aspect, and renew the plantations periodically. Seed sown in autumn will produce a fine crop the following year. A light, rich soil suits them best.

An old variety of the Strawberry is Cuthill's Black Prince, commonly call Black Prince, not half so

much esteemed as it should be, for it is both an excellent and an early cropper and bears most abundantly. In a general way the berries are not very big, not exceeding 1 inch in diameter on the average, but want of size is compensated for by quantity, and the quality and colour is good. Grown on a sunny bank, or at the foot of a south wall, and well done to, it comes in long before any other kind at present in cultivation, and is valuable on that account alone. We grow nothing else here for preserving purposes, and always force a good quantity of the same variety.

A good sort for filling baskets for market purposes is James Veitch, a comparatively new kind which we have not tried yet; but a friend in the trade who grows fruit for market near a large provincial town told the writer last year that he had made more money out of it than any other sort. The berries are all large and fine looking, and he put them in separate punnets of convenient size in the form of nice dishes and sold all at 1s. per lb. during the whole season. No doubt this is a good way of disposing of fine fruit, for look has much to do with selling, and few care to buy Strawberries for dessert off the heap on the shop counter where they are generally partially bruised and spoiled and besides of very unequal quality. Madame Héricart de Thury is at present the most popular Strawberry in general culture; being a prodigious cropper, certain in almost any soil or situation to bear, a good preserver as well as a fine forcer, it should be extensively grown. Keen's Seedling is an old sort, which for fertility is ill to beat, and it is an almost fail-me-never as a bearer. A grand forcer too, and good for preserving, one of the best, in fact. Perhaps no Strawberry has stood the test of time so well as Keen's; it is a fine sort, fruit large, round, bright coloured, and well flavoured, a variety well worth growing, and some of the finest crops of it we ever seen were grown in the sandy soils of Nottingham. Sir Charles Napier is another good-looking sort if not the best flavoured, and it sells well, and makes a prime looking basket in the window of the fruiterer who is partial to it. Wizard of the North is large also, but a shy bearer. In fact, in estimating good sorts one must always take the bearing qualities of a variety into consideration first, for unless a Strawberry is a good bearer it will not do for general culture, and that varieties differ greatly in this respect is well known. There are some generally good sorts, like two or three of the first sorts named in this paper, but many of the other sorts are not to be trusted, and we strongly advise growers before they go into Strawberry culture on any great scale to mark the sorts that succeed best in their own locality, or rather soil, for soil affects the bearing qualities of Strawberries more almost than any other other class of fruits.

H.

STRAWBERRIES FROM PREVIOUS YEAR'S RUNNERS.

INSTEAD of layering runners of the current season for this purpose in the way generally practised, we have for the past three seasons reverted to the plan of securing our supply of plants from runners of the previous year, and the results have been so gratifying that we intend for the future to adhere to this system. It is the most efficient and in the end the most economical. One great advantage of this method is that, independent of late or hot and dry seasons, early potting can be assured, and consequently pots well filled with roots and plump matured heart buds, conditions which, if unfulfilled, render satisfactory returns uncertain. Again, in June a multitude of matters of equal import require attention, and therefore the layering of runners not infrequently gets delayed until too late; then comes the preparation of the soil, pots, and pegs, along with the work of plunging and layering, all operations consuming a good deal of time; there is also the subsequent attention to watering, not to mention the inconvenience if the pots are plunged in fruiting quarters, and it is only in some of the larger places in which time and space can be devoted to plantations for the special purpose of supplying early runners for fore-

ing. Now all this can be obviated by the system just alluded to. Our practice in regard to obtaining runners for potting is as follows: Towards the end of April all out-door plantations are thickly mulched with long stable litter. This is done partly to retain moisture, which in dry seasons soon escapes from our shallow soil, and partly to form a bed for the ripe fruit to rest on; for, by the middle of June, the litter becomes, through repeated rain washings, clean. As soon after the crop is gathered as time permits all runners are cut, their removal being a very easy matter, as the thickness of the mulch prevents their rooting into the soil. The decaying straw is allowed to remain, except on that portion (always the youngest and best) from which runners are meant to be taken. From this all the strawy material is cleared and a light dressing of rotten manure is substituted. Thus treated, we find that a few rows of Vicomtesse Héricart de Thury will invariably throw out late runners more than sufficient for our wants, and that they root strongly before winter. Here they remain till March, when they are lifted and laid in about 4 inches or 5 inches apart in any spare border; the space and time occupied in doing this is trifling compared with the usual layering business. All the attention these runners require till potted the last week in June is pinching out any flower-stems they send up. After potting we place them on ashes in square blocks, gradually spreading them out to ripen as autumn advances. I may add that out of fifteen sorts tried only two really succeed here out-of-doors; these are Vicomtesse Héricart de Thury, or Garibaldi and Eleanor. We do not force a great number, but the Vicomtesse is used for that purpose almost exclusively, as we find no other so good. Its prolificacy outside, too, is wonderful; after the regular crop is over it will continue to throw up strong scapes all through the summer and autumn. A. MOORE.

Cranmore.

Dates of introduction of Grapes.—Will someone inform me by whom and in what year the following sorts of Grapes were introduced, viz.: Alicante, West's St. Peter's, Trebbiano, and Black Prince?—O. [According to Mr. Barron's new work on the Vine, there is no authoritative record as regards the introduction of the Alicante variety. The origin also of West's St. Peter's seems somewhat obscure, but Mr. Barron says, "A number of spurious varieties at one time existed; hence to distinguish it it was by some called Oldaker's West's St. Peter's, from its having been extensively grown by Sir Joseph Bank's gardener, Mr. Oldaker, at Spring Grove, while others named it Money's West's St. Peters. Some thirty years ago this variety was considered the best late Grape grown, and was extensively planted." The history of Trebbiano, says Mr. Barron, is unknown. Black Prince is said to be a very old variety, but no mention is made of its origin. We can give no information on the other subject.—ED.]

Charcoal for a Vine border.—The benefit likely to be derived from adding charcoal to a border for Vines depends on the nature of the soil to be used. Vines like strong soil rather than light. If that which "Constant Reader" is about to use is of the latter description, charcoal, by making it still more open, will do more harm than good; but if the soil is heavy and inclined to be adhesive, charcoal in moderate quantities will help it. What the proportion should be will depend on the more or less heavy nature of the loam; if very close in texture, a wheel-barrowful to a cartload of soil will be an assistance, but it is well to keep on the right side in the use of such material. At one time it was no uncommon thing to see brick rubbish added to Vine borders made of heavy soil to an extent that was not relished by the Vines. I have tried charcoal varied in quantity for many plants, Vines included, but never found it of much benefit except through its mechanical agency in keeping the soil more open for such things as require a porous soil. It no doubt acts to some extent as a storage medium for the manurial elements applied to the soil, and in this

way may assist some plants; but if gross feeders like Vines had to depend for sustenance on what they were able to get from any reasonable quantity of this material added to the soil in which their roots were placed, they would soon show the effects of short commons.—T. P.

STEVENSONIA GRANDIFOLIA.

MR. SMITH'S remarks (p. 233) with regard to this grand Palm call to my mind a fine specimen of it which I once grew over a tank of water, which was always warm, in the central bed of a span-roofed

this treatment, as I expected it would do, grew more vigorously than ever, till at last we were compelled to remove it altogether. For a little while we kept it in a somewhat lower temperature, but it quickly showed signs of suffering through the change. The *Stevensonia* is a grand Palm for a hot, moist stove where there is sufficient room for its perfect development. It does not succeed in a house that is often lower than 60°; on the contrary, coming as it does from the Seychelle Islands, it requires a high temperature in which to grow it successfully. Want of warmth has doubtless caused the premature death of many a

Stevensonia grandifolia.

stove, the temperature of which hardly ever dropped lower than 60° during the winter months. In the summer time the temperature was kept somewhat high, in order to suit a general collection of fine foliaged plants that required a warm, moist atmosphere. In this position, and under these circumstances, the *Stevensonia* succeeded most satisfactorily, having foliage nearly as long, but broader than that of those under Mr. Smith's charge, viz., "a height of 8 feet and a breadth of 4 feet." As the specimen in question attained nearly these dimensions, we were obliged to lower it into the tank in order to keep the glass from injuring the leaves. At first it was kept just clear of the water, but later on we dropped it about 6 inches into the water, which generally stood at about 85° or 90°. To my surprise, the plant, instead of suffering from

goodly plant of this species. *Verschaffeltia splendida* and *V. melanochætes*, from the same regions, are also similar in habit and character, but rather more disposed to become elongated in the stem. *Areca nobilis* (*Oncosperma Van Houtteana*), also from the Seychelles, is another Palm that is best grown in a high temperature. It makes a beautiful dinner-table plant, but for reasons just given it should be used with caution. We always found these Palms to succeed best when grown in nearly all peat; their roots, being more hard and wiry than those of many other kinds, causes them (at least so we found it) to take more kindly to peat than to loam. Red spider is troublesome to them, so also is a small kind of scale, but frequent applications of the syringe and sponging the foliage with an insecticide will destroy these troublesome

pests. Avoid overpotting at all times, relying rather on artificial stimulants to keep the plants in vigour; always water freely, and never allow them to become dry at the root.

Gunnorsbury House.

JAMES HUDSON.

ORCHIDS.

CALANTHES AND THEIR CULTURE.

READING the remarks of your correspondents as to the length of spikes and number of flowers on their *Calanthes* has induced me to furnish you with some brief details of *Calanthes* grown by me at Castle Hill, Devon. The variety to which I allude is *Calanthe Veitchi*, which has just finished flowering. Two bulbs were potted in a 6 inch pot, the largest measuring as follows last January: Length of bulb 14 inches, circumference at its base 9½ inches, length of spike from the bulb to the terminal point 4 feet 9 inches, number of flowers over fifty and large in size. Many authorities who have seen my plants last season have pronounced them as not an every-day occurrence as regards culture. But few Orchids equal *Calanthes* as decorative plants, and none surpass them for room embellishment during the four dull winter months, every point being taken into consideration. Indoors *Calanthes* can be used and arranged in many different and effective ways. The spikes are so flexible, they may be trained and twisted in different ways to suit positions, either vertical, horizontal, or drooping. In a group by themselves they are effective and last for a long time. They may be mixed with other flowers. *Calanthes*, being deciduous, or almost so, require while flowering other things to hide their fading leaves, and also to furnish them with foliage and colour. Ivies in small pots, with their green, silver, and golden leaves, together with *Panicum variegatum* and *Tradescantias* artistically twisted round the stakes to hide them are very effective. For places at long distances off, or where it is inconvenient to change these plants, often combinations of this kind are invaluable. *Calanthes* are also equally useful in a cut state; their long graceful spikes look at all times conspicuous in promiscuous groups of cut flowers.

Resting the bulbs.—This is very important as regards the successful culture of these plants. During this period the flower-spikes are forming. As soon as the bulbs have ceased flowering they should be stored on a dry shelf and kept perfectly dry until repotted. The bulbs ought to be kept in a stove temperature during the resting period, and not in an intermediate house, so often and erroneously recommended. The soil which we find best is good friable loam a little decomposed with the fibre intact. About four-fifths of loam to one-fifth of fibrous peat, leaf mould, and silver sand will be found to answer.

Potting.—There are two ways of potting the bulbs of *Calanthes*; one is to elevate them above the rim, the other to place the bulbs below it. Of the two ways the latter is the best and preferable. As regards potting, I use the soil in good condition—neither too wet nor too dry. Make it very firm before the bulbs are placed in it, and pot them so that they do not get loose; the pots should be well drained, but unnecessary crocks only fill up the pots and yield no nutriment to the plants. About 1 inch of crocks is sufficient for all purposes, and over them place a little dry Moss. After potting only give sufficient water to keep the soil moist, for if over-watered at first the soil becomes soured, and unhealthy growth is the result. When this happens the young shoots show a yellow spotted appearance. Drought, too, is equally detrimental, for if the soil becomes baked water runs through it without moistening it. After the roots get to the sides of the pots water may be given more liberally, and after the young bulbs have grown to half their size water copiously, as *Calanthes* at this stage want a good deal of water. Any quantity of liquid manure judiciously applied at proper seasons may also be given, but not until

the roots have got to the sides of the pots, and then it should only be administered in a weak state at first, gradually increasing it in strength until the pots are full of roots. When the young bulbs are half their size and the plants are inured to it, it may be given very strong with safety. It is best to continue its use during the whole season at intervals of, say, twice or thrice a week until the first flowers begin to expand. Sheep's manure diluted is one of the best for these plants, and cow manure is also good.

Temperature.—The East India house or hot stove is the proper place in which to grow *Calanthes*, as they delight in a high temperature. During the latter part of the summer and autumn keep the maximum day temperature at from 80° to 90°, and make it a rule to close early, when the temperature may reach from 95° to 100° for a short time after closing with adequate dampings. Under this treatment large bulbs will be produced, and consequently large flower-spikes. A shelf about from 1 foot to 18 inches from the roof where they can get abundance of light is the best situation for them. A three-quarter span-roof suits them admirably, i.e., if they can be placed on a shelf on the back wall, but any other position will answer, provided they are exposed to plenty of light and kept close to the glass.

Propagation.—*C. Veitchi* is readily increased; a strong bulb generally makes two side bulbs every season. After these are somewhat advanced and the bulb well established, the old bulb may be cut in two in the centre. The top half, if placed in a little good sandy soil and kept close for a few weeks, readily makes a nice bulb for the following year's flowering. I started seven or eight years ago with a few bulbs, and now I find that they number 190, counting all sizes.

D. WILSON.

PHALÆNOPSIS SANDERIANA.

WE saw the other day in Sir Nathaniel Rothschild's garden at Tring Park a flowering plant of this new Orchid, which promises to rival even the loveliest in the genus. The plant in question represents a much finer variety than that described at p. 255, which was the first produced in cultivation, and also flowered in this garden. The plant now in bloom has four flowers on a spike, each 3 inches in diameter. The two lateral petals are 1½ inches in width, rounded in form, and together with the sepals make a symmetrical, well-formed flower. The labellum resembles that of *P. amabilis*, but has more colour. The side wings are highly coloured with yellow, and in the interior are copious spots and freckles of crimson. The colour of the sepals and petals constitutes, however, its most beautiful and distinctive feature. This is a delicate mauve-purple such as no other *Phalænopsis* flower possesses. The foliage is apparently midway between that of *P. amabilis* and *P. Schilleriana*, being slightly mottled and having a purplish metallic lustre. The roots, moreover, are round, not flat as in *Schilleriana*. It is, in short, a lovely plant and a valuable addition to cultivated Orchids. It is grown successfully by Mr. Hill in company with the general collection of *Phalænopsis* in a small span-roofed house, specially set apart for the genus, and constructed with a view to the requirements of the plants. The stages are high, so as to bring the plants close under the roof, and they are covered with crushed flint, which looks neat and cleanly, and retains an abundance of moisture which is continually, but slowly given off. The house is provided with means for heating the spaces beneath the stages, and ample provision is made for ventilating, the importance of which in *Phalænopsis* culture is fully recognised here. Besides the ventilation in the ridge of the roof there are ventilators both at the back and front, in both cases arranged so that the inrush of air passes over the hot-water pipes. The outside air is admitted as much as the weather will permit, and to this free ventilation is ascribed the vigorous constitution of the plants. The majority are grown on wood cylinders 1 foot or 1½ feet in height, constructed of strips of Teak

wood. Near the base of the cylinders are cross strips in order to prevent the crocks and soil from falling out. The cylinders are filled with broken crocks and charcoal for a good depth, on which is placed a mixture of *Sphagnum Moss* and fibry peat placed around the plants. Under this treatment they luxuriate, as may be seen by the long healthy roots thrown out in all directions, and which cling firmly to the wood of the cylinder and even try to reach the moist gravel on the stage. The collection of *Phalænopsis* comprises some fine specimens of *Schilleriana*, a great favourite here; *P. amabilis* and *P. grandiflora*, together with such rarities as *P. intermedia Portei* (of which there is a luxuriant plant with five fine leaves), *P. Reichenbachiana*, *P. Stuartiana*, and *P. leucorrhoda*. There is also a plant of *P. Schilleriana* with leaves 17 inches in length, and one of *P. grandiflora* in bloom with flowers 3½ inches across and petals 1½ inches wide, forming one of the most perfectly formed blossoms we have ever seen.

W. G.

LONGEVITY OF ODONTOGLOSSUM CRISPUM.

REFERENCE is made to this species in *THE GARDEN* (p. 246), and it is there supposed that the imported plants do not retain their vigour for many years; in fact that they dwindle away, and that the stock of them has to be kept up by fresh importations. I do not think there is any reason to suppose that this is the case. Mr. Stevens, of Trentham, and some others could, I think, tell another tale. Our own collection is not a large one, but it is upwards of twelve years since the first of its contents was purchased, and I am not aware that we have lost a single plant during the whole of that period. The plants do not make more than one growth in a year, but I have not observed that they decline in vigour. Indeed, we have now an example in flower, one of the plants first introduced, and it formed a larger bulb last year than any it had previously made, while on the vigorous branched spike there are forty-four flowers open, the largest number we have ever had an one spike. I fancy some growers err in using too much peat in the compost, and eager to form large specimens quickly; the plants are also over-potted. The compost I use has been frequently described in *THE GARDEN*. It consists of peat, *Sphagnum*, and clean broken potsherds in about equal parts. Imported plants ought to be placed in as small pots as will fit the base of the bulbs, and the potting material should be well pressed round them; they will not require repotting for less than twelve or eighteen months, and then only a small shift is necessary. If the old compost is decayed it ought to be removed at the time of potting. Under ordinary treatment they will succeed well for many years, and the sure road to attain success is by taking care that the roots are kept healthy by not allowing any decayed compost to come into contact with them for a long period. When any plants show signs of waning vigour it may be necessary to shake the whole of the compost from the roots and wash them with clean tepid rain water, repotting again in clean compost and in smaller pots.

J. DOUGLAS.

The *Phalænopsis* house in Messrs. Low's nursery at Clapton is now and has been for several weeks past a most beautiful sight, such as one seldom sees; indeed, it is doubtful if any parallel exists, for nowhere are *Phalænopsis* grown in such enormous quantities as here. The house, a capacious span-roofed structure, contains thousands of plants, the majority of which are in bloom, forming a lovely floral display. The plants are all grown in square wood baskets placed on high flat stages, and looking over these one sees a perfect thicket of flower-spikes, as graceful in growth as they are lovely in colour. The bulk of the collection consists of *P. Schilleriana* and *P. amabilis*, but there are many of the choicest rarities besides. Of the two named, every conceivable variation may be seen from ordinary forms to those remarkable for large size and flower, and, in the case of *P. Schilleriana*, for depth and richness of tint. Ever since last November

this house has been gay with bloom, but the fogs did much injury to the spikes; in fact cut them in two in many instances. Those spikes, however, that were cut off have since broken again from below the injured part, and these secondary spikes are carrying a good many flowers of uncommonly high quality, large in size, and of firm texture, a circumstance no doubt attributable to a purer atmosphere at this season, and sun, light, and heat. In several instances Mr. Casey informed us he purposely cut back the primary flower-spike in order to induce it to break later in the season, and the experiment has been successful, for every spike so shortened produced a secondary spike much finer than the first one would have been if allowed to develop so early in the fog season. This hint is well worth taking a note of by cultivators of *Phalenopsis*, particularly if they are situated within the precincts of foggy London or any other great town. *P. amabilis* has chiefly been the object of these experiments.

Odontoglossum Halli.—Mr. Satow, of Stamford Hill, a successful cultivator of *Phalenopsis* and *Odontoglossums*, has at present in flower an uncommonly fine example of *O. Halli*. It bears a spike carrying no fewer than twenty-nine blooms, representing one of the finest forms of this handsome species.

Dendrobium Wardianum.—We have received some very large flowers of this Orchid from Mrs. Freeman's garden at Thirleston Hall, Obeltenham. They measure fully $4\frac{1}{2}$ inches across the sepals, which, with the labellum, are $1\frac{1}{2}$ inches wide. Each segment of the flower is tipped with a deep rich magenta-purple. The flowers were cut from a plant imported some few months ago. If it will in future yield such fine flowers, it will be a valuable variety.

Pruning Orchids.—By way of fulfilling a promise, I herewith send you two bulbs in flower of *Dendrobium Wardianum*, the larger bearing thirty-seven flowers and the lesser one twenty-nine. They are from the pruned plant several times referred to in THE GARDEN, and there are six proportionately well-flowered bulbs left. I have sent you only the flowering portion of the bulbs. I may just note here that the maximum number of flowers on a bulb, as given by Mr. Spysers, who has discussed this matter with me, is thirty. On our pruned plant the number of flowers on the eight bulbs is respectively 37, 29, 25, 18, 15, 13, and 6, and the plant is quite young.—J. S. W. [Two glorious spikes fully bearing out all "J. S. W." has said in reference to pruned Orchids.]

Odontoglossum Edwardi.—A flowering spray of this somewhat new and little-known Orchid, from Mr. Peacock's garden, Sudbury House, Hammersmith, shows admirably what a lovely plant it is when well grown. The flowers are not large, but they are produced in such numbers on a tall branching spike that deficiency in size is amply compensated. The colour of the blooms (which are about an inch across) is a cheerful violet colour, which, with the golden crest on the labellum, is highly attractive. The flowers emit a delightful fragrance akin to that of *Mignonette*, which is a most desirable property. It is grown at Sudbury House in a rather cool and moist house. It is a native of Ecuador, and was discovered by the brothers Klapprodt, after one of whom it was named by Prof. Reichenbach.

Odontoglossum mulus.—Of this Orchid we saw the other day a cut spike at Stevens' Rooms which is the finest specimen of it that we have yet seen. It came from Mr. Lee's garden at Downside, Leatherhead. The spike was $2\frac{1}{2}$ feet high, and had four branches spreading for about 2 feet at almost right angles. There were thirty-six flowers on the spike, each of which was 3 inches across; the sepals and petals were a primrose-yellow, heavily blotched with chestnut-brown, while the labellum was of a lighter shade, also deeply spotted with reddish brown. Such a huge and gracefully arching spike as this was highly attractive, for rarely has the variety been seen to such perfection, and it shows how finely Orchids

are grown by Mr. Lee's gardener. Though named *O. mulus*, this plant does not agree with what we had previously known under that name, and if anything was handsomer. Be the name what it may, the Orchid is one of the finest of its class.

Among Dendrobium flowers received from Mr. Peacock are excellent specimens of the pretty *D. litiflorum* and its variety *Freemanni*, both of which must be ranked among the choicest *Dendrobiums*. They are very similar in flower, but quite distinct in growth. The original has slender, pendulous growths, while that of *Freemanni* variety is stouter and erect. Both flowers have the cornet-shaped lip characteristic of the species, and are some 3 inches or 4 inches across, and of a deep rosy lilac and a deep violet labellum edged with white. It is more brilliant than the well-known *D. nobile*, and quite as easily grown. Some splendid forms of *D. Wardianum*, *crassinode*, and other species indicate that Mr. Peacock appreciates the finest varieties.

Sale of Orchids.—On Wednesday last the collection of Orchids belonging to the late Mr. Dodgson, Beardwood, Blackburn, was sold at Stevens'. There were in all 385 lots, which realised about £1970. Some extraordinary prices were given for a few of the greatest rarities; for example, Mr. B. S. Williams bought *Cattleya Trianae Osmani*—a splendid variety—for 215 guineas. It was a fine specimen, in good health, and is unquestionably one of the finest of all *Cattleyas*. This was the highest amount ever paid for an Orchid at an auction. For the fine original plant of *C. Trianae Dodgsoni*, also a magnificent variety, Mr. Lee, of Downside, Leatherhead, paid 185 guineas. Others bringing high prices were *Dendrobium Griffithianum*, 15 guineas; *D. Ainsworthii*, 66 guineas; *Lelia anceps Dawsoni*, 82 guineas; *Cattleya exoniensis*, 56 guineas; *Odontoglossum pulchellum majus*, 20 guineas; *O. radiatum*, 12½ guineas; *O. triumphans*, 11½ guineas; *Vanda tricolor Dodgsoni*, 20 guineas; *Cattleya labiata pallida*, 19 gns.; *C. Warneri*, 10½ guineas; *Cypripedium superbiens*, 10½ guineas; *C. Stonei*, 17 guineas; *C. Harrisianum*, 10 guineas; and *Calanthe veratrifolia*, 10½ guineas. The collection was, on the whole, in excellent condition, particularly the cool Orchids, such as *Masdevallias*.

NOTES OF THE WEEK.

APPOINTMENTS FOR THE WEEK.

April 10.—South Kensington: Meetings of the Scientific Floral and Fruit Committees of the Royal Horticultural Society, and spring show.

EXHIBITION AT ST. PETERSBURG.—We learn that the International Horticultural Exhibition which was to have been held in St. Petersburg during the ensuing May is postponed until next year.

SALE OF FLOWERS IN PARIS.—It is estimated that the daily sale of flowers in Paris realises some £4000. The flowers most in fashion at present are the *Gardenia*, which sells at 4s. each flower; the *Lily of the Valley*, worth 8s. the pot; the queen *Rose* and the purple *Rose*, the Spanish *Carnation* and the *Violet*. Of the latter a large quantity comes from Nice, but they have not the perfume of those grown round Paris. The *Camellia*, at one time so much prized, is now out of fashion.

A SALE of Orchids, Ferns, stove and greenhouse shrubs, decorative plants, &c., is announced to take place at Mount Annville Park, near Dublin, on April 23 and following days. Among noteworthy plants are two very fine *Lapagerias*, red and white *Beaucarnea recurvata*, *Eucharis*, and *Pancratiums*, large and fine, so also *Dracenas* and other choice foliage shrubs. Catalogues may be had on application to Mr. Fisher, the gardener, who, we hope, may soon meet with another suitable appointment. Mr. Fisher was some years at Drumlanrig as foreman, and served the late Lord Ilaldon as head gardener. We are quite sure so good a gardener will not long await the superintendence of a good garden.

REAFFORESTING IRELAND.—On Friday last a beginning as regards this matter was made by planting at Glencolumbkille, Donegal, some hundreds of thousands of trees, part of gifts kindly placed at Dr. Lyons' disposal by Scottish, English, and some Irish foresters. It is but a small effort in a gigantic enterprise, but it is a step in a direction which is daily being more and more recognised in its wide importance for the future of Ireland. Large scopes of land are, we hear, being placed at Dr. Lyons' disposal in various parts of Ireland, and we cannot doubt that the work will continue to progress.

STOVE AND GREENHOUSE FLOWERING PLANTS.—We have received the third edition of this book by Mr. B. S. Williams, Victoria Nursery, Upper Holloway. Its present form has been considerably enlarged and revised, and contains descriptions of 1300 species and varieties of plants, with notes on their culture, propagation, &c. It is illustrated by no fewer than fifty woodcuts—a valuable addition. Mr. Williams is so well known to be an excellent cultivator, that his instructions may be implicitly followed, and therefore his book should be in the hands of every young gardener in the country. The enumeration of choice plants is brought down to the present date, and the book altogether deserves unequalled praise.

NEW PALACE AT BATTERSEA.—This is to be erected in the Battersea Park Road by the Albert Exhibition Company, of which the Duke of Teck is president. It is proposed to erect something like a smaller Crystal Palace, 477 feet long and 100 feet broad, a large portion of the material for which has already arrived in this country from Dublin. The company have also purchased the Leinster Hall, and this is to be re-erected as an annexe for concerts and lectures. It is intended to hold industrial and other exhibitions in the palace. The building will not, it is said, be opened on Sundays, and it is to be closed at ten o'clock each evening. The company hold the ground from Her Majesty's Office of Works on a lease for 999 years.

TEA GROWING IN RUSSIA.—The Free Economic Society of St. Petersburg warmly advocates the cultivation of the Tea plant in the Caucasus. At Soukhoun, it appears, some Tea is already raised in the open air, notably in the botanic garden and in a garden belonging to a private gentleman. The experiment so far has proved successful, and the Economic Society thinks that in time Russia should compete with China and India in supplying the western nations with Tea. In the western parts of Trans-Caucasia the climate is said to resemble very much that of China. The *Noroe Vremya* newspaper, in referring to the subject, recommends the encouragement of Chinese immigration into the Caucasus to meet the demand for the necessary skilled labour.

NATIONAL DAHLIA SHOW.—The treasurer's report for last year, just sent to us, is as follows: Considering the number of years during which Metropolitan Dahlia shows had been in abeyance, the effort of 1882 may be regarded as fairly successful, though the subscriptions, aided by the Crystal Palace contribution of £50, did not quite cover the amount of prize money awarded. The object of the promoters was to secure a grand show, and, with this object, prizes amounting to £128 10s. were offered, of which sum £117 were awarded. The total amount of the fund raised was £123 12s. 6d., namely, by subscriptions £73 12s. 6d., and by contribution from the Crystal Palace Company, £50. After paying the various expenses incidental to the show, amounting to £13 13s. 6d., there was found to be a deficit of £7 1s., which was divided proportionally between the two largest prize-takers, Mr. Turner and Messrs. Keynes, and deducted from the amounts paid to them respectively, Mr. Turner losing £4 8s. 8d. and Messrs. Keynes £2 12s. 4d. It is to be hoped, therefore, that in future the funds provided shall be ample for the purpose, so as to relieve the executive officers from the unpleasant task of offering to the winners apologies instead of prizes. It is also further to be hoped that amateurs will more generally

take part in the competition under the several classes provided for them. The Crystal Palace Company, we learn, will provide, as before, a sum of £50 towards the prize fund. It has, therefore, been determined to hold a Dahlia show this year at the Palace on August 31 and following day on a scale at least equal to that of last year, and contributions in aid of the same are requested to be sent to Mr. Thos. Moore, Botanic Garden, Chelsea, London, S.W., from whom schedules of prizes may shortly be had.

EXHIBITION OF FOREST PRODUCTS IN EDINBURGH.—At a meeting held on the 29th ult., under the presidency of the Marquis of Lothian, it was resolved that an international exhibition of forest products and other objects of interest connected with forestry should be held in Edinburgh during the year 1884. Mr. Hutchison, of Carlisle, who had called the meeting, stated that such an exhibition would be important, not only in its relation to the question of arboriculture in this country and the colonies, but also to the proposed establishment of a National School of Forestry in Scotland. He also stated that the year 1884 in Edinburgh would otherwise be memorable as being the tercentenary of the University, the centenary of the Highland and Agricultural Society, and the thirtieth anniversary of the Scottish Arboricultural Society.

"THE FOREST FLORA OF SOUTH AUSTRALIA," by Mr. J. E. Brown, Government Conservator of Forests for that colony, promises to be a noble work. In the first part, just received, the following trees are described and figured in colour, viz., *Eucalyptus Gunni* and *E. obliqua*, *Banksia ornata* and *B. marginata*, and *Casuarina quadrivalvis*. The author's object is evidently to make the work a popular and useful one, and to form a collection of illustrations of the principal arboreal plants of that portion of the Australian continent. The names of the plants are adopted from the "*Flora Australiensis*." Even to European horticulturists the work is full of interest, describing and illustrating, as it does, many of our garden plants. For instance, the *Banksias* just named were once familiar objects in botanical gardens. The plates are excellent, nature-like, and artistic, and show that the art of colour printing at the Antipodes is not behind that in Europe. The paper and type too are good; we are pleased to note also that a popular name accompanies each plant described. For example, the *Banksias* are called Honeysuckle trees, *Casuarina* the Sheoak, and the *Eucalyptus* the Gum tree. It is published in Adelaide.

PHYLOXERA IN FRENCH VINEYARDS.—At a recent meeting of the committee appointed by the Minister of Agriculture to report upon the condition of the French vineyards, M. Tisserand, the Director of Agriculture, gave some interesting information as to the ravages of the *Phylloxera* up to the present time. It would appear that nearly two million acres of Vines have been destroyed, and that 1,500,000 acres more have been attacked, and are more or less affected in their yield. About 50,000 acres have within the last year or two been replanted, and the young Vines dosed with sulphate of carbon, while 30,000 acres newly planted have been protected by submersion; 40,000 acres more have been planted with American Vines, but though there has within the last year or so been a slight increase in the area of newly-planted vineyards, the total is very trifling compared to what has been destroyed. M. Tisserand mentions, however, as an encouraging circumstance that vine-growers are forming many associations for the purpose of conducting experiments as to the best mode of combating the *Phylloxera*; that these associations now have 12,338 members, and that they received last year subsidies amounting to £13,000 from the Government. The committee has decided that no remedy has yet been discovered entitling the inventor to the premium of £12,000 offered by the Government some years ago, but recommends the use of sulpho-carbonates and the submersion of the Vines as palliatives of the disease. The cultivation of the American Vine is authorised in twenty-three arrondissements, and it

was mentioned incidentally in the course of the meeting that seventeen fresh districts were invaded last year. The committee has prepared a Bill which will be introduced into the Chambers this session for guarding against the invasion of the Algerian Vines by the dreaded insect.

AUSTRALASIAN FRUITS.—In the neighbourhood of Sydney such fruits as the Peach, Nectarine, Apricot, Plum, Fig, Grape, Cherry, and Orange are as plentiful as Blackberries. The orange-trees and orchards of New South Wales are among its sights; and in the neighbourhood of Sydney and round Port Jackson there are beautiful groves of Orange trees, which extend in some places down to the water's edge. Individual settlers have groves which yield as many as 30,000 dozen Oranges per annum. One may there literally "sit under his own Vine and Fig tree." If a Peach stone is thrown down in almost any part of Australia where there is a little moisture, a tree will spring up, which in a few years will yield handsomely. A well-known botanist used formerly to carry with him, during extensive travels, a small bag of Peach stones to plant in suitable places, and many a wandering settler has blessed him since. Pigs were formerly often fed on Peaches, as was done in California, a country much resembling Southern Australia; it is only of late years they have been utilised in both places by drying or otherwise preserving. A basket-load may be obtained in the Sydney markets during the season for a few pence. The summer heat of Sydney is about that of Naples, while its winter corresponds with that of Sicily.

QUESTIONS

Roses.—Will some of the readers of THE GARDEN kindly inform me if there is a Rose called Nelly Curtis.—W.

Rabbits and Berberis japonica.—Would some of your readers be so kind as to say if rabbits eat this *Berberis*?—H. F. C.

Gun licences.—Can any of your readers inform me if it is necessary to take a gun licence in order to enable me to kill vermin in my employer's garden?—SUBSCRIBER.

Slag sand.—Will "R. C." kindly inform me of whom this can be purchased, and whether or not he is of opinion that it is superior to Cocoa-nut fibre for hot-house staging?—EDWIN LUCKRAFT, Mannamed, Plymouth.

Pipes for heating.—I should be glad if any of your readers who have used the downcast pipes and spouting for heating a greenhouse will give me their experience of the result, as I think of trying them.—W. G. L.

Fire balls.—Will anyone kindly state how these balls, composed of oil and anthracite dust mixed with clay, are made? what are the proportions used? and could coke dust be used instead of anthracite dust?—K.

—Would "W. C. T." kindly say where the Pembroke shire fire balls, which he recommends, are to be procured? I, for one, and I am sure many others of your readers would be glad to try them if we knew where to get them.—M. D.

Anthurium Warocqueanum.—I have a very good plant of this with seven fine leaves, but the plant has grown up high and I wish to cut down. Can I do so safely in a small, well-treated propagating house if shaded? It has already in the Sphagnum up the stem made some good roots.—H. H. C.

Decaying Willow.—I have a very old curled-leaved Willow in the garden here beginning to decay, and my employer is anxious to keep it alive as long as possible. I shall be glad if any of your readers will state their views on the matter, and also tell me how to propagate it; cuttings of it have been rooted, but they all go off in the second year.—T. P., Newark.

Lilies of the Valley not flowering.—Will some of your correspondents kindly tell me the reason why my Lilies of the Valley never produce blooms? They have been in a south border for a number of years, and the year previous to last we lifted all the crowns, gave the ground a good coat of manure, and replanted them, but we experienced the same result, namely, all leaves and no flowers. I lifted a quantity of them this year and forced them, but we only had two spikes on each plant, although plants received from the nursery grounds about the same size averaged from twenty to thirty spikes on a plant. Under a south wall we have more Lilies which flower fairly well, though precisely in the same kind of soil, which is black and rather heavy.—E. N. T.

PLANT ADAPTATIONS.

THE Rev. Prof. Henslow delivered the other evening a lecture before the members of the Ealing Gardeners' Society, entitled "*Plant Adaptations: Climbing, Propagation, Defence*," of which the following is an abridged report. The chair was occupied by Mr. R. Dean, one of the vice-presidents of the society, and there was a numerous attendance, especially of gardeners.

The Rev. G. Henslow commenced his lecture by calling attention to the infinite variety of forms of foliage, flowers, fruit, and stems prevailing in the vegetable kingdom. Nevertheless on a closer inspection, plants were found capable of being divided into groups which had various characters in common; hence, botanists could classify plants into families, genera, and species. The question then arose as to whether such had ever been the same since each came into existence, or had this diversity come about by some innate powers of adaptation impressed upon plants by the Creator, so that in successive generation the offspring had become more and more altered in form, and better adapted to the ever changing conditions about them. The lecturer said that the probability of the latter having been the case was so great, that the opposite view was now quite unthinkable by anyone who could appreciate the many lines of evidence in favour of what is called evolution. The object of the present lecture was to show one particular, though indirect, phase of that evidence, namely, the adaptability exhibited by the various organs of plants to acquire different functions, and then to assume different forms from what might be called the normal ones. Cases of interchange of functions are so numerous in plants, that all he proposed doing was to select one or two for each kind of organ. The word "member" is used to signify any member or part of a plant which has some special function or work to do; and all the organs can be grouped as stem-structures and leaf-structures; the former embracing roots, stems, branches, flowering stem, &c.; the latter are leaf and bud scales, true leaves, stipules, bracts, and the parts of flowers. Commencing with

The root, its normal function is to absorb mineral food, such as water with various salts dissolved in it, for the use of the plant, while the stem has to convey such crude sap up to the leaves, there to undergo certain chemical processes, which convert it into elaborated sap, out of which, like blood in an animal, the plant is nourished and grows. Roots, however, were often used by plants as reservoirs of nourishment, as in *Dahlia*, *Beet*, &c., while in *Ivy* and *Orchids* they are converted into climbing processes. Stems also could be utilised as reservoirs of nutriment, as in the *Flag* and *Sago Palm*, and often as a propagation organ as well, as in the *Potato* and *Crocus*. Another power added to many was that of climbing, as in such stem twiners as the *Convolvulus* and *Honeysuckle*; or, again the flowering branch might become a tendril, as in the *Virginian Creeper* and *Vine*. Once more, branches may be flattened out so as to resemble and to take on all the proper functions of leaves. Coming to

Foliar organs, leaf-scales, or underground stems, were of two kinds—protective, as in the *Lily* of the Valley, or as reservoirs of nutriment, as in bulbs. In both cases they constituted the base of a leaf, only on its leaf-stalk. Similarly, bud scales, which protected the delicate unformed leaves in winter, might be leaf-stalks, blades, or stipules. The typical leaf consists of stalk and blade, and either part might be modified to acquire new functions. Thus the former might become a phyllode, as in the Australian *Acacias*, or spine, as in the *Gum Tragacanth* plant or a tendril. The blade, too, may become a tendril, a pitcher or other contrivance for catching insects, or a spine, or become a propagative organ, as in *Ferns* and *Bryophyllum*, &c. Bracts are rudimentary leaves, found associated with flowers. They are either the entire leaf reduced in size, or else the blade or petiole. Being often brightly coloured, they then acquire the attractive functions of petals to invite insects to effect fertilisation of

flowers. Stipules, which often accompany leaves might be leaf-like, as in the Pea; or become bud-scales, as in the Lime or Elm; spines, as in the Acacia, or tendrils, as in the Sarsaparilla. Lastly, all these

Parts of a flower were modified leaves; in fact, they often did grow out as leaves, as in the green Rose, thus proving their origin; while each of the four floral whorls or calyx, corolla, stamens, and pistil, could more or less assume the character and functions of any other. A most important case of such to gardeners was the production of double flowers. This is arrived at by the conversion of stamens and carpels into petals, and the gardener must look out for any tendency to change which the plant may exhibit, and then propagate from that flower. From the few instances given in the lecture, and very many more might have been adduced, Prof. Henslow hoped he had satisfied his hearers in showing how the organs of a plant could, under certain circumstances, first acquire other properties, and, second, change their form in accordance with the new acquirements of their descendants. In conclusion, he could now return to his starting point, and say it was upon such like evidence that the process of evolution was believed to have been the method which the Deity had followed in peopling the world with an ever varying succession of animal and vegetable forms.

At the close of the lecture, a hearty vote of thanks was given to Prof. Henslow, and in response to a suggestion made by the chairman he expressed his willingness to continue the subject on some future occasion.

SOCIETIES.

EXHIBITION OF SPRING FLOWERS IN PARIS.

THE National and Central Horticultural Society of France opened its second exhibition of spring flowers on Wednesday last, March 28, in the Municipal Pavilion of the City of Paris, close to the Palais de l'Industrie, in the Champs Elysées, a building admirably adapted for such a purpose, and where the many beautiful exhibits were seen to the very best advantage.

This exhibition is in every way far in advance of last year's show, held by the Society in its own premises, No. 84, Rue de Grenelle, St. Honoré, which proved quite inadequate for the proper display of the exhibits or for the fitting accommodation of the numbers of the public who came to see them. The principal features of the exhibition were undoubtedly the fine beds of Indian Azaleas (in pots plunged to the rim so as to be invisible), and shown in nice medium-sized, naturally-grown plants, which are at all times so infinitely preferable to the stiff, unnaturally trained, pyramidal cones usually seen at our principal exhibitions in London and elsewhere in England. The newer varieties of these beautiful flowers were represented by nicely bloomed small plants of the following hybrid seedlings, Antigone, Elise Liebe, Docteur de Mil, Phœbus, Conte Charles de Kerchove, J. E. Planchon. Lovers of these plants will find well executed coloured portraits of most of these fine varieties in M. A. Van Geert's "Iconographie des Azalées d'Inde," a work of which the cessation, on completion of the first volume, is to be regretted. Unnamed seedling Cinerarias of an exceptionally fine strain and good dwarf habit of growth were shown in great perfection, filling several large beds most effectively arranged as to colour by the well-known firm of Vilmorin-Andrieux & Co., of Paris, and a specially interesting and effective bed was filled with fine, well bloomed specimens of some twenty seedling varieties of that handsome and free blooming Amaryllid, *Imantophyllum miniatum*, raised and sent out by M. L. Duval, of Versailles. To this collection the jury awarded a large silver medal. Orchids were represented by a small stand of some twenty-four well-bloomed plants, consisting principally of *Phalænopsis Schilleriana*, *P. amabilis*, and *P. grandiflora aurea*, *Miltonia cu-*

neata, *Dendrobium chrysotoxum*, &c., sent by M. Alfred Bleu. One of the large beds was most effectively filled with well-bloomed and neatly grown bushes of different varieties of *Azalea mollis* and the pretty little rose-coloured *A. amœna*, varied with *Andromeda japonica*, *Skimmia fragrans*, *Magnolia Halleana* and *Lennei hybrida*, and edged with small plants of different kinds of gold and silver variegated *Euonymus*, forming altogether a very handsome bed. Fruit was represented by two banks of well-berried forced Strawberries of the varieties *Marguerite Lebreton* and *Dr. Morere*, which on the Moss with which the bank in which they were plunged was covered looked very well. They were backed by some half-dozen finely-fruited specimens of Pine-apple. Some very fine unnamed seedling Pansies with blooms of great size were shown by M. Falaise, of Billancourt, which on the plants as they grew plunged in a bed had a very pleasing effect. A very pretty bank near the entrance was composed of some fifty well-bloomed plants of the charming sweet-scented hardy shrub *Choisya ternata*, which exhaled its delicious Hawthorn-like perfume all around it, and showed how well adapted this free-blooming shrub is for forcing for the decoration of drawing-room stands or the early greenhouse. These plants were sent by M. Vyeux-Duvaux. Two well-bloomed and good-sized specimens in pots of the curious and still scarce hardy South American flowering shrub *Neviusia alabamensis*, or the Snow-wreath of Alabama, the blooms of which resemble those of Myrtle, whose petals have been removed (as they consist entirely of bunches of whitish stamens enclosed in a green calyx), and which is only found wild in a single locality even in its native state, were among the most interesting exhibits at the show, as this is probably the first occasion on which this rare American shrub has been publicly exhibited in Europe. Two large bedsful of rather indifferently-bloomed Roses in pots were sent by Messrs. Levêque, of Ivry, but not for competition. Hyacinths were well shown plunged in raised tier beds by Messrs. Vilmorin-Andrieux & Co. and Messrs. Dupanloup, of Paris. Several large beds were also well filled with forced hybrid *Rhododendra* and well berried bushes of *Aucuba japonica*. A very interesting collection of new hybrid varieties of Agave, many of them in bloom, was sent by M. E. Simon, of St. Omer, near Paris, being entirely of his own raising, and reflecting much credit on his powers as a hybridiser and successful cultivator of these curious plants. The most distinct and noticeable varieties in the collection were named *A. xylinaecaulis*, a cross between *A. arborescens* and *A. ferox*; *A. albo-cincta rosea*, a very handsome plant with a large branched bunch of pale-yellow flowers like those of a small *Blandfordia*; *A. spinosa*, a cross between *A. humilis* and *A. arborescens*; *A. flava* var. *longifolia*. All these plants were exceedingly well grown and in vigorous health, and were deservedly awarded a silver medal by the jury. An interesting and well-bloomed collection of hardy herbaceous and bulbous plants in pots plunged in tiers in a bank on one side of the entrance formed a pleasing feature of the show, and consisted of a fine double row of seedling double Wallflowers at the back with numerous plants of *Doronicum caucasicum*, *Anemone fulgens*, various varieties of Daffodils, various coloured Primroses, *Aubrietia*, *Iberis*, *Van Thol Tulips*, *Crocus*, &c., in front. These were sent by Messrs. Vilmorin-Andrieux & Co.

The exhibition was visited during the afternoon by Monsieur Jules Grévy, President of the French Republic, and suite, who were received by Monsieur Alphonse Lavallée, president of the society, and several other members of the council who accompanied him round the exhibition, with which he appeared to be much interested. The exhibition remained open till April 1 inclusive, and may in every respect be considered a credit to the society.

W. E. G.

Deadly effects of flue gases.—On the 6th of January, at Glossop, Derbyshire, two domestic servants retired to rest in their usual health. The next morning they were both found

dead. Medical evidence having been given at the inquest, the jury found that death was caused by asphyxia, produced by inhaling carbonic acid gas admitted into the sleeping apartment through defective joinings in the flue or chimney. Young gardeners whose lodgings are often near stoke-holes must take care that their sleeping apartments are free from this deadly gas.—C. W. T.

Lambeth Palace grounds.—The Archbishop of Canterbury received at Lambeth Palace last night a deputation from the Lambeth Vestry, to ask his Grace to open a part of the meadow grounds adjacent to the Palace, for the benefit of the poor of the immediate neighbourhood, so far as it could be done without interfering with the residential portion of the palace. Mr. George Howlett, who spoke on behalf of the deputation, read a correspondence on the subject with Mr. Gladstone, who replied to the effect that he thought it was a matter for the Metropolitan Board of Works, and that the Government could not interfere. Mr. Howlett pointed out that the vestry looked upon it as very important for the health and benefit of the large number of poor waifs and strays of the immediate neighbourhood that they should have ready access to the grounds. There was at present no public place for recreation for children. The views of the vestry had been supported by a large public meeting, attended by about 3000 persons. While admitting that the grounds were used by cricket clubs, volunteers, and schools, he contended that the advantage those classes might obtain thereby would be far outweighed if the grounds were thrown open entirely free to the public. The Archbishop then put a series of questions to Mr. Howlett as to the proceedings of the vestry, and elicited that the resolution of the vestry in favour of the objects of the deputation was only carried by twenty-four votes to seventeen, and that the Metropolitan Board of Works had not pledged themselves to maintain the grounds, even if they were secured to the public as the deputation desired. Referring to the question of the alienation of the grounds his Grace stated that, being simply a trustee for the See of Canterbury, he had no power whatever to alienate the grounds, even if it were desirable so to do. He could do nothing of that kind without the consent of the Ecclesiastical Commissioners. The question, he said, was how could the limited area of nine acres be best utilised? and it seemed to him that his predecessor had endeavoured to do the best he could for the good of the people, and he desired to follow in that direction.

OBITUARY.

MR. GEORGE SMITH, of the Tollington Nursery, Hornsey Road, died on the 26th ult. in his 71st year. He was well known as a raiser of many fine florists' flowers, especially zonal Pelargoniums and Fuchsias. The Pelargonium *Le Grand*, raised by him, was the forerunner of other fine sorts in that direction. He was an excellent judge of florists' flowers, and a man much esteemed by all who knew him.

Mrs. L.—A villa near Rome.

Royal Botanic Garden, Edinburgh (B.)—Appl. to Mr. Lindsay, the newly-appointed curator.

Tar varnish (*Subscriber*, p. 282).—Wash your hot-water pipes with spirits of turpentine.—K.

Names of plants.—*Amersham*.—The white flowered shrub is *Choisya ternata*, a native of Mexico. We do not name varieties of *Azalea*.—*A. E. C.*—*Dendrobium aggregatum majus*.—*Ovar*.—1, *Cypripedium longifolium*; 2, *Oncidium sarcodeis*; 3, *Epidendrum coelebatum*.—*Chambers*.—*Gomphrena globosa*.—*A. N.*—1, *Diosma ericoides*; 2, *Alonsoa incisa*.—*W. C. Walker*.—*Gongora portentosa*.—*J. Probert*.—*Santolina viridis*.—*R. D. Taylor*.—*Lopezia coronata*.—*A. C.*—*Vanda teres* variety. An appropriate name for which would be delicate, as the colour is so much lighter than that of the type.—*Fern*.—Next week.—*S. D. R.*—*Narcissus nannus*.—*H. A. Spurrell*.—*Narcissus nanus*, a variety of *N. minor* of Linnaeus.—*Young & Co.*—*Coltsfoot* (*Tussilago Farfara*

"This is an Art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

CARNATIONS AT TRING PARK.

THE Carnation is largely grown in Sir Nathaniel Rothschild's garden at Tring Park, where it is a great favourite. At the present time the perpetual or tree flowering class forms one of the attractions of the place; a capacious span-roofed house solely devoted to them is gay with bloom, and has been so since last September. Indeed, it is the aim here to have Carnation flowers the whole year round, the duller time being about August, after the border kinds are past and before the tree varieties come in. The house in question seems to have been specially planned for Carnation culture. It is span-roofed and admits abundance of light and air, two important points in the successful culture of these plants. A wide stage, high enough to hold the plants close up to the roof, occupies the centre, and similar wide stages run round the sides. These side stages are occupied by some few hundreds of plants of that fine variety *Souvenir de la Malmaison*, now commencing to flower, succeeding the general stock of tree sorts that have bloomed the winter through. The *Souvenirs* carry the flowering season on until blooms out-of-doors come in, and these flower from August to the end of September, thus completing the cycle. In order to keep up this succession Mr. Hill's plan is to strike the main bulk of the collection in February in heat; when well rooted, the young plants are gradually hardened off and kept in frames, potting them on until placed in the Carnation house in September for supplying the winter bloom. Some, however, are struck later than February in order to have a late successional crop to flower about this time and onwards for a few weeks until the *Souvenirs* are well in bloom. After the plants have done service for one season they are thrown away, except those required for stock. A similar systematic course of propagation and culture is carried on with the border kinds, planted on a warm south border, and mainly relied on for furnishing the summer supply of bloom. The border kinds include all sections, Cloves, selfs, and edged varieties, as well as Picotees.

The collection of perpetual flowering kinds comprises a choice selection of the very best sorts. At the head of the list must be placed a beautiful new kind which probably could be only found here at present. It is called *Valencia*. The flowers are large and full, deep rich crimson, and endowed with all the delightful aromatic perfume of the old Clove, a characteristic which at once makes it remarkable, as the majority of the tree kinds are scentless. It is a valuable sort, and possesses the desirable advantage of having a robust constitution and of being a prolific flowerer. There are several beautiful white sorts grown. The best of all is considered to be *l'Hermine*, which has flowers of the purest white, and is an exceptionally free bloomer. *La Belle* is similar to it, but inferior in every way. *Ville de Nancy*, *Lady Sefton*, and *Empress of Germany* are all lovely white kinds; but one called *The Queen* is a great favourite here. Its flowers are snow white, and the edges of the petals so smooth as to give them a refined look. *Lady Musgrave* is a brilliant crimson, also *Sir George*, *Le Grenadier*, and *A. Alegatière*, which last has flower-stalks so rigid as not to require support. *Jean Sisley*, a large flower with a yellow ground and flesh-tinted edges, is a pretty sort, and so is *Mazeppa*, which is quite a bizarre. *Belle Rose* and *Governor Wood* are likewise well spoken of. One of the greatest beauties, however, is *Andalusia*, a variety first known in this country in this garden. It has large, full flowers of a beautiful sulphur colour tinted with pink. It has a robust constitution, and is remarkably floriferous. This was awarded a first-

class certificate last year by the Royal Horticultural Society, and has been put in commerce by Messrs. Veitch, Chelsea. W. G.

NOTES FROM BERWICKSHIRE.

In the beginning of March the weather was fine and mild, and many spring flowers began to bloom, being considerably later than last year. Snowdrops, winter Aconites, Christmas and Lenten Roses, Hepaticas, spring flowering Heaths, *Primula cashmeriana*, *Primula pulcherrima*, *Saxifraga Burseriana*, *Polygala Chamæbuxus purpurea*, and Dean's rich coloured Primroses were all in full bloom in my garden on the 5th, when on the two following days a severe storm of wind, hail, and snow from the north occurred. The keen, frosty wind on these two days completely withered up all the early flowers, even such hardy ones as Snowdrops and Lenten Roses succumbing to its rigour. Several inches of snow fell on the 9th and laid for about ten days, which served to protect plants from the effects of the frosty wind. For twenty-five nights during the month, the thermometer registered from 5° to 11° of frost, and such was the continued severity of the weather, that people in this district do not remember the like, during the month of March, for the last thirty-one years. Fruit buds of Apricots and Pears are very much damaged, and Currant and Gooseberry buds are blighted, while all vegetable crops, such as Cabbages, Broccoli, Greens, &c., are greatly injured. Roses have suffered much from the effects of the cutting frosty wind, especially in cases where winter protection in the shape of Spruce Fir branches had been removed. Even Tea Roses on walls, with a protection of Spruce Fir branches, have had their shoots blackened by the frosty blasts. Spring flowering plants, such as *Arabis*, *Aubrietia*, *Silene pendula*, *Myosotis dissitiflora*, Primroses, Daisies, &c., put into beds in the mild weather at the beginning of the month are all much hurt, their outside leaves being destroyed, and in some cases the plants have been killed.

HELLEBORUS NIGER MAXIMUS.—This plant begins to bloom with me about the middle of November, and continues to throw up its large white flowers in great profusion until about the middle of January. I protect the blooms from severe frost and heavy rains by placing a number of ordinary bricks around the plants in the form of a square to the height of about 9 inches, and then putting a band-glass on the top of the bricks, giving air in fine weather. By this means I get the flowers of snowy whiteness at Christmas. My experience is that the flowers of *H. niger maximus* do not come tinged with red or pink unless they are exposed to cold.

HELLEBORUS NIGER MAJOR OR H. ANGUSTIFOLIUS.—I have read with great interest the recent notes on this variety of the Christmas Rose in THE GARDEN. Mr. Brockbank has very kindly sent me a plant of the true variety, which will enable me to compare it with *H. n. maximus*.

HELLEBORUS NIGER.—This is never seen to greater advantage than in old farm gardens, where it has been allowed to grow undisturbed for perhaps twenty years in succession. It is then found 2 feet or more in diameter, and with hundreds of flowers. It does not come into full bloom in this country until about the end of January, and its flowers are consequently not available at Christmas. This circumstance renders *H. n. maximus* doubly valuable here.

H. NIGER MINOR.—I saw a plant so labelled in a garden in this district lately. The foliage seemed smaller than that of the ordinary kind, but I could not find any flowers on the plant. Can anyone give me information about this variety?

HEPATICAS.—I perused with much pleasure Mr. Brockbank's notes on these in THE GARDEN of the 10th ult. For a number of years there have been nine kinds in my garden here—the single blue, the single white, the single pink, also carnea, splendens, and Barlowi, the double pink, the double blue, and angulosa. I observe where some large clumps of Hepaticas are grown

under the shade of trees they retain their old leaves in a green state until they are done flowering, when the new leaves take the place of the old ones. This adds much to their beauty. In the open they lose all their old leaves, and flower before the new ones are developed, in which case the flowers have not such a rich and beautiful appearance. The Hepatica thrives best in the shade in good deep soil, where it is allowed to remain undisturbed for many years in succession. I have never seen a double white Hepatica, but a friend of mine told me lately that one of his double blue plants threw a double white sport in the autumn of 1881. It is to be hoped that a permanent double white variety may yet be obtained in this way.

CALCEOLARIA PLANTAGINEA.—Upwards of twenty years ago, when I cultivated alpine and herbaceous plants in East Lothian, this hardy Calceolaria was to be seen growing in the herbaceous borders of old gardens there, and I had several large plants of it. It used to grow with its light green leaves lying flat upon the surface of the ground, from the centre of which in summer it threw up several straight, slender flower-stems, about 9 inches high, which bore four or five pure yellow unspotted flowers. I have made numerous inquiries in East Lothian of late years about this plant, but have not been successful in hearing of it being found in any of the gardens in that county at the present time. I am afraid that some of the severe winters about ten or twelve years ago must have destroyed all the plants of it. I have not seen any for fourteen or fifteen years.

IRIS RETICULATA.—Notwithstanding the unusual severity of the weather here, I lately gathered some flowers of this lovely Iris from my rock border where it is planted in large clumps, the roots not being disturbed for several years in succession. I frequently purchased the imported roots of this Iris, but never succeeded in establishing it in my garden until I got a supply of plants from a neighbouring nursery where I found it growing in clumps from year to year like an ordinary hardy herbaceous plant. The imported roots used to flower and then disappear. *I. reticulata* is excellent as a cut flower for the table, remaining fresh for a week or longer.

NARCISSUS BULBOCODIUM.—I find that imported bulbs do not live in my garden beyond a year or so, although they flower well the first year; whereas seedlings given to me by a friend in 1877 grow luxuriantly and flower every year. They are never disturbed. GEORGE MUIRHEAD.

Parton, Berwickshire.

PLANTS IN FLOWER.

FORTUNE'S YELLOW ROSE at Westonbert, Gloucester, has for some time past been one of the chief attractions of the garden. One specimen of it has borne no fewer than a thousand blooms, and the plant is still bearing blossoms. The peculiar tint of yellow of this Rose makes it a lovely object, and particularly so when the flowers are so abundant as they are in Mr. Holford's garden. The plant under notice is growing in a Rose house, and is trained under the roof about a foot from the glass.

DIANTHUS NAPOLEON THE THIRD is one of the brightest and most useful of all the hybrid Pinks, particularly for pot culture. It grows about 9 inches high, and bears numbers of rosette-like flowers of a brilliant carmine-magenta. We were much struck with its beauty the other day in Messrs. Veitch's nursery, Chelsea, where it is grown along with Tree Carnations for a winter and early spring supply of blooms. Besides being so valuable for pot culture, it is also one of the prettiest of border Pinks.

THE GUELDER ROSE (*Viburnum Opulus*) forced into flower at this season forms a beautiful object in the greenhouse. Dwarf bushy plants of it are admirable for intermixing with other plants on stages, and it is an uncommon and beautiful object grown as tall standards, such as we saw the

other day in the conservatory at the Royal Exotic Nursery, Chelsea, where some care is taken to get these into a fine flowering state early in spring. These standards range from 3 feet to 5 feet high, and their wide-spreading bushy heads are completely covered with snow-white balls of blossom. For forcing they are taken up from the open ground in autumn, potted in loamy soil, and kept protected from frosts till March, when they are gradually inured to a warm house, where in a very short time they develop foliage and flowers.

A NEW DOUBLE MARGUERITE, called *Aurora*, has been sent to us by Messrs. Cannell & Sons, Swanley, who are now distributing it. It is said to be a variety of the common annual *Corn Marigold* (*Chrysanthemum segetum*), which, however, is doubtful. The flowers form a semi-globose head as circular and double as can be, and the whole rosette is of a clear, bright yellow. It will undoubtedly become a popular plant, particularly for cutting from, as the flower-heads last for so many days in perfection when cut and put in water.

IXORA PARVIFLORA.—The ordinary species and varieties of *Ixora* are, as a rule, characterised by brilliantly-coloured blossoms borne in close heads, but this one which is now flowering in the Palm house at Kew is quite different from all others both in habit of growth and flowers. The latter are exceedingly small, but are produced in myriads on long and wide-spreading feather-like panicles, more resembling some of our native *Bedstraws* (*Galium*) than any other plant with which we can compare it. Owing to the flowers being so numerous, they have a pretty effect, and they emit a pleasant perfume. It would be worth growing for cutting alone, as small delicate sprays of it would be useful for small vases.

OUT-DOOR HYACINTHS.—Finding a general impression to prevail that garden Hyacinths are not worth keeping beyond the first year, I send you a few from my border, where they have been exposed to the full severity of the winter and spring frosts. I plant out not less than 1000 of them, and they make a great show during March and the early part of April. They consist of bulbs which I have grown regularly, none of them less than five years old and from that to forty years, and I see no deterioration; they are not quite so large as usual this year, on account of the wet season, but of course they vary a little.—T. H. ARCHER-HIND, *South Devon*. [Very fine spikes for out-door plants.]

NARCISSUS IN LONDON.—We have received from Colonel Stuart-Wortley a very charming bunch of various kinds of Daffodils which thrive very well in his garden in the north-west district; the clay soil is not in the least against success in the culture of these hardy bulbs. These are among the most useful flowers for London gardens, owing partly to the long rest, during which they escape a good deal of the evils of the London atmosphere. Certainly it is not well to try Evergreens, Vines, Roses, &c., where the atmosphere is so much against them, but we should make up by greater attention to the many things that do not mind the London atmosphere.

VARIETIES OF TRUMPET DAFFODILS.—From Mr. Wolley Dod's garden at Edge Hall comes an interesting gathering of Narcissi of the *Ajax* section. The *Tenby Daffodil* (*N. obvallaris*) is one of the finest and also one of the most distinct; it is easily recognised by the firm-textured sepals and petals, both ovate in shape, but the latter narrower than the sepals and scarcely so long as the firmly-set corona, the rim of which is deeply lobed and crisped and decidedly reflexed. It is almost a self-coloured Daffodil, but the stouter texture of the crown renders the shade of yellow therein deeper than that of the segments. Another strikingly handsome kind is *N. maximus* of Sweet, which Mr. Wolley Dod sends under the name of *N. obvallaris maximus* of Barr, but the first name is superfluous, as there can be only one variety of *Pseudo-Narcissus* called *obvallaris*, and a multiplicity of names only tends to confuse. *N. maximus* is a large bold flower with a large recurved

immed crown and wide spreading segments of almost as bright a yellow as that of the crown. As regards the size and form of the flower, we fail to see any difference between this and the *N. major* figured in the *Botanical Magazine* (tab. 51), and it is doubtful if it is really distinct. A similar kind called *N. spurius* is apparently identical with *N. propinquus* of Haworth. It has not such a reflexed crown as typical *major*, and the segments are broader. Another form is what we consider to be the single form of the common double *Telamonius*. Some flowers are also sent of what Mr. Dod calls an intermediate form of *N. cambricus*, but no doubt their larger size is owing to good culture. *N. cambricus* may be best described as a magnified form of the common *N. Pseudo-Narcissus*, and one that flowers contemporary with *N. obvallaris*; we have seen it in bloom at Messrs. Barr's Daffodil grounds since the last week in February.

IBERIS GIBERTALICA HYBRIDA is a pretty new hardy plant, judging by some flowers of it from Mr. Deau's seed grounds, at Bedford, Ealing. It more resembles some of the varieties of the common annual *Candytuft* (*I. umbellata*) than *I. gibraltarica*; and if it be really a hybrid of the latter, it has quite changed its character. The flower-heads are dense, and the blossoms white when first expanded, but they change to a pleasing violet hue. It appears to be very floriferous. Perhaps Mr. Dean can tell us more about it.

STIFFTIA CHRYSANTHA.—A flowering branch of this rare shrub, described the other day in *THE GARDEN*, has been sent to us by Mr. Green from Sir George Macleay's garden at Pendell Court, Bletchingley, where it is grown to perfection planted out in free soil in a large stove. The flowers soon dropped after being received, but the long hair-like tawny yellow pappus which surmounts each flower spreads out into a large tassellike head, and is almost as attractive as the orange-red head of blossoms itself.

HARDY FLOWERS AT YORK.—The following are among the most noteworthy plants in bloom in Messrs. Backhouse's nursery at York, viz., *Fritillaria armena*, *tulipifolia*, and *Mogridgei*; *Tulipa minor*; *Ornithogalum sororum*, with dwarf umbels of white flowers, a winter-flowering species; *Crocus pusillus*; *Corydalis Ledebouriana*; *Crocus Boryi*, *albiflorus*, and *Aucherii*; *Scilla taurica*, *bifolia alba*, and *bifolia rubra*; *Anemone blanda*, hundreds of blossoms out; *Muscari rupestre* (sky blue), *Hel-dreichi*, and *compactum*; *Anemone vernalis*, and *Draba Maweani* (white).

NARCISSUS FLOWERS from Mr. Burbidge, Trinity College Garden, Dublin, include: *N. Emperor*, *N. Empress* (with eight perianth segments), *N. odorus fl.-pl.*, *N. Telamonius fl.-pl.*, *N. Pseudo-Narcissus fl.-pl.* (silver and gold), *N. bicolor Horsfieldi*, *N. Bulbocodium*, *N. B. minor*, *N. B. Graellsii* (this last pale sulphur is the nearest to white of any European *Corbularia*—crossing the Mediterranean into Algeria it becomes purely so), *N. monophyllus*, *N. Jonquilla fl.-pl.*, *N. albus* (white Daffodil). Mr. Burbidge also sends *Lachenalia Nelsoni* (very fine), *Tulips* (Dutch Rogues), *Roman Hyacinths* (far more common at Christmas than in April), *Aucuba japonica vera* (to show how well it fruits in Dublin), *Allium paradoxum*, and some fine flowers of *Anemone coronaria* from seed sown last year. These were chiefly double sorts, which Mr. Burbidge seems to prefer to the single.

CANTUA DEPENDENS.—One seldom sees or hears of this extremely beautiful Chilean shrub in flower, and rarely indeed is it seen in such perfection as in Mr. Holford's garden at Westonburt, where there is a large specimen of it trained against the back wall of a cool house literally smothered with blossoms, which hang in graceful profusion from every twig. It would be interesting to know how Mr. Chapman, the gardener, treats this shrub, for many fail to flower it. In the stoves in the same garden is a wonderfully fine example of *Bougainvillea glabra*, from which depend long racemes of brightly coloured bracts. *Thysanacanthus rutilans* is also grown uncommonly well here, and is indeed just now a charming sight, long slender spikes of

crimson flowers hanging on all sides of the plant from 2 feet or 3 feet in length. Fine bushy plants of *Azalea mollis* light up the greenhouse with their showy blossoms, so unlike those of other shrubs of the same stamp. The double *Poinsettia* (*P. plenissima*) has seemingly quite ousted the older variety here, being in every way greatly its superior. It not only bears larger and brighter coloured heads of bracts, but these remain in perfection much longer than those of the common variety. This double kind has been in perfection for six consecutive months by having successional plants. It is only just past.

EURYBIA ARGOPHYLLA.—Judging by some large flowering branches of this Australian shrub, sent by Mr. Green, it is grown to perfection in Sir George Macleay's garden at Bletchingley. This species has ovate leaves some 6 inches long covered with white woolly down on the under surface, and which if slightly rubbed has a pleasant musky odour. The flowers are borne in large terminal panicles, and though not showy in themselves, are so numerous, and their stalks white and silvery, as to have a pretty effect, particularly when seen gracefully hanging on the plant. Mr. Green grows this shrub against a wall of one of the vineries, a position which it evidently likes, for we have never seen it flower so abundantly before. It is almost a hardy shrub, and probably is quite so in Devonshire and Cornwall if planted against a wall. It is also known as *Aster argophyllum*. It is grown at Pendell Court chiefly for its sweet-scented leaves, more especially when gathered and dried.

SINGLE CHINESE PRIMROSES.—My statement in *THE GARDEN* the other day that flaked forms of the single Chinese Primrose were scarce has brought me from Messrs. Carter some beautiful flaked flowers of their *Village Maid*, an old striped and speckled form very charming indeed, and also of a much larger variety named *Venus*, which has besides beautifully flaked markings and a finch's mon eye. In addition to these were also sent *Peach Blossom*, a very fine variety, round the lemon eye of each flower of which is a distinctly marked ring of rosy pink, which on the outward side radiates or veins out over the white ground of the flower. The blooms are not large, but the season, of course, is very late. It is a decided novelty, and one that will inevitably be the parent of some pretty things. The depth of colour found in some of the dark coloured varieties sent is indeed marvellous. *Vermilion Queen*, for instance, glows like a true vermilion sunset; the colour is singularly beautiful, owing to its rich rosy shading. *Magenta Queen* is in the purple section what *Vermilion Queen* is amongst reds. It is maroon suffused with rosy magenta. The brilliant hues found in these and in some similar varieties give a charm to a collection of winter blooming Chinese Primrose that can hardly be over-estimated. In *Carmine Beauty* we get flowers of the old carmine type with a shading of rose, and it is worthy of notice that this infusion of richness into the ground colour tends to prevent burning or fading, a very common fault with the old carmines. Lastly, we have in this box of blooms in *Rosy Queen* a bold magenta-shaded form of the purple that must form a striking variety with good heads of bloom. These, with others we have seen, show that the colours of the Chinese Primrose are gradually improving.—A. D.

ELAEOPARPUS DENTATUS.—In the Palm house at Kew there is a flowering specimen of this shrub, which is as pretty as it is rare. It forms a compact dense bush, furnished with rather small leaves, and each twig is profusely laden with tiny white blossoms, bell-shaped and exquisitely fringed at the rims as if they had been cut out of paper with scissors. This shrub used to be grown well by the late Mr. Joad, but we should like to know more of its culture and propagation than we do, as it is a plant that deserves to be generally grown. It is probably identical with *E. cyaneus*, a New Holland plant that used to be grown finely about London, and notably in the late Mrs. Mary-att's garden at Wimbledon.

BOOKS.

A LADY'S TRAVELS ROUND THE WORLD.*

In this book we have an interesting narrative, or rather a full diary, of a lady's travels round the world. Each of the 400 pages contains some descriptive account of the places visited, its vegetation and other natural characteristics, its people, their manners and customs. Travellers as a rule do not think it worth while to take note of the

together with the following copious extracts, relating to the vegetation of the different countries visited. The motto selected for the title page—"I have related what I have seen, what I have heard, and what I have learnt by inquiry"—seems to have been faithfully carried out.

"The wind fell as we sailed across the Saronic Gulf (from Athens) to the island of Egina . . . and climbed over the rocks to the only Pine tree which was within sight, which, like every other we had yet seen, was tapped for resin to mix with the wine of the country." From Greece (where backsheesh does not seem to be the main object with the Greek peasant, poor as he is) to Cairo and the Pyramids is a transition as sudden and as in a sense unpleasant perhaps as is that between the "finely featured modern Greek and the depressed-looking backsheesh-imploing modern Egyptian," and of the voyage thence through the Red Sea to India we are brightly and pleasantly told. The Buddhist shrines at Ellora, "particularly the later ones of Hindoo deities, are much visited; sacred Marigold and Jessamine blossoms were lying before their altars," but in those at Ajanta everything was lonely and deserted. The birds built around

and Cauliflowers, which are a triumph of gardening skill in this country." On the way through

The Murree Pass in March the weather is stormy, and the "spring flowers have scarcely appeared as yet; only a few blossoms of alpine Violets and a hardy yellow Jessamine make the banks gay. Yesterday, not far from Murree, a group of crimson Rhododendrons just bursting into bloom was a gorgeous sight; one stem was 5 feet in circumference." All this is a great change from "Mango trees festooned with Orchids;" but we must remember that our fair traveller is ascending far from the plains, high up indeed over the mountain passes into Kashmir. On April 3 Rampoor is reached, and we read, "To-day our walk was through lovely scenery. Forests of Deodars (one of the mighty Cedars measured 20 feet in circumference) and Pine trees, under which were banks of all sorts of hardy and half hardy Ferns, fringing the edges of delightful little mountain torrents, and out into glades where a pretty Ixia (?), and wood Anemones, and yellow Jonquils (?) overshadowed by blooms of wild Apple and Plum trees, were just coming into blossom; crowns of orange Fritillary Lilies hung on the grey rocks, and green parroquets with yellow tails flitted about under the Cedars, almost hidden by their great branches. It was startling to come suddenly on a ruined temple of graceful design and proportion, surrounded by a cloistered courtyard of trefoil arches and Grecian pillars, so entirely unlike anything he had seen in India." The Vale of Kashmir is reached on April 4, "but everything looks brown and desolate—no life anywhere. The spring is late; the tall Poplars and magnificent Plane trees are yet leafless." On the following day "it was pleasant after a walk of 170 miles to glide in a shady boat past the grassy banks of a stream fringed with Willow and Plane trees, and now and then past farmhouses two or three storeys high, standing in orchards, recalling, except for the unfamiliar background of snow-topped mountains, an English landscape."

On the Dal Lake are the celebrated floating gardens, made of the matted roots of water plants cut close to the bottom of the lake and formed into long narrow beds resting on the water. On this a thick coating of mud is laid and Melon seeds sown, which during the hot summer produce large crops of fruit. *En passant* we may allude to similar floating gardens; or rafts attached to the boathouses of the lake-dwelling Chinese, who grow Onions and other pot herbs thereon, and tow them about after their boats whenever a change of locality is from any cause desirable. On the 18th of April the pass from the Wurdman Valley is crossed (altitude 11,600 feet), the path lying through the snow and among great boulders left there by former avalanches. Shod with shoes made of rice straw carried for the purpose, "we trudged on till we found ourselves amongst Birch trees and scanty Junipers, under which the lovely blue Gentian peeped out." Our travellers are bound for the great Lamaseries at Hemyss and Leh, and have now reached the Bhutkhul Pass (altitude 14,580 feet). "We are climbing by slow degrees to the 'roof of the world,' as the inhabitants of the high table land of Central Asia call their country—a very steep roof it is. Kashmir, 5000 feet above the sea, was the first step towards it from the hot plains of India; the Wurdwan valley, 7000 feet, the next; and now we are on the way to the Sooroo valley, 10,000 feet. Leh, where we hope to be in about three weeks, will be nearly 12,000 feet up on the world roof!" and yet to the northwards lies a giant peak—a sort of chimney-stack on this roof, let us suppose it to be, the top of which is over 26,000 feet high. The Sooroo valley is not inviting. "Except a few Willow trees carefully grown near the villages, there is not a shrub or tree or anything green to be seen."

A Tartar convent is visited, and the splendid Thibetan mastiffs, "who bark persistently all night long" are admired. Perhaps they see apparitions in the night-time, and so, as Homer bath it, must needs "snarl with their teeth;" at any rate, their size was found to be somewhat below Marco Polo's standard, none being seen "as big as

Lake Tahoe, formerly the crater of a volcano on the Sierra Nevada, California.

indigenous plants of the countries through which they pass, but our authoress is evidently a keen observer of Nature in all its aspects, for almost every page of her book touches upon the native plants, all of which are well described in a popular way. It is, however, to be regretted that botanic names have not been given in order that one could be sure what plants are being referred to, for she must have come across many things not generally known. Popular names in this case do not help us much; for example, the name Heavenly Bamboo is given to a plant which no doubt is *Nandina domestica*, a commonly cultivated Japanese shrub. The book is illustrated by about a score of effective woodcuts, examples of which we reproduce

the head of the great calm Buddha seated on the Lotus in the pillared halls of the monasteries, and the wild bees hung their nests from the beautifully decorated ceiling, and the jungle plants crept in, forming festoons over the fresco paintings of Buddhist legends above the pillars." From Ajanta to Bhopal is not luxurious travelling in bullock carts, even although the bad road lieth "through a forest of Mango trees festooned with Orchids, but Bhopal once reached the gardens are charming and the flowering shrubs lovely, a blaze of the orange-coloured, trumpet-shaped blossoms of a *Bignonia* climbing amongst the dark green leaves and waxy white flowers of a *Datura* tree." The native gardener was very proud of his English Roses, of John Hopper especially so, and our visitors "returned laden with flowers and fruit,

* "A Lady's Travels Round the World." By F. D. Eridges. London: John Murray, 1883.

donkeys." From Saspool, on May 23, a sudden descent is made to the Indus, here a deep mountain torrent near a smiling village. In this sheltered nook of the Indus valley, Apricots, Apples, and even a small kind of Grape ripen, and two crops of Barley (which here replaces the Rice of the hot plains) are sometimes grown in the year. One certainly appreciates the force of the expression "living waters" here where outside the cleverly managed irrigation works of the village all is death and desolation. "We came on three nuns to-day in a corn field; their red dresses amongst the bright green Barley, under the Apricot blossoms, lit up by the setting sun, had quite a pre-Raphaelite effect." Leh is reached on May 21, after a hot ride over sandy hills and deserts, the Indus like a silver thread in the distance, till turning round a rocky point Leh rose before us, backed by the great town barrier, beyond which (forty days' march over which after crossing passes 10,000 feet high) lies Yarkand. The "Bhotas" of the Leh district are "happy and dirty and comfortable, each man growing his patch of Barley, which he year after year ploughs up with the help of his yaks, and clothing himself with the homespun wool of his lanky mountain sheep, not troubled by progress or moral advance of any sort. He drinks his 'chung,' a rough spirit prepared from Barley, and marries as many or as few wives as he chooses; but, being of a prudent turn of mind, he generally only takes shares in one along with his brothers, regulating the size of his family by that of his Barley field, investing his spare cash in large silver earrings or a gay cap to surmount his pigtail."

Hemyss is described as a strange "huge pile of whitewashed buildings, grotesquely irregular in plan, studded all over with balconies, and verandahs, and gables, and windows, and rows of prayer-wheels, of which last there were said to have been 300,000 within the walls when the monastery was erected in A.D. 1644. A glacier stream rushes by the place, and here is an enormous cylinder on which prayers are inscribed which can, on occasion, be turned by water-power. Western visitors are perhaps a little apt to feel contempt for these mechanical contrivances used by the Lamas in their worship and "miracle" plays. Our authoress does not offer any opinion. Perhaps she remembered that their sheep's tails are uncut, and while looking on the revolving of the prayer cylinders, memories of the great organs blown by steam power in some of our own cathedrals at home may have flashed across her mind.

Three months' caravan journey from Leh is Lhasa, where the Grand Lama, a sort of archbishop, resides with a thousand of his devoted priesthood. The legend told to our authoress by a tea merchant who had arrived in Leh from Lhasa reminds one of those told of burly abbots and holy friars in the "merrie, merrie England" of early Norman times, when sherry, sack, or strong ale did duty for the "tea" and "chung" which flow always in the Grand Lama's palace at Lhasa. "Lhasa is almost the only place which is still forbidden ground to the traveller; only one Englishman, a Mr. Maning, has ever been inside its walls. He got there by great good luck in 1774 and left a short diary of his journey." *En route* to Hemyss in a palanquin with 20 bearers must have been better than the ague and fever (albeit cheered by a present of lovely white Roses) brought on by over-exertion ere Leh was reached. "A lovely morning; the larks singing up in the clear air over the small patches of irrigated Barley as we threaded our way through the broad street of the mud-roofed town, where Tartar women were already astir. . . . Then out of the city gate, crowded with wild-looking mountaineers and their ponies, laden with fresh Apricots and dried Currants." Oil made from Apricot stones is here used as fuel for lamps in place of the Walnut oil of Kashmir.

On the Killian Pass (alt., 9000 feet) there are (as H. tells the authoress who awaits him at Leh) "Sedums and other flowers in great plenty—a pretty cream coloured sort in clumps, and a very pretty pink one, not the ordinary Himalayan Primrose, which was there also, and a lovely

white Sedum, like a pearl button with a white centre. Often the flower tufts looked like patches of tinted snow." At Barab, July 10, H. writes, "quantities of fruit everywhere," and on July 14 "we got to Yarkand, very fertile country, splendid Sycamore and Mulberry trees, Poplars and Willows (very like Hampshire but for the people and the crop). Away to the west fine blue mountains with snowy peaks. Rice, Cotton, Indian Corn, Grapes, Melons, and a profusion of fruit trees."

At Basga, a few hours' ride from Leh, it was so hot that tents were pitched under some Apricot trees, and brown hands offered the golden fruits of the harvest, which was everywhere being gathered in. The ride to Sonomarg (August 28) is described thus: "At first up a pretty mountain river, through an alpine glade, which two months ago must have been a real garden of flowers, brushwood, and clumps of dark Juniper, from which hang festoons of Clematis, and a lovely wild Rose with golden autumn leaves and brilliant with coral hips cover the 'savage sculpture of the rocks.'" Then comes a ride through some splendid Spruce Firs, up magnificent cliffs and shiny glaciers, looking down on a fairland of flowers and Ferns, in which stood knee deep enormous Walnut and Sycamore trees. At Srinagar Trapa Nuts were being gathered from the lake, "but more beautiful than anything else was the Lotus, a glorified Water Lily, lifting its splendid rose-coloured flowers 2 feet or 3 feet above the water, each petal delicately tinted like a sea shell, and quite 3 inches long, and forming a magnificent goblet-shaped blossom, with a crown of golden stamens inside, more like the flowers one dreams of than anything one sees. A cluster of these giant Lilies rearing their grand rosy heads (which Hindoo legend relates owe their colour to the wound inflicted on Siva by the Love God) over an island of their own enormous, but delicately modelled leaves, some nearly 3 feet across, is a sight never to be forgotten. No wonder that Buddhism has adopted it as the symbol of sacred perfection, and enthrones as its type of human perfection Buddha on it. But long before the dawn of Buddhism, the most ancient of all mythologies, that of Egypt, had revered the beauty of the Lotus, and regarded it as the symbol of the universe; rising from its blossom, or crowned with its buds, the Apollo of Egyptian gods typified the victory of light over darkness, of good over evil. The birth of Harmachus was the first sunrise. Every morning, we are told, a boatload of Lotus blossoms is brought to the palace (at Srinagar), with which the Maharajah does 'poonjah,' and decorates the shrines of the Hindoo divinities in his private chapel. The blossoms we gathered drooped and faded almost before I had time to sketch them. Buddha was right to use the quickly fading beauty of the stately Lotus to illustrate the impermanency of all things."

"On the Dal lake all the afternoon, but, alas! the Lotus flowers are faded; bright kingfishers were flitting about among their giant leaves, and wild Grapes were hanging in clusters high up the tall Poplar trees, and making triumphal arches across the narrow channels as our boat passed round the lake. A little further on is the village where the 'feast of Roses,' a sort of Rose or attar-selling carnival, is held annually."

The Resident's garden is a very paradise of plenty. "Half an acre of Tomatoes, some as large as Turnips; fruit trees, borne down by their crop of splendid Peaches; and trellised Vines, whose luxuriance reminds us of a night we once spent in a garden at Astrakan, where in the darkness, under the hanging Vines, we pulled down great cool bunches of scented Grapes, and ate them with an appetite sharpened by a week's voyage in a Russian steamer, where little else besides the caviare was eatable. Some October Peaches were sent us this morning from a celebrated fakir's garden, who cultivates his soul and his fruit trees with great ardour near Srinagar. As these holy men are supposed to command the weather, our friend had exceptional advantages for raising large fruit." At Darjeeling, in November, we read: "In these Himalayan regions the climate and foliage seem to change at every step; yesterday we were

down among the Tree Ferns and Orchids and tropical vegetation; and to-day we are in a Scotch world of Bracken, Club Moss, Lichens, and Blackberries."

Burmah, Penang, and Singapore are visited, and the delicious Pine-apples of the latter port are awarded much praise; not so the Durian, of Malacca, of which, no doubt, an unripe or half-rotten specimen was tried, for in Durian testing, as in other taste-forming experiments, all depends on a perfect fruit being tried. Next, a short voyage across to Java, where some experiences of Dutch hospitality were to be had, and visits to ancient temples in the jungle were made. These temples appear to be of the ninth or tenth century, and are attributed to the dissenting Janas from Western India, who united Buddhism with Hindooism, as shown by the ornamentation of these ruins. In the Botanical Gardens at Batavia, each tree (the "Upas" also there) was festooned with garlands of greenhouse Ferns and Orchids, and strange parasites up to the very top. Coca and Nutmegs were in fruit, and black swans from Australia sailed majestically among the Victoria and other crimson Water Lilies on the lake. The curator told the visitors that the climate was too hot for Orchids, which had to be sent up to the Buitenzorg garden, which is at a much higher elevation.

China is next visited, and in the garden of the temple devoted to statues of Buddha—still Buddha—lovely Chrysanthemums, soft white, pink, and creamy blossoms as large as Dahlias were in bloom in February here at home. These have been, with a "miniature forest of trees and plants," taken up from the open ground and thrust into pots for this religious usage. This is the celestial empire where it is etiquette for the husband to reply to kind inquiries after his wife by referring to her as a "stupid old Thorn bush." Here again in the gardens Buddha's favourite blossom, the Sacred Lotus, is plentiful. "These people believe that all good thoughts of mortals here below are turned into flowers in the land of enlightenment—red and white Lotus, which become daily more large and glorious as self-improvement of the person develops; and the soul of one who advances and never turns back may be already a dweller in the Land of Enlightenment, reposing on the Lotus flowers of good thoughts, though his body still sojourns in this transitory world." This was the late Canon Kingsley's view in some sort. Indeed, how small is the world of thought and of Nature after all.

Yokohama is reached on February 15, after a rough voyage from China in an American steamer, through "bright cold air and bright blue sea." Here again are temples—still Buddha—perched on a "picturesque knoll and shaded by grand old Pine trees, with an undergrowth of Camellias glowing with crimson blossoms. Many market gardens supply Yokohama with flowers—no such thing as artificial heat, but these clever people somehow manage to have flowers all the year round." This last sentence comes on us somewhat like a whole avalanche—a revelation, in fact. Here is a whole nation of gardeners using no fire heat, no serpent-like coils of iron piping, no coal bills, no glass, we presume, either, and yet flowers all the year round. And all this in a climate not much better, if not actually worse, than our own. But perhaps the Japanese have devoted thought and care to their own native blossoms rather than developed a craze for everything foreign, although just now even that doggie has bitten them a little, as we know. Our authoress enlightens us as to how they do these things in Japan. "By making pits open to the sun and covering them up at night with mats they get warmth. Now with frost every night is the season for fruit blossoms, and the rooms are decorated with branches of double Plum and Peach, which put into water when in bud continue to blossom for ever so long. But the prettiest flower decoration is a little old fruit tree with black gnarled stem 2 feet or 3 feet high, uprooted and thrust into a dragon-painted pot of delightful blue china and then

forced into bloom. All sorts of shrubs and fruit trees are grown in all sorts of grotesque ways. The effect is charming; but the process of gardening, digging up the shrubs and Chrysanthemums without in the least injuring them, and growing Camellias from cuttings in the open ground as we do Laurels, we cannot understand. We saw a Camellia tree 20 feet high this frosty day being transplanted in full bloom; these people do anything with shrubs we dare not touch in a climate very much like our own."

At Kobe on March 27: "I sit in the sunny window of my sitting room, which Mosky has

market for twopence per pound in the season. There was also a triumph of art—a bit of bedding out, but one trusts the Japanese will not follow this foolish horticultural fashion. Large English Cabbages were a few years ago grown here as pot plants for decorative purposes, but are now sufficiently common to be eaten. The Japanese say, 'there is other snow than that which falls from the skies.' The double Azaleas (four blossoms in one) and the *Pyrus japonica*, with flowers as large as crown pieces, and the crimson-berried plants of the Heavenly Bamboo are lovely. Still, nothing has any perfume, not even the Violets, and we

country is charming; miles of pretty country like a wild park, small Oaks and tall Douglas Firs, familiar wildflowers and grassy glades . . . pretty little homesteads standing in Cherry orchards, covered with Roses and Woodbine, from which healthy English cottage children in sun bonnets looked out while the rosy British matron hung clothes on the drying line."

At Yale, in British Columbia, "the mighty forests of Hemlock and Douglas Spruce are magnificent, and out on the rocks the large-blossomed *Syringa*, now in full bloom, and clusters of Monks-hood and dwarf *Arbutus* and *Mahonia* are lovely."

At Yosemite the heat was very great, and dust and trout both very plentiful. Lake Tahoe was more promising—once the crater of a volcano, now a lake—and here were "wild flowers new to us; blue *Pentstemon* and scarlet *Columbine* grew on the river bank."

At Salt Lake rich crops of Maize and Wheat were seen, but the practical Mormons do not grow many flowers. Denver city and the silver mines, and of course the Colorado springs, were visited. Denver is a two-year-old city of 20,000 inhabitants, and no Chinese. The latter have so far been kept away by notices, "All Chinamen will be shot." "The wild flowers of Colorado are strange and beautiful—great *Yuccas* and giant Cactus plants. Some of the latter are said to be 20 feet high; forests of Sunflowers of a size undreamed of even by an aesthetic decorator, and masses of the white horned Poppy and lovely blue *Columbine*." From a garden lover's point of view this book is a remarkably good one, as the preceding extracts well prove it to be, but the fair authoress has also given us clear views on many other things of human interest. As a work of travel it is a remarkable one, and, what is more, original in many ways. In a word, it is a thoroughly good book, well written and fairly well illustrated, and one which author and publisher alike may feel proud to have issued. F. W. B.

GARDEN IN THE HOUSE.

PRIMROSES FOR DINNER-TABLE DECORATION.

DURING what is termed the London season a considerable number of gardeners are still directly or indirectly interested in the adornment of their employers' dinner table. In a few cases, to my knowledge, either the head gardener or the foreman travels to town with a large supply of choice fruits, flowers, and foliage whenever a dinner party is given and decorates the table. Still more, gardeners of my acquaintance receive instructions from their employers or some responsible person to forward by an early train a sufficiency of Moss, Ferns, and flowers for a table of a given size, and these are arranged by the lady or ladies of the establishment, a groom of the chambers, butler, or under-butler. At the same time there are many ladies and gentlemen who prefer to engage the services of a professional decorator, especially when it is considered desirable that the entrance hall and other prominent positions should be beautified with groups of plants. Others, again, and these comprise by no means a small number, are less ambitious, and are content with the outcome of an early visit to Covent Garden Market by the butler or under-butler. Doubtless professional decorators may in some respects be considered the most successful; nor is this to be wondered at, seeing the varied practice they are constantly having, the abundance of material, and the skilled assistance at their disposal. When I say successful, I mean as regards the completeness and grandeur of their displays, but after all that is said in their favour the professional touches are still strikingly apparent; in fact, their performances are too artificial. A liberal employment of wired flowers and fine foliage, either in masses on the cloth or in vases, and the groups of plants may strike the observer as being "grand," but such encomiums are not so satisfactory to me as the almost involuntary ejaculations, "Oh! how ex-

Heavenly Bamboo (Nandina domestica). Clusters of crimson berries.

adorned with a branch of Camellia, another of *Pyrus japonica*, and a long spray of Cherry blossom in a very high art blue china jar. Bouquet and jar together make a School of Art design, and the entire cost is eightpence. How to arrange flowers is one of the items of a Japanese young lady's education, and they certainly do it marvellously well." On the hills near are "long avenues of tall Pines, and then out amongst the cornfields, and by a pretty village, each house standing in a long garden with generally a small Cherry tree in glorious blossom, and a plant of the Heavenly Bamboo close by." In the Government Botanical Gardens experiments on European fruits and vegetables were being made. "Strawberries have been a great success, and can be bought in the

feel sure our south of England flowers are as beautiful."

San Francisco, and good wholesome food once more. Strawberries and cream, Apricots, Green Peas, honey, green Corn, Boston brown bread, Wheat cakes—a confusion of good things for people just come from a long sea voyage. "The cornfields of California are more productive than its gold mines; but even there bountiful Nature is getting somewhat tired of yielding four crops of Clover in a year without the aid of artificial manure, simply by pouring water on the rich ground, and emigrants are pushing up north-west," but what, when further west is no more? At Victoria, where protective duty has nearly succeeded in banishing trade, the surrounding

treribly pretty." Now, of all decorators, ladies generally display the greatest taste, and when they choose to exert themselves a charming effect is the result. Gardeners are too apt to indulge in

Carpet bed arrangements of highly coloured, fanciful designs, and of these, bright and complete as they may be, people with good taste take little or no heed beyond perhaps agreeing with the minority that they are very bright, and wonder where all the material comes from. Only recently I heard a gentleman's valet boast of being competent to form a fresh design for the dinner-table for any number of consecutive nights, these variously coloured designs including lions, dogs, and other animals, coats of arms, and various other extraordinary devices. Such miserably formal productions might answer for a prize model flower garden arrangement, but are altogether out of place on the dinner table. Some gardeners employ, and advise others to employ, a considerable number of plants for the decoration of the dinner table—whole groups, in fact—while at flower shows tall March stands, including the flowers, standing 3 feet high, are invariably encouraged by the judges. Well grown and in some respects suitable the plants may be, and there is no disputing the fact of the vases being most charmingly filled; but those who advocate the employment of one or both should remember that those for whose delectation they are arranged will be seated at the table, and that therefore anything tall will be ineffective, while any heavy plant or banks of plants will prove positively annoying. People do not meet at the dinner table to eat and drink only; on the contrary, they wish to enjoy the society not merely of their immediate neighbours, but also of those on the opposite side, and above all that of the host and hostess. Consequently,

Decorations should be low and light to be effective, and yet not interfere with the comfort of the guests. The choicest of choice flowers need not necessarily be employed; on the contrary, the commonest of common flowers may easily be made the means of giving far greater pleasure. Nothing can be more common than Primroses, and as far as my experience goes no flower excels them for the purpose of ornamenting the dinner table. They are within the reach of all, as those who are not in a position to arrange for a given quantity to be sent up from the country can, at a trifling cost, procure large quantities in Covent Garden Market, or through the agency of a florist or greengrocer. A dozen bunches seldom cost more than 1s. 3d., and at this date they can be bought much cheaper, and being surrounded by their own beautifully green foliage are ready for immediate use, no other greenery being required beyond, perhaps, a bed of Moss. Bunches of the latter again may be bought cheaply, five shillings' worth being ample for the majority of tables. Long wreaths of Ivy are also obtainable, and can be most effectively employed in connection with wild flowers. Primroses alone are scarcely commendable to all tastes, and with them may well be employed a few dozen trusses of zonal Pelargonium blooms or those of Rhododendrons, Azaleas, Bouvardias, Begonias, Polyanthus, or other similarly brightly coloured flowers, any of which can also be procured at a comparatively cheap rate in Covent Garden early on the mornings of Tuesdays, Thursdays, and Saturdays. How we have arranged such flowers, and

and blooms of *Imantophyllum miniatum* with part of the stems attached. On the table for which these were destined were to be four candlesticks and a silver centrepiece. About the latter I arranged for four low vases filled with the *Imantophyllum* and *Spiraea* blooms, and the foliage of the latter for greenery to be placed. Two of the branching candlesticks (and those with shades only ought to be admitted near the dinner table) were to be disposed at equal distances on each side of the centrepiece and through the centre of the table. The bases of these were surrounded, but not hidden, by Moss, which, being fringed with Ivy, formed a good groundwork for the Pelargonium trusses and a little *Spiraea* foliage. To complete the centre, two plants of *Dracæna gracilis* were employed. These, which were in 5-inch pots, were set on flat circular trays about 12 inches in diameter, and disposed between the pairs of candlesticks. The pots were banked over with Moss; Ivy was circled round the base, taking care to arrange the leaves as naturally as possible on the cloth; more sprays of Ivy were worked in, and then bunches of Primroses completed the banks. Twelve dessert dishes were allowed on the table, one at each end, and the others five on each side opposite the candlesticks and centrepiece. In a line with and between the dessert dishes were placed in small plates, seedling plants in 3-inch pots of *Blechnum corcovadense*, and these also had their pots mossed over. A narrow band of Moss was then made to connect these twelve small plants, an outward curve being given in front of each dessert dish, taking care, however, not to infringe on the space required for the plates or the comfort of the guests. Bunches of Primroses were then imbedded in the Moss so as to face outwardly. Ivy leaves fringed the outer side, and, with the addition of a choice button-hole bouquet for each guest, the arrangement was complete. If the materials had to be bought a difficulty would probably have been experienced in procuring the small seedling Ferns, and as a substitute or by

Way of a change, I would bed small fish globes in the Moss, and fill these with cut blooms of such flowers as Azaleas, Bouvardias, Anemones, with a frond of Maiden-hair Fern. This style of decoration may be modified to suit a table of any size and varied nightly, but necessarily with regard to the materials, but the design, and it admits of the utilisation of a considerable quantity of common flowers, such as those of bedding Pelargoniums, always abundant at this time of the year, these being fixed with liquid gum, or they travel badly, and afterwards disposed each in one of its own leaves. Rhododendrons are wonderfully effective by candlelight, and with abundance of these or Roses beautiful combinations can easily be arranged on the cloth. I have thus attempted to point out to dwellers in London, with or without resources for supplying flowers for the table, a cheap and simple method of decorating, and for the present must leave them to improve on the suggestions here offered. One arrangement leads to another, and those who delight in the work are seldom at a loss for an idea. I ought not to omit advising those who send or who receive flowers, and Primroses in particular, to place them in dishes of water a few hours prior to packing or use. The water which they then absorb materially increases the duration of freshness. W. J. M.

Digging shrubbery borders.—During the recent fine days Hyde Park has looked pretty with its dappling of Crocuses over the Grass; but still the long and wide shrubberies are bad to look at, with the dug borders and hesom-like shrubs. We have often said there is no need whatever for this, and that the needed change can only be wrought by ceasing digging altogether after the proper preparations are made. Mr. Burbidge, writing to us yesterday, says that during the five years he has been in the College Gardens at Dublin he has never dug a border. Annual top-dressing makes his plants grow better than they ever would

in the dug border, provided proper preparations are made at first.

FLOWER GARDEN.

NARCISSUS TELAMONIUS.

IN a certain Greek play, Teucer, the brother of Ajax major, and son of Telamon, somewhat disrespectfully speaks of his father as an ill-tempered old man, getting into a rage at nothing; so we may conclude that his anger would have been moved very often by seeing his name wrongly spelt in the gardening journals. The connexion, however, between this mythical King of Salamis and the common double Daffodil of gardens is merely fanciful, and the name was given, I think, by Haworth to this flower as the chief of the Daffodils, because Telamon was the head of the Ajax family at the time of the Trojan war. There is no doubt about the double Daffodil to which Haworth applies this name. It is probably one of the most generally distributed of garden flowers throughout temperate Europe. Parkinson has given its history; he calls it Wilmer's great double Daffodil, and informs us that it first flowered in the garden of one Wilmer, in the city of London, in the year 1621. It appears to have increased rapidly, for within a few years, and before the year 1629, in which Parkinson's "Paradise" was published, Mr. Wilmer seems to have distributed bulbs to several friends, including Parkinson himself and one Vincent Sion. This latter gentleman, greatly to Parkinson's disgust, brought out the Daffodil under his own name, which it bears to this day in Holland, appearing every year advertised in the well-known catalogue of Anthony Roozen, of Haarlem, by the name of Van Sion. Now, as raising a new double Daffodil seems to be a very rare achievement amongst gardeners, we may suppose, in the absence of evidence to the contrary, that all the large double garden Daffodils of this kind in cultivation are the offspring of this one bulb. It is true that within definite limits the form of the flower varies, and that semi-double and full double forms are equally common, but these are due merely to accidents of soil and cultivation, and are not persistent varieties. But, although Parkinson gives us this history of the double N. Telamonius, he informs us that neither he nor the raiser could tell anything of its pedigree, and to this day it is uncertain which of the many large forms of single yellow Daffodil was the parent of it and has the best claim to the name of Telamonius as the head of the family. Parkinson calls these large single Daffodils "Spanish," and we know that for a generation or two before his time there had been abundant intercourse, both friendly and hostile, between this country and Spain, and it is likely enough that they may have been introduced by Spaniards. Still, evidence that Spain is their native country would be interesting. Mr. Peter Barr tells me he has never received any of them direct from Spain, nor have I found any mention of anyone who has seen them growing wild or collected them in Spain. For many generations the bulb farms of Holland have been the chief, if not the only, source from which English gardens have been supplied with them. But, considering the great vigour of the common double Daffodil, and the readiness and persistence with which it becomes established in orchards and meadows, we might reasonably expect to find its single form established in similar situations, especially if it was in general cultivation before the now far commoner double form originated. If, however, we except the Tenby Daffodil, which certainly does not represent N. Telamonius, it is very hard to find an ancient colony in England of any single Trumpet Daffodil but the common wild one. The form and habit to be expected in the single Telamonius may be inferred from looking at those flowers which for some reason or other have nearly reverted from the double to the single form, and these are not very scarce. We find that the colour of the trumpet is considerably darker than that of the perianth or outer petals, and this requirement ex-

How they may be arranged, I will endeavour to briefly state. I recently collected upwards of 300 bunches of Primroses, each bunch containing about thirty blooms, and neatly surrounded by their foliage. They were packed in two Grape baskets closely and in layers, a sheet of packing paper being between each layer. A hamper was also three parts filled with clean green Moss, and on this was coiled a considerable quantity of the prettiest pieces of climbing wild Ivy procurable. Another box was filled with trusses of blooms of the rich pink-coloured semi-double zonal Pelargonium Madame Thibaut, a quantity of *Spiraea japonica* blooms and foliage,

cludes from the competition the so-called Spanish Daffodils, which are all selfs—that is to say, the colour of the different parts of the flower varies very little. If it were not for this, a variety called by Mr. Barr N. spurius might be the best claimant. It is a very fine free flowering kind, largely grown in Holland, and largely imported to this country as Trumpet major. Mr. Barr's N. major bears considerable resemblance to this, but is far less commonly met with, and indeed in my garden it thrives badly and makes very few flowers. I have a Daffodil corresponding in all its parts to N. spurius, but differing in the colour of the outer petals, which are much lighter than the trumpet. This is another claimant for the name Telamonius. It will be remarked by those who have studied Mr. Barr's last catalogue that the single Telamonius is not included in the list; but Mr. Barr warns me not to judge of the extent of his collection from the names in the catalogue, as he often holds some regiments in reserve for a season for the purpose of recruiting, and such is at present the case with the kind in question. Within the last few years he has received from Italy (where it grows wild in the Vale of the Arno) a Daffodil which seems more likely to be the origin of the common double garden kind than any we have before seen; and after all, Italy and not Spain may be the native country of these large Daffodils. Still, their natural history and pedigree is as yet by no means certain; and anyone who can throw light upon them by recording the habitat either in England or on the Continent of any large single Daffodil will be able to do a service to horticultural science.

C. WOLLEY DOD.

Llandudno.

SELF OR BICOLOR DAFFODILS.

ARE all Daffodils bicolor? Are there any selfs? Now, in the first place, as Mr. Burbidge excludes whites, I suppose he admits that there are white selfs. If not, then I say positively that both moschatus and tortuosus are such. Now, if there are self whites, why not self yellows? The only reason I can imagine is that the action of light bleaches the thinner outer perianth segments, and they thus become paler. In this way yellows have in process of time become bicolor, culminating in such marked varieties as Horsfieldi. But if you take a self yellow, such as obvallaris—the Tenby Daffodil—and flower it, as I did, without any artificial heat in a quiet overhead light, it comes perfectly self-coloured when viewed fairly. There were no conditions stated in Mr. Burbidge's challenge, and I won his kettle fairly, as it is only in this way that absolute purity of colour is obtainable. I have already stated that several competent persons witnessed this test of colour, and these declared that I fulfilled the conditions and proved my case. I do not wish to place the names on record, but I could show Mr. Burbidge two letters from very leading Narcissus growers who say I won the kettle. Of course, as he constituted himself sole judge, and drew his own conditions himself, and only at the time of judging, he can easily save his kettle; but I think he would have done better to have sent it on with a suitable inscription for my museum. Your correspondent "Rho," who is an Oxford scholar and no mean florist, was here yesterday, and as we had hosts of Tenby's in bloom, he examined them critically, and we found one clump especially in a quiet corner wherein almost all were selfs. He very decidedly pronounced these blooms as being true selfs, the tube or crown and the perianth segments being of precisely the same colour. Mr. Archer-Hind writes me to the same effect. He says: "I say with you that the Tenby is self-coloured, the slight difference, as you point out, being due to the thicker substance of the trumpet." Mr. Ewbank also considers I have won the kettle. However, I consider I have proved that practically there are both self whites and self yellows, and this was what I had in view.

Brockhurst, Didsbury.

W. BROCKBANK.

having slipped out of the florists' catalogues and being lost to our gardens. Mr. Krelage wrote me from Haarlem to say he had many of them and would offer me bulbs in the autumn, but when that time arrived I had a letter to say that unfortunately he could not carry out his promise, most of his stock also having dwindled away. My experience in other directions leads me to feel sure that all these Scillas may yet be recovered in old-fashioned gardens, and I hope a search will be made and the stray varieties recovered if possible. The large double variety which I had discovered amongst our clumps here, and which I called S. b. maxima fl.-pl., is again in flower and is likely to prove a very fine variety. A lady sent me from Ireland last year three bulbs of a large variety, and these were marked off accordingly. Oddly enough, one came up this spring with two leaves, quite correctly; the second had three, and the third four leaves, but there was nothing remarkable about the flower. Perhaps the transplanting altered its character, and we may get finer flowers and the proper count of leaves next season.—BROCKHURST, Didsbury.

The Sultan's Balsam (Impatiens Sultani).

—Of all decorative plants of recent introduction this is one of the neatest in habit, easiest of culture, and most floriferous. It may be termed a perpetual bloomer, since it has flowered here ever

Impatiens Sultani.

since last November, when I procured a small plant from Messrs. Veitch. Even quite small cuttings commence to flower as soon as roots are emitted, and as its propagation by cuttings is very easy, a stock of nice little plants is readily kept up. In habit it is better and more floriferous than its ally, I. alba, but it would be interesting to know what the result of a cross between these two plants would yield in the way of a hybrid. I know the experiment has already been tried, but one must wait a little longer perhaps for results to develop. The annexed sketch shows an average flower natural size, and being bright rosy red, it follows that plants 12 inches in height bearing a dozen or more such flowers are pretty little objects for either the conservatory or dinner-table decoration. Of all perennial Balsams this seems to be the best and most useful.—VERONICA.

Erica carnea.—During the latter part of the winter and in early spring this Heath is at its best, being then thickly studded with pale red blossoms. The fact of its flowering at this time brings it into prominence, as there is then so little in the open ground; besides, it is a very accommodating plant, and generally succeeds well in ordinary garden soil, unless too much shaded by trees, and even in that matter it is not very particular, as when partially shaded it often

thrives satisfactorily. It is, however, most at home when employed in company with others to form an outer fringe to groups of the larger Ericaceae, for which its low spreading growth eminently fits it.—ALPHA.

THE VARIETIES OF FREESIA.

THE flowers of Freesias received the other day, from Mr. Gumbleton we sent to Dr. Foster, of Cambridge, who is at present paying a good deal of attention to that genus. Concerning the flowers sent, he writes as follows: Mr. Gumbleton's form with the membranous spathe valve is the true F. Leichtlini of Klatt. The figure in *Gartenflora* which illustrates Klatt's description is not a good one; it misled me at first, but I sent a specimen of what is ordinarily called F. Leichtlini to Max Leichtlin, and he said he believed it was true, but he had distributed seedlings as well as offsets from his original form, and these he thought might have varied a good deal. The history of F. Leichtlini is this: Max Leichtlin found it growing in the Botanic Garden at Padua and took it home to Baden, where Klatt saw it, and then described it. Max Leichtlin has kindly given me an offset from his original bulb; this will be in flower in a few days, and then I can say exactly and positively what it is. I cannot find the authority for the term "aurea." I have a deep yellow form with a tendency to violet splashings, and mouth not patent, small flower, and green spathe valves; this I have always taken to be what is usually called aurea. Mr. Gumbleton's form with membranous valves makes another kind. Mr. Smith, of Guernsey, sent me some time back a form with greenish yellow flowers and spathe valves not only membranous, but long-pointed and diverging rapidly, so as to expose even the unripe ovary, whereas in the other forms (and indeed in Mr. Gumbleton's also) the ovary is not exposed until it is considerably swollen. This form of Smith's (in which as well the stigma was not raised above the anthers, as in other forms) answers very well indeed to Redouté's *Gladiolus refractus* (Redouté's *Gladiolus xanthospilus* is F. refracta alba with purple anthers; in nearly all the F. refracta alba there is a tendency in the anthers towards purple or violet before opening). I thought at first these narrow divergent spathe valves might serve to give it a specific distinction, but in going over the herbarium at Kew I found so many indications of intermediate forms that I gave up the idea. This form of Mr. Gumbleton's is intermediate between Smith's form and my aurea. Either the genus must be split up into a number of species, which will probably in the end number some twenty or thirty, or we must call them all one species. Here is an illustration. The ripening ovary in F. refracta alba is very warty and the grooves well marked; that of aurea is nearly smooth and almost globular. F. Leichtlini is just about half-way between the two—less warty and less grooved than the one, but more so than the other.

BEGONIAS FOR BEDDING.

ALLOW me to warn those who would wish to succeed with tuberous Begonias in the open air against starting them in heat or of relying upon young plants raised in spring from seed. These latter will bloom fairly well, but not with sufficient freedom to render them really effective, neither will they come into flower until quite late in the season. Young plants should be set out in good soil in June, so that they may make good growth, and the following year they will be in prime condition for bedding out. Started in heat, they require much care in hardening off, and I do not think they are ever so robust or grow away with such freedom as when allowed to start naturally. It is also a bad plan to pot the tubers, as more labour and worse results are thereby incurred. Most cultivators consider the potting of plants which have eventually to be planted out to be an evil, and there is no doubt about its being so in the case of Begonias, as rooting naturally when strong very freely, they are apt to form coils

Scilla bifolia.—Last year about this date (*GARDEN*, April 1, p. 212) I directed attention to this Scilla, many of the sorts which I enumerated

of roots, and the soil becomes matted with fibres before they can be turned out of their pots. A far better plan is to set the tubers out at once in good, free, rather light soil in a cold frame in a sunny position far enough apart that they may have room enough to develop until the time comes for their removal into the open air. A frame is far better than a cool greenhouse, as the lights can be pushed off on fine days and left off on fine nights. Growth thus made will not be so rapid as when the plants are kept closer, but it will be of greater substance and in every way better fitted to withstand the variable weather we so often experience during the early summer months. Lifted carefully and placed in position promptly, there will be no flagging and scarcely any check; watered in well should the weather prove dry, the roots will lay hold of the ground in the course of forty-eight hours. One word in conclusion by way of caution: do not use raw manure for Begonias; they do not like it; rather mix a few handfuls of some fertiliser with the soil—some powerful, yet safe stimulant. J. C. B.

THE FORKED SPLEENWORT AND OTHER RARE PLANTS IN CARNARVONSHIRE.

WHILST spending Easter with a friend at Gwydyr-ucha I was delighted to be shown several fine specimens of the forked Spleenwort, now one of our rarest Ferns, growing on an old wall, where long may it remain hidden from the keen eyes of botanical collectors and plant exterminators. Formerly the primitive old bridge of Llanrrost was literally covered with this Fern, but, alas! its exposure doomed it to sudden destruction, for there is not now a vestige of it left. In other parts of the Gwydyr estate, where this Fern once grew plentifully, it was fast becoming exterminated, and would no doubt soon have become a thing of the past had not Mr. McIntyre, of Gwydyr-ucha (agent for the Gwydyr estate), who saw its pending doom, put a stop to its complete eradication. It is now rarely to be met with in places where it was once abundant; indeed the finding of a plant is considered quite a prize, although we were fortunate enough last season to discover the mountain habitat of a few specimens—remnants, no doubt, of once a goodly number, and relics of a bygone day. It is well known, at least to those interested in the cultivation of native Ferns, that the forked Spleenwort is rather a difficult subject to deal with as a pot plant, being especially sensitive to damp at the crown; but the great master, Nature, has now taught us a lesson from which we hope to derive great benefit. A careful examination of the dry stone wall revealed the secret that these rare Ferns only grew on the perpendicular, in which position they were securely guarded from excessive moisture at either crown or root. The soil in which they grew was simply an accumulation of dust from time to time formed in layers between the stones of the wall, and without the least trace of lime. We had also noticed this Fern's choice of a perpendicular position in its mountain home, as well as the shady position in which it loved to grow. Another rare and beautiful plant found in the same district is *Dryas octopetala*, and still further on the now almost extinct Mountain Tulip (*Lloydia serotina*) finds a home. The latter plant is found nowhere in Britain save in one or two small colonies here on the Welsh mountains, and, happy to relate, in positions almost inaccessible. It seems almost a pity that the natural tendency of small isolated colonies of plants is to die gradually out, for the constitution becomes so enfeebled and weak by constant in-breeding with one another that almost imperceptibly they dwindle away, lacking a healthy infusion of fresh external blood. I am afraid, however, that this will not be the case with our Welsh plants, as already a goodly number of the *Lloydia* has been ruthlessly carried off by the desecrating hands of plant collectors, not to flourish, for we have it on the best authority that not a specimen taken is now to the fore.

Llandegai, Bangor.

A. D. WEBSTER.

THE CHRISTMAS ROSE.

(HELLEBORUS NIGER ANGUSTIFOLIUS.)

"F. W. B." is determined on fastening an Irish name on an English or Scotch garden favourite. Time will show if he has power to over-ride our English prejudices. I say he has no right to do this, because it is in no sense an Irish plant. It is not to be had from Irish nurserymen; it was not at Glasnevin three months ago; and it is not to be found in the great majority of Irish gardens. St. Brigid's is the principal exception. I believe I have done more to distribute this Christmas Rose than most people, as many English amateurs know. It grows here in quantity, and has done so for years. All my neighbours have it, and I know where it is grown by the acre. It is an old friend, but I take no credit for this, as all my knowledge of the Christmas Roses came originally from Miss Hope, and it was a surprise to me to find that the plant which "Veronica" was writing up was this old favourite of Miss Hope's. The plant needs no new name. Nobody grows the wild Christmas Rose (*H. niger*), except in botanic gardens. This is our old Christmas Rose, and so let it be. I know neither "St. Brigid" nor "Veronica," so there is nothing personal whatever in my remarks. No doubt they are both worthy florists, but, for all that, the Christmas Rose is far more our property than theirs. W. BROCKBANK.

Brockhurst, Didsbury.

NOMENCLATURE OF PLANTS.

I AM not interested in the controversy between Mr. Brockbank and Mr. Burbidge regarding the right of the latter to give an English name to *Helleborus angustifolius*. All popular English names of plants must have been given in the first instance by some individual, and why should not Mr. Burbidge originate a name as well as any other? But, as in more important matters, though "all things may be lawful, all things may not be expedient," and I certainly more than doubt the expediency of any attempt to supersede scientific names by so-called popular names. These latter have been the source of much confusion. They lack the authority derived from general consent. They frequently have merely a local recognition, and are known in different places by as many aliases as though their characters were of doubtful reputation. They are palpably useless for international correspondence or information; and their use, either to the formal or the practical superseding of the scientific name, is a backward step to the days of our grandmothers or great grandmothers. Against all this I ask what advantage is gained by trying to impose a brand new popular (?) name on a plant already sufficiently known and differentiated by a scientific name? If this thing spreads and becomes the fashion, as there are indications, as a part of supposed aesthetic simplicity, the inconvenience will be very considerable to anyone who fails (in what I allow is his duty) to read diligently his weekly copy of THE GARDEN. It was but a short time since that I was posed for some time by the mention in your columns of "the Rush Lily." There was no mark of identification, and only that I had been diligent in the discharge of the aforesaid duty, I should never have known that in a previous number someone had so designated *Sisyrinchium grandiflorum*. This same plant has also recently furnished an example of the arbitrariness and confusion of so-called popular names, inasmuch as someone else contends for the suitability of the title "the Satin Flower." I must, therefore, enter my protest against the supercession of scientific names of plants except in those cases, which are not a few, where the English name is so thoroughly familiar as to be unmistakable. Everyone knows what is meant by a Christmas Rose, and no harm happens from so calling *Helleborus niger*. But I confess I do not see the utility of giving, or the pre-eminent claim on the part of *Helleborus angustifolius* to receive a new English name. I read the first steps which may lead us, in the case of plants, into the labyrinthine confusion of popular names, of which Hogg's

"Fruit Manual" furnishes so appalling an example in the case of Apples and Pears.

FREDERICK TYMONS (Clk).

Cloghran, Co. Dublin.

Narcissus Bulbocodium.—"Echo's" note, like several others which have recently appeared in gardening journals, conveys the idea that this *Narcissus* can only be successfully grown in pots and under protection from frost, but this is not so. Under proper management I consider it to be perfectly hardy, and the main thing is to plant it in light soil, where it is thoroughly dry after blooming time. We have many patches of it here which have lived for years, and one of these yielded abundance of seeds last summer. After this unusually severe weather I find it coming up again quite strongly, and there are plenty of buds visible. In a new lot of bulbs supplied by Mr. Hartland, of Cork, and which we have grown in pots, there are at least three well-marked varieties of the common Hoop Petticoat, confirming "Echo's" remark that there are in Spain many distinct varieties, and that this species may prove variable, as will the common Daffodil.—BROCKHURST, Didsbury.

Narcissus minor.—In almost every instance where this name has latterly been used it refers to the variety which Mr. Barr calls nanus. A woodcut of *N. minor*, illustrating Mr. Wolley Dod's paper, appeared two weeks since in the *Gardeners' Chronicle*, and Mr. Barr wrote the following week that the portrait was that of nanus and not the true minor. At my request he very kindly sent me blooms of each variety, as I have *N. minor* here from half a dozen different growers, and so far every one of them differs from Mr. Barr's minor, and agrees with his nanus. The inference is that Mr. Barr is wrong, and that he had better alter his two names, as he is against everybody. Perhaps he will give his authorities for the names he has adopted. Miss Owen refers to *N. minor* in her note (p. 318) on March flowers, but her variety is Mr. Barr's names, as I have a good deal of it grown from bulbs sent from her garden some years ago. As nanus is smaller than minor, it appears as if a mistake had crept in somewhere in the nomenclature.—BROCKHURST, Didsbury.

Chrysanthemums out of doors.—Plant in a good soil and keep the plants securely staked from the first. They are increased by means of cuttings and division in spring, and it is well to provide a new stock every year, destroying the old stock when a sufficient number of cuttings has been obtained. In order to insure fine flowers, the soil should be well manured and the plants freely watered, and the shoots should be reduced to six for each plant at the utmost. The top flower-bud on each shoot should alone be allowed to remain after the buds have become fairly visible. Though stopping does increase the number of shoots, yet it causes the plants to flower later than they would do if not stopped. Very much has been said in books about stopping. It may be well to mention here that *Chrysanthemums* for out of doors ought never to be stopped. Some of the best *Chrysanthemums* are: Early-flowering varieties—Aureole, Bois Duval, Bolide, Fred Pelé, Gold Button, Nanum, Jardin des Plantes, Chromatella, Précocité, and St. Mary. Large-flowering varieties—Annie Salter, Emblem, White Globe, John Salter, Sam Weller, Progne, and Prince Alfred. Pompones—General Canrobert, Rose d'Amour, White Trevenna, Brown Cedo Nulli, and Kenilworth.—A. E. HALL.

Spring Anemones.—"Veronica" need not despair of obtaining good Crown Anemone seed. There are many fine strains of these Anemones, or perhaps I should rather say a fine strain is being widely grown, producing large, finely formed flowers of many hues; some are intense crimson and scarlet, while others are cerise, magenta, purple, and blue, and others, again, are handsomely flaked. Then there are many white flowers, others white with a blue or red base; in fact, variety amongst these flowers seems endless, and all are

singularly beautiful. As regards culture, I may mention that I sow under glass, lift the seedlings when strong enough to handle, and then dibble them out into a bed of well-prepared soil where they are to bloom. Anemones rather like plenty of sun heat, and seldom suffer if they get a good roasting during the summer months. I have a sowing now just up, and plants from it put out about the end of May will yield a grand lot of bloom during the autumn, winter, and early spring. From the present season's flowering, also, I shall save seed as soon as it is ripe. The plants from this sowing will bloom finely late next spring, or indeed I need not say late, as now beds from a summer sowing are not only blooming freely, but were producing flowers plentifully in February.—A. D.

Narcissus tortuosus.—My good friend Mr. Brockbank has recently described this Daffodil, and seems to have sufficient confidence in his opinion to arbitrate on the genuineness or spuriousness of all rival claimants to the name. I will not differ from him, but will merely call attention to the fact that the names of the white-flowered section of Daffodils are in worse confusion than those of any other section of this much-disputed class. Mr. Brockbank tells us that the flower he describes is the whitest of the Daffodils, and that it is figured in Curtis's *Botanical Magazine*, 32, No. 1300. So far I agree with him, but when he tells us that this is the *tortuosus* of authors, and that it is so-called because it twists its perianth petals, I find that different authorities do not agree. Dean Herbert, for instance, in his "Amaryllidaceæ" (page 303) follows Linnaeus in making *moschatus* the generic name for all white-flowered Ajax Daffodils, but gives the name *candidissimus* to Curtis's fig. 1300, mentioning *tortuosus* segments as one of its characters. The name of *tortuosus* he gives (professing to follow Haworth) to fig. 924 of Curtis's *Botanical Magazine*, a larger and less white variety. Mr. Peter Barr, whom for the present I am content to follow on this matter of names, as he has given great attention to the subject, is less confident than Mr. Brockbank. *Tortuosus* does not appear in his 1882 catalogue, but in that of 1881 it is described as "primrose trumpet, white perianth," referring to the same plant, I suppose, as that described under the name by Dean Herbert. These Daffodils ought to be seen growing together by the thousand to enable us rightly to distinguish their characters.—C. WOLLEY DOD, *Llandudno*.

NOTES ON BIRDS

In the Garden, Sheen Lodge, Richmond Park.

(Continued from p. 303.)

I HAVE entered in my "garden book" the name of every kind of bird which I have noted there, distinguishing the permanent dwellers from the occasional residents, and the latter according to the periods of their temporary sojourn, whether to breed or to feed—in other words, the summer and winter visitors.

The list, however, would have been incomplete without the aid of my lamented friend, John Gould. It was ever with him a favourite summer afternoon's holiday, after a ramble in the park, to pass an hour in the garden. On one of these occasions, in early June, we rested on a seat over-shadowed by a Weeping Ash, but allowing a view of the lawn. With us, on that occasion, was my equally dear and lamented friend, W. J. Broderip.* Happening to show them my ornithological list at that date, Gould said, "You have got more birds in the garden than I see here."

He possessed in a remarkable degree the faculty of imitating the various notes of all our vocal species. He bade us sit still and be silent; then began. After emitting a particular "motivo" for a few minutes, he would quietly point to a little bird which had flown from an adjoining bush upon the lawn, and was there hopping inquisitively to and fro, gradually nearing the locality

of its specific song. We could then recognise the species to which Gould gave the name. This attraction and its result was repeated; and we enjoyed the same instructive amusement in subsequent summer vacations, to which I am indebted for additions that would otherwise probably have escaped my observation.

The following is my latest list of birds seen in the garden of Sheen Lodge, Richmond Park:—

SPARROW HAWK (*Falco nisus*), **HEN HARRIER** (*Falco cyaneus*).—These raptorial I have noted soaring over the garden in wheeling flight with outstretched, seemingly motionless, wings and fan-like tail. It needs cautious concealment to enjoy the spectacle, and especially to witness a downward swoop on some unlucky passerine. A forward step upon the lawn or gravel walk is discerned at a great altitude by the circling soarer, who thereupon darts straight away and is speedily lost in space.

WHITE or BARN OWL (*Strix flammea*), **BROWN OWL** (*Strix aluco*).—Both these nocturnal birds occasionally, the latter rarely, proclaim their presence by their "screech" or their "hoot," or they may glide into view in their noiseless flight. In the park-discipline they are included in the list of birds to be extirpated by the keepers.

A pair of white owls had, nevertheless, by themselves or successors, kept possession of an ancient Oak long enough to leave a considerable deposit of pellets and remains of their prey at the bottom of the hollow trunk. The late head-keeper, Mr. Sawyer, requested me to examine this collection for evidence of the poaching practices of the owl. The majority of the bones and teeth which I extricated from the debris were of field mice or voles (*Arvicola agrestis*), and of shrews (*Sorex araneus*), there were a few young rats (*Rattus*); also many sparrows which had been abroad too late at night, or too early at dawn, and with them were a few young thrushes or blackbirds. I searched in vain for any evidence of partridge or pheasant; there were some remains of small rabbits. These rodents abound in unwelcome numbers in the park, and on their scanty remains only could the charge of destroying game be laid to the owls. I drew up a memorial in favour of the nocturnal raptorial, the balance of good enormously exceeding the exceptional damage, but it was feared it might loosen the discipline of the staff if they were exempted from any part of the old accustomed extirpating duties.

I was surprised at the length of time, indicated by the remains of many meals, during which the owls had baffled the keen quest and practised eyes of the keepers. To one of them, my neighbour, I remarked, "And you have never traced your supposed enemy as he flits, ghost-like, as silently as snowflakes fall, to his hiding-place at early dawn?" "Oh, yes, sir, we have found that out with some of 'em, but not with our eyes." "How, then?" "Why, sir, by our ears, and in broad daylight; they do snore so when fast asleep!" In truth, the owls are the only stertorous birds with which I have made acquaintance.

NIGHT-JAR, OR CHURN OWL (*Caprimulgus europæus*).—I owe an occasional sight and more frequent hearing of this strange bird to the advantageous location of my garden and abode. Close to it begins a preserve, which extends along the eastern boundary of the park to near Roehampton Gate. On one side of the preserve is the park with old Oaks; on the other side is the quietest and least frequented of commons, hight "Pale-well" from the spring of pure water rising therein. No cultivation is carried on outside the garden wall. Such are the conditions suitable to the night-jar's singular habit of oviposition and hatching of the eggs, usually a pair, on the bare ground; of nest-building the bird seems ignorant. She selects some bare spot with which her own colours so closely match that she is hard to recognise even when you are near, and she is so hardy that you may stand and contemplate her for some time, and may have to move a step or two nearer before she takes to flight. Since my first acquaintance I have never disturbed mother or eggs, but always quietly retired when I have come in view of them.

And, so retiring, I have marvelled at the seeming knowledge possessed by the bird of her own tints, and have pondered upon the instinct which has guided her choice of the limited patch of ground best according with them. If a night-jar possessed the strange faculty of the chameleon, the trout, or the cuttle fish, and was able to change its colour to that of the spot on which it rests and nidificates, the explanation of the baffling correspondence would be easy; but the mystery of the colorific movements in the skin and of the volition, conscious or unconscious, which the chameleons obey, remains. I have generally recognised the advent in May of this migratory bird by its singular jarring note. But when its favourite food, the large moths and chaffers, abounds, its active wheeling flight about the old Oaks is remarkable.

Gilbert White writes: "This bird sometimes makes a small squeak, repeated four or five times, and I have observed that to happen when the cock has been pursuing the hen in a toying way through the boughs of a tree." I have not been so fortunate, and have commonly both lost sight and hearing of the night-jar after the month of August.

GREEN WOODPECKER (*Picus viridis*).—Of the woodpeckers we have three kinds in the park; but of these one only, the handsomest and largest, has visited the lawn here at early morn, to attack the ants' nests which here and there may deface it.

The little **NUTHATCH** (*Sitta cæsia*) makes its home and hides its winter store in the old Elm grove leading to my gate. There I hear it occasionally, hammering away or quickly repeating its single note; but, for near inspection, I am indebted to its visits in the depth of hard winter. Then a crumb breakfast is scattered beneath the verandah, which attracts the sparrows chiefly; but usually also a single nuthatch, contrasting with the crowd by its glossy plumage, would come down, and, seizing always the largest morsel, fly at once away with it to its store, returning perhaps a second or third time for the same purpose. The cock sparrow gives way to it, but I once saw a fight with a cock-robin, who resented the intruder. The combatants made repeated springs into the air, pecking at each other, but the nuthatch always finally made good its possession of the coveted crumb.

CUCKOO (*Cuculus canorus*).—I have evidence every summer of the rearing of one of its offspring in the garden. My attention was drawn one July morning to what seemed to be a dirty greyish clout on a distant part of the lawn, a neglect, I thought, of the gardener. But before walking on I noticed an active little bird occasionally hopping up to the clout; so, stopping to watch more attentively, I saw the bird evidently supplying the object with the insects it picked up, and then I observed a reciprocal movement of the thing so fed. Slowly and cautiously advancing, I made out that this was a well-grown young cuckoo lying with both wings outspread on the green. The little feeder was the hedge warbler. This first took flight on my approach, and its huge spurious offspring lazily followed, flapping its way into the adjoining shrubbery to its foster-parent's abode.

In relation to the question whether the cuckoo lays more than one egg during the breeding season, I obtained a female bird shortly after its arrival. On dissection I found one ovum in the oviduct, situated in the terminal "calcifying" segment, "uterus" so-called, with the shell partially formed. The rest of the oviduct was disposed in close transverse folds not exceeding two lines in diameter. The ovary contained one yolk-ovum, nearly half an inch in diameter, with a cluster of minute germs. I concluded that the larger one would pass into the oviduct when that tube was disburdened of the egg which it was then perfecting; and, as a corollary, that though the parasitic bird would not deposit the second egg in the same nest as the first, it might occasion a similar trouble to another little mother, hedge warbler or wag-tail, as the case might be. The systematic murder of the legitimate occupants of the nest by the callow intruder, who shoves them over the brim one after the other, has been abundantly

* Stipendiary magistrate at the Thames Police Office, author of "Recreations in Natural History."

confirmed since Jenner's discovery of that strange instinct.*

One grieves to make any note affecting the pleasant associations with that of the cuckoo; but truth must be told of the nature of the bird. In it both conjugal and parental instincts are alike depraved. The female bird indicates her desires by short, monotonous, impatient quacks; Jenner compared them to those of the dabchick. She gads about attended by two or three males. One recognises no sign of a constant pair—nothing to remind us of wedded attachment or mutual help, such as we see with pleasure in our small warblers. Neither sex of the cuckoo spends time on a nesting abode, and yet they have as much summer leisure at command as the nightingales. Their illegitimate offspring is abandoned, like Rousseau's, to the charity and care of strangers; and its first instinct when hatched is murderous, and that under revolting conditions, the victims being the legitimate children of the deceived foster-parent. I know of no phenomena of living species that perplex the conscience with darker thoughts—with more sombre speculations as to origin and cause—than those of the cuckoo.

RICHARD OWEN.

GARDEN FLORA.

PLATE CCCLXXXIV.

NYMPHÆAS.†

THE annexed plate is a good representation of two of the most beautiful of Water Lilies. The blue flowered species, *Nymphæa gigantea*, has long been an inmate of our gardens, though from some cause or other it does not produce flowers of such large size as it is known to do in its native habitat. The minor form represented here is, however, a most beautiful Lily, and from its free blooming and lasting characters it may safely be pronounced superior to any other blue-flowered kind at present known, the numerous petals of clear porcelain blue which open out much wider than those of most *Nymphæas*, and display a large mass of bright yellow stamens, remaining expanded all day, a character not possessed by any other species. The splendour of the large form has been a subject of comment with all who have had the good fortune to see it growing in the lakes and rivers of Australia. A lake in front of the Parliament houses at Brisbane is literally covered with the dark green leaves and blue flowers of this *Nymphæa*, and the beautiful and artistic representation of this species among the collection of pictures painted by Miss North excites almost as much admiration as the grand picture of the Victoria regia, also in the same collection, and enables lovers of *Nymphæas* to perceive what a magnificent Lily this is when the large forms are fully developed. The plate in the *Botanical Magazine* which appeared thirty years ago is a faithful representation of *N. gigantea*, taken, however, from dried specimens. Seeds of this plant were introduced at that time as those of a new Victoria, *V. Fitzroyana*, and in 1855 plants were in flower in the nurseries of M. Louis Van Houtte. Much disappointment has been, and indeed continues to be caused, by the failure of this plant to attain its full dimensions under cultivation—both tubers and seeds, which have again and again been imported as the largest form, invariably proving to be nothing better than those already possessed. The question which naturally suggests itself on these repeated failures is—are we right in our

treatment? is there not some hitch, some flaw somewhere in the cultural management? It seems incredible that collectors should have always failed to procure the large form; and it is most disappointing that, notwithstanding so many attempts, this sister to the Victoria is still a desideratum in our gardens. Mr. Bentham describes *N. gigantea* as being a very variable species, having flowers of white, rose, and purple colours as well as the typical blue, whilst their size varies from 6 inches to 1 foot across. The foliage, too, on the largest forms measures 2 feet across, and has a turned-up rim of 2 inches all round, as may be seen in Miss North's picture. The plant which flowered at Kew was a recently imported one, and appears to be larger than that known as *N. gigantea* var. *minor*. From this plant our drawing was made. The tubers of this species are long and thick, with eyes scattered over their surface in the same way as those of Potatoes. It requires a tropical tank and thrives best in a well manured loam. Whether grown in pots or planted out, the crowns should be about 2 feet from the surface, as this species likes to be grown rather deep in the water.

N. flava, the yellow North American Water Lily, is of recent introduction, and, beyond mere mention in a catalogue of North American plants recently published, there is neither record nor figure of this species in any botanical work known to us. Strange to say, a figure of this plant exists in Audubon's work, the "Birds of America." We are therefore pleased to direct attention to this beautiful *Nymphæa*, which, both from its hardiness and colour, unique in the genus to which it belongs, is destined to become very popular. In the old Lily house at Kew several large specimens of it have borne a quantity of flowers, and, comparing these plants with those cultivated out of doors, we should recommend indoor treatment for this plant where obtainable. It has been recorded that *N. flava* stood out of doors in the winter of 1880-81 and bore flowers the following season; no doubt need, therefore, be entertained of the plant being hardy in this country. Unlike the rest of the *Nymphæas*, this species reproduces itself by means of long stolon-like rhizomes, from which at intervals a bud is pushed forth. No tuber appears to be formed, from which it will be evident that the drying-off treatment to which other species are often subjected would prove fatal to this one. Our system is to keep the plants growing in a temperate house all winter; in the spring to shake them out of the old soil and re-pot in a good loamy soil, taking off any of the smaller pieces for stock. If grown out of doors, this species should be placed at a good depth in the water, so as to be out of the reach of severe frost. The fast-spreading desire for *Nymphæas* and other aquatic plants has resulted in the introduction of many kinds, some of which are distinct species, while others are but forms of already well-known kinds to which a new name has been attached. It may be well, therefore, to offer a few notes on those known to be in cultivation, pointing out the affinities of each with a view to reducing the large number of names now in existence, and furnishing further information as to the merits of some of the kinds at present but little known. I may say that so far as

The botanical classification of *Nymphæas* is concerned, there appears to be wide differences of opinion as to what are species and what are but geographical forms of other species,

some authorities reducing them to about twenty distinct species, while others make of them at least fifty or sixty. The genus has such a wide geographical range, and from its nature and mode of reproduction capable of being carried to such great distances by means of water, birds, &c., that one would expect to find great variety of form and colour. The modification of such characters under different conditions as regards heat, light, and soil is bound to be conspicuously apparent in this genus, so that those botanists who adopt the minimum number as that which embraces the whole of the distinct species are most likely nearest the mark. If we take our *N. alba*, we find that the variations in size and colour are very wide, the varieties *rosea*, *cashmeriana*, and *candidissima* being well-known examples, while *N. Lotus*, *N. stellata* and, as already alluded to, *N. gigantea* show the same disposition to vary considerably. Although for garden purposes it may not be necessary to stand too much on botanical characters, I shall place the different forms in cultivation under their respective species, as by so doing one gains a better knowledge of the characters and variety of each. Commencing with our own

N. alba, whose grace and beauty give so much interest to our lakes and streams, whose delicious fragrance greets us in our rambles through country scenes, we have a Water Lily of the greatest value to the cultivator, from the way in which it may be employed for the ornamentation of pools and streams, for our aquaria, and for the usefulness of its flowers. The charms of this Lily have been the theme of many beautiful lines of poetry. Moore, in his "Lalla Rookh," thus describes the opening of these flowers in the morn and closing at night:—

Those virgin Lilies all the night
Bathing their beauties in the lake,
That they may rise more fresh and bright
When their beloved sun's awake.

The Japanese, it is said, employ the flowers of white Water Lilies in the funerals of young persons as emblems of purity. The cultivation of this *Nymphæa* is so easily accomplished, that one often wonders at the bareness of lakes and ornamental water about residences where it might be, and indeed often is, employed with excellent effect. To sow the seeds all that is necessary is to envelop them in clay and then sink them in the water, where they will soon germinate and take root, after which all the attention they require is to keep them from being choked by other water plants.

The variety *rosea*, sometimes called *N. sphaerocarpa* and *N. caspary*, was figured in these pages (see Vol. XV.). It is a native of Northern Europe, and has been found so far north as Sweden. It flowered at Kew in 1878, and since then has become fairly well known. It is a delicate kind, and, strange to say, the flowers do not always come rose-coloured; one of our finest hardy *Nymphæas*, but at present not well understood in regard to its cultural requirements. We grow ours in a large pot, placed in the outdoor tank in the summer and during winter sheltered in a frame.

The variety *candidissima* is a large pure white-flowered form, very floriferous, with flowers over 12 inches in diameter when well expanded. It thrives under hardy treatment, but is best when cultivated in an indoor tank. At Chatsworth it is grown well in this way.

N. odorata.—This white flowered North American species is hardy in this country, where it has been long known. The flowers are 6 inches in

* See his paper "On the Natural History of the Cuckoo," in the *Philosophical Transactions*, 1775.

† The annexed plate was prepared from plants which flowered at Kew in August last.

diameter, and open in the morning, closing in the afternoon. It thrives well under the same treatment as that advised for *N. alba*. In the extreme north of the United States occurs a beautiful rose-coloured variety, tubers of which were introduced last year and flowered both out of doors and in the tropical tank at Kew. This variety is equal in beauty to the rose-coloured *alba*, and is sure to become a popular plant. A small white variety, with leaves and flowers 2 inches in diameter, also occurs in the United States, but, so far as I know, this is not yet in cultivation here. Another variety called *N. nitida* is a small white-flowered form of long introduction.

N. tuberosa is a third North American species with white flowers. It resembles the last mentioned in both floral and leaf characters, differing in the shape of the root-stock and in having small lateral tubers on the side of the larger ones. The habit of pushing up its central leaves above the water and almost perpendicular to it is a distinguishing characteristic of this species. It is quite hardy in this country.

N. Lotus.—This is the well-known sacred Egyptian Water Lily, which is held in the utmost reverence by the inhabitants of the Nile regions. Its distribution ranges over the Nile regions, Northern Africa, Indian Archipelago, Madagascar, and Southern Europe. From this it may be expected that this species shows great variation, and from the large number of forms which have been considered specifically distinct, it will be seen that such is the case. The leaves of the commonest form measure 9 inches across, are pubescent and purple coloured beneath and toothed. The flowers measure as much as 9 inches in diameter when fully expanded and are sweet scented. In colour this species varies from deep scarlet to pure white, and in the size of the flowers from 2 inches to 9 inches across. Both in shape and size the foliage varies considerably, some forms measuring only 2 inches in diameter, while others reach as much as 1 foot, with intermediate sizes. *N. Ortgiesiana* is placed under *N. Lotus*, as also are *N. sagittata*, *pubescens*, *rubra*, *Boucheana*, *dentata*, and the hybrid *devoniensis* which was raised at Chatsworth from the var. *rubra* and the type. This fine *Nymphaea* is one of the grandest of the whole genus, its large scarlet flowers being 8 inches in diameter and very sweet scented. It is a very free flowering variety, producing its gorgeous blossoms in abundance from May until October. The leaves of this variety are also of large dimensions, measuring on strong plants 18 inches across. The variety *Boucheana* is a seedling from the same parents as the Chatsworth plant was raised from, the flowers in this form being pale rose with a deeper rose tint suffusing the broad stout petals. The rather broad deep yellow stamens contrast well with the rose of the petals. It is a very fine variety. *N. Ortgiesiana* was raised from the vars. *rubra* and *dentata*, and resembles *devoniensis* with the exception of the petals being striped with a deeper scarlet. It is also a free blooming kind. A beautiful white flowered variety is known as *N. dentata*, a large flowered form, and an excellent companion to the scarlet ones. The underside of the foliage of this *Nymphaea* lacks the purple colouring found in most of the *Lotus* forms. Being a tropical species, *N. Lotus* and all its varieties require water heated to from 70° to 80°.

N. thermalis.—This fine *Nymphaea* is a native of Hungary, and bears so close a resemblance to

the Egyptian one as to have been mistaken for that species. In the *Botanical Magazine* and Andrew's "Repository" it is figured under the name *N. Lotus*. It may be distinguished from the large forms of that species by the absence of hairs on the undersides of the leaves, and the large depression in the crown of the germen. From a horticultural point of view, however, there is very little to choose between the two species. *N. thermalis* bears large white, sweet-scented flowers, which open in the afternoon and remain so all night, closing in the morning.

N. stellata.—In the warmer parts of India and Southern Africa this *Nymphaea* is plentifully met with. Forms of it are known under the following names: *N. coerulea*, *capensis*, *parviflora*, *versicolor*, *cyanea*, *scutifolia*, *micrantha*, and *madagascariensis*. The hybrid *N. Daubenyanana* is most likely only a large flowered variety of this variable species. The prevailing colour in the flowers of the above-mentioned kinds is blue in its various shades. The type plant is a first-class *Nymphaea* having leaves orbicular in form, with a plain or sometimes slightly undulated margin and blotched with purple beneath. The flowers are about 6 inches wide with tapering petals, which are azure blue at the base, becoming darker near the tips. The stamens are yellowish. These flowers are very sweet scented, and are freely produced during the summer months. The variety *cyanea* has flowers of a smaller size than the last mentioned, blue, and not so fragrant as most *Nymphaeas* are. *Versicolor* is distinguished by its numerous stamens and the variety of colours it presents, blue, purple, flesh-coloured, and white flowers being borne by forms of this variety. *Coerulea* is the common blue *Nymphaea* of the Cape of Good Hope; it has flowers 4 inches in diameter, fragrant, deep blue, with numerous stamens, the filaments of which are yellow, while the anthers are dull blue. The foliage in this form is heart shaped and of a clear shining green above, blotched, as in the typical form, with purple on the under side. *Daubenyanana* is a very beautiful form of *N. stellata* of garden origin, and is one of the freest blooming of Water Lilies. The flowers are of good size, pale blue with a large bunch of yellow-blue tipped stamens, and sweetly scented. It grows very rapidly, and on strong plants dozens, almost hundreds, of flowers are borne in a season.

N. zanzibarensis is a new introduction of great promise. I have not had the pleasure of seeing the large blue flowers it is said to bear, but from the high praise bestowed on it in these pages and elsewhere there can be no doubt of its possessing qualities of a high order. The flowers are said to be 9 inches in diameter, and characterised by a purple margin to the green sepals which surround the numerous deep blue petals. These flowers are said to last on the plant several days, and are borne in twos and threes. They are also described as possessing the excellent character of remaining expanded all day, a character the lacking of which is the only drawback in most of the Water Lilies. Possibly this noble plant is an unusually fine form of the Cape species, *N. stellata*.

N. pygmaea is a pretty little species from India, China, &c., which may be grown out-of-doors in the summer, requiring only protection from severe frosts to maintain it in health. The leaves of this small water gem are not much larger than half-a-crown, while the flowers are about the size of a shilling. From its smallness and sturdy

nature this plant may be recommended for those small window aquaria for which plants are often inquired after in these pages. With the water frequently changed there is no reason why this plant should not succeed.

N. Rudgeana is the only species, exclusive of *N. flava*, with anything like an approach to yellow in the colour of its flowers. It is generally known as *N. blanda*, and has been figured as *N. amazonica*, or rather what is but a form of *N. Rudgeana*. It is a native of the New World, being plentiful in Brazil, Guiana, and Jamaica. From the last-mentioned place tubers were received at Glasnevin, and flowered there for the first time in this country. In the "Flore des Serres," t. 1086, there is a figure of this species which represents it very much finer than I have ever seen it either as regards the colour of the flowers or size of leaf. The normal size of the flowers of *N. Rudgeana* is about 4 inches in diameter, while that of the foliage varies from 5 inches to 8 inches across. The flowers are yellowish white, rather muddy looking, very fragrant, and generally open late in the evening.

N. ampla.—A large-leaved white-flowered Water Lily from Jamaica, where it is common in the ponds and lagoons. The foliage is almost round, green above, deep red below, and deeply notched round the margin. The flowers are pushed up above the water and open in the morning, closing at noon—a fine sweet-scented free-blooming *Nymphaea*. This completes the list of cultivated *Nymphaeas* of which anything is known. There are plants in gardens under such names as *N. pectilis* and *N. biradiata*, of which I know nothing, and I am not aware that Mr. F. Miles, who has these two plants growing in his collection, has flowered them. So far as is known, there are no *Nymphaeas* to introduce whose claims on the horticulturist are superior to those we now possess, always, of course, excluding the large form of *N. gigantea*.

The cultivation of Water Lilies is so simple, that in gardens of even the most modest pretensions some of these plants may be grown without much difficulty. Where space cannot be spared for a tank, a large tub or a number of tubs may be used with satisfactory results for *Nymphaeas*, as is proved by the success of Mr. Lynch at Cambridge, and others who grow them in this way. A large tank such as *Nymphaeas* are grown in at Kew, Oxford, Chatsworth, and elsewhere, where these plants are one of the most attractive features during the summer season, is, however, the most desirable place for them, the plants thriving better looking more at home, and being seen to better advantage than is possible where tubs are used. To my mind there is no more charming picture to be seen in gardens than a large, well-grown collection of *Nymphaeas* growing together and intermingling their handsome flowers, rich odours, and variously formed leaves; and if other aquatic plants are grown along with them and a few graceful plants, such as *Cyperus*, *Cannas*, *Musas*, are tastefully arranged here and there among the *Nymphaeas*, they add greatly to the effect. In some gardens it is the practice to dry off the *Nymphaeas* and rest them during winter, and where the tank is wanted for other plants at this season this practice may be adopted. It is, however, by no means a safe one, the tubers often succumbing to dry rot similar to what attacks *Caladiums*; still, if the temperature of the water is gradually lowered and the water gradually run

off so that the decay of the foliage may not be too rapid, the tubers will then ripen and may be taken out of the soil and stored in sand in a warm place, or they may be left in the soil and the pots placed under the stage in any warm house where they can be watched and a little water be given when the soil gets over dry. In March the tubers may be repotted in a mixture of rich loam, cow manure, and rough sand, and placed in their positions for the summer. Large pots should be used, as *Nymphaeas* are best let alone when once they have started into growth. A temperature of from 65° to 75° will suit all *Nymphaeas*, though, of course, the cool or hardy ones will do in a lower one. It may be mentioned as an instance of the readiness with which these plants adapt themselves to altered conditions as regards temperature that the cool species thrive as well, in some cases even better, in a warm tank than out of doors, and do not appear to be exhausted or in any way weakened thereby. *N. flava* is much better when grown indoors, as has already been mentioned, and the North American and other hardy kinds are known to grow and flower excellently in the same tank as the tropical *Lotus*, *gigantea*, *minor*, and others are grown in at Oxford.

The importation of *Nymphaeas* may be accomplished either by means of tubers or seeds. Tubers should be gathered at the end of the flowering season and packed in damp earth or Moss. Seeds may be sent dry in their capsules, or, better still, in clay, in which they should be enveloped and sent in a moist state. They also travel well in bottles of water. They germinate freely enough when sown in soil and submerged in water at a temperature of about 70°. At Oxford Mr. Baxter preserves his seeds through the winter in bottles of water, which are placed in a shady corner in a warm house. Treated in this way they germinate in the bottles, and in the spring they are pricked out in pans of soil and placed in the tank. It has been suggested that by judicious hybridising there seems no reason why the beautiful colours known only to the tropical kinds might not be seen in hardy ones, and certainly the rich blue of *N. gigantea*, *N. coerulea*, and *N. stellata*, the bright reds and pinks of *N. Lotus* and its varieties would be a valuable acquisition in our hardy aquaria and lakes. In *N. alba* var. *rosea* we have already a beautiful rose-coloured hardy Water Lily, and another rose-coloured kind (*N. odorata* var. *rubra*) has also been raised, which, according to its lucky raiser (M. Lebeuf), is superior to *N. alba rosea*. B.

The ventilators on the Embankment.

—These are very ugly! It would be impossible to see anything more condemnatory of the mode of managing this greatest of cities than these ugly openings, vomiting forth poisonous vapours in the midst of a pleasant garden. It is only a few years since those gardens were secured for the public, as we thought, for ever, and now by means of a "private bill" they are spoiled by an ugly structure, the purpose of which is letting out foul air. The effect on the garden is very bad indeed, but we trust it may have one good effect in drawing attention to the way in which the public gardens of London are liable to spoliation. After this it will be difficult to surprise us. In the two best and largest gardens the ventilators are built in the very centre of the "landscape," ruining it in that respect alone, apart altogether from the ugliness of the courtyard-like structures, and the clouds of steam and currents of impure air which escape from them.

SEASONABLE WORK.

FLORAL DECORATIONS.

GARDENIAS will now be yielding an abundant supply of their highly fragrant flowers. We find it a good plan to cut them before they are fully expanded, as thus treated they keep their colour longer. Flowers that begin to open early in the morning are fit to cut the same day. If it is desired to keep any for a few days they should be put into a cool, dark place till wanted. Where the stock of plants is large and healthy the best plan is to cut them with stems sufficient to secure some of their own foliage, than which nothing with which they can be associated is so suitable. They may be arranged effectively in a flat glass dish in company with buds of *Madame Falcot* Rose, a little fresh Moss or *Selaginella* making a nice groundwork for them. *Stephanotis*, which will now be coming on fast, may be arranged in a similar manner with the same kind of Rose, or with a pink or dark red variety instead. The *Flamingo* Plant (*Anthurium Scherzerianum*) is now expanding its showy spathes, but it is a pity to cut them except for very special occasions. They look best, perhaps, when cut, arranged in specimen glasses with a spike or two of *Hoteia japonica* and fronds of a durable Fern, such as the smaller kinds of *Davallia*. Spikes of either *Lachenalia tricolor* or *pendula* we find to be most serviceable, and also very durable in a cut state. They associate well with white *Azaleas*, *Deutzia gracilis*, and a dark self-coloured *Cineraria*. Lately we have used the same spikes in several different arrangements, finding them to keep so well. For specimen glasses *Camellias* are still doing excellent service, and trusses of *Azalea mollis* make a pleasing change. For entwining around the slender stems of glass vases, or for suspending from tall trumpet vases or epergnes, an excellent subject is just now in perfection, viz., *Chorozema Chandleri*, than which nothing in the way of a conservatory climber is prettier at this season of the year. We have it here festooned over an arch about 10 feet high, allowing it full freedom of growth. From this plant we often cut long sprays for the purposes just named. For coat flowers or button-hole bouquets there is now an abundance of appropriate material from which to select. Buds of Tea-scented *Roses* are always admired, and among the very best are *Souvenir d'un Ami*, *Niphetos*, *Madame Falcot*, and *Josephine Malton*. Small sprays of *Epacris Eclipse* are also very effective when nicely arranged. *Carnation Grenadin* is just now becoming invaluable for this kind of work.

PROPAGATING.

Selaginellas.—The propagation of these is generally regarded as but a simple matter, which is indeed true as regards the majority of them, but there are a few that are rather difficult to increase. All the creeping kinds may be divided to any extent desired, and the more woody ones, such as *africana*, *Wallichii*, *Lobbi*, and *Wildenowii*, may be broken up and separated into as many pieces as have roots attached to them. Cuttings of the branches, too, of these large growing kinds may be put in, and if kept moist and close for a time soon root. Difficulty is often experienced, however, with the propagation of those Fern-like kinds in which the young fronds are unfolded from a single crown, and which therefore do not admit of division. Concerning this latter class, of which involvens and *paradoxa* may be cited as examples, cut off some of the fronds, and lay them on the surface of well drained pots or pans, filled with light sandy soil, securing them in their positions with small pegs, in order that the undersides of the fronds may press on the soil; then place them in a close case, and keep them moist. Atmospheric moisture alone will keep the fronds fresh, when after a time buds will be developed on various parts of their upper surface; from these roots will descend, and thus young plants will be formed, which when large enough must be pricked off. Besides this, *Selaginellas* may be raised from spores, which in the majority

of cases are freely produced. These spores should be sown and treated in every way the same as those of Ferns.

Stove plants, such as *Dipladenias*, *Franciscea*, *Stephanotis*, *Rondeletias*, *Gardenias*, and others, may now be struck from cuttings made of the young shoots; they must not be allowed to flag, and therefore it is best to cut off but a few at a time. After inserting them, give them a good watering and keep them close and shaded. That useful Palm, *Rhapis flabelliformis*, may now be increased by division. With a little care the old plant may be turned out of its pot and the suckers removed, repotting the plant. In taking off the suckers make sure that roots are attached to them before separating them. Use good, loamy soil, with a slight admixture of sand, put them in as small pots as possible, and plunge them in a gentle hot-bed.

Double Primulas intended for division in about a fortnight will be the better now for being thoroughly cleansed and kept rather close till that time, as by so doing the formation of roots is hastened; indeed, after being so treated it is often possible to see the young roots just protruding from the exposed parts of the stem.

Cantuas.—These pretty, but seldom seen, plants strike freely at this time if the cuttings are made entirely of the current year's growth, which will now be in a soft condition. If allowed to get hard they remain a long time without rooting, while the young soft shoots strike root in about a fortnight.

Tuberous Begonias will now require pricking off in pots or pans of good light soil, that is to say, seedlings of them, while tubers started a month ago will in many cases have grown sufficiently long for the tops to be taken as cuttings if required. When put in keep them close and shaded, but do not over-water them, as they are somewhat liable to damp. The useful double *Matricaria inodora* is rather difficult to winter, but those that survive, turned out of their pots now and divided into as many pieces as possible, will soon yield a good stock if placed in a cold frame, where they grow away freely.

FLOWER GARDEN.

Chamærops Fortunei (*Chusan Palm*).—This, though classed and cultivated as a greenhouse Palm, having in many parts of the kingdom withstood without or with but a slight amount of protection the recent rigorous winters, may now, we think, be included in the hardy list; at any rate, it may safely be classed as one of the hardiest among plants suited for sub-tropical bedding, a purpose for which it has proved invaluable, being specially effective in isolated positions on turf, as a recess plant, or for breaking the sometimes unavoidable formality that exists when a number of beds have to be arranged in a restricted space. Plants of it when used for the latter purpose must be grown in large pots or tubs, and be given house room in winter; but where permanent effect is desired, the situation a sheltered one, and the sub-soil well drained, then by all means plant out. A couple of plants of this useful Palm have withstood all weathers in Hants since 1869; they are now nearly 14 feet high, and in the most luxuriant growth. Even small plants of it, too, have just as successfully defied our sharp winters. Moderately stiff loam is the soil in which they appear to do best, and when planted out it is necessary to apply a fresh top-dressing of this annually. Those in pots or tubs, however, do not need this if during the summer they are given manure water once a week. They are raised from seeds, which germinate in about a month if afforded a bottom heat of 75°.

Herbaceous borders.—All plants in these will now be above ground, and therefore as soon as the necessary digging and manuring have been done all vacant plots should be filled up with *Gladioli*, *Hollyhocks*, *Campanulas*, *Antirrhinums*, *Pentstemons*, *Foxgloves*, *Violas*, *Pinks*, *Sunflowers*, *Sweet Peas*, and other suitable annuals. The whole of the border should be lightly forked over, and

stakes should be placed to kinds liable to be injured by winds or heavy rains. Delphiniums, Dielytras, and the flower-stems of Geums are among those that at the present time need support. Any bare spots near the margins of borders should be sown with Mignonette, Virginian Stocks, and dwarf Silenes, or, as soon as weather permits, be planted with Lobelias, variegated Mesembryanthemums, Verbenas, and Heliotropes.

Planting hardy bedders.—In order to keep pace with the work to be done at the general planting-out time, every kind of plant that can now be put out should be so. Edgings and ground-works consisting of hardy Sedums, Saxifrages, and Cerastiums are what we are now planting; next will come Violas, Verbenas, Calceolarias, the hardier succulents, and Golden Feather Pyrethrum, and when these have all been planted the remaining vacant plots will be labelled and the plants put out as soon as they can be safely exposed. Meanwhile some of the plots will have special attention as to soil; those for Alternantheras will be given a dressing of half-decayed leaf-mould and horse droppings; plots for Calceolarias, Violas, Fuchsias, and Verbenas will receive an extra good dressing of manure, and all the plots will be forked up and left rough till planted, in order that they may be subjected to the ameliorating influences of sun and wind.

General work.—Cuttings of tender kinds of bedding plants may still be put in, others may be potted off, and so should seedling sub-tropical plants. The earliest sown Castor-oils and Solanums will now require a shift into 5-inch pots; old roots of Cannas must be divided, potted, and placed in warmth, and in order to make room for these gradually remove from the pits all the kinds that will stand a degree or two of frost. Tuberous Begonias should now be started into growth. Plant them in boxes, placing the tubers about 3 inches apart. The soil should be at least half leaf-mould; they will then transplant with abundance of fibres. Seedlings of the present year to be of much service during the coming summer will still need all the heat that can be afforded them, and about the middle of May they may be removed to cooler quarters. Our experience in the use of the current year's seedlings of these plants is such, that to any who may be depending on plants of that age we would say, "Don't." Be content to wait another year, and in the meantime grow on the seedlings as vigorously as possible; the tubers will then be in good order for next summer's arrangements. Tubers or roots of every other kind should also now be taken out of their winter quarters, and be placed in pits to start them steadily into growth. In the open air the most pressing duties are the completion of pruning shrubs and hedges, and the placing of supports to and mulching the roots of recently moved trees, an operation which the still continued cold weather renders necessary. Newly-sown lawns should be frequently rolled, and if neatness be valued, do not neglect to mow, and also to dress with soot or wood-ashes any portions of the turf that have a sickly hue.

INDOOR PLANTS.

Daphne indica.—Young or medium-sized plants that have done flowering should at once be placed in an intermediate temperature, for if only treated as ordinary greenhouse stock the progress they make is slow, and the flowers they produce small and wanting in quantity. As to the amount of pot room given, it is necessary to adopt a medium course, for although this *Daphne* cannot bear over-potting, yet if the opposite extreme is followed, it gets into a stunted condition, out of which it is difficult to move it. Old examples are much benefited by the use of weak manure water at the time when they are making growth.

Room plants.—These are now in such general request that sufficient must be provided to meet the demand. In the selection of varieties, particularly of such as are grown for their handsome leaves, it is advisable to choose those that are capable of keeping up a healthy appearance

under the adverse conditions by which they will be surrounded. Amongst the species and varieties that will bear the atmosphere of living rooms where gas or oil is burnt are some of the hardier kinds of Palms, the green and variegated forms of *Aspidistra*, the India-rubber plant, and small growing green kinds of *Dracæna* that will thrive in a greenhouse, such as *D. congesta*, *D. lineata*, and *D. rubra*. The *Aspidistra* may be increased by division of its creeping underground stems now when commencing growth. The Palms are raised from seed, but their propagation is better left to those who raise them in large numbers. Small plants beginning to show their natural habit can be kept in a healthy state in very little pots by the use of manure water through the summer season whilst the most active growth is going on. Palms will grow in almost any description of soil, but where they are to be subjected to the rough usage indispensable from being located in rooms, loam imparts more substance to the foliage. The India-rubber is easily increased from cuttings made of the young shoots with some two or three leaves each; they will root if kept confined under a propagating glass either with or without heat, but where they can have warmth the rooting process will be sooner effected. Each spring a sufficient quantity of this description of stock, to take the place of that which gets too large, ought to be provided. Amongst Ferns that will bear full exposure to the atmosphere of a room may be mentioned *Davallia canariensis*, *Adiantum cuneatum*, *A. pubescens*, *Pteris serrulata*, and some of the crested forms of this Fern which attain a much larger size than the type, and *P. cretica* and its variegated variety. These, if regularly supplied with water and allowed to make their growth in the rooms in which they are to be kept, will produce fronds of a hard, enduring character that will last much better than those that are grown in plant houses and afterwards moved to the rooms.

Pelargoniums.—Exception is often taken to the formally-trained examples of the large-flowered and fancy varieties of these plants seen at exhibitions, and for ordinary decorative purposes it is not necessary nor desirable to either grow them to the size of exhibition plants or attempt the same form of training. But in other matters the general cultivator will do well to adopt the treatment that the exhibitors follow, which is first to induce the greatest amount of root formation of which the plants are capable, and afterwards to sustain them by liberal stimulants in the shape of manure water applied at the right time, which is when the flower-trusses are formed in quantity; without this the bloom will be deficient in size, and the foliage will be wanting in the rich green colour that adds so much to the general appearance. If the plants have all along been kept, as advised, through the winter close up to the glass, the shoots will be so stout and short-jointed as to require not more than half-a-dozen small sticks to each to give the requisite support. Many of the newer varieties of zonal *Pelargoniums* are alike remarkable for the size of the individual flowers and for the size of the trusses, but where the bloom is much required for cutting this is a questionable advantage, as small bunches forthcoming in quantity are generally more useful. It is, therefore, well to select such kinds as will best meet the purpose required. In the case of young stock propagated last autumn it will be advisable to stop the shoots sufficiently often to lay the foundation for bushy examples with a view of having them at their best towards the latter part of summer, when the ordinary spring-flowering plants are over.

Primulas.—Some seed of these, if not already sown, should at once be put in, so as to give time for the plants to get large enough to bloom strongly in the last month of the year, for if the stock is late and weak their flowering will be proportionately meagre. Hardy Primroses, such as the different coloured varieties of *P. cortusoides* with *P. japonica*, are deserving of pot culture wherever there is a greenhouse, for when well managed they are beautiful objects in no way inferior to the more generally grown Chinese

varieties. Now is a good time to get up a stock; small plants procured at the present season will, if well cared for, make strong examples before the end of summer that will bloom freely next spring.

ORCHIDS.

East India house.—During the last few days the sun's rays have been sufficiently powerful to injure plants exposed to them; but the careful cultivator, while he does not shade too much, will doubtless have prevented such an occurrence. Some Orchids will stand sunshine better than others; consequently they must be arranged according to their requirements in this respect. *Vanda* trees and *V. Hookeræ* do not yet require shading. All the deciduous *Dendrobiums* do well, at least such as require a high temperature in the lightest part of the house. The evergreen species, too, of the *D. thyrsiformum* type, after having been rested in a cool temperature, should be placed in the cool end of this house, i.e., if a *Cattleya* house temperature is not available. *Cypripediums* must be placed in a rather shady position, as some of them are easily injured by sunshine. We have had the leaves of *C. Veitchi* (superbiens) injured even under the shading. Last season a number of seedlings between that kind and *C. villosum* placed amongst other hybrids, although shaded with a thick blind, were injured, while the others were untouched. The whole of the *Phalænopsis* must be on the shady side of the house. *Angraecums*, too, do not succeed on the sunny side. We had a plant of *A. articulatum* which was doing well at a distance from the glass; thinking to get better growth, it was suspended about 18 inches from the roof, when it ceased to do well. It has been placed in its old position, and is slowly recovering. All plants making growth must be freely supplied with water.

Cattleya house.—Watering and shading must now receive special attention. The leaves of *Cattleyas* seem to absorb heat very rapidly; if touched by the hand after the sun has shone upon them in the morning for about a quarter of an hour, they will be found to feel quite warm, and if they were to be exposed for some time longer they would certainly be hurt, even if they did not show the injury immediately. We keep our thermometer in a partially shaded part of the house, and when it has risen about 5° by means of sun heat the blinds are let down. If the day should be sunny with few clouds they are left on until the sun has passed so far to the westward that no harm will be done, but we like to have sufficient of his parting rays to again raise the temperature a little. Then as to watering. If such Orchids as *Cattleya Mossie* are examined, a mass of fine healthy roots will be found pushing out from the base of the last formed pseudo-bulbs; they are mostly above the surface of the potting material, and it is best to let them alone. We have known lumps of peat, &c., to be put over them to induce them to root into them, but it is better not to do so; they will run along a little on the surface and then push downwards. All plants that are doing this should be well supplied with water, and a moist atmosphere is also very desirable. *Odontoglossums*, such as *O. vexillarium* and *O. Roezli*, are pushing new roots freely from the base of the growing bulbs, and also require a considerable amount of water. *O. citrosimum* is now starting freely into growth and showing its flower spikes, from which slugs must be kept; if these pests are numerous the young spikes must be protected by means of cotton wadding. *O. grande* and *O. Inseayi*, both autumn-flowering species, should be kept rather dry at the roots; indeed, it is best not to water them until it is seen that the compost is quite dry. We have tried these two species in the cool house, but they did not succeed; they are now doing much better in the *Cattleya* house; still, we have seen them do well with cool Orchids. Evaporating troughs should now be kept filled with water, and the house ought to be damped twice daily.

Cool house.—Many have their *Odontoglossums* and *Masdevallias* placed in a lean-to house

facing the north; in that case but little shading will be required until the sun gets round on afternoons of sunny days, when it may be necessary to shade for an hour or so. If the house is exposed, say a span-roofed one running north and south, the shading will have to be let down very soon after 7 a.m. on the east side, and that on the west side about two hours later. Nearly all the plants in this house will require very considerable supplies of water; they seem to do best when the Sphagnum on the surface is growing freely. No rule can be laid down as to the quantity of water to be given, or how often it should be applied. Plants that are established and that have well filled their pots with roots will require it much oftener than newly potted ones, and much, too, will depend upon the form and position of the house. One advantage of a lean-to facing the north is, that the plants neither require so much water nor so much attention as those in a different aspect. Any Orchids that have been wintered in the warmer house may now be removed to this one. If the temperature of the two houses vary to the extent of say 10° , it would be well to increase that of the cool house say 5° , in order to meet the requirements of the plants newly placed in it half way. Our experience in exhibiting, as well as in shifting plants from one house to another, has taught us that the fewer changes Orchids are exposed to the better, and cool Orchids are quite as likely to suffer as those from the East India house. We had about thirty Orchids in flower which were left at an exhibition last year for a week, many of them from the East India temperature, and none of them suffered except the *Masdevallias*, most of which lost their leaves. The temperature of the house falls now to about 50° at night, seldom lower, even with the ventilators open a little all night.

FRUIT.

Hardy fruit.—If not already done, Figs may now be pruned and nailed or tied to the walls, care being observed that a space is not left to admit of a current of air behind the shoots. As we have before observed, pruning should simply consist of thinning out the shoots and arranging the past year's growths, so as to have an even spread of well-ripened shoots, studded with embryo fruit, all over the space allotted to the tree, and as all the fruit of any value will be found near the points of the shoots, the latter should never be shortened at the spring pruning unless young breaks are wanted to fill up vacancies.

Apricots bloomed very strongly, but not so early as we at one time anticipated. Where broad coping boards and heavy coverings have been used, a little judicious management in their removal will be necessary. The boards will, of course, remain for some time longer, but the canvas must be taken off every day and put back at night on the approach of danger. Disbud gross shoots and keep a sharp look-out for the active little grubs, whose whereabouts is easily detected by the rolled-up appearance of the points of the young shoots.

Peaches and Nectarines, now in full bloom, and many of the early kinds just setting, will require constant attention to keep them from aphids until it is safe to apply the usual dressing. Already Tea Roses on open walls are teeming with green fly, and unless the wise precaution of winter dressing the trees and walls with some insecticide has been observed, Peaches and Nectarines will soon be affected. Avoid the use of dangerous dressings until their strength has been properly tested. Our forefathers used soft soap, sulphur, and tobacco water; their trees were kept alive for half a century, and if they did not cultivate so many kinds, they grew quite as good Peaches as we do.

Cucumbers.—With increased daylight and sun-heat these hard-worked and often abused subjects will now take heavy supplies of generous liquid, particularly where the roots are in pots and the plants have been in bearing since the end of the past year. Good syringings overhead after

the house is closed will also play an important part in keeping [the foliage] clean and healthy, as old plants in hot-water pits are sure to get more or less infested with spider, and it is only by constant application that this troublesome insect can be kept in check. From this time forward healthy plants will make rapid growth, and the usual stopping and dressing will require attention at least twice a week, as nothing more quickly resents neglect or suffers more from the handling and pulling about which invariably follows neglect. It sometimes happens that old plants show signs of faltering under bright sunshine, and require shading more or less every day. When this is the case, make speedy examination of the roots, remove all old manurial top-dressings and inert soil, dust with quicklime, or water with lime water to destroy worms, frequently the cause of the mischief, and top-dress with fresh turfy loam, charcoal, or old lime rubble. Renovate the bottom heat, and when fresh root action sets in feed with clarified liquid, but avoid the use of manure as a top-dressing. Damp the floors and walls two or three times a day. Syringe the foliage overhead about 3 p.m. when fine, and close with sun-heat, which will run the house up to 90° . Maintain a good heat in manure pits and frames. Train and peg out the growths, add large lumps of turf and pieces of charcoal to the hills as the roots appear, and still be very careful in the application of water to the foliage, as the nights are very cold and sudden depressions when the leaves are wet very often produce mildew. Sow a few seeds at short intervals for succession, and throw away all surplus plants before they become infested with spider.

Pines.—When the flowering process is over, the early batch of Queens will derive great benefit from a light dewing over with the syringe after the house is closed for the day, care being observed that the quantity of water used is not sufficient to concentrate in the axils of the leaves and saturate the soil about the collars of the plants. Examine the plants once a week, and, while avoiding indiscriminate watering, see that those actually requiring it do not suffer. If they are not over-potted and roots are plentiful, give warm clarified liquid in a diluted form and weak guano water alternately, and produce a stimulating atmosphere by sprinkling paths and drying surfaces with the same when the ventilators are closed for the day. Ventilation through the months of April and May (two uncertain months) will require constant vigilance, otherwise sudden external changes will cause great fluctuations, at all times injurious to plants which have been kept at a high temperature through more than half the winter. The safest and best course to follow is to keep a good heat in the bed, which will always prevent sudden depressions, to shut off fire-heat early, and to give sufficient air to draw moisture off the foliage before the sun strikes the roof of the house on bright mornings. If the latter is glazed with large squares of glass, a very thin shading for two or three hours each day may be necessary, until the still tender foliage becomes firmer and better able to stand bright weather, but, the roots being right, its continuance will not be needed. The old-fashioned practice of driving the fires to maintain a given temperature throughout all weathers having been given up, 65° to 70° at night and 80° to 85° by day, with a bottom heat of 85° to 90° , will suit Pines in every stage after they are started into fruit, and successions will do very well under an all round reduction of 5° . If extra stock is not wanted, do not let fruiting plants carry more than one sucker each. Remove all gills from the stems at the base of the fruit, and secure the latter in an upright position by placing two sticks to each plant and passing bands of matting above and below the fruit.

Melons.—Keep the atmosphere of the house in which early Melons are setting their fruit moderately dry with a circulation of air; fertilise all blossoms on fine days, and give very little water to the roots until a good set has been secured. With pot plants this is not difficult, as the most troublesome setters can be brought into subjec-

tion by the application of bottom-heat, and withholding water from the roots. As soon as the fruit begins to swell syringing may be resumed to keep them free from spider; but water must be sparingly given at first, as a flush before the fruit attains the size of Walnuts would most likely cause it to turn yellow and go off. If the compost—stiff calcareous loam and bone dust—is dry and in a fit state for use as a top-dressing, see that it is made as warm as the soil in which the plants are grown before it touches the stems, and guard against injuring them in its application, as canker is often brought on by undue pressure or the use of cold materials. As soon as the roots have taken to the top-dressing apply warm stimulating liquid as often as the plants can take it. Keep the bottom-heat at 85° , syringe at 80° on fine afternoons, and run up 5° to 10° after closing. Give a little front air at the close of the day, and let the night heat range about 70° .

Thin out and train the laterals on succession plants, pinch the points of leaders where they have covered two-thirds of the trellis, and induce a firm wiry growth by giving plenty of heat and air through the early part of the day. Make fresh sowings for succession and for planting in pits and frames after Potatoes and other forced vegetables are cleared away. Hardy kinds like Golden Gem answer best for this culture. In pits and frames keep up a bottom-heat of 85° by means of linings and cover the glass at night. Earth up with fresh friable loam as the roots require it, using lumps of charcoal or broken brick to keep the soil away from the stems of the plants. Avoid wetting the foliage until the weather becomes warmer, as moisture is generally abundant where fermenting material is used as a heat-producing agent.

MARKET FRUIT GARDENS.

GRAFTING is now an important operation. By means of crown or rind grafting, Apples, Pears, and Plums are converted from unsatisfactory trees into fruitful and profitable ones. Top-dressing trees recently planted must no longer be delayed; it is the drought in spring before the roots get established that is so much to be dreaded. Last season a large quantity of Cob Nuts and Filberts were planted late on a south slope, and a severe drought followed. The greater portion of these bushes had each about a barrowful of manure spread over their roots, and amongst them not one failed, whilst of some left bare nearly half died, and the rest only just kept alive, but made no growth like those that were mulched. Orchards on Grass, to which farmyard manure was applied during the winter, will now need bush harrowing and rolling, at the same time picking off stones and forking up Docks, Thistles, or Nettles. Orchard Grass should never be made into hay, but fed off closely, as is just now being done by ewes and lambs. Orchards or fruit gardens dug up roughly in winter should now have the soil made fine by means of prong hoes. Strawberry beds must be divested of weeds and heavily mulched with fresh stable manure, the good properties of which will get washed down to the roots by rain, and thus stimulate growth and form a clean, dry bed for the fruit to rest upon.

Birds must be kept off fruit buds either by powder and shot or by means of some other remedy, for if allowed undisturbed access to trees and bushes but little fruit will come to maturity. Sparrows are especially troublesome to Gooseberries, and bullfinches to Plums, Cherries, and Apples, and the next month will be their period of greatest activity. Hedges of White Thorn well kept are a speciality in some counties; by repeated clipping they get almost as thick as walls; the only way by which they can be kept in good condition for many years is keeping them clean at the base. At this time of the year about 2 feet on each side is lightly forked over; all Couch Grass and other weeds are carefully picked out, and after that hoeing a few times during summer will keep the ground thus treated quite clean, and the hedge will grow right down close to the soil. Roads and walks cut up with heavy carting in wet

weather must now be levelled and rolled. In large fruit plantations the cross walks may be of Grass; such pathways for carrying the fruit to the main walks or roads answer exceedingly well, and look at all times neat and trim. In young plantations recently planted the work of putting in a row of Potatoes will now need attention; a furrow made with a plough and the sets laid in answers well. Potatoes and fruit do well together for the first year or two after planting.

KITCHEN GARDEN.

Now is a capital time for sowing a good quantity of Peas. We generally form miniature Celery trenches for their reception, and earth up by cutting down the sides of the trench. When earthed they become level with the rest of the ground. Our special variety is Laxton's Standard, a really good bearer and otherwise excellent Pea; but we have many more that are perhaps equal to it. Pride of the Market and Stratagem are both good where 6 feet stakes and plenty of room is no object; Telephone and Telegraph are likewise two grand varieties. Broad Beans have now become an indispensable vegetable; eaten when about the size of large Peas, they are both delicate and delicious. Green Windsor and Mazagan are as yet the best; they are so easily satisfied, that they will succeed almost anywhere provided the soil is rich. Stretch the line on the ground proposed to be planted, and dibble the seed in on each side of it at from 6 inches to 9 inches apart. Keep the hoe well at work amongst Lettuces and Cabbages, and, in fact, amongst all growing crops. A contemporary advises its readers to sow French Beans on sheltered borders. We agree so far as sowing goes, but it should be done in cold pits instead of outside. Even in the sunny south French Beans are not considered safe until the third week in April.

TREES AND SHRUBS.

OSIER PLANTATIONS.

ON reading the short article by "R. G." on Osier planting in THE GARDEN of March 31 last I was not astonished at his cost of planting an acre of Osiers when he had to purchase his sets from a basket maker. I have been helping a gentleman in the neighbourhood to plant a small Osier bed as a cover for game. I asked a basket maker, more by way of amusement than anything else, what he would charge for Osier sets; he said 10s. per 1000, and then came down to 8s. I declined his offer, for I knew where I could get them more to my mind and at a much less cost. I sent a man over to some Osier beds where they grow for sale, and found I could have a ton cut for me and carted to the railway station for £4. I ordered a ton, as furnishing ample sets for the ground I wanted to plant, which was 250 yards long by 40 yards broad. On their arrival we set to work to cut them, and to be expeditious in that respect it takes a man and a boy to cut them. The Osiers are placed in a barrel the butt ends down; the longest are drawn out first, which are the strongest; the boy thrusts the butt ends of two if strong, three if moderate, against the man's chest, he grasps them with his left hand and with a sharp saddler's or shoemaker's knife cuts them off 10 inches or 12 inches long. The process is repeated as long as the wood of the Osier is hard; the moment it becomes pithy throw the rest of it away. One man is employed sorting into strengths, putting the eyes the right way, and binding in bundles. They are then ready for setting, which is done by thrusting them into the ground till about only three eyes are left above ground. A gardener's line should be used to keep a straight line. The distance between the sets is 10 inches, and between the rows 2 feet. We cut 32,000 sets, as being about the number required to plant the ground, and then there were about seven hundredweight of thin Osiers left out of the ton.

Here in Lancashire the professional Osier growers use sets of 10 inches, planted 10 inches

asunder and 22 inches from row to row. The extra 2 inches were given to admit of a larger horse being used to keep the Osier bed clean, and the great secret of a successful Willow bed is to keep it scrupulously clean for the first two years, and generally after that they smother all weeds. Here they are now sold by weight, which is a much fairer way than by bundle. This season they were £4 per ton, newly cut.

It took 31,000 to plant the piece of ground. The cost was—Men's time in cutting, sorting, and planting sets, £5 8s. 10d.; ploughing, harrowing, and manuring ground, £6 10s.; 32,000 sets, £2 12s.; carriage of Osiers, 15s.; total, £15 5s. 10d. I have charged the horse work on a very liberal scale; only a slight dressing of manure was used, and the extra thousand sets are included, and there are seven hundredweight of Osiers left.

C. H. W.

THE BIRTH OF THE CHILIAN PINE.

READING quite recently in THE GARDEN of the grand examples of this tree now to be seen at

Germinating seed of *Araucaria imbricata*. 1, seed or nut; 2, swollen tigellum or neck; 3, root; 4, ground level.

Dropmore, at Bicton, at Lord Poltimore's place near Exeter, and at Woodstock, in Ireland, it occurred to me that some at least would like to learn how the large edible seeds germinate in our gardens. Having a friend who seems to know by intuition what things are of interest to me, he of course sent me a couple of *Araucaria* seeds just before I had time to ask for them, and the annexed illustration is a sketch made of one of these of the natural size. As will be seen, the mode of growth is analogous to that of Palms, Yuccas, and other monocotyledonous plants. It is interesting to remember that the noble specimen at Dropmore, 61 feet in height, was forty years or so ago in the diminutive state of our little friend, whose portrait is here given. We may add as a matter of fact that the specimen of *Araucaria imbricata* at Kew is the oldest in England, although not the largest, it being one of the original plants introduced by Mr. Archibald Menzies, who sailed with Capt. Vancouver to the coast of Chili in 1795. The seeds of the Chilian Pine are or were largely used as food by a tribe of Chilians, the Araucarians, just as seeds of the Stone Pine are to this day exposed for sale among the food products in the markets of Italy.

F. W. E.

TRANSPLANTING EVERGREENS.

THE best season for moving Evergreens depends somewhat on their size, age, and the distance to which they have to be moved, but, as a rule, I am in favor of autumn planting. From the first week in August to the second in October is a much longer time during which Evergreens of all kinds can be safely moved than that available in spring, with the still further advantage that the autumn-moved plants require no after attention in watering the following summer, such as is necessary in dry weather with spring-moved plants, even if they get well over the ordeal of transplanting. When plants moved in spring in any considerable quantities have to be moved for any distance by rail in the hot, dry weather that often prevails at that time, frequently necessitating their being out of the ground for a week, they seldom come off without a check that throws them into a stunted state which takes two or three years to get out of. The 10-foot or 12-foot plants which "S. D." moved in spring, divested of soil, if moved any distance will shed their leaves, and not make as many new ones for the next two summers as would admit of a sparrow hiding itself in them. With small ordinary nursery stock, when in a right state for removal by sufficiently frequent transplanting, where the quantities to be got through are not too great to admit of their removal within the short time available, spring will answer well enough; but even these will do just as well if moved within the much longer period in autumn, admitting of their making some roots after planting, when they are safe from any weather, no matter how severe. Between the beginning of September and the end of October, last autumn, I planted in several places considerable quantities of Hollies, from 2 feet to 5 feet high, that scarcely lost a leaf, and have come safely through the last month, which, as few will dispute, has been one of the worst within the recollection of anyone living for newly planted stock; and the same holds good in the case of other Evergreens. The mildness of the two last winters, if we except the past month, is such, I admit, as not to afford a fair test of the effect on autumn-planted Evergreens; but I may say that between the beginning of September, 1881, up to December last, I have planted in different parts of the kingdom, in soils and situations as different as they well could be, over 8000 Hollies, with a loss of not more than 3 per cent.; but the whole were selected with a view to their being in right condition to bear removal, on which it is needless to say so much depends.

In regard to the removal of large Evergreens of a miscellaneous character, including Hollies, success may be reckoned as certain if the work is properly done and completed between the beginning of August and the end of September, and the earlier within this time the better. Between the second week of August and the middle of the following month, in 1878, I was engaged at Glansevern, Montgomeryshire, in moving a number of Hollies from 18 feet to 22 feet high, some of them being as much through, that had been planted the first or second year in the century, and had never been interfered with during that time. No preparation by previously opening a trench round them had been made. They were moved with large balls of earth, which, from its close, heavy character, and the dry condition it was in, stuck together, so that when placed on the machine there was no more crumbling away in conveying them to their destination than if each ball had been a mass of concrete. I had a little brook near at hand dammed up, so as to get the water to run down a trench to each tree as it was planted, leaving it running for six or eight hours, so that the balls were thoroughly soaked through. I mention this because, unless the soil is properly moistened, the roots cannot start away freely. Through the autumn the plants showed no more effects of their removal than if they had never been disturbed, and in the excessively severe frost that ensued there was no loss of leaf; whereas quantities of others of like description that were growing beside them, and not disturbed,

lost most of the leaves on the previous summer shoots, the wood of which was in many cases killed back also. The check which the moved plants received solidified and hardened up the preceding summer's wood, so as to make it able to withstand the severity of the frost, which the more succulent unmoved trees could not sustain—a result by no means exceptional.

Another case of moving big Hollies, in which I assisted when a youngster, in the gardens at Cloughton Hall, Lancashire, this time in the spring, turned out very differently. A considerable extent of new shrubbery was being made, and to give immediate effect, a number of large Hollies were got on the estate. These were moved with large balls, weighing two or three tons each, about as big as in the case of the Glanfevern plants; their stems, to even up amongst the branches, were wound round with hay ropes, and kept moist, a man doing little else through a good part of the summer than giving water to their roots, and dousing them overhead with the engine. Nearly the whole of them lived, but they shed their leaves so as to be as bare almost as Peasticks, and, as always is the case when this occurs, they were three or four years before they moved much. I mention these two out of a good many instances I have seen of moving large plants at different seasons, where in each case there was the requisite amount of labour bestowed on them to warrant an expectation of success; but in every case the late summer or early autumn showed a like advantage over spring. It is all very well to recommend the planting of Hollies and other evergreens just as they are breaking into growth in spring where only a limited number of small or ordinary sized plants have to be moved; but where large quantities have to be transplanted, and often conveyed considerable distances, it is impossible to get the work done in the time during which the plants are in the required state to move. From a fairly wide experience, I have no hesitation in saying that, for one Evergreen that dies after removal before November, there are twenty that go off or are rendered useless by removal in spring.

T. BAINES.

Pernettya mucronata.—With me this grows in a light black peaty sandy soil, and sends up suckers in all directions; it is now covered with crimson berries. Seedlings come up all over the garden. One bed of it is particularly pretty just now, having a white heath in full bloom coming up through its branches. Later on the *Pernettya* is beautiful with its young red stems and small white bell-shaped flowers spread all over it.—R. B.

New hardy flowering shrub (*Adenocarpus decorticans*, Boissier).—The *Révue Horticole* in its first number for April gives a coloured plate and description by M. E. A. Carrière of this new and beautiful hardy flowering shrub, which will shortly be sent out by Messrs. Thibaut & Keteleer, of Sceaux. It is said to be a native of the mountain chain known as the Sierra Nevada, in Spain, where it grows in common with the *Pinus Pinsapo*. Its flowers are produced in great abundance, and are of a clear, bright yellow, reminding one somewhat in appearance of those of our common *Furze*. It is said to thrive best (at all events when young) in peaty soil, and is impatient of moving, so will be the best kept in a pot till ready to put out where it is finally to remain. It was entirely uninjured in the open ground at Sceaux by the very severe winter of 1879-80, so is perfectly hardy. It multiplies freely from seed.—W. E. G.

Decaying Willow (*T. P., Newark*, p. 323).—Willows thrive best in good loamy soils rich in organic matter. When the roots reach a subsoil composed principally of inorganic constituents, such as clay, sand, or gravel, the top branches lose their vitality and the trees become stunted and unsightly. In order to renovate the tree in question see that the drainage is effective, remove all exhausted soil, cut or pare off all dead roots, and fill up with good rich fresh soil, and if not too far gone the tree will soon push fresh roots into the new soil. Remove any dead branches in a sloping

direction, pare and smooth the wound with a sharp knife, and paint the surface with tar to prevent any lodgment of water. Willows are easily propagated by cuttings made of one or two-year-old wood put in in spring; but as you seem to have been unsuccessful in this matter, you should insert them in different soils and aspects, when surely some of them will succeed.—J. B. WEBSTER.

FERNS.

BEST CULTIVATED FERNS.

(Continued from p. 317.)

Botrychium.—This interesting genus contains many very curious plants, all deciduous, but which are seldom seen in cultivation, probably on account of the difficulties experienced in keeping them through the winter, when they should not on any account be allowed to get dry, or death will speedily and assuredly ensue. They are found in all parts of the globe—in Ceylon, in N. America, in New Holland—and the genus is represented at home by *B. lunaria*, or common Moonwort. They are of very little use as pot plants, but their fertile fronds have a very pleasing appearance among other Ferns when planted on the rockery, in which case they should be planted on some nook naturally damp where they will not be disturbed, and where constant moisture will be secured for them while they are at rest. The difficulty in taking them up is to get the crowns with their roots, as the crowns are found generally deep in the ground. They succeed best in a mixture of sandy loam and only a small portion of peat.

B. australe.—This handsome species from New Holland has finely divided fronds, produced from a fleshy underground crown; the sterile segments are bi or tripartite, decomposed, and serrated on the margins, while the fertile ones are pinnate, the whole plant being of a bright green colour. Greenhouse.

B. Lunaria.—This truly European species is widely distributed, and found principally in all parts of Western Europe. It is a very pretty and interesting plant, with fronds erect, varying from 6 inches to 10 inches in height, divided into two segments; the sterile are pinnate, glabrous, and of a pale glaucous green colour with lunulate pinne, the margins of which are in some specimens entire, and slightly crenate in others, usually six pairs in each bunch; the fertile ones are bipinnate, contracted, and forming little spikelets, completely sporangiferous. Although quite a hardy species, it will be found to do best in a greenhouse.

B. lunarioides.—A handsome strong growing species from North America, reaching the height of 12 inches to 15 inches, with fronds of a dark green colour; the sterile ones are bi or tripartite decomposed, segments broad, oblique, slightly serrated on their margins; the fertile ones are pinnate, and somewhat resemble those of the *Anemia* in general appearance. Although perfectly hardy, this species, like the preceding one, thrives best in a greenhouse.

B. virginianum.—This, perhaps the most manageable of all *Botrychiums*, is found growing throughout America and India; it is very interesting on account of its large, dark green, decomposed sterile fronds; the fructification forms a panicle of fertile segments. In Canada, where it is very plentiful, it bears the name of Rattlesnake Fern, and although quite hardy succeeds best in a greenhouse.

Brainea.—This very curious genus contains only one species, *B. insignis*, which for a long time was thought to be peculiar to Hong-Kong where it was first discovered; however, it has since been found in Khasia, and these are the only two places at present known where it exists in a wild state. It is an arborescent kind, forming a somewhat stout stem which is seldom perfectly straight, and which attains, when fully developed, the height of 4 feet, and measures about 2 feet in circumference. The leaves, which are produced in

profusion, are from 2 feet to 2½ feet long and pinnate, pinnae linear-lanceolate in form, bright green on the upper surface, and of a greyish hue and with peculiar markings on the underside. The beauty of the plant is still more enhanced by its fronds being of a beautiful metallic colour when partly developed. Its roots are wonderfully brittle, and great care must be taken in repotting it; if that operation is done at all in a careless manner, the chances are that the plant will never recover if too many roots have been mutilated. Good sandy peat seems to suit it best, and it should also receive plenty of water at the roots and on the stem. Stove.

Ceratopteris thalictroides.—This extremely curious and interesting aquatic plant, forming a genus by itself, is better known as the Floating Stag's-horn Fern, in consequence of its habitat and its forked fronds, which are of two very different shapes, the fertile ones being perfectly distinct, decomposed, upright, and from 2 feet to 3 feet in height, with segments forked and linear, whereas the sterile are bipinnatifid, from 1 foot to 2 feet in length, and prostrate. Both kinds are produced from a thick, fleshy crown, which should always be kept under water. The whole plant is of a cheerful light green colour, and the sterile fronds are highly proliferous, being completely covered with bulbils, which soon produce a crop of young plants of quick growth if pegged into a surface of moist soil. This being an annual Fern, the spores must be preserved, and require to be sown early in the spring on some very moist loam, where they will germinate and grow freely. When sufficiently strong they should be plunged into the water, so that the crowns should be quite covered. It is a native of Tropical America, and if the water in which it is grown can be kept to one uniform temperature of 65° to 70° it will, in the course of the season, make a very handsome and highly ornamental and effective specimen. Stove.

Ceterach aureum.—The only exotic species represented in this genus comes from Madeira and the Azores, and is at once very distinct and very effective, differing essentially from our own *C. officinarum* in being of a much more vigorous habit, its beautiful fronds rising from a tufted crown; they are pinnatifid, often pinnate towards the base. Instead of being about 5 inches or 6 inches high, like those of *C. officinarum*, they often measure 22 inches or 24 inches in cultivation, the pinnae deeply lobed, and sometimes auriculate at the base. They are leathery, smooth, and dark green on their upper surface, and their underside is densely clothed with brown, imbricated, large squamose scales. It is much easier to cultivate than our own British species and will be found to do well in a mixture of three parts peat to one of loam and sand, mixed up with little pieces of limestone, in which mixture it seems to delight. When planted or potted in such light material it requires a good lot of water at the roots. Greenhouse.

Cheilanthes.—One of the most interesting genus amongst evergreen Ferns, including, as it does, some of the most elegant and exceedingly beautiful forms of Ferns whatever in cultivation. Although coming principally from tropical countries, nearly all of them succeed best in an intermediate house where the temperature seldom exceeds 60°. This is no doubt owing to their being found in their native habitats at great elevations. Anyhow, wherever they are seen at a disadvantage and in bad condition, it is invariably where they are kept in the stove and frequently syringed, in which case they are treated with too much kindness, and which treatment results in having shapeless and thrifty plants deprived of all beauty. They should be grown as near to the glass as possible, either on shelves against the glass or else in baskets suspended from the roof, for which purpose many of them are wonderfully well adapted. No watering or syringing overhead should be allowed to them, as this is as injurious to all of them as any extra heat, but they should be supplied with an abundance of water at their roots. For that purpose they must be either potted or basketed in good fibrous peat and sand, with their

crowns kept up well above the rim of the pot whenever they are repotted. The compost should be made very porous, and to that effect a small portion of sandstone or charcoal broken in pieces of small size should be added to it. For the successful management of these charming plants, then, the two great evils to be avoided are strong heat and moisture overhead, and the principal points, or those most beneficial to their welfare, are abundance of water at the roots, plenty of light overhead, and an open and porous compost to grow in.

C. argentea.—A well-known and much appreciated species from Tropical America, with fronds produced abundantly from an upright crown. These grow to 6 inches or 8 inches high, and are triangular in form. Their upper surface is of a bright, dark shining green, while their underside is covered with a farinose powder of a pale lemon or straw colour at first, but which becomes gradually as white as snow. The curious contrast formed by the black marginal line all round the frond produced by the presence of the sori is remarkable in the extreme, the effect of it being very pleasing. This evergreen species should be grown in a naturally moist place in the cool fernery, where it soon would become a favourite.

C. Bergiana.—This South African species of comparatively recent introduction is one of the most handsome of its tribe. Its beautiful quadripinnatifid fronds of a triangular shape and bright shining green are produced from a single crown, and borne on long stout stalks, hairy throughout. They often attain the height of 12 inches to 14 inches, and are proportionate in breadth, with pinnae finely cut and loosely set, giving the plants a very elegant appearance. It is singularly prolific, and the way by which it reproduces itself most readily is very peculiar, and confined only to this species; from the roots spring a quantity of small seedlings, which in a very short time develop into good-sized plants. This evergreen kind requires to be grown in the cold fernery.

C. elegans.—This very delicate-looking, handsome species from Tropical America, where it is found growing everywhere, is generally considered a stove Fern, but it will afford much greater satisfaction if grown according to the treatment recommended above. It is commonly called the Lace Fern; its beautifully divided fronds are produced in great quantities from crowns clustering together; they grow to about 18 inches or 20 inches in length, are tripinnate, and the whole of their underside as well as the stalks on which they are borne are wholly hairy; the fertile fronds have a very peculiar appearance, produced by their little pocket-shaped roundish pinnules.

C. fragrans.—An elegant little Fern of dwarf dimensions, from Madeira and Algeria, deliciously scented, the fronds retaining their agreeable perfume for a very long time when dried; they are from 6 inches to 8 inches high, of a bright green colour and bipinnate with obtuse pinnae, the basal ones often being pinnatifid and the stalks hairy. Greenhouse.

C. frigida.—A very handsome tropical American species rarely seen now in cultivation. It is particularly well adapted for basket work, as its long fronds, produced from a creeping rhizome, thickly covered with brown chaffy scales, often reach 18 inches or 20 inches in length; they are tripinnate, triangular in shape, of a shining dark green colour on the upper side, with the whole of the underside covered with long brown hairs. The stems are brown, and also liberally clothed with hairs of the same colour.

C. hirta.—This South African species is very free growing, and one of the prettiest of the genus. The fronds, which are very hairy, subtripinnate, and pale green in colour, are produced freely from a single crown; they grow to about 18 inches in length, and are of an erect habit. This species has produced a magnificent variety called *C. hirta Ellisiana*, with fronds very broad and of a naturally more pendulous habit, and growing into a very handsome specimen.

C. spectabilis (chlorophylla).—A very strong growing species, a native of Brazil and the Organ Mountains, well adapted for growing in baskets, as its handsome tripinnate fronds, produced from an upright caudex, often attain the length of 4 feet, especially if grown in heat. It forms a charming object when planted out in the rock fernery so that its fronds hang over the rocks; they are slightly hairy, as also are the jet-black stalks on which they are borne.

C. tenuifolia.—This exceedingly handsome species from the East Indies and Australia is partially deciduous. Its fronds, of a bright green colour, are of upright habit and produced from a creeping rhizome; they grow from 15 inches to 20 inches high, and are somewhat ovate in outline.

C. viscosa (tomentosa).—This is a totally distinct species from Tropical America, and of which the outline of the fronds essentially differs from any of the other Cheilanthes. It is generally grown in a stove, but it will be found to thrive admirably under the treatment recommended previously. The fronds are produced in great quantities from a creeping rhizome; they are tripinnate, triangular in shape, and pale green in colour; the whole of the plant is covered with viscid or glutinous hairs.

PELLEE.

NEW METHOD OF SOWING FERNS.

NEVER, perhaps, was the word "new" applied more *à propos* than in the case before us. The honour of the discovery belongs to M. Dugourd, a gardener of Fontainebleau. To cultivate the Ferns he gathers in his herbalising, M. Dugourd has sought to reproduce the conditions in which they naturally grow, and for this purpose he has constructed rockeries with various exposures, as well as underwoods, thickets, &c., which are furnished relatively to the conditions they afford. In pursuing this course M. Dugourd meets with full encouragement from his employer, M. de Circourt.

The mode of sowing Ferns adopted by him is as follows: The ruggedness of a small rockwork of millstone placed in a gloomy corner behind a greenhouse was required to be hidden by Ferns such as would accommodate themselves to this situation. Scolopendriums were considered appropriate to the object in view, but as certain parts which it was desired to cover were devoid of earth, and only presented the natural rugged surface of the millstone, M. Dugourd formed the idea of sowing the spores by a procedure totally different from that generally followed. He took some Scolopendrium fronds well furnished with sori, and brushed them strongly into the water of a basin at the foot of the rock, in order to separate the spore cases and disengage the spores; after which, from time to time, with the help of a syringe, he took, after having stirred it, some of the water in the basin, and squirted it over the parts of the rockery which he desired to cover with the Fern. At the end of some months little spots appeared, which constantly increased in number, and these became larger, and at length developed into young Scolopendriums. I can only attribute the presence of these plants, he says, to the operation I had performed, since besides these there are not any roots of this Fern in the garden.

The result thus obtained by M. Dugourd seems to open out a new way of multiplying not only Scolopendriums, but Ferns in general, as well as to facilitate the covering with these plants the surface of certain denuded spots the access to which seemed so difficult as to oppose all attempts to furnish them—for example, rock walls raised in such a perpendicular manner that it is almost or quite impossible to plant them successfully. Thanks, however, to the procedure invented by M. Dugourd, it appears probable that they might be covered with verdure. For that purpose it would suffice to drop into tubs or basins filled with water some fertile fronds of various Ferns adapted to the circumstances, to draw up this water with the syringe, and shoot it over the various parts one has to furnish. The operation should be repeated more or less frequently.—E. A. CARRIERE (abridged from *Revue Horticole*), in *Florist*.

INDOOR GARDEN.

SARRACENIAS AND THEIR CULTURE.

As it is now about the time when these plants should be repotted and started into growth, a few observations on the best treatment for them may not be unwelcome. Although the singular structure of the leaves and the fragrance and remarkable forms of the flowers together with the interest which attaches to them from their supposed carnivorous habits have brought these plants with their allies more into notice than hitherto, their cultural requirements are not so generally understood as would seem desirable judging by the frequency with which one sees them in poor condition. Like a good many other plants whose names will suggest themselves to cultivators, Sarracenias appear to have the disagreeable nature of making themselves at home in some places, and defying all attempts to coax them into good behaviour in others. No doubt in some of these cases the causes of failure are as mysterious as the use of the caught insects appears to be to the Sarracenias, but in others the cause is to be found in the absence of some requirement known to be essential to the good health of the plants. Sarracenias appear to belong to the latter case. When once we comprehend the nature of the plants and the conditions under which they thrive naturally, their cultivation is then nothing but a question of convenience. It is not difficult to grow a fine specimen plant of Sarracenia when you know how to do it and have the means of doing it, and the means are not of any special or costly kind. Mr. Baines, who grew these plants to the highest possible perfection, will tell us so. He told me how it was to be done, and by following his instructions I have satisfied myself of their correctness. Glasnevin, too, knows all about Sarracenias. The late Dr. Moore was as happy in his treatment of these plants as he was in almost everything he took in hand—a man of extraordinary sagacity in all that appertained to gardening—the sort of man required in a public establishment. To Glasnevin we are indebted for

The first hybrid Sarracenia, as well as for others of more recent raising. Mr. Bull and Messrs. Veitch & Sons are also famed for their cultivation of these singular plants. Turning to details, the first object is to secure sound rhizomes. A disease, which springs no doubt from ill-usage, often attacks these plants and prevents them from ever making much headway. It appears to be a fungus of some kind, and, attacking the old end of the rhizome, it proceeds onwards, and both roots and leaves are seriously injured by its ravages. For a compost in which to grow them, peat fibre, with just a little of the mould left in it, Sphagnum, charcoal, and a good sprinkling of coarse silver sand are the best materials to use. Pans or pots well drained, in the latter case half filled with drainage, and large enough to allow the rhizome to lengthen and to hold sufficient moisture to keep the ball always wet, may be used to plant in. If the plants are newly imported, they should be carefully overhauled, and all the decayed roots, rhizomes, or leaves removed; if established, then all the old soil should be shaken from the roots, the decayed portion of the rhizome removed, and the bad leaves and pitchers cut off. Whatever may be the truth as regards the pruning off old Orchid pseudo-bulbs, I am of opinion that it is better to remove all old leaves from Sarracenias. We make a practice of leaving two or three good leaves on each rhizome and removing all the rest, thereby ensuring strong young foliage in plenty. When the old leaves are not removed there is a waste of energy in supporting them, and the consequence is shorter and weaker pitchers than are produced when the old leaves are removed. Of course good healthy pitchers from last year are worth keeping, but where they are decayed or brown I should not hesitate to remove them before starting the plants into growth again. Pot firmly and plant some patches of Moss over the surface. This holds the water and prevents the rhizomes from getting dried. Do not pot too deeply,

but keep the young growing end of the rhizome level with the top of the soil. A good saturating should be given, and after this the soil should never be allowed to approach dryness. This is the one great difficulty experienced in the management of these plants—those in charge cannot be persuaded that a swamp-frequenter must be kept saturated, or it will go wrong. In the summer and late spring I water our plants three times a day, pouring a good potful of water into each specimen. I would not recommend standing the pans in water; those who have had any experience with peat soil submerged in water will know how sour and disagreeable it smells in a short time. I never use

and I agree with him, but a temperature of 80° to 85° in a scorching sunlight is not too high, if high enough, to be safe. There is great mischief done by trying to keep a low temperature in bright sunshine. Those who advocate exposure to sunlight for Orchids do not expect us to open the top and bottom ventilators, so that a rapid current of air shall pass over the plant. Draughts of cold air are dangerous to a sun-scorched plant as to a man. The temperature for plants under glass should in some measure correspond with the intensity of the light admitted to them. Very little air is given to our plants during their growing season. The temperature is allowed to fall with the decrease

structure of the pitchers points to some such intention on the part of Nature. Large quantities of these insects are found in the pitchers, and the effect of such on them is sometimes the opposite of beneficial. Where too many flies, &c., are found to be trapped, it is a good plan to set other traps in the shape of bottles of sugar and water, poison, &c. Some growers adopt the practice of stopping the mouths of the pitchers with cotton wadding, so that no insects can enter. The *Sarracenia*s have not escaped the attention of the hybridist, and several good and distinct hybrids have been added to the cultivated species. Messrs. Veitch have had their usual good fortune in the

Flowering spray of *Dioscorea retusa*.

peat for aquatics because of this, and I am certain that if the *Sarracenia* pans were to be placed in saucers of water, the soil would soon become sour, the roots rot, and the verdict in some people's minds would be, "*Sarracenia*s do not like much water." But they like plenty of it when it is fresh and there is nothing stagnant. The syringe, too, must be frequently used and the atmosphere kept at saturation point during the time the pitchers are developing. No shading is required. Our plants grow in a house exposed to the glare of the sun all summer, and that this has suited them is proved by the size of the pitchers. I cut half a dozen pitchers from a plant of *S. flava*, each measuring 3 feet and a little more in length; of *S. Drummondii*, 2 feet 3 inches and nearly 3 inches across the mouth, and beautifully coloured. Now, this was never possible when the plants were shaded. I attribute success as much to

High temperature as the other conditions mentioned. Mr. Baines says a high temperature is not necessary for the production of large pitchers,

of sun heat, no fire heat being used. Aphides often attack the young pitchers, and if not quickly removed they make sad havoc, causing the pitchers to curl and sapping all the strength out of them. Tobacco fumigation should be resorted to whenever this pest makes an appearance. Scale also attacks *Sarracenia*s, and should be removed with the hand. After the pitchers are mature more air may be admitted until in the autumn the temperature is almost the same as that out of doors. During winter all that is necessary for the preservation of the plants is protection from frost. Water must still be freely supplied, though of course not in such quantities as is necessary in warm weather. The

Attraction for insects, in the shape of blue-bottle flies, ants, and even beetles, which these plants possess is a matter of great scientific interest, and although in the case of *Sarracenia*s it remains to be proved that the capture and decomposition of insects in the pitchers play any part in the economy of the plants, yet the peculiar

raising of hybrid forms, for in addition to those described below they have raised several other good hybrids, some of which must in time become as great favourites as the best of those sent out.

S. Drummondii is a richly-coloured species, and one of the most beautiful of side-saddle flowers. The pitchers are about 2 feet in length, erect, funnel-shaped, and beautifully veined and blotched with red on a whitish ground on the upper portion. The undulated, broad lid is almost erect, and marked even more richly than the pitcher. A well-grown specimen of this species is one of the most attractive of plants. In addition to the beauty of the pitchers, the handsome flowers of *Sarracenia*s are very attractive, as much for their singularity of form as for their delicate colours. *S. Drummondii* has flowers about 4 inches across of a rich red colour tinged with brown.

S. flava.—This is a tall-pitchered species, and one of the most variable as to form and variegation. The pitchers of the tallest form reach a height of 3 feet, and are green with yellow markings about

the upper portion. The curious wing which runs from the base to the apex of the pitchers of *Sarracenia* is in this species unusually broad. The flowers are as large as those of the last mentioned and brightly yellow. The named varieties of this species in cultivation are *picta*, remarkable for the size of its pitchers and their red veinings; *ornata*, somewhat similar to the last, but producing flowers about 7 inches across; *atro-sanguinea*, a form with narrower and shorter pitchers, the lids of which are beautifully variegated with red; *crispata*, near in shape of pitchers to the type, but differing in the lighter yellow of its flowers. The above varieties are very handsome plants, for most of which we are indebted to Mr Bull, in whose nursery I saw them in very fine condition last summer.

S. rubra is a less ornamental plant than the foregoing, but still an attractive one. The pitchers are about 1 foot in length, erect, about 1 inch wide at the mouth, with a tail-pointed lid, which along with the upper portion of the pitcher is veined with dull red. The flowers are about 3 inches across and brownish red coloured.

S. purpurea is the most common of the side-saddle flowers in gardens, and is often met with growing out-of-doors with little or no protection from frost. Grown under the conditions above-mentioned, its scoop-shaped pitchers assume a colour almost blood purple, the veining being of a still deeper shade. In a sheltered corner on Messrs. Backhouse's reckery we have seen some fine specimens of this plant.

S. psittacina is a curious little species with horizontal pitchers, which are curiously curved at the apex and shaped not unlike a parrot's head, hence the name. The pitchers are from 6 inches to 9 inches long, and are pale green with deep purple blotches. This species does not seem to flower so freely as the others do.

S. variolaris, a small growing, erect, pitcher-shaped species, not so ornamental as most of the *Sarracenia*s, but distinct in the curiously hooded form of the lid of the pitchers, which are green, mottled with a yellowish colour about the mouth and on the lid. The flowers are pale yellow and 3 inches in diameter.

S. Chelsoni is a very handsome hybrid, raised by Messrs. Veitch from the parents, *S. purpurea* and *S. rubra*, whose characters are traceable enough in the offspring. The pitchers of this kind are erect, growing from 12 inches to 18 inches long, broad and round like *S. purpurea*, and colouring to a deep purple wine colour when well ripened. The flowers are 4 inches across and of a reddish brown colour.

S. Moorei was raised at Glasnevin from *S. Drummondii* and *S. flava*. It has pitchers of some 2 feet in length, erect and in form not unlike *S. Drummondii*, although showing the *flava* blood both in markings and the shape of the lid. The flowers are sweet scented, rosy pink, with tints of green and yellow, and 4 inches across. It is a free flowerer and in every way a most desirable plant.

S. Popei is another Glasnevin hybrid raised from *S. flava* and *S. rubra*, and is remarkable for its beautiful flowers, which are deep crimson margined with yellow.

S. Stevensi resembles *S. Chelsoni* in form of pitchers, but lacks the deep colour of that kind. The flowers are very large on well-grown plants, measuring quite 6 inches across, and are bright pink and white. It is a very fine kind both as regards pitchers and flowers.

There are other hybrids and varieties not included in this list owing to their being similar to others mentioned, though some of them no doubt equally deserving. As I have said, Messrs. Veitch possess some very distinct hybrids which I believe are not yet in the trade. B.

Psychotria cyanococca.—The blossoms of this stove shrub are inconspicuous, but they are succeeded by clusters of bright blue berries, each about the size of a small Pea, and the effect of a plant studded with bunches of such fruit is very

striking in winter. It is readily propagated by means of cuttings; although seed of it germinates freely, yet when obtained in this way it does not fruit so plentifully as from cuttings. This plant is easily grown, and will succeed in any moderately light soil. It is a native of Central America.—H. P.

DIOSCOREA RETUSA.

ONE of the most elegant plants one can have in a greenhouse is this twiner, a native of South Africa. It has slender stems clothed with distinctly veined leaves, and produces a profusion of creamy white fragrant flowers in pendulous clusters, as shown in the annexed engraving, for which we are indebted to Messrs. Veitch, of Chelsea, who distributed the plant a few years ago. On several occasions Messrs. Veitch have exhibited it trained parasol fashion and covered abundantly with elegant drooping clusters of flowers, and as such it has been much admired. When planted out in a warmish greenhouse and allowed to twine at will round an upright pillar it is seen to the best advantage, and, though not showy, makes a pleasing contrast with other gaily tinted flowers. It is so unlike any other ornamental plant in cultivation, that it ought to become more widely known than it appears to be at present.

Allamanda violacea.—I can assure "B." (p. 310) that his not being able to procure this *Allamanda* has saved him from disappointment, for it has not a single property to recommend it. Of all plants of a distinct character, for distinct it is, it is the least worthy of the name and description which it has received of any with which I am acquainted. It is an indifferent grower as compared with others of the genus; it is difficult to bloom, and when it is induced to produce flowers, their dull ugly colour at once condemns them. They are not blue or anything that can pass for that colour. If asked to describe them I should say that they are something between a washed-out lilac and a muddy reddish purple. Much as individual tastes differ in the matter of flowers, I never met with anyone who liked this *Allamanda*.—T. B.

Mr. James's Cinerarias.—In his note upon select strains of this beautiful greenhouse flower Mr. Douglas has in no way over-estimated the exceeding beauty and fine quality of Mr. James's strain. I saw not fifty, but nearly a thousand plants of it in fine bloom a few days ago, and truly the sight was a striking one, for the colours are in many cases quite gorgeous in bright sunlight, whilst the form of the flowers is equally good. Lovers of starry single flowers such as the *Paris Daisies* give would perhaps take exception to the wondrously rotund and full form of the flowers at Woodside, for it cannot be too distinctly understood that Mr. James has left Redlees, Isleworth, where he had resided for thirty years, and has settled in the elevated, healthy, and charming locality of Farnham Royal, Slough, and is within easy reach of such attractive places as Burnham Beeches, Dropmore, and Clevedon. I lay stress upon the fact of this removal from the near neighbourhood of London because the pure air of the Bucks locality seems not only to favour robustness and dwarfness of habit in the *Cineraria*, but the colours seem so much brighter and purer. Mr. James's strain is peculiarly rich in self colours, and it is entirely due to the fact that he favoured self hues that such deep intense colours have resulted. We should never have seen such crimsons, purples, magentas, and many other singularly striking colours in the *Cineraria* had the ringed strain or marked flowers been strictly adhered to. Then the rayed form of petals seen in the blooms shown at South Kensington, and by some fondly thought to have been produced by dressing, is here seen in thousands of blooms, so that it is plain enough the dressing is Nature's only, and not that of the expert. The entire collection is being grown in long, low, span houses admirably suited for the *Cineraria*, and were being well washed by busy bees seeking for food. Generally the flowers

slightly reflex, and many are of enormous size; still the most perfect form is invariably found in those ranging from 1½ inches to 2 inches across.—A. D.

ORCHIDS.

HYBRID ODONTOGLOSSUMS.

IN Messrs. Shuttleworth & Carder's nursery at Park Road, Clapham, the following hybrid varieties of *Odontoglossum* have shown themselves among the thousands of plants of *O. crispum* (*Alexandree*) which are being continually imported from Tropical South America. The handsomest of these hybrids is *O. Wilckeanum*, described in *THE GARDEN* (p. 292), but its distinguishing characters are seemingly not invariable, for here is another quite as fine, but differing as regards the colour of the markings of the flower, which has also rather narrower petals and sepals. This is unquestionably among the handsomest of all the *Odontoglossums* of what may be conveniently called the luteo-purpureum section. Another handsome variety is *O. lyroglossum*, which is at once distinguished by the labellum being lyrate or contracted in width in the middle. The flower is 3½ inches across the sepals and petals, which have a ground colour of primrose-yellow, heavily blotched with cinnamon-brown, the lip being white, suffused with yellow. A plant of this bore two fine spikes from one bulb. *O. mulus*, also in bloom, agreed exactly with that shown by Sir Trevor Lawrence on Tuesday last, but which was said not to be the true *O. mulus*. The original plant to which this name was first given by Prof. Reichenbach is said to be that in Mr. Lee's possession, a fine spike from which we noticed last week. It is certain that both Sir Trevor Lawrence's plant and that under notice are distinct from Mr. Lee's, and not a whit less handsome. There was also in bloom a singularly pretty form of *O. hebraicum*, the one distinguished by the markings of the flower, resembling Hebrew characters. There seems to be numerous forms of this hybrid; this one has narrow, wavy-edged sepals, almost white, and copiously spotted, particularly towards the base, with reddish brown. Among other noteworthy kinds of *Odontoglossum* in bloom in this nursery are some uncommonly fine forms of *O. triumphans* just flowered out of a large importation; also *O. hystrix* and *O. gloriosum* and odoratum, both of which yield some richly spotted forms. Among these is the *O. naevium majus* of Reichenbach, which is but a good form of *O. gloriosum*. The true *O. naevium*, now so scarce, is quite a different plant.

Dendrobium densiflorum at Oakville.

—I noticed here the other day a remarkably healthy young specimen of this *Dendrobe* in a comparatively small pot. It had two fine pendulous spikes, each containing upwards of forty fully developed blooms. I know of no Orchid which possesses such a beautiful tint of gamboge-yellow on the peculiarly frizzed delicate lip as this. It made its growth in the stove, and has now been in bloom for some time in an intermediate house, along with other cool house *Odontoglossums* and Ferns, such as *Athyrium Goringianum pictum* and other fine foliaged plants.—W. J. M., *Clonmel*.

Odontoglossum Pescatorei Veitch.

—At South Kensington on Tuesday last this unique plant was shown by Mr. Ballantine from Baron Schroeder's garden, at The Dell, Egham. It is a magnificent variety, as distinct from an ordinary form of *O. Pescatorei* as it is possible for a variety to be. The flowers are larger than those of any variety we have seen, and the broad sepals and petals completely overlap, so as to form a symmetrically shaped bloom. The great beauty of the flower is its colour, which is snow white heavily marked with irregular transverse bars of a rich plum-purple, but leaving the upper half of the segments unmarked. No other *O. Pescatorei* that has yet flowered out of the thousands imported into this country have shown any tendency to become barred in the sepals and petals, though

frequently the labellum is richly blotched. This plant first flowered in Messrs. Veitch's nursery at Chelsea last year, and on being exhibited at South Kensington and Regent's Park was unanimously awarded a first-class certificate. Soon afterwards it passed into Baron Schroöder's possession, and since then has improved wonderfully. Last year it had a short spike bearing some four or five blooms; now it has a spike nearly 2 feet high carrying ten fine blooms.

Oncidium fuscum.—Mr. Denny, Sir William Marriott's gardener, at Down House, Blandford, sends us a spike of what he considers a very fine variety of this *Oncidium*. Compared with the ordinary form, it is indeed very fine, the labellum being considerably larger and more richly coloured; but still it has the characteristic blotch of brown, which shines as if it had been varnished. Fine varieties of *O. fuscum* like this are quite equal to *O. Weltoni* or *Miltonia Warszewiczii*.

Vanda suavis.—I herewith send you a spike from one of our Vandas. The plant from which the spike sent was cut has at present two spikes exactly the same as the one sent, and other three spikes which promise to be quite as good. The house in which our Vandas are grown has on several occasions during the past winter been as low as 45° at 7 a.m. I do not recommend quite so low a temperature, but owing to circumstances over which I had no control I could not give them a higher one.—DAVID KEMP, *Dunlop, Ayrshire*. [A glorious spike of *V. suavis*, carrying fifteen fine flowers as finely coloured as any we have yet seen. Our correspondent also sends three flowers belonging to varieties of *V. tricolor*, also very fine, particularly that called insignis.]

Miltonia spectabilis.—With reference to "Peregrine's" remarks upon this Orchid, I may observe that one great mistake in its culture is that of giving it too much heat. The finest plants of it I ever saw were grown along with a miscellaneous collection of Orchids and warm house plants where the temperature never exceeded 55° in winter, and where no fire heat was applied from the middle of May until the end of September. The largest specimens were 3 feet across, and carried a large number of highly developed blooms. They were potted in Sphagnum and charcoal only and were grown in baskets, being shifted from one to the other when needful, without in any way disturbing the roots. I have often remarked when on the Continent that *Miltonias* seemed to be better grown there than in this country, large plants in very good health being frequently met with, a fact which I attributed to the cooler treatment given them. Continental Orchid growers seldom cultivate species which demand high temperatures, so that one often sees kinds which are supposed to require much heat grown comparatively cool, and in many cases they appear quite happy under such circumstances. We have much, I suspect, to learn in this respect.—J. CORNHILL.

Ada aurantiaca is not one of the most showy or beautiful of Orchids, but, nevertheless, it is one that should be grown even in select collections. Its orange-red colour and the quaint formation of its flowers set upon neat arching spikes mark it out as a most distinct plant, and it can be purchased at a cheap rate. No one need spend guineas for it, as five shillings will purchase a good established plant, which does not take long to grow into a specimen. In the nurseries of Mr. B. S. Williams, of Upper Holloway, there is at present two handsome plants of it in flower, each with about a score of spikes on it. The flowers are more richly coloured than usual, and more closely set on the spikes. When grown into such handsome specimens as those to which I am now alluding, it is not only well adapted for decorative purposes, but would make excellent specimens for exhibition, the distinct colour of the flowers being much wanted amongst exhibition Orchids. The cultural requirements are exactly the same as those needed by the cool section of *Odontoglossums* and *Masdevallias*.—J. DOUGLAS.

Cattleya Backhousiana, one of the finest of all the varieties of *C. Trianae*, is, we hear, now in bloom in Mr. T. Shadford Walker's collection at Liverpool, to which it was imported as an ordinary *C. Trianae*. It will thus be seen that lovely varieties may crop up from any imported batch of *Trianae*'s *Cattleya*.

Highly-coloured Dendrobium Wardianum.—Some flowers of this *Dendrobe* from Mr. Horsman, of the New Plant and Bulb Company, Colchester, are without exception the finest as regards size and colour that we have yet seen. They measure fully 4½ inches across, and the petals are nearly 1½ inches in width. A third of each segment is coloured with a rich deep plum-purple, and the colour is not only confined to the tips of the sepals and petals, but is carried down the margins of each, and there are conspicuous mottlings over the whole of the segments, rendering the flower very beautiful. The labellum is of course proportionate in size and also richly tinted. This fine variety flowered in the collection of Mr. D. de Ybarrodo, of Liverpool.

Sarcocylus Hartmani and S. Fitzgeraldi.—These are now flowering in the cool Orchid house at Kew. They are small *Aerides*-like plants natives of Australia, and worthy of a place beside *Aerides japonicum*, *Comparettias*, &c., the treatment for which is such as suits these little Australians. The flowers are produced in racemes about 6 inches long, those of the first-named being the size of a sixpence, and white with purple-brown bars on the lower part of the sepals and petals, and of the second half as large again and white with blotches of a pale rose colour.—B.

NOTES OF THE WEEK.

APPOINTMENTS FOR THE WEEK.

Ghent International Exhibition opens on the 15th inst. a continues to the 22nd.

April 19.—Dublin, Spring Show of Royal Horticultural Society of Ireland.

ALEXANDRA PARK.—Mr. Mundella has stated that there is no likelihood of the Government purchasing the Alexandra Park estate in order to convert it into a public park.

KEW GARDENS.—In future these gardens will be open to the public at 12 o'clock on week days and at 1 o'clock on Sundays. On week days the houses and museums are not opened until 1 o'clock.

CUCUMBER AND MELON DISEASE.—We have been asked to say that, if any nurserymen or gardeners have their plants attacked by the above or with cob-web fungus on seeds or cuttings, they can be supplied with material that will probably destroy the disease, with instructions, gratis and carriage free, from E. W. Smith, 109, Cheapside, E.C.

FUCHSIA MRS. RUNDALL.—At the last spring show in Paris we learn that this beautiful new hybrid *Fuchsia* was shown by Messrs. Cannell & Sons, Swanley. A first-class certificate was awarded it, and it appears to have been much admired. It is in the way of *Lord Beaconsfield*, but much finer in every respect, and a remarkably free flowerer.

TURNERA TRIONIFLORA.—This is a pretty little tropical shrub with Malva-shaped flowers and Elm-like leaves. The white purple-eyed flowers, about 1½ inches across, are produced on the ends of the shoots. Unfortunately, they are rather too fragrant to be of much use for horticultural purposes, although both this and several other species of *Turnera* found favour with our forefathers. The home of this interesting plant is Brazil, but from the ready manner in which it reproduces itself from seed it has become a weed in most tropical countries. We saw a plant of it in flower the other day in the Begonia house at Kew.—B.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.—The spring flower show of this Society, held in Edinburgh on Wednesday and Thursday last week, was a great success in every respect. During the two days nearly 20,000 persons visited the

Waverley Market, in which it was held, including many of the leading aristocracy. This number is, of course, largely exceeded in some of the large towns in England at horticultural *fêtes*, but on most of these occasions there are fireworks and other attractions which combine to draw out the multitude. At Edinburgh the shows are always purely horticultural, if a military band may be excepted. The Society dates from 1809, and although probably the oldest, is still one of the most vigorous in the kingdom. Besides the money taken at the gates on the show days, the Society derives a considerable income from its guinea and half-guinea memberships, to which there has been lately a considerable addition, owing to the vigorous appeal made by the Council of the Society to the public of Edinburgh and neighbourhood. This year—an ordinary one—£800 is offered in prize money in the aggregate, according to the prize schedule, at the three shows to be held during the year. The entries are open to all competitors free, and the prize money is paid on the show days. Edinburgh is fortunate in having a building like the Waverley Market, quite independent of the caprice of wind and weather, which frequently makes havoc at horticultural exhibitions held under tents.

AN EXHIBITION OF GARDEN FURNITURE, including greenhouses, boilers, seats, summer-houses, rollers, lawn mowers, &c., is to be held in the Agricultural Hall, Islington, in connection with the furniture exhibition, from April 23 to May 16 next, which, judging by the number of entries, promises to be very interesting. Every foot of available ground space has been engaged for some time, and also most of the galleries.

NEVUSIA ALABAMENSIS.—This little-known shrub, mentioned in *THE GARDEN* (p. 324) as having been exhibited in bloom for probably the first time in Europe at an exhibition in Paris, was last spring in full flower on one of the walls at Kew. Judging by the specimen there it does not seem likely to take high rank among flowering shrubs, the clusters of stamens constituting the principal display being of a yellowish green colour, and although produced in such profusion as to completely wreath the shoots, their colour does not justify the name of Alabama Snow Wreath. It may be that some are purer in colour than others, but that time will prove, for I see it is now catalogued by most of dealers in such plants. The specimens exhibited were no doubt grown under glass, and in that case would be better coloured than in the open air. I find that it strikes readily from cuttings made of the young shoots.—T.

ROYAL HORTICULTURAL SOCIETY.—We learn that an important change is about to take place with regard to the work to be done by the scientific committee of this society. It is intended to so constitute this committee as to make its proceedings more useful to horticulturists generally, and the chief means by which this is to be effected will, we understand, be in holding meetings, at which papers on horticultural and botanical subjects will be read and discussed from both a scientific and practical aspect, and to which anyone interested in such subjects will be admitted. The use of rooms of the Linnean Society at Burlington House has, we understand, been obtained for the purpose, and the first meeting of the society will be held there on May 8, at 8 p.m., when various papers on different subjects will be read. This movement or any other tending to extend the usefulness of the Royal Horticultural Society has, we need hardly say, our warmest support.

Wasp stings.—In *THE GARDEN*, February 24, under "Hornets and Wasps," are given various remedies for their stings. I have tried hazeline, and found it the best remedy for wasp stings. Some time ago while going through my garden my hat touched the branch of a tree on which a wasp's nest was fixed; down came a number of wasps and stung my forehead and face. The pain was great. I happened to have a bottle of hazeline. I poured some on my hand and rubbed it several times over my forehead and face. In less than a

minute all the pain of the sting was gone. These were small wasps. On another occasion I was stung on my hand by the common yellow wasp of India. The result of the hazeline was exactly the same. On a third occasion my native gardener was stung, and the result of applying hazeline was also like the above. I think hazeline a very valuable remedy for such a purpose. It is clean, has a pleasant smell, and can always be handy.—E. BONAVIDA, M.D., Surgeon-Major, I.M.D.

RECENT PLANT PORTRAITS.

THE April number of the *Botanical Magazine* contains portraits of the undermentioned plants:

MEDINILLA AMABILIS (Double Plate 6681).—A handsome stove shrub producing large bunches of rose-coloured flowers, a native of the island of Java, whence it was imported about ten years ago by Mr. Bull, who presented the plant, whence this illustration was taken, to the Royal Gardens, where it bloomed in August last.

HOYA LINEARIS (Plate 6681).—A curious slender habited trailer with narrow hairy leaves and creamy white waxy flowers from Nepal.

LÆLIA MONOPHYLLA (Plate 6683).—A native of Jamaica, also known under the names of *Trigonidium monophyllum* and *Octadesmia monophylla*. An Orchid of slender habit of growth with solitary medium-sized orange flowers resembling in colour those of *Epidendrum vitellinum*.

HAMAMELIS VIRGINIANA (Plate 6684).—Native of America. This is the common Wych Hazel of the United States, and is also known under the names of *H. virginica*, *H. dioica* and *androgyna*, *H. corylifolia*, *H. macrophylla*, and *Trilopus virginiana nigra*. At the fall of the leaf its foliage assumes a gorgeous colour, and contributes not a little to the beauty of the American forests at that season. Its flowers consist of curious yellow filaments, and are produced in midwinter.

CADIA ELLISIANA (Plate 6685).—A native of Madagascar. A small, slender-growing shrub, with rose-coloured campanulate flowers of medium size. It is a member of a small family of which only three species are known, and all of which are natives of Eastern Tropical Africa, Southern Arabia, and Madagascar. The specimen here figured was communicated by Mr. Day, of Tottenham, with whom it flowered as a small bushy plant in a pot in December, 1882.

W. E. G.

QUESTIONS

Adiantum farleyense.—Will some correspondent tell me whether it injures this Fern to syringe it occasionally? and if it ought to be kept quite out of the sun?—ROSELEAF.

Tree Ferns dying.—Will someone kindly explain why my Tree Ferns begin to die off directly the leaf is fully expanded? They have been repotted, are kept moist and well syringed.—NORWOOD.

Old-fashioned Lobellias.—Will some reader of THE GARDEN kindly inform me where I can get old-fashioned herbaceous Lobellias exactly like *Lobelia fulgens*, but in colours: dark blue, maroon, and dark violet? They used to be common in Devonshire gardens.—B.

Killing mice.—Can any of your readers help me in the following case?—A pit in our Melon ground, which is close to or rather on the edge of a wood, in which I force Strawberries, got infested with mice, those long-snouted, brown-backed ones, which have completely spoiled a lot of plants by eating the flower-spikes clean out of the crowns. I have for some weeks been using Battle's vermin powder as per directions, which the mice eat ravenously, but hitherto I have found no dead mice, and still the destruction goes on. On the last occasion of laying the poison, I mixed it in oatmeal with lard, but added as much pure arsenic as Battle's, but still can get no dead mice. Happening the other day to catch one alive in a stove adjoining the pit, I cut him open, and was most miserably surprised to find the little brute's stomach literally crammed with the oatmeal, of a Battle's blue colour, and that highly charged with arsenic. I was in despair, and give it up. Can anyone give me help?—J. K.

SOCIETIES.

ROYAL HORTICULTURAL.

APRIL 10.

THE principal features of the display at South Kensington on this occasion were the *Rhododendrons*, hardy *Azaleas*, *Narcissi*, and *Anemones*. These, together with some miscellaneous groups and some admirably grown *Orchids*, made the conservatory in which the show was held attractive. Contrary to expectation, but few new plants were submitted to the committee, and only one received a first-class certificate. This was

MASDEVALLIA SCHLIMI, a very distinct species and a handsome one. It has erect foliage, of thick texture, and flower-stems about a foot high. The plant shown bore two spikes, five flowers being on one and four on the other, borne close together on the upper part of the stem. The three sepals have long yellow attenuated tails, each about 4 inches in length. The ground colour of the flower is reddish brown. Exhibited by Mr. Baxter, gardener to Sir Trevor Lawrence, Burford Lodge, Dorking.

From Sir Trevor Lawrence's garden also came a wonderfully richly coloured *Odontoglossum vexillarium*, one of the deepest we have seen, the colour a dark purple-rose. A cultural commendation was accorded to Sir Trevor's gardener for a finely-flowered specimen of *Brassavola Perrini*, a species with long terete foliage and with ivory-white blossoms over 2 inches across. The plant was one large tuft attached to a block of Tree Fern placed in a pot. There were some thirty spikes on the plant, each with two or three flowers. A cultural commendation was also given for a finely-flowered plant of *Odontoglossum mulus*, a species or variety with flowers some 4 inches across, with a ground colour of pale primrose-yellow, heavily blotched with chestnut-brown. There were thirteen blossoms on one long, arching spike. A cut spike was sent of *Lælia elegans Turneri*, which is one of the finest of all *Orchids*. The flower is larger than that of the type, and the petals and sepals are a rich plum-purple, and the labellum of an intensely bright amethyst.

A cultural commendation was awarded to Mr. Parr for two very fairly bloomed plants of *Cœlogyne ocellata* from Mr. Russell Sturgis' Garden, Givon's Grove, Leatherhead. So numerous were the flower-spikes, that the plants looked like masses of white. The same exhibitor also showed a *Carnation* called *Perfection*, with prettily pencilled pink flowers, and a beautiful *Gloxinia* called *Spotted Beauty*. It was one of the erect-flowered group, and appeared to be extremely floriferous. The flowers were white, profusely spotted with violet-purple.

Mr. B. S. Williams was awarded a silver medal for an attractive group of miscellaneous plants, among which were a few choice *Orchids*, such as *Odontoglossum vexillarium*, a fine plant with five spikes; *Lælia elegans Lecana*, a new variety in the way of *Turneri*, but much lighter; *Dendrobium densiflorum*, *Masdevallia Harryana*, *Trichopilia lepidota*, a rare species with flowers about the size of the better-known *T. suavis*, but of a deeper colour; and *Ada aurantiaca*, a handsome specimen with nearly a score of bright orange flower-spikes. The group also contained a few good *Rhododendrons*, such as *Countess of Sefton*, with large white blossoms; *R. ochraceum*, a species with dense trusses of white flowers; and *R. Lady Alice Fitzwilliam*, a lovely variety with flowers fully 4 inches across and pure white. Among the *Imantophyllums* were the highly coloured *Martha Reimers*, *Madame Van Houtte*, and *grandiflorum*, three of the very best for richness of colour, size of truss, and flower. Two varieties named *Mrs. Rawson* and *Dr. Masters* were among the most beautiful of the *Amarylises*.

The double *Cineraria* named *Mrs. Thomas Lloyd* was shown in an admirable condition by Messrs. Cannell and Sons, Swanley, better than we had hitherto seen it, and showed what a fine plant it is when well grown. A dozen and a half plants were shown all in 6-inch pots, and each carried hugespreading heads of bloom, each of which were

about 1½ inches across, perfectly double and globular, and of a rich purple. Messrs. Cannell also showed numerous cut blooms of *Anemone coronaria*, one of the finest strains, and specimens of *Salvia interrupta* with large spikes of purple flowers, the white *Nicotiana affinis*, and *Chrysanthemum segetum* variety *Aurora*, an extremely fine double *Marguerite* of a clear chrome-yellow.

One of the brightest features in the show was an extensive collection of *Anemone coronaria* flowers grown in the south of France, and exhibited by Messrs. Collins & Gabriel, Waterloo Road. The flowers represented every possible tint to be found among *Crown Anemones*, and the blooms were enormous, some being fully 4½ inches across. They were named the *New Victoria Giant Anemones*. Would that we could grow such *Anemones* in our English gardens. The group also comprised flowers of *Anemone fulgens*, both the original single and the semi-double *multipetala*, and also the *Peacock Anemone* (*A. pavonina*), a wild variety of *A. fulgens*. It has larger flowers than the latter, and inside the cup there is a distinct ring of a yellowish colour. It was shown under the name of *A. coronaria Dazzler*. This group, together with a smaller display from Messrs. Cannell, won a fair share of admirers.

The pretty old *Tropæolum tricolorum* was shown by Messrs. Carter, High Holborn. The plants were trained on balloon-shaped trellises, which were studded with the bright little red blossoms. This is a very pretty plant for the greenhouse in spring. A beautiful double white *Indian Azalea* was shown by Mr. Nicholl, Lower Merton Nursery, Surrey. It was named *Princess of Wales*. The flowers were 3 inches or 4 inches across, quite double, and of snowy whiteness.

Azalea rosæflora, or *Rollissoni*, as it is often called, was shown beautifully in bloom by Messrs. Veitch, and was much admired, inasmuch as it is so unlike any other *Azalea*, the flowers being double and of a soft salmon-pink colour. The plants are dwarf and bushy, and bear flowers very freely. In a half-expanded state the flower-buds are like miniature *Rose* buds.

Some plants in flower of a new *Rose* called *Merveille de Lyon* were shown by Messrs. W. Paul & Son, Waltham Cross. The flowers are large, of good form and substance, and almost pure white, there being only a faint suggestion of pink in the blossoms. It is one that, like *Mabel Morrison* and *Madame Lacharme*, will sure to be appreciated, as there are so few Hybrid *Perpetual Roses* of such a light colour.

A new *Rose* called *Her Majesty* was exhibited by the raiser, Mr. Bennett, Shepperton. It is unquestionably one of the finest of all *Roses*, the flowers being unusually large and full petalled, and the constitution of the plant is most robust. The colour is a pleasing deep pink. We shall undoubtedly hear a good deal in future respecting the beauties of *Her Majesty*, though at present it appears to be scentless.

A group of hardy *Rhododendrons* exhibited by Mr. Lane, Great Berkhamstead, was highly attractive, as all the specimens were large standards densely covered with bloom of varied hue. Inter-mixed with these were bushes of *Ghent Azaleas* and *Azalea mollis*, the latter of various colours, from orange-red through pink to almost white. Nothing can well be more beautiful than *Azalea mollis* when well flowered, for the delicate, yet bright, hues of the flowers harmonise so beautifully with the tender green of the unfolding foliage. A silver *Banksian* medal was awarded.

In order to show what can be done with *Daffodils* in a cut state, Mr. Aldous, the florist in Gloucester Road, sent a huge bouquet some 2 feet across, composed of nothing but varieties of *Narcissus*, of which there were no fewer than forty-four in the bouquet. The large trumpet kinds were most conspicuous as they stood out from a dense groundwork of less showy sorts. It was a masterpiece in the art of bouquet making, and strikingly attractive and uncommon. A large basketful of *Daffodils* mixed with *Ferns* was also shown by Mr. Aldous, and, like the bouquet, was much admired.

An extensive collection of Narcissi, including nearly 200 varieties, was exhibited by Messrs. Barr & Son, King Street, Covent Garden. It included not only the older kinds, but many new seedling varieties not yet in commerce. We should say that every known variety of the Ajax section or Trumpet Daffodils was shown, from the noble *N. maximus* to the tiny *N. nanus*, minor, and *pumilus*, and had it been rather earlier the tiniest of all, *N. minimus*, would have been represented. Here was ample material for a close study of cultivated Narcissi, but those who knew only the older types were no doubt puzzled when they came to the new hybrids, such as the Barri, Humei, Burbidgei, Vincenti, Nelsoni, and Leedsi races, all of which are intermediate between type species. It was rather too early for the *N. incomparabilis* type, but there was a good sprinkling of varieties; and of the Poet's Narcissi there were some fine bunches of *N. poeticus ornatus*, one of if not the earliest of all. From this vast collection we singled out about a dozen which would, we consider, represent most of the various types. The selection was *maximus* (which should always be included), *bicolor Empress*, *lorifolius Emperor*, *cernuus pulcher*, *luteus major* (similar to *maximus*), *obvallaris* (the Tenby Daffodil, very early), *Hudibras* (a fine trumpet variety), also *stellatus*, *N. incomparabilis Harpur Crewe*, *Leedsi amabilis*, *Vincenti Katherine Spurrell*, *N. odorus*, any or all of the poeticus varieties, Humei and its varieties. Messrs. Barr & Son deserve praise for bringing together such a wonderful array of Narcissi. The group was awarded a silver Banksian medal.

Some choice Primroses, the pick of a large collection, were shown by Mr. R. Dean, from his nursery at Bedford, Ealing. Among these were *Magenta Queen*, a beautiful sort with very large finely-shaped blooms of a clear, bright magenta. *White Queen*, similar in flower, but white with yellow centre, and, like the last, remarkably floriferous; *Polyanthuses Scarlet Gem* and *Orange Beauty* were both beautiful duplex or Hose-in-hose sorts, the first being a bright red, almost a scarlet, the other a rich orange-yellow. Mr. Dean also showed plants of *Myosotis dissitiflora* the best of all the Forget-me-nots, together with the pure white flowered variety of it, which is a lovely plant, a charming contrast to the other.

From the society's garden at Chiswick, Mr. Barron exhibited a miscellaneous group, consisting chiefly of *Polyanthus*, *Narcissi*, *Spireas*, *Azalea mollis*, some admirably grown *Cinerarias*, *Primula rosea* and *cashmeriana*, *Carnations*, *Tulips*, and *Begonia carolinæfolia*, a pretty species with elegant sprays of small rose-pink blossoms. These gay flowers, intermixed with some huge specimens of *Pteris serrulata*, *Adiantum farleyense*, and other fine-leaved plants, was a much admired feature of the show.

Fruit.—The most important exhibit was a collection of Apples from Messrs. Rivers, of Sawbridgeworth. It numbered some sixty dishes and as many varieties, and the fruits on the whole were in admirable condition. Some of the most noteworthy were *Blenheim Orange*, *Wadhurst Pippin*, *Betty Geeson*, *Beauty of Kent*, *Reinette du Canada*, *Lord Burghley*, *Rymer*, *Gloria Mundi*, *Cornish Aromatic*, and *Syke House Russet*. A good-looking Apple named *Moss' Incomparable*, in excellent preservation, was shown by Messrs. J. Veitch, who also exhibited fruits of the new Pear of French origin called *Directeur Alphand*, an illustration of which was given in *THE GARDEN*, p. 632, Vol. XVIII. The committee desired to see it again. A certificate was proposed and seconded, but as the rule is not to grant a certificate unless at least six fruits are exhibited, the certificate was withheld. It is a large, handsome-looking Pear and a good keeper, but its eating quality is not highly spoken of. A cultural commendation was voted to Mr. McIndoe, Hutton Hall, Yorkshire, for a dish of *Early Beatrice Peach*. The fruits, of course, were small, but were admirably coloured. A cultural commendation was also given to Mr. Fife, Ditton House, Thames Ditton, for a fine dish of *President Strawberries*. Messrs. Lane, Great Berkhamstead, exhibited samples of their new *Prince*

Albert Apple, a large handsome sort, of good quality, and highly spoken of.

Committees.—The members present were: *Floral*.—Mr. B. S. Williams (chairman), Messrs. G. Henslow, G. F. Wilson, J. Douglas, H. Bennet, W. Bealby, J. Laing, H. Ebbage, J. Wills, J. Cutbush, H. Cannell, T. Moore, S. Hibberd, H. Ridley, G. Duffield, H. Turner, H. Ballantine, J. Dominy, W. B. Kellock. *Fruit*.—Mr. J. Lee (chairman), Messrs. G. Goldsmith, J. Willard, J. Roberts, W. Paul, J. E. Lane, W. Denning, A. Sutton, R. D. Blackmore, L. A. Killick, J. Woodbridge, J. Smith, F. Rutland, H. J. Veitch, R. Hogg, and G. Bunyard.

Lecture.—Mr. Henslow drew attention to some *Azaleas*, the forms being innumerable. Now, the old *A. indica* was very rare at the beginning of this century. *A. pontica* appears to have been the species with poisonous honey, and which stupefied the soldiers of Xenophon. It has been used in its native country, east of the Black Sea, for medicinal uses. *Rhododendron ponticum* was supposed erroneously to be the deleterious plant. A third genus, *Rhodora*, of which *R. canadensis* was introduced by Sir J. Banks in 1767, is closely allied. Indeed, though called genera, they can all three be cross-fertilised, which proves them to be the same genus. Mr. Henslow then made some remarks on physiological affinity not always corresponding with morphological, in that plants may differ very much in structure can yet be grafted on one another or cross-fertilised. Thus, *Garrya elliptica* can be grafted easily on *Aucuba*, and *Hibiscus* will fertilise *Abutilon*. The lecturer called attention to a curious phenomenon sometimes seen in *Tulips*, in that a leaf or petal may be half green and half coloured and situated on the stem. The coloured part ceases to grow, so that it checks the growth of the peduncle. This heads over, and may even crack and decapitate the *Tulip*.

Scientific committee.—Sir J. D. Hooker in the chair.

Peas, &c.—Mr. MacLachlan showed *Peas* received from America attacked by *Bruchus Pisi*, also dipterous larvæ cases found about the roots of *Dendrobium crassinode*, and a beetle (*Donacia* sp.) with *D. Devonianum*. The two latter were received from Col. E. S. Berkeley.

Fossil cone.—Mr. Boulger showed a specimen of *Pinites hexagonus* from the Gault, related to *Pinea*, which, like recent species, is still associated with *Sequoia*.

Narcissus sp.—Dr. Masters showed specimens from Prof. M. Forster, amongst which was the rare *N. rupicola* of Spain.

Sclerotia of Potatoes.—Mr. G. Murray replied to certain comments of Mr. A. Stephen Wilson upon his remarks at the last meeting. Mr. Murray adheres to his opinion that there is no sufficient proof of the mycelium arising from the plasm state, and asks if a seedling be so severely attacked, why is it perfectly healthy? He cannot yet pronounce what they are without further material.

Puccinia Buxi.—Mr. W. G. Smith showed specimens of *Bux* badly attacked by this fungus, which will germinate on the *Olive* in twenty-four hours.

Greyia Sutherlandii.—He showed drawings of flowers of this plant, pointing out the long and short styled conditions, though the stamens were long in both cases. The flowers are provided with a circlet of glandular bodies of unknown use.

Violets killed by cold.—Mr. G. Lee, of Clevedon, sent *Violet* plants completely killed throughout by the late severe cold weather.

Shrubs injured by cold.—Mr. Loder showed many kinds of shrubs severely injured by the late cold, the temperature having fallen to 3° on March 10.

Camellia reticulata.—Mr. Boscawen sent a blossom with the observation that "it had been out-of-doors unprotected for years against a wall with an east aspect. This *Camellia* is by far the hardiest of all; not a leaf has ever been injured."

Frost at Lamorran.—He also sent a list of temperatures for March, the lowest of which was 22° of frost on Saturday, March 10.

OBITUARY.

JOHN COLLINSON, for forty years head gardener at Eaton Hall, died the other day at Chester, aged eighty-one. In bygone days Mr. Collinson was a prominent exhibitor of fruit, both at Chiswick and Regent's Park, competing successfully with such good gardeners as Ingram, Spencer, Fleming, and Hill—all now, alas! gone. Ten or twelve years ago he retired from the gardens at Eaton Hall with a pension from the duke of his full salary, with a house and garden rent free. He was interred at Eccleston Church, the Duke of Westminster, Lord Arthur Grosvenor, and Lord Henry Grosvenor being among the numerous relatives and friends present at the funeral.

WE have to record with regret the death of Mr. JOSEPH SPYERS, which took place a few days ago at Torquay. Mr. Spyers till within the past few months had been *Orchid grower* for some ten years to Sir Trevor Lawrence at Burford Lodge, Dorking. His skill as an *Orchid cultivator* was universally acknowledged, and of this the celebrated collection alluded to bears ample evidence. Besides being an expert cultivator, Mr. Spyers was a frequent contributor to the gardening periodicals—*THE GARDEN* amongst others, and his writings always contained sound practical information. He was held in high esteem by Sir Trevor Lawrence, whom he had served so long.

WE hear also of the death of Mr. HERBERT SMITH, eldest son of Mr. James Smith, of the Darley Dale Nurseries, Matlock, at the early age of forty-six.

BOOKS RECEIVED.

"The Lily of the Valley," by William Roberts. London; L. Upcott Gill.

"Prize Essays on Celery Culture," written for D. Landreth & Sons, Seed Growers, Philadelphia.

"Landreth's Prize Essays on Onion Culture," published by D. Landreth & Sons, Seed Growers, Philadelphia.

CATALOGUES RECEIVED.

Hooper & Co.'s (Covent Garden) Rustic Garden Furniture Landreth's (Philadelphia) Almanack and Catalogue. Brunt's (Poitiers) General Plant Catalogue.

B. S. Williams' (Upper Holloway) New and General Plant Catalogue.

Barr & Sons' (Covent Garden) Descriptive Spring Catalogue.

Delesalle's (Lille) Plant Catalogue.

Ellwanger & Barry's (Rochester, N.Y.) Catalogue of New and Rare Roses.

B. Harlow (Macclesfield) Horticultural Appliances.

Lovell & Son's (Duffield) Strawberry Plants.

Cape bulbs (*E. F., Paris*).—We are unacquainted with any wholesale dealers in such things, except those you mention.

Odontoglossum Alexandræ (*T. L. Cater*).—The flower you send represents a very pretty and scarce variety, and rarely have we seen a flower with such a rich suffusion of rosy purple tint in the sepals.

Rabbits and Berberis japonica (*H. F. C., p. 323*).—Rabbits are not fond of *Berberis japonica*, but in times of scarcity, i.e., during severe frost and snow, I have known them to nibble it.—J. B. WEBSTER.

Names of plants.—*J. D. N.*—1, *Davallia decora*; 2, *Pteris cretica*; 3, *Poly-tichum angulare proliferum*; 4, cannot identify for want of spores; 5, *Pteris hastata*; 6, *Hypolepis* (?), possibly *distantis*.—*A. C.*—*Adiantum*, forked variety of *A. concinnum*. If all the fronds are forked like the enclosed it is not known in commerce.—*J. Jennings*. *Maxillaria Harrisonie*.—*Puzzled*.—*Allium neapolitanum*.

—*T. S. (Coventry)*.—The Fern is *Davallia Nova-Zelandie*. The *Orchid* flower did not reach us; please send again.—*C. A.*—*Canadian Blood-root* (*Sanguinaria canadensis*).—*W. M. (Perth)*.—*Odontoglossum spectrum*. A very finely coloured variety of *Dendrobium nobile*, one of the deepest we have seen. We do not recognise the *Burlingtonia*, but will endeavour to ascertain the name. The *Cattleya* intermedia is marked in an uncommon way.—*J. B.*—1, *Cytobochium Karwinskii*; 2, *Oncidium sphacelatum*; 3, *O. stelligerum*.—*Col. S. W.*—*Narcissus moschatu s.* Plants tied in Moss no name attached, *Anemone vernalis*, *Scilla sibirica*, *Pulmonaria angustifolia*, *Narcissus albicans*.—*M. J. (Arbroath)*.—*Clematis montana*.

No. 596. SATURDAY, APRIL 21, 1883. Vol. XXIII.

"This is an Art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

NOTES AND READINGS.

WELL-PRESERVED APPLES AND GRAPES.—I have before me now fine examples of the Northern Greening Apple, grown by Mr. Batley, of Wentworth Castle, Yorkshire, which were gathered in 1881 and 1882—both examples sound, firm, and excellent. Mr. Batley informs me that he has often had Apples two years old stored in a fruit room of a very common description partly sunk in the ground, the shelves not being sparged in the usual way, but consisting of plain deal boards laid closely together, so that no air circulates amongst the fruit from beneath. This storehouse is at the present time still well filled with as fine home-grown Apples from old orchard trees as we have ever seen. The trees are not formally trained, but are old, though carefully looked after, and the plantation has been gradually weeded out, till now Mr. Batley thinks he has got just the varieties he can depend on and needs. His Grape room is a dry loft in the sheds behind the vineries, and here are to be seen some of the most perfect examples of the black Alicante ripened at the end of last October, the Vines from which they were cut still standing at rest, and not a bud on the move. The foot-stalks of the berries are perfectly green, and not a speck of bloom is rubbed off. In past years we have seen the same variety in equal perfection in June. Once Mr. Batley exhibited two bunches at South Kensington that attracted much attention and were awarded a first-class certificate—two moderate-sized bunches that afterwards sold for £4. The Royal Horticultural Society wrote requesting Mr. Batley to furnish it with an account of his culture, which he did, but although that is years ago the paper is still in the archives of the Society.

*

FLUED WALLS FOR PEACHES.—From the same garden and the same gardener many years ago used to come constantly to the Barnsley autumn show grand Peaches that invariably were awarded a first prize. These came from an open flued wall, where some hothouses now stand, and Mr. Batley declares that his fine outdoor Peaches departed with his flues, which he regards as far before protectors and other novel appliances recommended as substitutes. He still grows Peaches outdoors in the same exposure, but the crops do not equal the old ones. Heated walls are now regarded as old-fashioned and out of date, but Peach culture in the north has been a dead letter in the open air ever since they were given up. The warm bricks repelled late frosts from the blossoms and ripened the wood in autumn, the two main points in open-air Peach culture.

*

PEARSON'S GOLDEN QUEEN GRAPE.—The same good grower reckons this to be one of the best late white Grapes in cultivation. Grown in a Muscat temperature, he says, it assumes the golden colour claimed for it originally by the raiser, and has a distinct Muscat flavour. No examples we ever tasted, however, possessed the last quality in a degree to be sensible to the palate.

*

HARDINESS OF HYBRID RHODODENDRONS.—It would be useful to learn some particulars on this subject. It is well known that many of the garden hybrid Rhododendrons are of mixed blood derived from species obtained from different parts of the world and of different degrees of hardiness. Probably there are no varieties so hardy or vigorous as the old ponticum so extensively planted in past times, enduring our severest winters with impunity, and thriving in different kinds of soil; but planters are now inclined

to employ the better and gayer coloured hybrids, and there is some doubt about their suitability for many situations. A grower of Rhododendrons in the south, who has planted the latter somewhat freely, says he has been disappointed to some extent, not a few of the plants having died or made but a feeble growth and flowered but sparingly. Without some experience or special information on the subject, it would not be advisable to plant hybrids extensively, unless it be the hardier descendants of catawbiense and ponticum. Any of the varieties, but especially the tender ones, are greatly benefited by shelter from cold winds, hence should occupy the lee side of plantations, have a dry bottom, and be thickly mulched with dead leaves and other decaying vegetable matter during the winter as a protection. Like Roses, Rhododendrons are greatly benefited by such treatment.

P'EREGRINE.

AURICULAS AND POLYANTHUSES.

NEXT Tuesday brings us again the annual show of the National Auricula Society at South Kensington. On the Tuesday following the northern section of the Society will hold its great show in the Manchester Town Hall, and on the Wednesday local Auricula shows will be held at Rochdale and Newcastle-on-Tyne. It will be a busy time for florists and an exciting one for those who have carefully tended their pet plants throughout the hard winter and the harder spring, and who must in spite of the inclement season contrive to have their plants in perfect condition, and fit for the stage, in competition for the coveted prizes.

Auriculas and Polyanthuses may be said to lie dormant through the winter, and, alas, many of them have lately slept the sleep of death! With some Polyanthuses in particular the mortality has been very great; the cold, damp weather continuing so long, has caused the plants to rot away, so that some collections have dwindled down to a few survivors. Congleton Queen and President have gone by hundreds. Many of the survivors are weakly and want genial weather to make them vigorous and to give them growth, for as a rule all are stunted and lack the usual wealth of bloom which characterises the Polyanthus in a good season. Last year they were nearly all over by the show time; this year they are late; but for all this there is likely to be a good display, and there are some good seedlings going up from Lancashire for the prizes so wisely offered by the southern section of the Society.

Auriculas, as a rule, look well this year. They are harder, and their habit of growth fits them better for extreme cold, so that whether grown in frames or in cool greenhouses they have an equally healthy appearance, and are just coming freshly into bloom at the showing time, so that we may look for a large and effective display.

The last month of dry weather has helped Auriculas. The awakening takes place in February, when from a tightly furled plant the leaves gradually unroll, and display their delicately mealed foliage, sometimes edged with a white line, as with Richard Headly, or with a white and deeply serrated edging, as with Mrs. Douglas and Frank Simonite, or heavily mealed to a creamy whiteness, as in Catherina, but always freshly beautiful and charming even without the future promise of flowers. Then the truss appears, nestling deep down in the crown of leaves, and as March passes it is gradually lifted aloft from day to day, and on sunny days so quickly that you fancy you can almost see it grow. Next the buds begin to separate, and you have to keep them carefully apart with soft wool, so that the flowers may be circular and even, and you thin out the superfluous buds, so as to leave a sufficient number to fill the space without crowding the truss; and you have to consider the time, so that your flowering be neither too early nor too late, for it is better far to show a flower waxing than when it is past its best. If you try to retard the growth by moving plants to a cooler or shadier place, you frequently find they lose ground, and so you have to watch them where they stand, and to regulate the shading, giving sunshine or shade to meet the

requirements of the day, keeping back the over early and coaxing on the laggards, aiming for the happy result of equal blooms in all the classes at the precise day.

And what a thrill passes through the mind of the florist when he sees his John Simonite, or Acme, or Alexander Meiklejohn, his Prince of Greens, and Colonel Taylor coming well; when his Lancashire Hero wears its best green edge instead of its grey; when Lovely Ann is in correct form, for she is capricious, and wears at least four different dresses, which she doffs and dons as it pleases her. Then he has to see that his self does not come earlier than the rest, as they are very apt to do, and that he has good plants in each and all of the four classes, for it sometimes happens that you lose the prize because you are deficient in self, although very strong in the three edges, or you may very easily be weak in green edges when you abound in grand plants of all the rest. And so it will be seen that there is abundant room for anxiety and plenty of daily work to be done in caring for a large lot of Auriculas and Polyanthuses, and therefore the florist requires many wholesome qualifications for his hobby, and patient, persevering work for many months before a show. Poor Tom Mellor used to say that he never lost heart if his own plants were poor, because he thought others might probably be as poor as his were, and it often proved to be so when the rival plants were staged. Likewise, when your own are good it does not do to be over-confident, for the chances are that good plants may be plentiful elsewhere. The season is the same to all, and the best cultivator wins the day. The London and Manchester shows are for the large growers. It takes a bold man to show in these against the large collections of such amateurs as Mr. Horner and Mr. Whitburn and the trade collections of Mr. Turner, Mr. Booth, and Mr. Pohlmann. The Rochdale and Newcastle shows should be left more to the small amateurs, especially the weavers and colliers and handicraftsmen, who make this florist hobby their aim and great delight. These local shows should be encouraged everywhere.

WM. BROCKBANK.

Brockhurst, Didsbury.

PLANTS IN FLOWER.

CALCEOLARIA VIOLACEA.—Flowers of this charming little Slipperwort have been sent to us by Mr. Wolley Dod, from Edge Hall, Malpas. He adds that it is nearly or quite hardy with him in Cheshire, though it does not flower well in the open border. The flowers are small and helmet-shaped. Their colour is a delicate mauve copiously spotted with purple. It is well worth pot culture in a greenhouse.

NARCISSUS CAPAX.—I send you three blooms of this the Queen Anne's primrose double Daffodil. Two of them are from the open rockery exposed to the N.E. blasts and close to the coast; the other is from the alpine house. You will notice little difference in the flowers, which speaks volumes for their ability to withstand our heavy gales without injury.—W. H. BROWNE, *Aldbrough Hall*. [The finest blooms we have seen this season.]

HELICODICEROS CRINITUS, sometimes known as *Arum crinitum*, is one of the most singular of all Aroids. A plant in the T range at Kew is now bearing a second inflorescence, which is something unusual in these plants; at all events it never occurs in the allied *Arisæma*. The stem of this remarkable plant is curiously spotted, and the leaves are divided in such a manner as to give them the appearance of a pair of horns standing erect. The flower (inflorescence) is about twice the size of that of the common *Calla*, somewhat similar in shape, but curled back above, so as to display the inner surface, which from the density of the hairs placed there appears to be wholly purple, whereas the surface itself is yellowish green. Like many of these annual stemmed Aroids, the flowers of this plant have a very disagreeable odour. Although grown in a warm house at Kew, where, along with a fine col-

lection of *Arisæmas*, it appears to be quite at home, this plant is said to be almost hardy, requiring protection only during the most severe weather. As a pot plant, however, it would appear to be most at home. If grown out of doors, the tubers should be taken up and stored during winter in a cool frame, for a wet cold season would most likely prove fatal to them. It is a native of Corsica and several adjacent islands, and appears to have been cultivated in this country so early as 1777.

FLOWERS FROM DUBLIN.—Herewith I send you *Nicotiana affinis*, side branch only; *Sarracenia flava*; *Narcissus Horsfieldi* and *Jonquilla*; *Spiræa Reevesi*, graceful spray, lovely when fresh; *Asparagus consanguineus*, fine for bouquets, and very enduring in water; *Lachenalia luteola*, often miscalled *L. tricolor*; *Iris (Moræa) chinensis*; and Ghent *Azaleas*, lovely in pots in the greenhouse along with Japan Maples, Solomon's Seal, Hoop-petticoat Daffodils, and similar plants.—F. W. B.

MAGNOLIA FUSCATA.—The whole of the southern end of the temperate house at Kew is now filled with the delicious fragrance of this *Magnolia*, a fine bush of which is planted in one of the borders there, and is at the present in full flower. Being of easy culture, one would expect this *Magnolia* to be more frequently met with than it is, especially as it is nearly hardy. Its blossoms are, however, not showy; on the contrary, they are dull purplish brown in colour, and hid beneath the foliage. Their only charm is their sweet scent.

AGAPETIS BUXIFOLIA.—This is a neat branching Ericaceous shrub, well furnished with small, bright green, glossy foliage, and bearing a general resemblance to the *Vacciniums*, except when in flower; the shoots are studded with bright red tubular blossoms about an inch long and borne in great profusion. They hang down gracefully from the branches, and have a wax-like appearance common to the *Thibaudias* and some of their allies. It requires greenhouse culture, and is now in flower in the temperate house at Kew.

THE YELLOW ROOT (*Xanthorhiza apiifolia*).—To lovers of showy shrubs this would scarcely commend itself, yet a fine mass in the dell near the flagstaff at Kew is just now very interesting. It is a small bush, with yellow creeping roots, from which suckers are thrown up in such profusion as to soon form a large clump. The leaves are irregularly pinnate, and the minute flowers, which are borne in comparatively large branching spikes, are a peculiar dark purple in colour. A cool, rather moist soil suits it perfectly. It is a native of North America and quite hardy.

ANTHURIUM ANDREANUM.—I send you a flower of this *Anthurium* for your opinion. It measures $7\frac{1}{2}$ inches by 6 inches. It is the largest flower we have had, but perhaps not the best shaped one. The flowers have increased in size as the flowering has gone on. The variety from which this flower is taken is dwarf compared with some I have seen, and the flowers of dwarf growing plants are superior to those on plants that grow very tall. Are there two varieties? or what is the cause of the long stem in the case of some kinds?—T. C. ANDERSON, *Milner Field, Burghley*. [A remarkable flower, very brilliant in colour.]

The hardy *Primulas* in Mr. Ware's nursery at Tottenham are just now well worth a long journey to see. Never have we seen the charming *P. rosea*, the undisputed queen of hardy *Primulas*, so numerous or so finely flowered. This does best when given plenty of moisture. The snow-white *P. nivalis*, too, is lovely, particularly plants of it that have had the slight protection of a frame in hard weather. Some of the plants (large spreading tufts) are literally masses of snowy blossoms. The innumerable forms of *P. acaulis* include such beautiful ones as *platypetala* and its double form, the scarlet-flowered variety.

RHODODENDRON AUCKLANDI.—The Himalayan *Rhododendrons* in the temperate house at Kew are now rapidly approaching the flowering stage; indeed, the blossoms of some of them have already expanded. *R. Aucklandi* is at its best, but it does not bear this season so many flowers as usual. The

latter are white, slightly suffused with blush, about 6 inches in diameter, and borne in an open, bluntly pyramidal shaped truss, so that even though few in number, they render the plant one of the chief ornaments of the house in question. A large plant of a bright coloured form of *R. arboreum* is also in full bloom, and in a few days the list might be much increased.

AMARYLLISES AT WESTONBERT.—In his garden at this place, near Tetbury, Mr. Holford has got together the finest private collection of *Amaryllises* in the country, mostly seedlings raised at Westonbert. The flowering bulbs alone number from 900 to 1000 besides a large collection of seedlings raised from some of the finest varieties. Mr. Holford is fond of the *Amaryllis* family, and watches with the keenest interest the opening of new flowers. Bright self colours are his special favourites, and there is scarcely a week throughout the year in which one could not see *Amaryllises* bloom at Westonbert. The plants are very healthy; they are grown in a viney plunged in stable manure underneath the Vines.

BROWNEA ARIZA.—This magnificent flowering stove shrub is just now, says the *Irish Farmer's Gazette*, commencing to make the stove conservatory at Glasnevin particularly attractive. Its great glowing, pendulous, crimson tassels are indeed marvels of floral beauty, which even the most indifferent cannot fail to admire. The more familiar species, *B. grandiceps*, of which there is a grand specimen in the same compartment, is not likely to afford this season its usual gorgeous display of flower, as it has only recently been retubbed, which, of course, will interfere with the flowering this season, but only, doubtless, to make it all the more profuse another year. The finest collection of these noble flowering trees anywhere is that at Lakelands, Co. Cork. If we remember rightly, it includes some fifteen species.

PHRYNIUM SANGUINEUM.—If we except the *Cannas*, the *Maranta* family is not particularly strong in floral attractions, yet in this *Phrynium* we have a striking exception. True, it is a common plant, but grown generally only for its foliage, and as the ornamental character of this is best seen in young or dwarf compact flowers, the proper habit of the plant is seldom allowed to develop itself. At Kew just now, however, there is a fine specimen of this *Phrynium* some 5 feet high and bearing long-stalked, dense panicles of reddish coloured flowers of the most attractive kind. These flowers last for some weeks in perfection, and therefore form good subjects for vases, &c. The foliage of this *Phrynium*, which is like that of most *Marantas* in shape and texture, is dark green above and purple beneath. It is a stove plant and should be treated similar to the *Marantas*.

THE BROMELIADS AT KEW are rapidly assuming a much healthier and more promising appearance since their removal from the Palm house into more suitable quarters. We noticed in flower the other day some interesting kinds, amongst which *Caraguata cardinalis* was particularly noticeable. It is a rare plant of recent introduction, not unlike the better-known *C. Zahui*, but differing from it in the foliage being longer and less distinctly striped with purple and in the more brilliant colours of the inflorescence; the latter consists of brilliant red bracts surrounding some bright yellow ones in the middle, from which the white flowers are pushed several at a time. *Billbergia Liboniana*, an old, but pretty Bromeliad, bears drooping panicles of tubular flowers 3 inches in length; the sepals, which are $1\frac{1}{2}$ inches long, are vermilion-red and the petals deep violet. *Pitcairnia echinata* has a tall branching spike of yellow and white tube-shaped flowers, the sepals of which are covered with thick fleshy hairs, which have won for it the name *echinata*, or hedgehog-flowered. *Tillandsia splendens* is a handsome foliaged plant, the leaves of which are ornamented with broad chocolate bands. The flower-spike is sword-shaped, 15 inches in length, and bright red, the flowers, which are comparatively insignificant, being yellow. *Macrochordium tinctorium* has an *Echmea*-like inflorescence and small black flowers

set in a head of whitish wool. *Billbergia viridiflora* bears a drooping spike of green flowers, those on the lower end having at their bases long, dark crimson bracts. Several other less noticeable species are also in flower.

LATE CHRYSANTHEMUMS.—It may possibly interest some of the readers of THE GARDEN to know that *Chrysanthemums* are still in flower with us. We have been cutting blooms every week since October, and could, I am certain, if we so desired it, continue to do so for some weeks longer, having still some plants well set with flower buds. I find, however, that as the days lengthen and the weather becomes warmer, the flowers become thin, flimsy, and poor just in proportion to the amount of heat and light to which they are subjected.—JOSIAH JEFFERY, *Derry, Co. Cork*. [With this came blooms of Fair Maid of Guernsey and Venus, still fresh and good.]

CEREUS MALLISONI is the most attractive plant in flower just now in the Cactus house at Kew. A fine specimen of it grafted on the night-flowering *Cereus* (*C. McDonaldii*, of Honduras) has numerous flowers on long, round, fleshy stems, which depend grotesquely from the rafter to which the plant is fixed. The blossoms are very showy, being about 4 inches across and of a bright cherry-crimson colour. This is one of the most satisfactory of all the Cacti to grow, for it never fails to produce a copious annual crop of blossoms. Whether it succeeds better grafted on the night-flowering *Cereus* than on its own roots we are unable to say, but the Kew plant evidently thrives admirably so treated. *C. Mallisoni* is, we believe, of hybrid origin, and has been many years in gardens. It likes a warm, dry atmosphere and would flourish well at the warmest and driest end of an ordinary stove.

RUDGEA MACROPHYLLA.—This is again in flower in the T range at Kew. We do not remember to have seen this plant anywhere except at Kew, and are surprised that so fine a stove-flowering plant should be so little grown. It was introduced some fifteen years ago by Mr. B. S. Williams, of Holloway, where it flowered and was figured in the *Botanical Magazine*. It is a thick woody-stemmed plant with stout leathery leaves. It grows to a height of 6 feet and bears on the ends of the shoots globose heads of white fleshy flowers not unlike a large head of *Bouvardia* blooms. It is a slow growing plant, and not easily propagated. The best way is to cut an old plant in hard and to take off for cuttings the young shoots as soon as ripe with a little of the old wood attached to them. Being a native of Rio Janeiro, it requires a moist stove temperature and plenty of water at the root when in flower. It is an attractive plant, and for the last fortnight has been one of the most interesting plants at Kew.

CENTROSTEMMA MULTIFLORUM.—This pretty *Asclepiad*, often known as *Cyrtoceros reflexum*, and resembling both in foliage and flowers some of the *Hoyas*, is a really serviceable plant if grown so as to form a compact shrub and treated so as to induce it to bloom freely. The flowers, which are in umbels similar to those of *Hoya carnosa*, are produced from the axils of the leaves on the young wood in summer and are creamy white, the lobes being well reflexed and tipped with yellow. It is not a climber, as has been stated by some, but grows to a height of from 5 feet to 6 feet if not kept cut back. For tying to a pillar or post in a stove this plant would prove serviceable, and as it likes moisture and thrives under the same conditions as the *Hoyas*, its cultivation is extremely simple. A good plant of it is now in flower in the T range at Kew. Near the *Centrostemma* is a well flowered specimen of *Hoya campanulata*, of which a woodcut was given in THE GARDEN some time ago. It is one of the best of the *Hoyas*, and from its free flowering character it may be recommended for cultivation in stoves of limited dimensions, as quite small plants of it produce flowers annually.

The Garden.—General Index to the first twenty vols. now ready, strongly bound, price 12s. 6d.

NOTES ON BIRDS

In the Garden, Sheen Lodge, Richmond Park.
(Continued from p. 334.)

THE WRY-NECK (*Jynx torquilla*).—Welcome is the loud repeated monotone of the bird, which, like the cuckoo, harbingers the spring. The keeper's name of "cuckoo's mate" is suggested by this contemporary arrival. And as they proclaim the advent, so they become simultaneously silent, arriving and departing together.

THE SWIFT (*Cypselus apus*) introduces the summer by its lofty aerial flights; rarely have I noted the arrival before the entry of June. Its favourite nesting-place is, with me, beneath the thick reed thatch of the cottage, and very deeply has its way to the nest been bored therein year after year.

in any tree of the garden. An old Thorn bush shows occasionally an impaled cockchafer.

JENNY WREN (*Motacilla troglodytes*) stays with us the year round.

* CHIFF-CHAFF (*Motacilla loquax*) announces its early arrival, at the middle or before the end of March, by its shrill, metallic, bitoned "chilp-chiip" from the topmost bough of an Acacia or other tall tree. My grandsons call it the "little blacksmith." Like the common wren, it makes a domed nest, but usually in a sheltered shrub, never in such odd localities as, with other observers, I have found the common wren's nest and its numerous family.

THE WILLOW WREN (*Motacilla trochilus*) proclaims its arrival on April 1, or thereabouts; its ten "tweets" cease to be heard in July; its nest is often hidden in the Ground Ivy; and it

has startled him in this calm dawn of prevailing frost? The handsome greater tit takes his place, and not until he is satisfied does the smaller one resume his breakfast. But the pugnacious robin is not to be so scared. It is true he cannot cling while fighting like the tits; but he takes his stand on the window-sill, ruffles his plumage out to make the most of his size, and attacks *Parus major* by successive flights, assaulting him from below. The tit gives way, and the redbreast then makes a series of flying pecks at the suet.

When the hard frost has held for a few weeks, the poor shivering, starving blackbird dismisses his shyness, and from the window-sill takes also his flights at the tempting bait, and the robin gives way. Finally the tits return, and little, if any, of the heat-imparting food is left when they have finished their breakfast. Awakening from a

Plan of Professor Owen's garden at Sheen Lodge, Richmond Park.

THE SWALLOW (*Hirundo rustica*) and the HOUSE MARTIN (*Hirundo urbica*) are earlier arrivals by a few weeks. The latter, one spring, made its nest beneath the verandah at the angle of this with the cottage wall. The frequent traversing of the sheltered way and occupancy of the seats commanding an extensive view of wood and water along the park failed to frighten the parents from their choice of nesting-place, scarcely a yard above the head of the sitter. The young on their first venture from home flitted no further than the antlers of the deer suspended under the verandah; the next day, encouraged by the parents, they flew to the fence dividing the front lawn from the park; and soon after they accompanied the older birds in their aerial chase, distinguishable always by their shorter and less forked tails. We were careful to abstain from undue notice or disturbance of the trustful parent birds. However, they never returned to the verandah, where their deserted nest still remains.

RED-BACKED SHRIKE (*Lanius collurio*).—A year rarely passes without a visit from this gay and active butcher bird; its nest I have failed to find

usually rears two broods before it returns to winter, like the chaffinch, in Africa.

THE GOLDEN-CRESTED WREN (*Regulus cristatus*) adorns the garden for a greater proportion of the year. It seems to be a partial or not distant migrant, and does not tarry like the tits through the winter.

These lively little birds—the GREATER TIT (*Parus major*), the BLUE TIT (*Parus cœruleus*), with the rarer LONG-TAILED TIT (*Parus caudatus*)—I tempt into view at the time of hardest frosts. Then to the leafless branch of a creeper, which crosses my bedroom window, I suspend by a wire, with a fishing swivel, a small wire cage, about the size of a nutmeg. This is filled at night with a lump of suet. At early dawn I note from my pillow the swift flight of a little bird to a branch of the *Gleditschia*, also in view, on which it turns or jerks about as if moved by a spring. Then mustering courage it darts upon the suet cage, clinging like a parrot to the wire, and whirling about to show all its plumage. It is the blue tit; but hardly has he enjoyed a few pecks when he suddenly lets go and is off again to his post on the great tree. What

morning doze and noting their gay colours. active flights, and clinging powers, these little birds have seemed to me to represent in the garden the scansorial parrots of warmer climes.

FLYCATCHER (*Muscicapa grisola*).

CREEPER (*Certhia familiaris*).—Only once or twice have I got a glimpse of this little active, but inconspicuous bird, running up and down the trunk and larger boughs of a garden tree; and I was not surprised at the remark of a little grandson, then with me, to whom I pointed out the climber: "I thought it was a mouse."

BLACKBIRD (*Turdus merula*).

THROSTLE (*Turdus musicus*).—There are a few old Cherry trees in the garden; one of them a Bigarreau. This I netted in my first summer's possession to preserve the tempting fruit. When the dish came to table, I thought of the frequent pleasures which the morn and evening warblings of the little robbers had given me, and felt ashamed at fencing off what I could cheaply get, as fresh and better, from neighbouring market gardens. I never repeated the practice, but left Bigarreaus

with the other Cherries as "salary of the orchestra."

But their notes I found, as seasons ran on, were not the only repayment. I often had to listen to complaints of neighbours at the damages they sustained from snails and slugs. I found that they or their gardeners kept up ceaseless war against the fruit pilferers. Now the rarest zoological phenomenon in my garden is a living slug; a snail I remember not to have noticed. The extirpators are the thrush and the blackbird. No bird's-nest of any kind is ever disturbed here; that order is stringent. I have felt surprise, as both blackbirds and thrushes rear, as a rule, two broods a year, that their numbers never seem to increase. The young songsters, I suppose, are driven off, compelled to migrate to other groves. As many remain, however, as amply repay me for the Cherries by their clearance of vermes and mollusca; and then I still have all the pleasure which the white blossom of the old fruit trees yield in early spring. 'Tis true, a similar pleasure in autumn by the scarlet berries of Hollies and Barberries is cut short by my molluscivorous friends.

MISSIL-THRUSH (*Turdus viscivorus*).—In the autumn season, even to its end, the bold, loud notes of this fine bird are pleasant to the ear. I was engaged in planting, early one spring morning, when I was startled by a rushing flight directed, as it seemed, at my head by a largish bird, with an angry cry. I turned round to see who the audacious enemy was and where he fled to, when, from a neighbouring tree, a missil-thrush turned about, and made another vicious dart, passing close to my head, which I jerked aside. I now saw that on the tree from which he made his first attack was the nest in a somewhat exposed position, and the flower-bed was near it. It was a rude "notice to quit;" so I gave up my work and retreated. A few days after I found that the nest was deserted. It was not finished when this boldest of the thrush tribe had been disturbed at the work.

REDWING (*Turdus iliaeus*).—If this winter immigrant favours us with a warble it is in early March, on the eve of its flight to its northern nesting latitudes.

REDSTART (*Motacilla hippolais*).—Her nest is commonly in some hollow of the old park wall, which bounds a part of the garden. The glossy black waistcoat of this visitor attracts notice about the middle of April: he is not seen here after September.

REDBREAST (*Motacilla rubecula*).—The pretty welcome plaintive note of our constant guest is almost the only one to be heard throughout the winter season. The robin is a bold and also a trustful bird. He will venture, at the hardest period, to take his pet "meal-worm" from your hand. The males in spring are desperate fighters.

NIGHTINGALE (*Sylvia luscinia*).

HEDGE-WARBLER (*Acecentor modularis*).

GARDEN-WARBLER, OR LESSER FAUVETTE (*Motacilla passerina*).—A deceptive little bird to determine by note, from its faculty and practice of imitating those of other birds.

PIED WAGTAIL (*Motacilla yarrelli*).

GREY WAGTAIL (*Motacilla boarula*).

Both kinds of these *Cantores* occasionally enliven the lawns during their breeding seasons. The gayer coloured, yellow-breasted grey wagtail is the rarer of the two. Near our "sheen pond," or rather "mere," the pied wagtail (*Motacilla alba*) may be seen; but of late years, with the increase of visitors to our corner of the park, due to rapid growth of the village, they have not returned.

A waste appendage to the garden, known as the "nettle nook," seems to attract the **GARDEN WARBLER** (*Sylvia hortensis*). There or thereabouts I have usually first noticed its arrival in mid-April. Its streams of demi-semi-tones, like a musical scale, well suggest its name.

SKYLARK (*Alauda arvensis*).—This bird nests and rears its brood in the meadow to the west of

my Privet hedge; but as I listen to its carol as the songster soars over the garden to be lost in the blue, the rich trill diminuendoing to pianissimo by a gradation worthy of the most practised orchestra, I cannot exclude the skylark from my list.

THE YELLOW BUNTING (*Emberiza citrinella*), or yellow hammer, builds her simple, almost slovenly, nest yearly in the flowering thorns or copse bushes, and usually rears two broods. The Blackberries in autumn seem to be special attractions, but I have not noticed an increase in the numbers of this pretty ornament of the garden during the last twenty years. Its ally, the **CIRL BUNTING** (*Emberiza cirius*), announces its presence from the topmost boughs of our old Elms in autumn it seems to have gone south.

RICHARD OWEN.

INDOOR GARDEN.

CAMELLIAS IN THE GROWING SEASON.

MARCH, April, and May are the months during which the majority of Camellias make their growth and form their bloom buds, and the more luxuriant and substantial we can make these growths now the greater in both quantity and size will the blooms be. A proper condition of the roots is one of the main promoters of success, without which other attentions will prove unavailing. I must therefore especially impress upon all who desire to have their Camellia plants in the finest possible condition the necessity of looking to their roots at the outset, and then by proper attention afterwards success will be ensured. While making its growth we know of no hard-wooded plant which will stand watering at the root more freely than the Camellia, and where the drainage is in good working order water should be applied unstintingly. Whether in pots or planted out, aridity at the roots or in the atmosphere is an evil of the greatest magnitude in the case of Camellias. The soil in which our Camellias luxuriate is never really dry at any time, but it is extra wet during the growing season, and it would be satisfactory to me if the leaves could be kept wet night and day at this time. As it is they are heavily syringed morning and evening, and the ground underneath is always humid—indeed, almost steaming. Under these conditions the young growths are produced in clusters of from four to a dozen, as thick as the quill with which I write, in length from 8 inches to 12 inches, and all with at least one and many with five and six bloom buds. One or other of half a dozen plants in the conservatory begin to open their blooms in October, as they did last year, and now in April there is still some fine blooms opening. Where many cut flowers are in demand,

A SEVEN MONTHS' SUPPLY OF CAMELLIA blooms is very acceptable, and the plants are well worth all the attention we can give them during the growing season as well as at all other times. All kinds of dirt and insects should be cleared off the old wood before the young growths have made much progress. When in bloom it is difficult to syringe them without blemishing the flowers. As a rule this operation has to be stopped during the flowering season, and then the plants sometimes become unclean; in all such cases it is well to have them thoroughly cleaned before the young leaves are formed. Sponging is one of the surest ways of cleaning them, but it is rather tedious, and where dirt and insects are not very hard and fast heavy syringings will remove the greater part. In the case of Camellias which are planted out, of course they are stationary, and cannot be moved into any particular atmosphere, but this need be no drawback against their perfect development, as they will just grow as freely and more satisfactorily in an ordinary greenhouse or conservatory than in any vinery or hot, steaming place. When the plants are in pots or boxes, they are generally shifted into some other house to make their growth different from that in which they have been blooming, but a very hot house

should always be avoided in such cases. There is no denying that Camellias will make long shoots in a close heated, shady atmosphere, but the finest flowering plants will never be produced in such a place. A temperature of 60° at night and 70° by day with sun heat is most suitable to the substantial growth and perfect development of the wood and buds of the Camellia. A liberal admission of fresh air on fine days does them much good, as the growth is then rendered firm from the first, and its thorough ripening early in the season is an absolute certainty. Apart from securing plenty of wood and buds, the

RIPENING OF THE WOOD is of the utmost importance, and too much attention cannot be given to this, as imperfectly opened flowers and buds dropping prematurely are some of the results of dealing with unripe wood. It is now many years since one of our Camellia plants was shaded during the growing season, and the advantages of full exposure to the sun at this stage has been proved to us over and over again. At first we were half afraid that the plants, and particularly the young tender growths, would be scorched and ruined, but nothing of the kind occurred; on the contrary, when fully exposed to the healthy influence of the sun's rays, the wood was shorter jointed and the leaves thicker and deeper green than we could manage to get them in the shade. In the case of shaded plants the sun often plays sad havoc; those in charge of them are generally very particular in shading them at first, but by-and-by when more exposed the tender leaves nourished in the shade become blotched and spotted by the sun or through exposure to draughts. There is nothing more satisfactory than sturdy growth produced in the full heat of the sun and with plenty of clean water at the roots. With the latter in proper order there is nothing to fear. The earliest wood will, as a rule, give the earliest blooms, and when Camellia flowers are wanted in October and November, early growth and early ripening of the wood will supply these without much difficulty. When once the bloom buds have been formed syringing should cease and more air should be given, but nothing like a dryer state of the roots should follow. CAMBRIAN.
